Abstract

A decision making process behind the management of pediatric patients with asthma exacerbations in the Emergency Department includes three stages: data collection, diagnosis formulation and treatment planning. These stages are associated with activities involving different types of clinical knowledge: factual, conceptual and procedural. Effective decision support should span over the entire decision making process and facilitate the use of diversified clinical knowledge. In this paper we present MET3-AE – a point of care decision support system that satisfies this requirement. The system helps emergency physician collect data, evaluate exacerbation severity, plan corresponding treatment and retrieve clinical evidence associated with a given treatment plan. It was developed using ontology-driven and multi-agent methodologies and implemented with open source software. The system is accessible on tablet and desktop computers and smartphones, and it interacts with other hospital information systems. It was successfully verified in a simulated clinical setting and now it is undergoing testing in a teaching hospital.

Decision support systems, Clinical, Pediatrics, Asthma, Patient management, Emergency care.

Introduction

Asthma exacerbations are one of the most common medical conditions for children that are brought to the Emergency Department (ED). These visits, and subsequent hospitalizations required by many of these patients, account for nearly 65% of all direct costs of asthma care. Children with asthma, compared to other non-asthmatic patients use more prescriptions and require more ambulatory care and ED visits.

A decision making process associated with the management of pediatric asthma exacerbation in the ED is presented in Figure 1. It reflects a hypothetico-deductive model of clinical decision making [1] with three main stages: data collection, diagnosis formulation and treatment planning. Activities associated with specific stages are diversified and require different types of clinical knowledge (indicated in Figure 1).

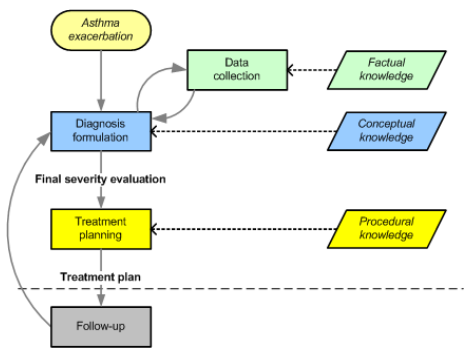

Figure 1 - Decision making process for the management of pediatric asthma exacerbations

The management process starts with the emergency physician (EP) formulating a diagnosis by assessing the severity of exacerbation. This initial evaluation is revised in an iterative way when more patient data is being collected until a final severity evaluation is established. Establishing the severity of exacerbation involves *conceptual knowledge* that is acquired during formal training and life-long learning. The collection of patient data requires the knowledge of what to collect and how to collect it efficiently and accurately. Use of this *factual knowledge* can be supported through a variety of structured data collection tools.

An established asthma severity level drives the development of a treatment plan for the patient. Knowledge required for developing a treatment plan (*procedural knowledge*) is associated with the notion of evidence-based medicine, i.e., making clinical decisions on the basis of the best available evidence. Existing research shows numerous benefits of supplementing a treatment plan with underlying clinical evidence [2].

The goal of effective decision support is to help with all stages of the entire decision making process presented in Figure 1. Moreover, according to [3] such decision support needs to be available in a computerized form and easily accessible at the point of care. All this should contribute to more efficient management of a patient during an encounter. The clinical decision support system (CDSS) described in this paper, called MET3-AE, meets these requirements. It helps collecting and accessing data, evaluating the severity of exacerbation and developing appropriate treatment plans relatively early (at around 2 hours after nursing triage), and it links each treatment plan with evidence – systematic reviews of clinical trials – extracted from The Cochrane Library[1]. Moreover, the system runs on various computing platforms including mobile devices and it can be used directly at the point of care during an encounter.

The paper is organized as follows. In the next section we describe detailed requirements for the MET3-AE system. Then, we discuss the architecture of the system and its implementation. It is followed by an example that illustrates how the system supports diagnostic and treatment decisions. In the subsequent section we describe testing of MET3-AE in a simulated setting. Finally, we conclude with a discussion.

Requirements for the MET3-AE System

In order to meet the goal of effective decision support, MET3-AE has to satisfy two main requirements that are derived from research described in [4-6]:

1. Provision of comprehensive support for the entire decision making process,
2. Availability at the point of care during a patient-physician encounter.

The first requirement translates into satisfying information needs of the EP and assisting the EP with the use of different types of clinical knowledge linked to the specific stages of the decision making process.

Satisfying information needs maps into the ability to access patient information regardless of where it is stored. This requires MET3-AE to interact with other hospital information systems (HISs), especially with an electronic patient record (EPR), in order to exchange and share patient data.

Supporting the use of clinical knowledge requires encoding of its different types in form of different abstract models and associating these models with functions that facilitate their use – they are listed in Table 1.

Linking the stages of the decision making process with abstract models and related functions constitutes the main idea behind the MET3-AE design:

- Supporting the data collection implies prompting the EP to consider specific clinical attributes and providing means for structured data entry. This calls for the data model defining the clinical attributes and the user interface model defining the structured data entry components, both codifying the factual knowledge.
- Supporting the diagnosis formulation implies the ability to arrive at an assessment for the exacerbation severity. This calls for a diagnostic model codifying the conceptual knowledge.
- Supporting the treatment planning implies the ability to recommend treatment plans and to provide underlying evidence. This in turn requires having the treatment and evidence models encoding the corresponding procedural knowledge and allowing for retrieval of clinical evidence.

Table 1 - Models and functions supporting the decision making process

Process stage	Abstract model	Function
Data collection	Data model User interface model	Structured collection of patient data
Diagnosis formulation	Diagnostic model	Suggestion of possible diagnosis
Treatment planning	Treatment model Evidence model	Suggestion of treatment plans Provision of clinical evidence

The second requirement for effective clinical decision support translates into MET3-AE ability to run on different computing platforms, thus satisfying the "multi-device architecture" postulate [7]. More precisely, MET3-AE has to be accessible on a tablet computer, desktop computer or smartphone so the EP can use it when and where necessary.

The set of requirements discussed here does not cover issues of security and privacy. However, when implementing the system we used a policy-based encryption to ensure appropriate level of access control and data security.

Implementing the MET3-AE System

Architecture

Comprehensive clinical decision support calls for a distributed architecture that facilitates multiple relatively independent function. These functions should be modeled as independent entities that provide or request services [8]. Such architecture may be implemented following service-oriented or multi-agent principles. In MET3-AE persistence of the entities is crucial, as they need to exist all times to monitor HIS or to respond to user requests. Such persistent existence is normally accomplished in a multi-agent system (MAS).

The MET3-AE architecture presented in Figure 2 was developed using multi-agent methodologies enhanced with ontology-driven design for better maintainability and extensibility. It builds on our earlier research, specifically on the multi-agent

[1] http:///www.thecochranelibrary.com

design process (described in [9]) and on the ontology-driven design for CDSS (introduced in [10]).

MET3-AE includes the following agents:

- *Encounter assistant* that provides a graphical user interface to the EP and interacts with other agents based on the user actions,
- *Model manager* that manages abstract models stored in the *model repository*,
- *Data manager* that manages patient data stored locally in the *data repository*,
- *Diagnosis suggester* that suggest a possible asthma severity level on the basis of patient data and using the abstract diagnostic model,
- *Treatment suggester* that suggests a treatment plan on the basis of the patient data and using the abstract treatment model,
- *Evidence provider* that provides clinical evidence from the *evidence repository* on the basis of the patient data and using the abstract evidence model,
- *HIS synchronizer* that receives and passes the messages between MET3-AE and HISs via the HL7 *interface engine*.

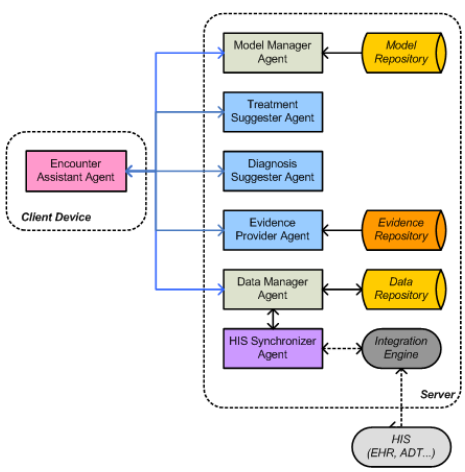

Figure 2 - Architecture of MET3-AE

The encounter assistant agent, acting as the EP's gateway to the system, runs on a "client" device (tablet computer, desktop computer or smartphone), while the remaining agents and repositories reside on a dedicated server.

The MET3-AE system was implemented in two phases discussed in the next subsections. The first phase involved creating the technological infrastructure according to the architecture presented in Figure 2, and the second phase involved implementing all abstract models listed in Table 1.

Technological infrastructure

The MET3-AE agents were programmed using JADE (Java Agent DEvelopment Framework) that provides middleware to manage agents and controls communications between them.

The repositories with abstract models (the model repository) and with patient data (the data repository) were created with Protégé. The evidence repository with systematic reviews from The Cochrane Library was implemented as a MySQL database enhanced with the Apache Lucene text search engine.

We also used Mirth Connect to enable communication between the MET3-AE and HIS. Specifically, we integrated with the ADT (admission-discharge-transfer) system through the HIS synchronizer agent using HL7 messaging.

Abstract Models

The data model for MET3-AE specifies clinical attributes that are routinely considered when managing asthmatic patients. These attributes were defined in cooperation with EPs – they come from the emergency assessment record and the asthma clinical pathway and they describe basic patients' demographics, history of asthma and the current exacerbation episode. The user interface model manages structured collection of values of the attributes from the data model. It was constructed following user- and task-centered design principles [11].

The diagnostic model employs a decision tree to predict asthma severity (research leading to its development and empirical validation is described in [12]). It was developed from a retrospective chart study using data mining techniques. Prior to building the model, collected data was preprocessed by normalizing age-dependent clinical attributes and by removing questionable patient records – we used Pediatric Respiratory Assessment Measure (PRAM) to identify these records.

The treatment model consists of decision rules that assign appropriate treatment given the asthma severity level. These rules were extracted from a pediatric asthma clinical guideline published by the Canadian Association of Emergency Physicians[2].

The evidence model defines terms used for indexing systematic reviews and introduces mappings between attributes from the data model and the indexing terms. These terms were identified using the UMLS Metathesaurus and located in the systematic reviews from The Cochrane Library with the help of the MetaMap Transfer (MMTx) system [13].

An Example of MET3-AE Operations

To provide a better understanding of how MET3-AE works we provide in Figure 3 a scenario of a clinical case in the ED. The scenario focuses on two stages of the decision making process – diagnosis formulation and treatment planning (due to limited space the data collection stage has been skipped). Corresponding agent interactions are presented in Figure 4 and 5.

[2] http://www.caep.org

At the diagnosis formulation stage (Figure 4) Dr. Brown asks for a diagnostic suggestion (1). The encounter assistant agent sends a request (augmented with available patient data) to the diagnosis suggester agent (2), which in turn sends a request to the model manager agent for the diagnostic model for asthma (3). The model manager retrieves the model from the model repository (4) and sends it back (5). Then the diagnosis suggester agent applies the diagnostic model to Peter's data and returns elaborated diagnostic suggestion to the encounter assistant agent (6), which finally reports it to Dr. Brown (7).

Peter Smith, a 2-year old boy with asthma exacerbation, has been brought by his parents to the ED in a pediatric hospital. Following nursing triage, Dr. Jane Brown takes care of Peter's management. After the first round of standard treatments according to hospital's asthma pathway, Dr. Brown continues Peter's assessment and is using MET3-AE running on her tablet computer to record patient data and to get decision support. Her initial hypothesis is that Peter suffers from severe asthma exacerbation. She consults MET3-AE for diagnostic advice and in return receives a suggestion pointing towards moderate asthma exacerbation. Dr. Brown decides to continue with observing the patient and monitoring oxygen saturation level. After short period of observation she assesses Peter again and diagnoses him as having moderate exacerbation (confirmed by MET3-AE). According to asthma practice guideline embedded in the MET3-AE, administration of systemic corticosteroids is a recommended treatment. Dr. Brown asks the system for the evidence regarding such treatment for a young boy and MET3-AE responds with a ranked list of abstracted systematic reviews. After consulting the summaries, Dr. Brown prescribes systemic corticosteroids and proceeds to discharge Peter to care of a family physician.

Figure 3- A scenario of a clinical case

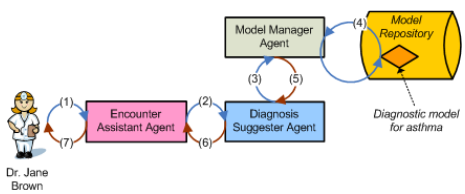

Figure 4- Agent interactions during diagnosis formulation

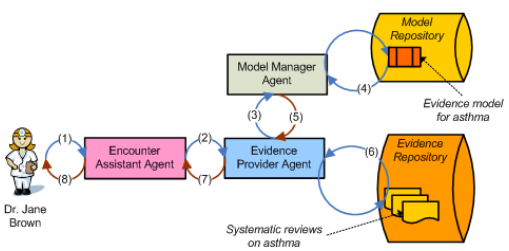

Figure 5- Agent interactions during treatment planning

At the treatment planning stage (Figure 5) Dr. Brown asks for a treatment suggestion and for evidence supporting suggested treatment. Agent interactions for providing treatment suggestions are very similar to the interactions described above, therefore they are not repeated. After MET3 has provided treatment suggestions, Dr. Brown asks for evidence supporting the use of systemic steroids (1). In response the encounter assistant agent sends a request to the evidence provider agent (2). This request includes all Peter's data, as well as the initially suggested treatment. The evidence provider agent sends a request to the model manager agent for the evidence model for asthma (3). The model manager retrieves the proper model from the model repository (4) and sends it back (5). Then, the evidence provider agent applies the model to the patient data and obtains a set of indexing terms that can be used to query the evidence repository for relevant systematic reviews (6). Retrieved reviews are ranked according to their relevance and passed back to the encounter assistant agent (7) that finally presents them to Dr. Brown (8).

Testing MET3-AE Operations in a Simulated Clinical Setting

MET3-AE is currently undergoing a clinical testing in the ED at the Children's Hospital of Eastern Ontario (CHEO) in Ottawa, Canada. The test involves a team of EPs, nurses and residents, who use MET3-AE on a tablet computer (Motion Computing C5). The test aims at evaluating and comparing predictions of EPs with those of the diagnostic model of MET3-AE and PRAM. The secondary goal of the test is to verify computing technology acceptance by EPs.

Prior to starting hospital testing we evaluated MET3-AE integration with a HIS and assessed how the system was handling typical information load. Based on published data we simulated a typical day in the ED at CHEO assuming 120 visits over a period of 12 hours (a relatively heavy workload). Amongst these visits there were 40 patients with asthma exacerbation that needed to be processed by MET3-AE. We simulated 10 concurrent sessions of patient management (i.e., up to 10 patients had to be handled by the system at the same time) covering all functionalities of the MET3-AE. All load tests were successful and system responded with no delays and no operational problems.

We also verified accuracy of advice (suggested diagnosis and evidence documents) produced by the diagnosis suggester and evidence provider agents. The performance of diagnosis suggester agent was tested on 120 unseen retrospective patient records giving sensitivity and specificity of 0.84 and 0.71 respectively. The evidence provider agent was tested using 15 prospective patient records and systematic reviews were retrieved with precision and recall of 0.89 and 0.81 respectively.

Discussion

Management of pediatric asthma exacerbations in the ED involves a complex multi-stage decision making process, where activities associated with specific stages are diversified and require different types of clinical knowledge. An effective CDSS should provide comprehensive support for all stages and be available the point of care. In this paper we demon-

strated that such a CDSS can be designed following the ontology-driven and multi-agent methodologies. We also presented MET3-AE – a proof-of-concept CDSS that provides a comprehensive decision support for data collection, diagnosis formulation, treatment planning and evidence retrieval.

MET3-AE belongs to the latest generation of CDSSs [8] that depending on desired functionality are designed according to service-oriented principles and implemented as web services (for example the SEBASTIAN system [14]), or designed and implemented as MASs. However, even those implemented as MASs do not combine all functionalities required to support all stages of a decision making process and do not offer as comprehensive support as MET3-AE. For example, the PalliaSys system [15] facilitates collecting palliative patient data and alarms physicians about abnormal values and the K4Care platform [16] facilitates execution of personalized treatment guidelines.

To the best of our knowledge, MET3-AE is the first CDSS that supports the entire decision making process associated with management of asthma pediatric asthma exacerbations. The system is accessible on multiple computing platforms directly at the point of care. It supports the HL7 standard to interact and exchange data with HIS. Finally, MET3-AE was implemented using open source software to limit the cost of proprietary solutions and long-term limitations that come with their use, thus this should be seen as is additional advantage.

We successfully tested the MET3-AE operations in a simulated ED setting under realistic load conditions, and now system is being tested in a teaching hospital.

Abstract

Modern Electronic Medical Record (EMR) systems often integrate large amounts of data from multiple disparate sources. To do so, EMR systems must align the data to create consistency between these sources. The data should also be presented in a manner that allows a clinician to quickly understand the complete condition and history of a patient's health. We develop the AALIM system to address these issues using advanced multimodal analytics. First, it extracts and computes multiple features and cues from the patient records and medical tests. This additional metadata facilitates more accurate alignment of the various modalities, enables consistency check and empowers a clear, concise presentation of the patient's complete health information. The system further provides a multimodal search for similar cases within the EMR system, and derives related conditions and drugs information from them. We applied our approach to cardiac data from a major medical care organization and found that it produced results with sufficient quality to assist the clinician making appropriate clinical decisions.

Keywords:

Clinical Decision Support Systems, Multi-modal Analytics

Introduction

As EMR systems are more widely adopted, clinicians are becoming deluged with data. While they may no longer need to decipher illegible handwriting in a hard-copy chart, they now have to review and understand a patient's EMR. This may include records of dozens or even hundreds of clinical encounters with multiple health care providers. As clinicians are increasingly evaluated by the quality of care they provide in diagnosing and treating patients, it becomes critical to quickly extract and understand the relevant parts of the patient's record, develop an accurate gestalt or mental model of the patient's clinical status, make a diagnosis, and then select an appropriate treatment. The speed of the analysis is especially important in Emergency Departments, where physicians make instant life-and-death decisions largely based on the patient's EMR. The daunting task of EMR systems is to support the work of clinicians by displaying a patient's record in a complete, consistent and clear way. In this paper, we address this issue for cardiac related data of a major integrated health care organization through a system that implements advanced analytics on patient records.

One challenge in displaying a patient's health history is the fact that the EMR frequently combines records of multiple clinical encounters of different types and from different health care providers. The record of an encounter may contain progress notes, diagnoses, procedures, test results and/or any type of clinical data. Combining information from these encounters can be difficult, as the information in the records may be imprecise, contradictory, erroneous, or missing. In addition, the information might be distributed among several software systems. Physicians need to absorb this information, reconcile contradicting and/or missing data, and arrive at a diagnosis and treatment plan. To compound the problem, the treatment plan should agree with clinical guidelines, best practices developed by subject matter experts, and the clinician's anecdotal experience with patients of "similar" cases (sometimes denoted as *similar patients*).

Although most EMR systems have user friendly front-ends, they generally only provide an "encounter-by-encounter" view of a patient's longitudinal data. Reviewing a patient's record in this manner is time consuming; moreover it is also challenging to gain insight about the temporal relationships between events. One way of providing a more complete picture of the patient's history is through "problem lists" extracted from the patient's health history. Enumerating past diseases of the patient is an example of such a list. However, such lists usually hide the temporal relationships between events. More sophisticated EMR applications therefore include charts and graphs that allow clinicians to view longitudinal changes in specific tests or measurements.

This paper describes the Advanced AnaLytics for Information Management system (AALIM). The AALIM system extracts information from different data sources and presents the data in a coherent Clinical Decision Support view of an EMR (see Figure 1). It uses advanced analytics to extract diagnostic information from data such as specialist text reports as well as medical imaging. To the best of our knowledge, this is the first system to search and identify a population of patients with

similar cases, diseases, comorbidities and medications. AALIM brings the longitudinal and cross-sectional information of that population to the point of care. It provides clinicians with a consistent view of the patient's history as well as the ability to compare comparing this history with that of other patients with similar test results and disease profiles. This comparison supplies the clinician with a refined insight as to the patient's diagnosis and the comparative effectiveness of different treatments on outcomes. The system displays the information in an easy to use graphical user interface, For the initial demonstration of AALIM, we limited the scope to the field of cardiology. However, the same paradigm can be applied to other medical specialties.

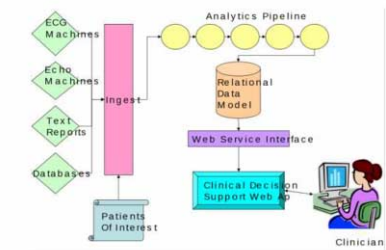

Figure 1 - Simplified block diagram for the AALIM System.

Related Work

The AALIM system, originally introduced in 2007 [1], is a first-of-a-kind in that it combines clinical image data and textual information for patient-search and analysis in a clinical setting.This interdisciplinary work combines multi-modal image and video analysis, signal processing and pattern recognition, text analysis, supervised and unsupervised learning, information fusion and content-based retrieval - in which similar clinical cases are sought. In its multi-modal search for similar cardiac cases, AALIM analyzes, indexes and retrieves information from free text (cardiology reports), patient demographics, temporal data (ECG waveforms), and imaging studies (echocardiogram videos) [2,3,4]. In its goals, AALIM can affiliate itself with Case-Based Reasoning (CBR) as well as Clinical Decision Support (CDS). Furthermore, its front-end provides special visualization and usability features, designed for physician tasks. Due to space limitation we can touch upon only a few of these domains and mention related work in those areas.

Clinical decision support systems and their effectiveness have been studied for decades [5-7]. Early systems, such as MYCIN [8,9], were targeted towards explicitly capturing expert human knowledge and transferring it to other clinicians via rule-based expert systems. It is clear that in some domains rule-based systems are the ideal solution. However, they have challenges in that they are hard to develop and even more difficult to maintain given the rapid progress of modern medicine. Recent publications suggest that this issue can be addressed via case-based reasoning (CBR).

CBR produces conclusions by applying search and retrieval techniques to the EMRs of patients (for a review see [10]). Examples of CBR in the medical domain include the INRECA system [11] for diagnosing intoxications by drugs, the enhanced literature search engine developed by Coiera et. al. [12], and the heart failure decision support tool by Purin et al [13,14], which searches through EMRs stored in the XML format. Most CBRs in the medical domain focus on text searches.and thus ignore important information in a patients' EMR, such as medical scans and videos ([15]).

Decision support systems that analyze image information generally focus on one imaging modality. For example, Drazen et. al. [16] and GE Healthcare [17] built systems specifically for ECG analysis. In [18] Patil and Kumaraswamy applied multi-modal analysis of patient data and trained a neural network to predict heart attacks. However when dealing with a large number of cardiac diseases and many combinations and comorbidities, training for each possible case is not feasible. One way to address the limitation of training for particular cases is via multimodal search systems.

Multimodal search systems fuse data from several modalities, such as text and medical scans. For example, Ruiz et al. [19] designed a multimodal search engine that combined content-based image retrieval (GIFT) with structured data (SMART) and free text (MetaMap). However, their search engine lacks automatic decision support capabilities.

In both its search engine and graphical user interface, the AALIM system uses temporal representation, integration and visualization of data. Chronological description of medical events is imperative to clinical decision making. Time line display of the patient's medical history was proposed in an early work by Cousins and Kahn [20]. Combi and Shahar [21] provided an overview of time-oriented tasks, approaches and systems in several clinical domains including cardiology,

and studied temporal reasoning extensively.

To the best of our knowledge, AALIM medical decision support system is the first multimodal search system that includes decision support. The system uses case-based reasoning [22, 1] and provides multimodal search of the EMRs of cardiac patients. AALIM requires a minimal amount of manual feedback for training as its queries are based on the current patient's status as well as similar cases. Similar cases are extracted from the database via data mining, which does not require any manual data annotation. The remainder of this article describes the system in further detail.

Methods

We previously mentioned the challenges of synchronizing information between multiple sources in an electronic medical record. In this section, we discuss our solution to transfer important information from multimodal reports into a structured diagnosis database. AALIM uses structured databases to provide clinicians with a variety of views on the state of a patient's health and on tracking of disease trends in a served population.

Figure 2 - "At a glance" overview of cardiac health.

The AALIM software package is layered on an existing EMR system deployed in a major integrated health care organization. Like many such systems, AALIM is a "work in progress", providing many features that represent a significant improvement over existing systems but still having gaps in some areas.

Rather than applying AALIM to the entire EMR at once, we focused the application on data related to cardiac diseases. We chose this strategy to target a single domain which allows us to present our system to a specific group of physicians, the cardiologists.

Data Sources

Data for this project was extracted from a variety of sources throughout the target hospital network. Depending on the source and data, the information is structured, semi- or unstructured.

Structured data acquired through routine patient care can be generally captured through fixed database tables and rigidly defined forms. In our target hospital, structured data included International Statistical Classification of Diseases and Related Health Problems (ICD9) diagnoses entered during outpatient visits, lists of significant ongoing problems, patient demographic information and medications prescribed.

In contrast, semi-structured data has defined list of fields whose content is free text. Examples of this type of data are human and computer generated data from ECG reports, the header blocks of echocardiogram reports, and the "signal" trace of an ECG report that is parsed from a printed report.

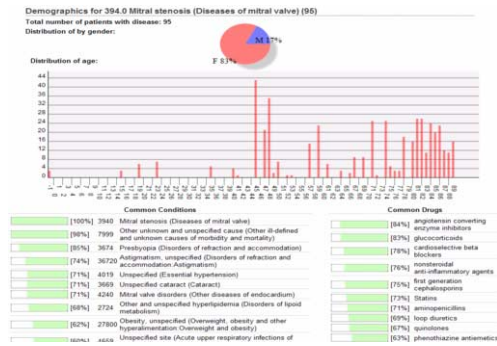

Figure 3 – Associations with comorbidities and drugs

Lastly, some data in our system comes with virtually no structure. Dictated reports for cardiac catheterizations, free text in echocardiogram reports, and streaming video from the echocardiogram procedures all fall into this category.

Once acquired, the information is stored in our data model (a relational data base plus files for binary object data) where it is made available for both analytics and presentation.

Examples of Advanced Analytics

AALIM generally first extracts features from the multi-modal data. These features are then included in the disease database, which AALIM uses to search through the data. In the remainder of this section we provide three examples for such searches.

Given a patient's ECG waveform, AALIM uses an advanced shape matching algorithm based on dynamic shape warping to find other similar ECGs. Different morphological variations of the shape corresponding to the same disease are modeled as a constrained non-rigid translation transform [2]. The ECG interpretations (a combination of computer diagnosis and cardiologist overreading) are then pooled forming a statistical diagnosis profile.

Another example is the automatic extraction of spatio-temporal motion patterns from echocardiogram videos. Our approach combines active shape model-based registration with region extraction and tracking using multi-scale normalized graph cuts [3]. These features, such as septal wall motion and ejection fraction, are added to our information about the study.

Finally, we analyze free text reports by matching keywords and phrases common in cardiac diagnosis via a taxonomy. Furthermore, we perform a shallow parse to identify modifiers and negators of these terms, for example "no evidence of mitral stenosis" or "severe case of atrial fibrillation". As can be seen, the relevant features for similarity differ from modality to modality. As new features are developed they are tested against known diseases for patients in a test set to identify how well they predict presence or absence of a disease.

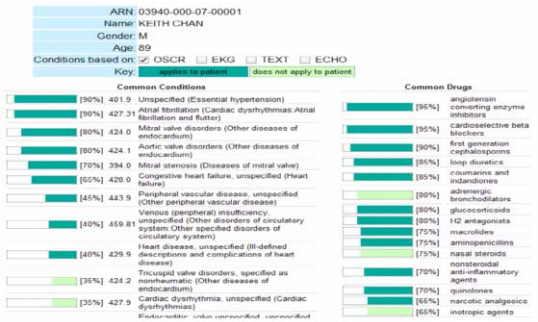

Figure 4 - "Micro cohorts" of related cases

In all cases, these additional features developed with AALIM analytics are added to the patient record as "derived" features. These features are generally considered of lower confidence than those specified by physicians. However, this type of data often provides important and valuable cues for selecting and presenting information on a patient's overall health.

Ultimately, each modality creates its own rank ordered list of most similar patients. These lists are then combined through a voting method [23] to generate a candidate list of similar patients for use in the presentation. Each modality chooses how many candidates to return based on its internal confidence thresholds.

Presentation

Our goal in the presentation of the collected information is to provide the physician with a complete overview of cardiac status of the patient. The presentation system (and thus all the underlying analytics that drive it) was motivated through interaction with clinicians, and seeks to explicitly present information about patients and diseases in a way that clinicians implicitly do when considering a patient. The difference is that instead of working with anecdotal and population studies, the system has thousands of complete medical records to draw upon for making comparisons of results and comorbidities.

We display this information via a few different "perspectives". The first perspective gives a patient overview, including a history of recent studies, current diseases and drugs (Figure 2). This gestalt view is useful especially in cases where a doctor sees a new patient that has an ongoing disease history.

The second kind of display is an overview for a selected disease (see Figure 3) such as the disease demographics, common comorbidities, and common drug prescriptions. Clinicians use this perspective to learn about common characteristics of a disease, such as the fact that mitral stenosis is more common among women than men.

The third screen (see Figure 4) helps with differential diagnosis. It shows diseases and drugs common with patients similar to the case being looked at. We define the similarity between patients by analyzing a combination of their ECG, echocardiogram, cardiac catheterization, diagnoses and other data. Users can influence this matching process by selecting specific criteria to define commonality between patients.

Heart Rate Extraction	91%
Arrhythmia detection	94.5%
Ejection Fraction	81%
Mitral Stenosis Detection	99%

Figure 5 - Selected results of the advanced analytics

Results

Today's EMR systems frequently require human intervention to accurately extract important information from multimodal reports into a structured diagnosis database. This is especially true for diagnosis information captured in non-structured modalities. An example would be a transcription of a catheterization procedure or visual evidence in an echo video.

We applied AALIM to several different collections and measured the accuracy of the tool to a given reference set. In the first experiment, we used our advanced analytics to recognize and tag patients with arrhythmia from the ECG database, which contains 20,077 12-channel ECG scans. Of these, our method could reliably extract heart rate for 18210 cases (91%). We found 1952 cases of tachycardia and 1066 cases of bradycardia. The accuracy of our approach reached 94.5% for arrhythmia patients. In all cases accuracy was computed by comparing with disease labels from an expert following the American Heart Association guidelines.

The automatic tagging capability enables AALIM to notify clinicians in the patient's "overview" screen (such as in Figure 2) of important medical conditions, such as arrhythmia. These notifications are important as they may be symptoms or complicating factors of other diseases. We note that some ECG scanners provide arrhythmia information. However, our approach can generate this tag from any (even historical) ECGs resulting in a consistent presentation of the labeling.

Ejection Fraction (EF) captures the pumping efficiency of the left ventricle, an important metric for identifying ventricular diseases. Our analytics automatically estimate the EF from the videos, which are then compared to written cardiologist reports. Out of 1604 echo videos, the algorithm agreed in 81% with at least one human manual interpretation. AALIM flags those reports where it failed to extract an EF and had to provide an estimate, and encourages the cardiologist to re-examine and correct the estimate, if necessary.

In the last experiment, we discuss the issue of diagnosis propagation. In our test set of 1173 cardiac patients, the original EMR system listed 95 patients with mitral stenosis. However, our analysis tool on the echo and textual data identified 128 cases. Of the 128 patients flagged, a cardiologist examined 105 cases in detail which included all of the 95 cases already flagged in the system. Using all available evidence, the cardiologist concluded that the assessment of disease/no disease done by AALIM was correct in all but one case, whereas the recorded diagnosis was correct only in 54 of the 95 cases.

These examples highlight the potential of advanced analytics in EMR systems. While our prototype system is still being

validated using expert supervision, the tool already allows clinician a quick presentation and a more complete view of a patient's complete health. It is clear that such a tool can be of use in many different specialties of medicine, although the underlying advanced analytics will of course differ in extracting information from the tests and procedures of each specialty.

Conclusion

Modern EMR systems are often hampered in their ability to present comprehensive, complete and coherent views of patient health due to misaligned and missing data. Such challenges can be mitigated via advanced analytics.

We found that our analytics are of sufficient quality to improve aligning records from disparate sources as well as providing estimates for missing values. We used this more complete and comprehensive data set to produce and present gestalt overviews of a patient's health status. We also identified micro-cohorts of related patients for which we computed statistics of disease prevalence and medication usage. These statistics can then assist in the differential diagnosis.

Although the AALIM system is still under development, in preliminary evaluations we found that our advanced analytics are useful to assist clinicians in improving the quality of care. Results of user studies indicate that such consolidated presentation of information is extremely helpful to clinicians, especially for emergent cases in which they may have no prior information about the patient. Further, continued development will enable clinicians to make informed decisions from multimodal analytics and promote “meaningful use” of cardiac data.

TADAA: Towards Automated Detection of Anaesthetic Activity

Bryan Houliston[a], Dave Parry[a], Alan Merry[b]

[b] *Department of Anaesthesiology, Faculty of Medicine, University of Auckland, Auckland, New Zealand*

Abstract

Task analysis is a valuable research method for better understanding the activity of anaesthetists in the operating room (OR), providing evidence for designing and evaluating improvements to systems and processes. It may also assist in identifying potential error paths to adverse events, ultimately improving patient safety. Human observers are the current 'gold standard' for capturing task data, but they are expensive and have cognitive limitations. Our current research – Towards Automated Detection of Anaesthetic Activity (TADAA) - aims to produce an automated task analysis system, employing Radio Frequency Identification (RFID) technology to capture anaesthetists' location, orientation and stance (LOS), and machine learning techniques to translate that data into low-level and high-level activity labels. In this paper we present details of the system design and promising results from LOS sensing testing in laboratory and high-fidelity OR simulator settings.

Keywords:

Anesthesiology, Task performance and analysis, Automated pattern recognition, Radio

Introduction

Anaesthesia, generally regarded as more complex than aviation [1], seems a suitable and worthwhile field for the application of similar techniques. Numerous studies have found that human factors, such as poor record keeping, ignorance of standards or failure to adhere to them, and lack of communication, are major contributors to preventable adverse events during anaesthesia [2].

Weinger, an authority in anaesthetic task analysis, sums up his motivation: "A scientific description of the anesthesiologist's task patterns and workload would aid in our understanding of the nature of the anesthesiologist's job and provide a more rational basis for improvements" in processes, equipment, OR layout, training and other aspects of anesthesia [3]. Having a 'scientific description' is particularly important in medicine, with its requirement for improvements to be evidence-based [4] . However, existing methods for anaesthetic task analysis are limited in their ability to produce scientific data in a timely, cost-effective way.

This provides the motivation for our current research project, Towards Automated Detection of Anaesthetic Activity (TADAA). In the next section we briefly introduce anaesthesia, review recent literature on anaesthetic task analysis and automated activity detection, and describe our prototype TADAA system. We then present initial results from evaluation of the system in our lab and in simulated anaesthetic procedures. Finally we outline outstanding issues and plans for future development.

In New Zealand hospitals there is always one anaesthetist present during an operation. They are assisted by a technician and possibly a nurse. Additional anaesthetists may be present as supervisors, trainees, or assisting in complex procedures.

Anaesthetic Task Analysis

Anaesthetists currently record some of their own activity in an anaesthetic record completed for each procedure. While this is a clinically important task, treating the patient always takes precedence. Thus parts of the record are often completed from memory, or with normalised activity [5], and its accuracy cannot be guaranteed.

When more rigorous activity recording is required, the gold standard approach is to employ independent observers [3, 6]. The observers, either in the OR or viewing video recordings, classify anaesthetists' activity into a number of *a priori* categories. A typical list of categories is shown in Table 1.

Table 1 - Anaesthetic activity categories used in [3]

Manual - Prepare drugs, Line placement, Give drugs, Mask ventilation, Bag ventilation, Suction, Manipulate airway, Intubation, Laryngoscopy, Adjust anaesthetic machine, Adjust monitors, Adjust IV
Communication - Attending, Nurse, Surgeon, Patient, Teaching, Other
Observing - Anaesthetic machine, Monitors, Patient, Airway, IVs, Surgical field, Other
Other – Anaesthetic record, Position patient, Clean up, Other

But human observers are not the ideal instrument for recording scientific data. They may make errors when fatigued, distracted, or their view is obstructed. Maintaining intra- and inter-observer consistency in classifying activities can be difficult [7].

Automated Activity Detection

Automation in anaesthesia is nothing new. Computerised systems that record patients' vital signs, and raise alarms when certain conditions occur, are widespread [5]. However systems to record anaesthetists' activity are rare, with none seeming to have progressed beyond very limited use [11, 13-15].

Activity recognition systems can be characterised in various ways, including:

- The type of sensor(s) used.
- Whether sensors are part of the environment or worn or carried by the research subject(s).
- Whether sensors detect body motion, location or movement around an environment, or object use.
- Whether sensor data is analysed for activity using *a priori* rules, or machine learning.

These were the four aspects that most informed the design of our TADAA system.

Methods

TADAA System Design

We selected RFID as the most suitable sensor technology. The TADAA system uses RFID to perform location sensing. An RFID-tagged person can be located by readers embedded in the environment, using the received signal strength (RSS) of their tag's transmissions. The RSS varies by the distance between tag and reader, as per the principle of lateration-by-attenuation (LAT) [12]. However, location sensing is complicated by the fact that RSS is affected by many factors other than distance (such as tag orientation, intervening objects or people, interference from other electronic devices, atmospheric conditions) in ways that are difficult to quantify.

Nevertheless, real time location systems (RTLSs), a common RFID application in hospitals, employ this approach to locate tagged people or equipment in wards, floors or entire buildings, generally to within a few metres. Research suggests that more precise location is possible over smaller areas [13, 14].

To support activity recognition, the TADAA system is intended to detect an anaesthetist's orientation and stance in addition to their location. An anaesthetist located next to a patient may be performing a number of activities, but the list of possibilities can be greatly reduced if it is known, for example, that they are facing the anaesthetic machine, or that they are seated rather than standing. The TADAA system therefore has an anaesthetist wear two tags, one front and one back.

Several tags are also placed at 'landmark' locations within the anaesthetic triangle, such as the drug trolley, anaesthetic machine, and the patient.

Finally, a few tags are suspended from the ceiling to act as 'canaries in the coalmine'. Since these tags do not move, change orientation, or get obstructed, their RSSs should remain relatively stable. Any changes would indicate a general environmental effect that may also affect other tags.

RFID Equipment

The TADAA system uses Wavetrend active RFID equipment, operating in the 433MHz radio spectrum. Tags transmit every 1.5 seconds. The readers can process only one tag transmission at a time. So if multiple tags transmit at the same instant, then all but one transmission will be lost. The reader ID, tag ID, date, time, and RSS are captured for each transmission. (RSS is expressed in an arbitrary unit that doesn't appear to correspond to any standard unit of power or signal strength.)

Accurate LAT requires a fine-grained and relatively stable RSS, and a predictable RSS-distance relation [13]. Effective activity recognition requires that the time between tag reads should be less than the shortest activity duration of the activities being performed [13,14].

Tests were performed in the AURA Lab to determine how well the RFID equipment satisfied these requirements:

- Time between reads, for 20 tags with 1 reader.
- RSS-distance relation, over distances from 0.5m to 6m. This was done once with the tag stationary at each 0.5m interval, and then with the tag moving.

No specific tests were performed for RSS granularity and stability, as the existing tests provide the necessary data.

Tests were also performed to gauge the impact on a tag's RSS when an anaesthetist:

- Wears the tag.
- Changes tag-reader orientation, by changing stance.
- Obstructs the tag, by standing between it and the reader.

LOS Sensing

The TADAA system was deployed in a high-fidelity OR simulator. Data was first collected from two dry runs during which one of the authors simply adopted 17 typical LOSs, without performing any activity.

The main data collection was from 40 simulated procedures, performed over 20 days by 20 different anaesthetists. Along with the RFID data, the procedures were also videotaped and recorded by a human observer. Each anaesthetist was asked to rate the distraction caused by the RFID tags, the RFID readers, and the observer on a visual analog scale (VAS).

The videos served as the ground truth, with an LOS determined manually for each second of video. The RFID data was aggregated to produce one record per second, combining the

RSSs for all tags and readers. Missing RSS values (due to the 1.5s transmission rate and lost transmissions) was filled in with the average RSS for the relevant tag, reader and known RSS values.

The RFID data was then clustered using the Self Organizing Maps (SOM) functions in MATLAB's neural network toolbox. Analysis was first performed on the dry run data. SOMs were trained with the data from dry run 1 and tested on the data from dry run 2, using different combinations of SOM size and tag subsets.

SOMs were evaluated using precision, or positive predictive value. Each cluster was assigned to the LOS which contributed the largest number of records. Those records were considered true positives (TP). Any other records in the cluster (from other LOSs) were considered false positives (FP). The SOM's precision was calculated as total TP / (total TP + total FP).

Results from analysis of the dry runs informed further analysis of data from the simulated procedures.

Results

RFID Equipment

The average time between reads was approximately 2.5s, with a standard deviation of 1.7s.

The minimum RSS value recorded during testing was 89 and the maximum 212. RSS granularity, up to distances of 6m, was therefore 123 points. The standard deviation in RSS was approximately 0.8% of the average RSS value.

RSS did vary by distance for all tags, but not in a predictable way. The RSS-distance relations shown in Figure 1 are typical: an overall downward trend, but with peaks and troughs. Different tag-reader combinations exhibited different RSS-distance relations. As Figure 1 illustrates the RSS at a given distance varied by up to 40 points depending on whether the tag was moving away from or towards the reader.

Table 2 shows the maximum effect on RSS of common interactions between anaesthetists and tags.

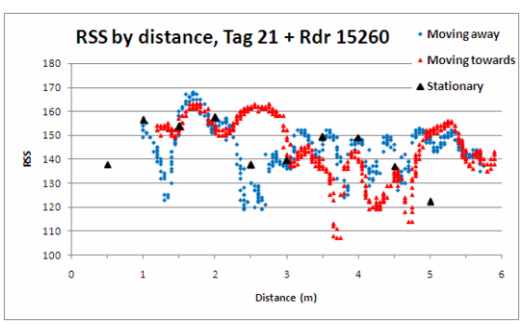

Figure 1 - Example RSS-Distance Relations

Table 2 – RSS effect of anaesthetist-tag interactions

Condition	Maximum Change in RSS
Change tag orientation	+30 points
Wear tag	-20 points
Obstruct tag	-10 points
Wear + obstruct tag	-35 points

LOS Sensing

Table 3 shows the maximum precision achieved by training SOMs on the data from dry run 1. When the most precise SOM was tested on the data from dry run 2, it gave only 39% precision. Similar results were found with SOMs trained on dry run 2 data and tested on dry run 1 data.

Given the results of dry run testing, a few changes were made for the analysis of simulated procedure data :

- Tag subsets were removed as a variable since there was minimal difference between the various combinations at the larger SOM size. All tags were included.
- RFID data cleaning method was added as a variable. Given the variation in RSS values across the two dry runs, we expected there might be differences in SOM precision depending on whether missing RSS values were filled in with averages based on other data for the procedure (as had been done for the dry runs), other data for all procedures on the same day, or other data for all procedures. For the sake of completeness we also tried no data cleaning.
- Larger SOM sizes were tried, since video analysis identified 150-200 LOSs per procedure, rather than the 17 used in the dry runs.

Table 4 shows the maximum precision achieved by training SOMs on the data from one procedure. When the most precise SOM was tested on data from another procedure on the same day, precision decreased to 54%. When the SOM was tested on data from procedures on different days, precision fell within the 40%-50% range. Similar results were found when repeating the SOM analysis starting with different procedures.

The anaesthetists' VASs for distraction were converted to values in the range 0 (No distraction) to 100 (Worst distraction). Table 5 shows a summary of results.

Table 3 - Maximum SOM precision for dry run 1 data

Tags	SOM Size 5	SOM Size 10
Anaes.	84.1%	95.2%
Landmark	98.3%	99.7%
Ceiling	80%	98.9%
An. + Lnd.	98.9%	99.7%
An. + Clg.	80%	99.8%
Lnd. + Clg.	80%	99.9%
All	80%	99.8%

Table 4 - Maximum SOM precision for procedure 39 data

Cleaning	SOM Size 10	SOM Size 20	SOM Size 30
None	17%	40%	77%
Proc.	58%	92%	96%
Day	56%	84%	92%
All	39%	61%	78%

Table 5 - Distraction Ratings (n=20)

Distraction	Min	Max	Average
Tags	0.25	25.5	5.55
Readers	0.75	10.75	3.94
Observer	1.00	70.00	3.94

Discussion

Based on the laboratory test results, the Wavetrend RFID equipment seems suitable for LOS sensing in most respects. The average time between tag reads of 2.5s is significantly better than the 7.5s - 30s reported in [13,14]. Likewise, tag granularity of 123 points is significantly better than the 8 points reported in [13]. The RSS standard deviation is small in relation to the average, indicating that RSS is very stable.

The major challenge presented by the RFID equipment is the RSS-distance relations. While we didn't expect the tags to exhibit ideal inverse square relations [12], we were surprised at so much variation between different tag-reader combinations. This would seem to preclude the use of LANDMARC-style RSS comparisons across tags [14]. But it doesn't disqualify the equipment from use for LOS sensing; the inherent tag-reader differences can be regarded as simply another source of RSS variation, alongside movement, orientation, and so on.

Our assumption that the RSSs of the ceiling tags would remain relatively stable was proven to be true only for the tags closest to each reader. They can continue to serve as 'canaries'. For the ceiling tags directly over the anaesthetic triangle, RSS does appear to be affected by anaesthetists' movement. We were surprised to see that, at larger SOM sizes, the landmark and ceiling tags both seemed to be more useful for LOS sensing than the anaesthetist tags (see Table 3).

The very high precision scores of SOMs trained on the dry run data (see Table 3) was encouraging, albeit achieved in a very 'sensing-friendly' environment with only one person and a small number of LOSs. We expected much lower precision in the more realistic simulated procedures, so 90+% scores were surprisingly high. Such scores clearly won't be possible in a real-time system, since they rely on having all the data for the procedure / day. Having to fill in missing RSS values using data from previous days, or even earlier in the same day, can reduce precision significantly, although is still an improvement over no cleaning at all (see Table 4).

Some decrease in precision when testing SOMs across procedures / days was expected, but such large decreases were surprising. Comparing the RFID data for matching tag-reader-LOS combinations across the two dry runs revealed that the RSS values in dry run 2 were up to 30% higher. The 'canary' tags showed increases of up to 10%, suggesting that some general environmental effect may have accounted for some of the difference. The remainder likely reflects changes in the location and orientation of anaesthetic and landmark tags between procedures. For example, the operating table is frequently moved between procedures so that the floor underneath can be cleaned. If it's not replaced in the same location and orientation, even a small change could result in large differences in RSS (see Figure 1 and Table 2). These differences could possibly be detected, and corrected for, with a calibration process before each procedure or at the start of each day.

Unsurprisingly, the anaesthetists found the RFID tags and readers much less distracting than a human observer (see Table 5). The cost of the TADAA system's hardware is approximately the same as a human observer's tablet PC. The system's ongoing cost, replacing active RFID tags every 5 years, is significantly less than an observer's remuneration.

Future Work

We continue to develop the TADAA system's RFID data cleaning, and SOM analysis approaches, and to prepare Hidden Markov Machine (HMM) algorithms for activity recognition testing.

In the medium term, we intend to complement RFID with additional sensors. RFID is best suited to LOS-specific manual activities (see Table 1). Detecting LOS-independent activities would be better done by other sensors. Communications, for example, might use a microphone suspended above the anaesthetic triangle. We are also considering means of recognising not just when a drug is administered, but which drug and how much. Analysis of patient vital signs may assist this, as in [10].

We ultimately see the TADAA system as a tool for improving patient safety. "In anaesthesia every complication has the potential to cause lasting harm to the patient. Therefore deviations from the norm must be recognised and managed promptly and appropriately" [5]. Activity data collected over time could be mined to produce 'norms' for procedure types, patient conditions, and so on. These would be as detailed as the Hierarchical Task Analysis (HTA) in [15] but based on actual practice. Anaesthetic activity detection in real-time could then compare actual activity with the norm, recognise deviations and raise alarms.

Conclusion

Task analysis has the potential to "provide more rational basis for making improvements" in anaesthesia, and ultimately to improve patient safety. But to do so it must capture scientific data to satisfy the requirements of evidence-based medicine, and not be too intrusive or expensive to implement in practice. Current task analysis methods, based on theory or observation, are unlikely to meet these criteria.

The TADAA system is intended to automate anaesthetic task analysis, through use of active RFID technology, and a combination of SOM and HMM machine learning informed by existing task analysis data. Testing in our lab and in high-fidelity

OR simulations suggest that the TADAA system is less intrusive and expensive than observers. However accurate location sensing, a first step towards activity detection, remains a challenge in the face of a complex interaction of factors affecting RFID's radio signals.

As development of TADAA continues we envisage adding new sensors, and means of storing, mining and visualising activity data. We see the system as potentially a valuable tool to improve patient safety in anaesthesia, and in other medical disciplines.

Acknowledgments

The authors wish to thank Dr Craig Webster and staff at the University of Auckland's Advanced Clinical Skills Centre, particularly Dr Jane Torrie and Kaylene Henderson, for allowing us to participate in the simulated anaesthetic procedures, and to HamIT Ltd for providing the RFID equipment.

A Model Driven Approach to Imbalanced Data Sampling in Medical Decision Making

Hong-Li Yin, Tze-Yun Leong

Medical Computing Lab, School of Computing, National University of Singapore

Abstract

Classification is an important medical decision support function that can be seriously affected by disproportionate class distribution in the training data. In medical decision making, the rate of misclassification and the cost of misclassifying a minority (positive) class as a majority (negative) class are especially high. In this paper, we propose a new model-driven sampling approach to balancing data samples. Most existing data sampling methods produce new data points based on local, deterministic information. Our approach extends the idea of generative sampling to produce new data points based on an induced probabilistic graphical model. We present the motivation and the design of the proposed algorithm, and compare it with two representative imbalanced data sampling approaches on four medical data sets varying in size, imbalance ratio, and dimension. The empirical study helped identify the challenges in imbalanced data problems in medicine, and highlighted the strengths and limitations of the relevant sampling approaches. Performance of the model driven approach is shown to be comparable with existing approaches; potential improvements could be achieved by incorporating domain knowledge.

Keywords:

Random sampling, Synthetic Minority Over Sampling (SMOTE), Model driven sampling, Imbalanced data learning

Introduction

Classification is an important medical decision support function that is often seriously affected by disproportionate class distribution in the training data. A main motivation of this work is the data imbalance challenge we have encountered in building classifiers in many real-life medical domains, including head injury, asthma, breast cancer, etc. An imbalanced data set contains a disproportionately high number of data in one or more classes than those for a class that is of interest. Traditional machine learning methods cannot work well with such data to build an accurate classifier; they tend to bias toward the majority class data and result in a low positive rate. In medical decision making, the cost of misclassifying a minority (positive) class as a majority (negative) class is especially high. The imbalanced data problem is increasingly being actively addressed in the field; some recent work include: Mazurowski et al. [1] studied the effect of imbalanced data to neural networks in medical decision making; Cohen et al. [2] deployed existing imbalanced data learning techniques in the surveillance of nosocomial infection.

There are two main categories of approaches to address the imbalanced data problem: 1) Algorithmic level approaches, where new machine learning algorithms are proposed or standard machine learning algorithms are modified to accommodate imbalanced data, *e.g.* learning rare class only [3], cost sensitive learning [4], etc., and 2) Data level approaches, which re-sample the imbalanced dataset to produce a new training dataset with balanced class distribution. We focus on the data level approaches in this work.

In this paper, we propose a Model Driven Sampling (MDS) approach to solving the imbalanced data problem. Unlike existing sampling approaches that use local, deterministic information to generate new data points, MDS learns from the whole labeled data set and possibly domain knowledge to induce a probabilistic graphical network to generate new data points. We also examine the performance of MDS as compared with two representative sampling approaches - Random Sampling (RS), and Synthetic Minority Over Sampling (SMOTE), on imbalanced data sets with different characteristics in medicine. We compare the three approaches on four medical data sets varying in complexity or dimension, data size and imbalance ratio, using different machine learning algorithms to build the resulting classifiers.

Related Work

Random sampling generates duplicated data without creating any new information. Random under-sampling randomly removes instances from the majority class to balance the class distribution. The disadvantage is that there is a risk in deleting useful information. Random over-sampling, on the other hand, randomly duplicates instances in the minority class. The disadvantage is that the decision region for the minority class may become more and more specific and possibly lead to data over fitting. In this paper, random sampling includes both random over-sampling and random under-sampling.

On the other hand, SMOTE creates synthetic data along the line between two nearest data points. In SMOTE, the minority class is over-sampled by taking each minority sample and introducing synthetic examples along the line segments joining with any of the k (k is 5 in the current implementation [5]) nearest minority neighbors. Chawla [5] showed that the synthetic examples generated by this technique cause the classifier to create larger and less specific decision regions as compared to random over-sampling.

Progressive sampling is systematically described by Foster et al. [6]. It was later used in [7, 8] for imbalanced data learning. However, the main advantage of progressive sampling is to improve the system efficiency by making use of minimal training data. The follow-on work [7, 8] either assumes there is sufficient training data, or use random sampling when there is insufficient data [7].

Random sampling is case duplicating based on one data point; SMOTE generates synthetic data based on two data points. They are representative of the sampling techniques that generate data based on local information. Recently, Liu et al.[9] proposed a generative oversampling approach which attempts to generate data based on the probability distribution of the minority data. This is similar to the idea presented in this work, with a major difference in the form of the probabilistic distribution generated.

A Model Driven Sampling Approach

In many biomedical domains, minority data can be sparse, but domain knowledge is commonly available. Model Driven Sampling (MDS) is an approach to learning from the whole training data set (both minority and majority, learning from majority can prevent generating noisy minority), and supports incorporation of domain knowledge into the induced model.

In contrast to the generative sampling approach [9], which builds a probabilistic distribution as the generative model, We induce a probabilistic graphical model or Bayesian Network for data generation. Bayesian Network is a factored representation of a probability distribution, representing the probabilistic relationships among a set of random variables. For example, Figure 1 shows the commonly cited Asia network. In a Bayesian network, the nodes indicate the random variables; the arcs indicate conditional dependencies, and there is a conditional probability distribution embedded in each node, denoting the conditional relationships of the values of the random variables with respect to different configurations of its parent nodes. The advantage of Bayesian Network is that it can easily combine both observational (data) and domain knowledge. For example, the causal relationship between smoking and cancer can be added from domain knowledge if it was unknown from the training data.

The MDS algorithm is as follows: As shown in Figure 2, we first build a model A from the original data set; model A generates new data based on the characteristics of the whole data set; the generated data is combined with the original data to form a new training data set to train classifiers. Specifically, we learn a Bayesian model using the K2 structure learning algorithm [10] from the data set. Then we generate minority data from the model using the Markov Chain Monte Carlo (MCMC) method [11].

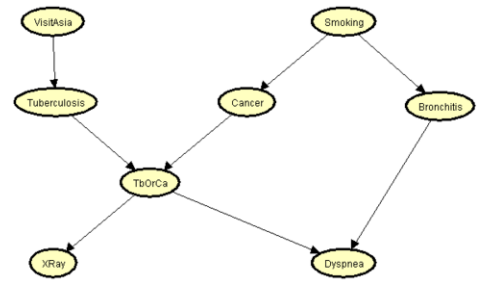

Figure 1 - Bayesian Network model for the Asia data

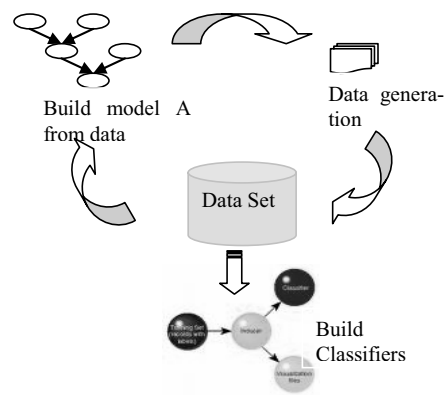

Figure 2 - Work flow in Model Driven Sampling

Comparing to other common sampling approaches, MDS generates new data based on the whole data set, thus the generated data would be more "meaningful" from a global perspective than the data generated randomly (random sampling) or data generated from local information (SMOTE). Due to the lack of domain knowledge and in fairness, we did not consider domain knowledge in the comparison analysis reported below, although we demonstrated the feasibility and promise of its inclusion.

Datasets

The data sets selected for the analysis span a wide spectrum in terms of complexity or dimension, imbalance ratio, and size; they are meant to illuminate the strengths and limitations of the algorithms studied under different conditions in medical domains. The data sets are: Asia, Mammography, Indian Diabetes, Asthma First Visit data. The Asia data set is commonly used in machine learning communities as examples illustrating

Bayesian Network learning. The asthma data set is collected, under proper approval and usage guidelines, from the hospitals in Singapore. The other two data sets are from the UCI Machine Learning repository [12] which were used for imbalanced data learning in [5]. The characteristics of the data sets are: binary data, unevenly distributed with different imbalance ratios (IB) as shown in Figure 3 and Table 1. IB ratio is equivalent to the percentage of minority examples in the training data; the lower of the value the more imbalanced the data is.

Table 1 - Class distributions (in numbers)

	Majority	Minority	IB ratio	Features
Asia	530	42	0.073	7
Indian Diabetes	500	268	0.349	8
Mammography	10923	260	0.023	6
Asthma First Visit	678	213	0.239	40

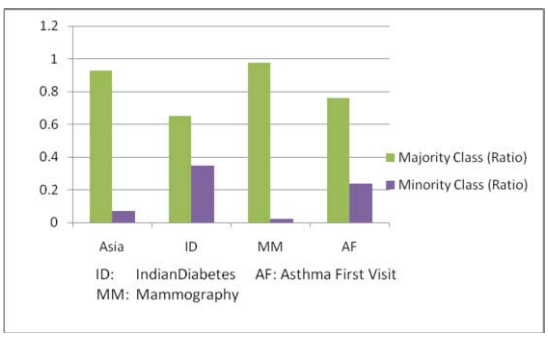

Figure 3 - Data class distributions (in ratio).

The Asia data set is about people who visited Asia and whether they had developed dyspnea or not. In our experiment, the Asia data set includes 42 positive cases, and 530 negative cases.

The Pima Indian Diabetes [12] data set includes 2 classes and 768 samples. The data is used to identify the positive diabetes cases in a population near Phoenix, Arizona. There are only 268 positive class samples.

The Mammography data set has a high skewed ratio: 10923 negative examples versa 260 positive examples. The trained classifier needs to be highly sensitive to detect the positive cases.

The Asthma First Visit data records the information when asthma patients visit the respiration centre for the first time. It has 40 attributes recording patients' general information, asthma history, treatment history, etc. There are 213 positive samples out of total 891 samples. The main problem is to determine whether a patient will encounter any control failure in the future based on the information provided on his first visit.

Experiments

We conducted experiments on the four data sets using three classifiers (C4.5 decision tree, Bayesian Network, Support Vector Machine) and three data sampling techniques (RS - Random Sampling , SMOTE, MDS). The experiment design is as shown in Figure 4, and each experiment ran through 10 fold stratified cross validation. The original data was split into 10 folds, and in each fold, training data was sampled by various approaches to build a new model which would run on the testing data.

Prediction accuracy cannot be used as the evaluation criteria because it is shown to discriminate the minority classes [13]. As shown in Equation (1), we use the geometric mean(g-mean) [14] of the accuracies measured separately on each class (where a^+ is true positive rate and a^- is true negative rate) as our evaluation criteria. The basic idea behind this measure is to maximize the accuracy on both classes.

$$\text{g - mean} = \sqrt{a^+ \times a^-} \quad (1)$$

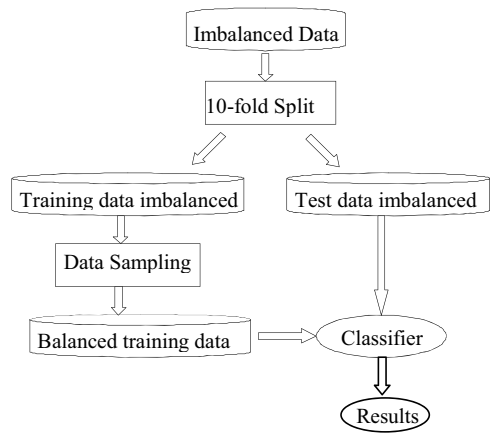

Figure 4 - Experiment design

Only the Bayesian Network (BN) results are reported in detail in this paper. This is because, as shown in Table 2, while the Bayesian Network performance may not always be the best in all experiments, it is generally more stable than others.

Table 2 - Performance of various algorithms on MDS

	Asia	Asthma	Diabetes	Mammography
BN	0.88	0.759	0.759	0.622
C4.5	0.266	0.591	0.771	0.886
SVM	0.428	0.591	0.777	0.874

Asia Data

The Asia data set has the lowest number of minority examples and the second lowest imbalance ratio 0.073. As shown in Table 3, the original data set without any sampling has a high prediction rate on its majority samples (98.7%), but a low prediction accuracy on its minority samples (7.1%), thus the overall performance is the lowest at 26.5%. Random sampling and SMOTE both significantly improve the predictions on minority samples and achieve a much better overall performance. MDS achieves the best performance 88% overall and 90.5% on minority data set.

Table 3 - Asia data running results

	Original Data	RS	SMOTE	MDS
TP[1]	0.071	0.881	0.69	0.905
TN[2]	0.987	0.863	0.925	0.856
G-Mean	0.265	0.872	0.799	0.88

Indian Diabetes Data

Indian Diabetes data is a relatively balanced data set with the highest imbalance ratio at 34.9%. Therefore, without any sampling, the original data set can achieve a satisfying performance on minority data and a good overall performance. The three sampling approaches equally improve the performance especially on minority by11%. The overall performance is not much improved. (As shown in Table 4)

Table 4 - Indian Diabetes data running results

	Original Data	RS	SMOTE	MDS
TP	0.669	0.783	0.787	0.772
TN	0.836	0.741	0.745	0.745
G-Mean	0.748	0.762	0.766	0.759

Mammography Data

Although Mammography data set has the lowest imbalance ratio 0.023, it is still relatively simple as it has only 6 features which result in a low data complexity. In

Table ***5***, the original data set can achieve 85% overall performance. The other approaches can equally improve the minority prediction by 15%. SMOTE has the best overall performance 89%, and MDS has a comparable performance of 88.3%.

Table 5 - Mammography data running results

	Original Data	RS	SMOTE	MDS
TP	0.735	0.888	0.873	0.885
TN	0.981	0.857	0.908	0.881
G-Mean	0.849	0.872	0.89	0.883

Asthma First Visit Data

The Asthma First Visit data has 40 features, the highest dimension among all. In Table 6, none of the approaches can achieve a good performance. Relatively, random sampling gives the best minority prediction (15% improvement) and the best overall performance (5% improvement). MDS approach ranks the second.

Table 6 - Asthma First Visit data running results

	Original Data	RS	SMOTE	MDS
TP	0.419	0.576	0.448	0.5
TN	0.852	0.732	0.805	0.775
G-Mean	0.598	0.649	0.6	0.622

Discussion

There are three important challenges for learning with imbalanced data sets: 1) the imbalance ratio, 2) the absolute size of the minority data, 3) the dimension of the data set. The three factors are common in most medical data sets, and they vary among the four representative data sets chosen in this work. We have examined relatively easy problems which are less imbalanced, low dimensional, with sufficient minority samples (e.g., Indian Diabetes and Mammography datasets), to hard problems which are highly imbalanced, high dimensional (e.g., Asthma), or with scarce minority samples (e.g., Asia).

The three approaches considered represent a wide range of data sampling efforts in tackling the imbalanced problems. They can be categorized by their learning scopes. Random sampling duplicates the data without creating new information; SMOTE algorithm creates new synthetic data based on local information – the nearest neighbors; MDS approach generates data based on global information – the knowledge model built from the full training space. As illustrated in Figure 5, random sampling produces data from a single data point; SMOTE generates data over two data points; MDS generates data from a model built from all labeled data or domain knowledge.

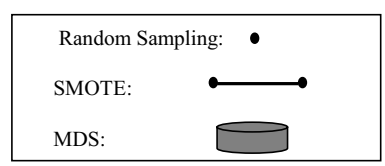

Figure 5 - Learning scopes for 3 sampling approaches

[1] TP is true positive rate for predicting minority samples.
[2] TN is true negative rate for predicting majority samples.

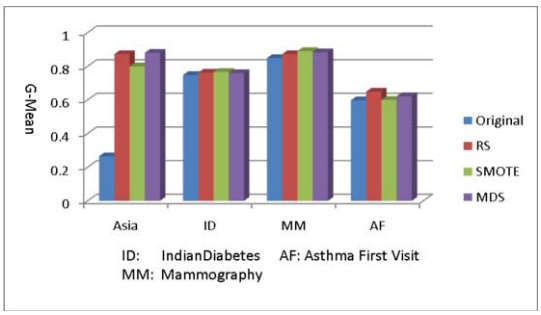

Figure 6 - Overall performance (G-Mean) comparison

Figure 6 shows that all three sampling approaches can improve classification performance on imbalanced data sets, especially on minority data. Comparing these three sampling approaches, random sampling is easy to implement and efficient; SMOTE will perform well especially when the minority data is tense; MDS will perform well when we have a reasonable accurate model to generate minority data, and this model could be from our medical domain knowledge or learning from existing data or both. Thus MDS can potentially address imbalanced problems with scarce or sparse minority data. In future work, we will incorporate domain knowledge into our model. This capability is a major difference from and a potential advantage over the other generative sampling approaches [9].

Conclusions

This work examined and analyzed the challenges in the imbalanced data problems in medical decision support. We proposed a new approach – Model Driven Sampling that can potentially make use of all available data and domain knowledge to sample new data for balancing class distribution. We compared the performance of different major sampling approaches on four representative data sets. We showed that data sampling approaches can improve classification performance to a reasonable level most of the time. In particular, they can significantly improve predictions over the minority data, which is important in medical decision support. We showed that MDS is comparable in performance with respect to the other approaches considered, and can outperform them in certain cases. In future work, we will incorporate domain knowledge into MDS, and extend it to multi-class problems.

Acknowledgment

We thank the reviewers for their valuable comments, and thank Prof Tow-Keang Lim for providing us the asthma data set. This work was partially supported by Academic Research Council grant R252-000-327-112 and grant R-252-000-309-112 from the Ministry of Education of Singapore.

Feature importance analysis for patient management decisions

Michal Valko, Milos Hauskrecht

Department of Computer Science, University of Pittsburgh, Pittsburgh, PA

Abstract

The objective of this paper is to understand what characteristics and features of clinical data influence physician's decision about ordering laboratory tests or prescribing medications the most. We conduct our analysis on data and decisions extracted from electronic health records of 4486 post-surgical cardiac patients. The summary statistics for 335 different lab order decisions and 407 medication decisions are reported. We show that in many cases, physician's lab-order and medication decisions are predicted well by simple patterns such as last value of a single test result, time since a certain lab test was ordered or time since certain procedure was executed.

Keywords:

Data interpretation, Statistical, Decision support systems, Clinical, Decision support techniques, Evidence-based medicine.

Introduction

Advances in data collection and electronic health record technologies have led to the emergence of clinical datasets, where data instances consist of sequences of clinical findings, lab values, measurements, and medication actions [7]. Such multivariate time series data provide us with a complex temporal characterization of the patient case. Analyses of these clinical datasets can be extremely useful for building models supporting patient outcome prediction, early detection of adverse events, or clinical decision making [8].

The key challenge when analyzing the clinical datasets is the complexity of the multivariate time series and the number of possible temporal features (patterns) one may generate to characterize such data. Inevitably we ask what types of features are the most important to represent the patient case. Are patterns related to most recent patient history more important than the distant past? What features do the physicians base their decisions upon? Are *values* or *trends* more important? Do physicians tend to look into simple trends and simple time constrains or into more complex temporal characteristics between several clinical variables?

We study this problem by analyzing the importance of various temporal features for lab and medication order decisions. More specifically, we investigate what temporal characteristics of the patient state influence the physician's decision the most.

Our analyzes on a collection of 4486 post-surgical cardiac patient records show that a relatively simple temporal characterization of the patient state is often sufficient to predict well many lab order and medication decisions. Moreover, we identify which of those simple characteristics are the most valuable sources of information for such a prediction.

The paper is structured as follows. First, we introduce the post-surgical cardiac dataset and temporal features used in our analysis. After that, we analyze the data and present statistics reflecting how different features predict the lab order and medication decisions. Finally, we discuss the results and conclude.

PCP Dataset

Post-surgical cardiac patient (PCP) database is a database of de–identified records for 4486 post–surgical cardiac patients treated at one of the University of Pittsburgh Medical Center (UPMC) teaching hospitals. The entries in the database were populated from data from the MARS system, which serves as an archive for much of the data collected at UPMC. The records for individual patients included discharge records, demographics, progress notes, all labs and tests (including standard and all special tests), two medication databases, micro-biology labs, EKG, radiology and special procedures reports, and a financial charges database. The data in PCP database were cleaned, cross-mapped, and are currently stored in a local MySQL database with protected access.

Dataset used in the analysis

To conduct our analysis, we used time-stamped data stored in the PCP database and converted them into a vector space representation of a patient state at discrete time points to get a collection of patient state examples. More specifically, each patient record in the PCP was used to build a sequence of patient state examples reflecting scenarios the physicians faced at 8:00am every 24 hours when managing the patient (Figure 1). Only the information available up to the segmentation points was considered in the vector space representation. Our 24-hour segmentation led to the total of 30,828 patient state examples.

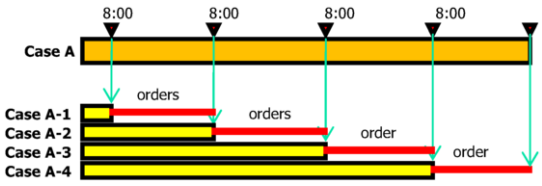

Figure 1 -- A segmentation of a patient case (Case A) to multiple patient state instances (A-1 to A-4) at 8:00am. Lab and medication orders for the following 24 hours are associated with each instance.

Patient-management decisions. In addition, every patient state example in the dataset that was generated by the above segmentation process was linked to lab order and medication decisions that were made for that patient within next 24 hours. Patient management decisions considered were:

- Lab order decisions with (true/false) values reflecting whether the lab was ordered within the next 24 hours or not
- Medication decisions with (true/false) values reflecting if the patient was given a medication within the next 24 hours or not.

A total of 335 lab order and 407 medication decision values were recorded and linked to every patient state example in the dataset.

Features

To represent a patient state we have adopted a vector space representation that is convenient for machine learning approaches. In this representation a patient state is represented by a set of features characterizing the patient at a specific point in time and their corresponding feature values. Features represent and summarize the information in the medical record such as last blood glucose measurement, last glucose trend, or the time the patient is on heparin. These representations were also used in our experimental studies published in [1–3].

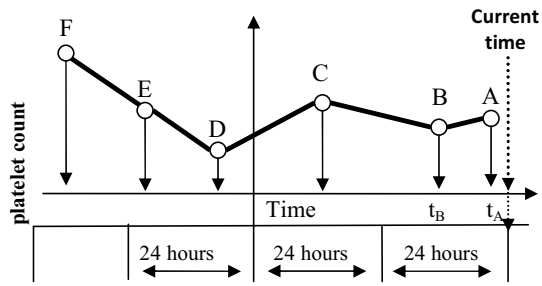
The features used in our experiment were generated from time series associated with different clinical variables, such as blood glucose measurement, platelet measurement, Amiodarone medication. The clinical variables used in this study were grouped into five categories:

1. Laboratory tests (LABs)
2. Medications (MEDs)
3. Visit features/demographics
4. Procedures
5. Heart support devices

We now briefly describe the features generated for clinical variables in each of these categories.

Lab Features

For the categorical labs, for example the ones with POS/NEG results we used the following features: Last value; second last value; first value; time since last order; whether the order pending; whether the value is known; and, whether the trend known. For the labs with continuous or ordinal values we used a richer set of features including features as difference between the last two values, slope of the last 2 values, and their percentage drop/increase. We used the same kind of features for the following pairs of lab values (last value, first value), (last value, nadir value), (last value, horizon value). Nadir and horizon value are the lab values with the smallest and the greatest value recorded up to that point. Figure 2 illustrates a subset of features generated for the labs with continuous values. The total number of features generated for such a lab is 40.



Temporal features:
Last value: A
Last value difference = B-A
Last percentage change = (B-A)/B
Last slope = (B-A) / (t_B-t_A)
Nadir = D
Nadir difference = A-D
Nadir percentage difference = (A-D)/D
Baseline = F
Drop from baseline = F-A
Percentage drop from baseline = (F-A)/F
24 hour average = (A+B)/2

Figure 2 -- A subset of temporal features generated for continuous valued lab tests.

Medication Features

For each medication we used four features: 1) indicator if the patient is currently on the medication 2) time since the patient was on that medication 3) time since the patient was put on that medication for the first time and, 4) time since last change in the status of patient taking the medication.

Visit/Demographic Features

We only have 3 features in this category: age, sex, and race. These are static and same for every time point we generate.

Procedure Features

Procedure features capture the information about procedures such as *Heart valve repair* that were performed either in OR or at the bedside. In our data we distinguish 36 different procedures that are performed on cardiac patients. We record four features per procedure: 1) time since the procedure was done

last time 2) time since the procedure was done first time 3) whether the procedure was done in last 24 hours, and 4) whether the procedure was ever done to this patient.

Heart Support Device Features

Finally, we describe the status of 4 different heart support devices: Extracorporeal Membrane Oxygenation (ECMO), Balloon counter pulsation, Pacemaker, and other Heart Assist Device. For each of them, we record a single feature which describes whether the device is currently used to support patient's heart function.

Altogether, our dataset consists of 9,223 different features describing 30,828 patient states. As noted earlier, we use the patient state to evaluate our ability to predict 742 lab and medication order decisions.

Methods

Univariate AUC analysis

Our objective is to evaluate the significance of a feature for predicting either the lab order or medication order decision.

Feature categories

While one can always analyze predictive relations in between features and individual decisions, the aim of this paper is to understand what kinds of features influence lab and medication orders the most. Hence our analysis focuses on summary statistics across multiple labs and medication decisions, and across multiple feature categories. To conduct these analyses we grouped 9,223 different features into:

(1) Five categories corresponding to lab, medication, demographics, procedures, and heart support device features.

(2) Forty temporal feature categories, each representing the same temporal characteristic of the time series. For example the category 'Time since last LAB' subsumes 'Time since last Platelet count' and 'Time since last Glucose lab' features.

Assessment metric

We used the AUC score to assess the feature significance. AUC score is an area under the Receiver operating characteristic [4] which is used to measure the predictive strength of a feature. To assess the importance of each feature category we computed the number of times the feature in the category is the best AUC feature for predicting the decisions.

Multivariate analysis

The limitation of the univariate analysis is the focus on an individual feature and it ability to predict the order decisions. In general, a better result may be often obtained by combining multiple features into a predictive model. To assess how helpful it is to use information from multiple features as opposed to just a single feature we have conducted a limited multivariate predictive analysis. Due the large amount of data, we used linear SVM classifier [5, 6]. In particular, for each order decision we trained such a classifier using 1) top 1; 2) top 3; and 3) top 30 features according to their AUC score computed on a subset of 2900 patients. After training the performance of the multivariate models was assessed by calculating their AUC on the remaining patient cases.

Results

Prediction of LAB orders

Figure 3 summarizes the most influential category for lab order decisions. The categories considered are labs, medication, procedure, demographics, and support devices features. Clearly, the most influential predictors for lab orders are features derived from lab and procedures data. Briefly, the best predictors for the next lab order are past labs. Intuitively, the lab order decision is typically driven by the existence of previous abnormal value of the same or other lab, and time since this lab has been measured. Procedure features are important as the type of surgical procedure and the time elapsed since the procedure may prompt close monitoring of certain organ functions and hence corresponding lab orders.

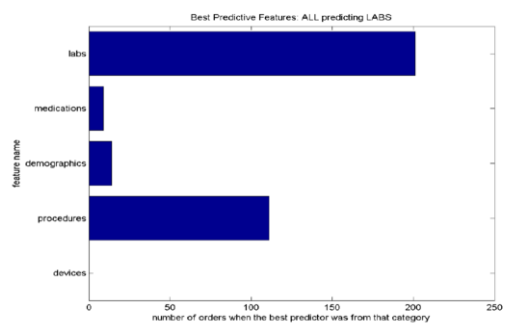


Figure 3 -- The importance of labs, meds, procedures, demographics and support device information for lab order decisions.

The next histogram (Figure 4) shows the top 10 most important temporal lab features for predicting the orders of the same lab. The best feature categories were the times since the last lab order and lab results, in particular last value, nadir, and horizon values. The fact that the time since last measurement is the dominant feature is somewhat surprising but can be explained by the fact that many labs for our cohort of patients are done regularly and routinely, and the time since the last test was done is a good indicator of the upcoming lab order. Also surprising is a relatively low importance of trend features, in general absolute values of labs appear to be more significant for predicting the lab orders. This suggests value based prediction patterns are dominant for lab order decisions and trend information (if used at all) typically refines the pattern.

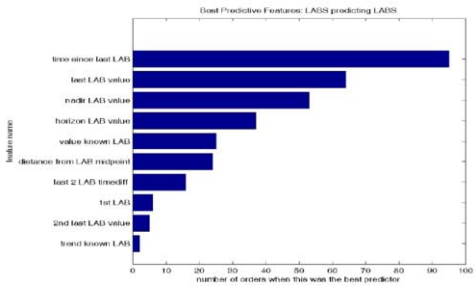

Figure 4 - The most influential temporal lab feature categories for predicting lab order decisions with the same lab features.

Figure 5 illustrates which temporal lab features predict the order of a different lab (i.e. not itself) the best. In this case, we observe that the last lab value is the most significant predictor of the order decision. This can be explained by the fact that an abnormal value of one test prompts the order of the other test. Also some lab tests are organized in panels and panels are typically ordered together creating this dependency.

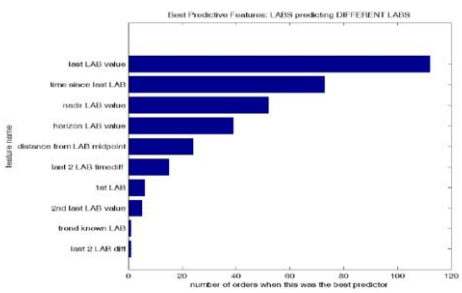

Figure 5 -The most influential temporal feature categories for predicting lab order decisions with other lab features.

Prediction of Medication orders

Figure 6 shows the influence of labs, medication, demographics, procedures, and support device features for predicting medication orders. In particular, we are showing the prediction of a medication *commission*, provided that a patient was not on that medication before. We see that the list is dominated by procedure features as some medications tend to follow certain procedures.

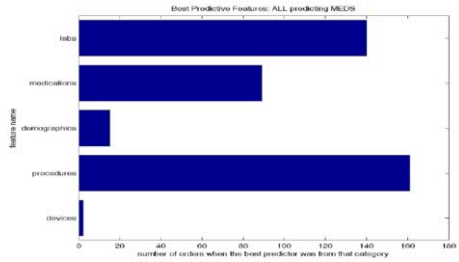

Figure 6 - The importance of labs, meds, procedures, demographics, and support device information for medication commissions.

Figure 7 breaks down the categories shown in Figure 6 and shows the top 10 most predictive features. For many medications the time since last procedure was the most predictive feature. For examples commissions of Papaverine could be most predicted (AUC= 95%) with the time that passed since the last Coronary Artery Bypass for that patient.

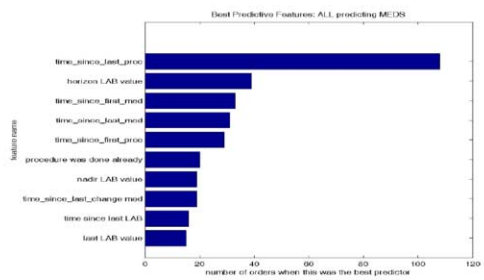

Figure 7 -The most important temporal lab features for predicting medication commissions.

Figure 8 shows the importance of medication features from different medications on the decision. One possible explanation for this dependency is that many medications are complementary and administered together, while other combinations are not used because of possible drug interaction. Therefore, a presence of one medication can often explain (predict) the presence or absence of another one.

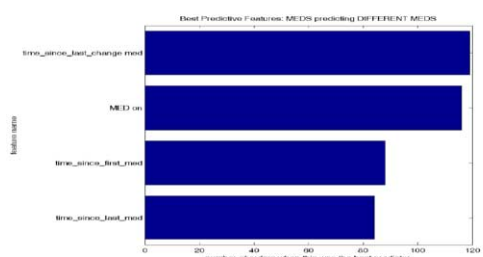

Figure 8 -The importance of temporal features for predicting medication order decisions with other medication features.

Multivariate prediction

The goal of this experiment is to explore the benefit of combining information from multiple sources or features. Tables 1 and 2 show AUC scores for prediction of top 10 highly predictive labs and medications from the linear SVM classifier. The classifier was trained on a subset of all features, in particular top 1, top 3 and top 30 best performing features in the training data. All results are reported on the independent test set.

We note that the feature selection for models with over 9000 feature candidates is an important and challenging problem and that the greedy selection applied in the experiment may not be the best one. However, this (somewhat limited) experiment indicates that a single feature is often a good predictor of the decision, suggesting simple patterns and their refinements may be able to capture well the prevalent lab order and medication order patterns.

Table 1- AUC for linear SVM trained on top 1, 3 and 30 most predictive features, showing 10 highly predictive labs

	top 1	*top 3*	*top 30*
GLU	87.46%	85.97%	87.73%
TCPK	79.56%	81.38%	82.68%
PPO2V	79.71%	79.70%	85.00%
VANMCR	74.15%	79.60%	82.13%
LD	79.22%	79.14%	82.69%
HPA	83.54%	83.03%	84.97%
RETAB2	75.83%	75.67%	81.89%
TEGMA	75.91%	85.36%	84.76%
TEGR	75.91%	85.35%	85.30%
TEGALP	75.91%	85.38%	85.09%

Table 2- AUC for linear SVM trained on top 1, 3 and 30 most predictive features, showing 10 highly predictive medications

	top 1	*top 3*	*top 30*
Nitroglycerin	71.48%	79.50%	80.53%
Papaverine	82.34%	83.83%	89.19%
Ioversol	87.65%	88.58%	89.50%
Aminocaproic	79.49%	79.39%	86.83%
Aprotinin	80.67%	78.65%	85.99%
Thiopental	76.40%	75.62%	85.30%
Eptifibatide	87.22%	89.13%	89.75%
Darbepoetin	86.22%	90.33%	88.85%
Iodixanol	69.62%	87.99%	87.26%
Vitamin K	85.87%	86.08%	86.61%

Conclusions

Our univariate analyses of relations in between patient states and patient-management decisions revealed that the lab and medication order decisions are often driven by simple predictive patterns that involve more recent set of values, or times since the occurrence of some event (e.g. procedures, or previous lab/medication orders). Our (limited) analyses of more complex multivariate models suggest that lab and medication order decisions are likely based on only few clinical variables and their characteristics (features). In the future, we plan to further expand this study by analyzing feature dependencies and by developing more advanced feature selection for building multivariate predictive models.

Abstract

We have designed and deployed a novel approach to protecting Personal Healthcare Information in environments where a data center is remote and its physical security cannot be assured. Our "KeyServer" methodology uses a server-client-server architecture to dynamically serve keys from a distant server in a separate secure data center in the US. The approach combines pre-existing and novel techniques into a layered protective barrier around compromise of patient data. We describe how this technology provides scalable security that makes security breaches highly unlikely. With some careful planning a Clinical Data Repositories fed by Electronic Health Records can be placed in relatively insecure settings, with a high-level of security surrounding data theft, even in the event of hardware theft. Such security architecture is ideal for not only developing nations, but for the evolution of health information to cloud computing platforms.

Introduction

In many countries with mature healthcare IT infrastructure, security of Personal Healthcare Information (PHI) is often provided by a multilayered approach that includes robust physically secure data centers, complex network security protocols, and a legal framework with effective enforcement. These approaches may or may not be suitable in developing countries with low evolving IT infrastructure where the risks of data theft by physical and electronic intrusion can be high. A review of the literature

To address health data security issues in high-risk environments with low level technological infrastructure,[1] we designed a novel encryption and authentication pathway. We posit that our approach to protecting PHI will be generally useful for cloud-based computing solutions in healthcare.

Methods

Data security is an important component of any electronic health record (EHR). We have designed and deployed an EHR in a Middle Eastern country that posed numerous challenges including remote data protection in a setting where we were concerned about physical security of the data. Because of low bandwidth between the Middle East and the US, deployment from a US based Tier-3 data center was not an option and we designed the system with the plan to place servers in a small commercial ISP data center located in the Middle East. Ultimately we were able to deploy in a secure government based data center, but this was well after the design phase was complete.

The core systems design consists of a MySQL 5.1 Community Edition relational database management system (Sun Microsystems) with a JAVA based application (Sun Microsystems) running on Apache Tomcat 6 (Apache Software Foundation) application server.

The original deployment strategy posed a number of problems, foremost being loss of control over the server environment. Furthermore, the database is designed for heavy secondary use of data in public health monitoring and research, making openness of the server based Clinical Data Repository (CDR) a high-risk asset.[2] Given these risks, we designed a multitier security strategy that utilizes a novel encryption and authentication pathway to provide network security and physical theft risk mitigation.

We started with the assumption that we could not assure physical security, and that our database and server code could be physically stolen given the lack of high end data facilities available in the region.[1] We were also cognizant of the fact that both the passwords and certain aspects of PHI, even with encryption, are vulnerable to preimage attacks, also known as a "dictionary attack". Passwords are notoriously susceptible to dictionary attacks,[3] and the nature of medical record numbers (MRN) as sequential non-sparse integers make them trivially susceptible to a preimage attack. Although we do have influence over password entry by users, we do not have influence over

existing medical record numbering schemes, so a secondary method of attack prevention is required.

Our initial approach was to encrypt the entire database except for any field that could be used for identification of patients. This is easily accomplished as MySQL natively supports symmetric encryption via full Advanced Encryption Standard (AES-128) support and asymmetric encryption via the Secure Hash Algorithm (SHA1). The AES-128 algorithm is a substitution permutation network encryption algorithm authorized by National Institute of Standards and Technology (NIST) for protection of information classified up to the "secret" level,[4] making it appropriate for storage of PHI. The use of AES encryption is highly secure, as no successful attack other than brute force, has been demonstrated in the literature. However, as in any password-based system, the system is vulnerable if you can discover the key since the data would be freely readable.

JAVA, while a highly secure language, has a vulnerability of being able to be easily human-readable reverse-compiled as it is not fully compiled, but rather partially compiled into byte-code. This means that storage of encryption keys in the code would be easily retrievable by having possession of the server/drives or compiled application. Having the keys in the source code also does not allow for easy changing of the codes as compilation and redeployment of the application is required.

We have created and deployed a novel "KeyServer" methodology that uses a server-client-server architecture to dynamically serve keys from a distant server in a separate secure data center in the US. The concept is that every column of every table in the remote MySQL database that needs to be encrypted, is encrypted with a column key. This key is only held in memory on the application server implementing the KeyServer client, and written to disk only on our secure KeyServer.

Each key can either be human-readable or machine-created thus protecting against dictionary attack by the use of random alphanumeric strings. Various identification attributes of the client network environment are also recorded on the KeyServer, including IP address and a hardware key of a physically separate device on the client network which is sent with every client request. These identification attributes make it very difficult to spoof the client's identity.

On boot the KeyServer client sends a getInitKey request with the identification information gathered from the client network via an encrypted web services call to the US KeyServer, and if authenticated the current keys are returned, and the application will start as shown in Figure 1.

At intervals varying between minutes and hours, the column keys on the KeyServer are changed; the KeyServer client checks its keys via a CheckKey request with the KeyServer master keys. The request sends the identification attributes described above, as well as the client's current keys. The KeyServer then checks the identification attributes, confirms the requesting client's authenticity and returns a pair of keys, the client's current key and the KeyServer's new key. For any given column, if the KeyServer and client keys are the same then the current settings are still valid and no change is made. If the client key is different to the KeyServer key then the master keys have been changed and the column is dynamically decrypted with the old key and encrypted with the new key. Figure 2 demonstrates this.

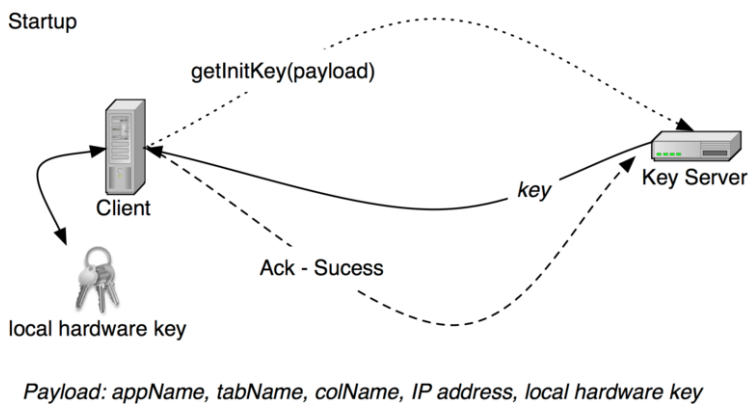

Figure 1 - Initial getInitKey request

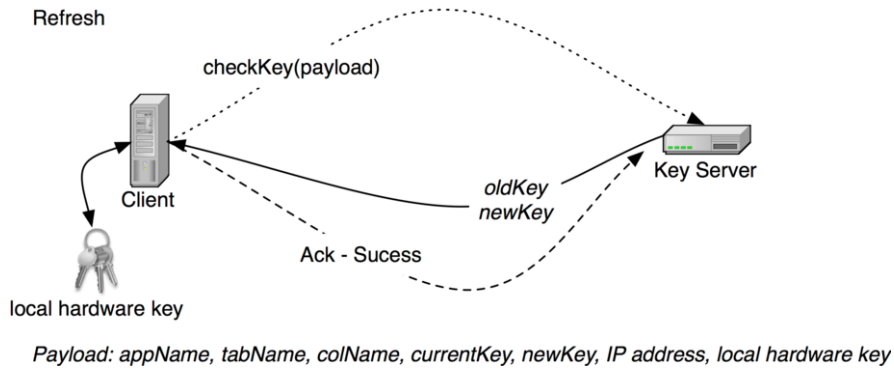

Figure 2 - Subsequent CheckKey request

The KeyServer never updates its own tables until an acknowledgement packet is returned from the client stating it has completed the key change successfully, as a failure could render the data unreadable. The transaction is carefully and securely logged on the server for future auditing. A network failure resets the timer, and the transaction will retry in the future.

A more detailed examination of the encryption process presents further security issues. A problem with PHI encryption is that predictable data, such as the non-sparse sequentially numbered MRN fields or names, require protection against preimage attacks. This is because if one encrypts a simple string using the same algorithm and key pair it will always produce the same hash every time. This is true regardless of the encryption method, whether symmetric or asymmetric, as both methods will produce the same output (a "collision" in encryption parlance) with the same source/key information. This is a much greater problem with asymmetric algorithms such as SHA1 where the key is fixed. It is less of a problem with random text, however patient identifiers, such as medical record numbers are simply sequential numbers 0-*n* and last names are known, so the creation of a preimage attack is trivial. For example, on a typical desktop computer you can generate the 128-bit SHA1 hash value dictionary for 10 million medical records numbers in less than 1 minute. Figure 3 demonstrates a MRN dictionary attack.

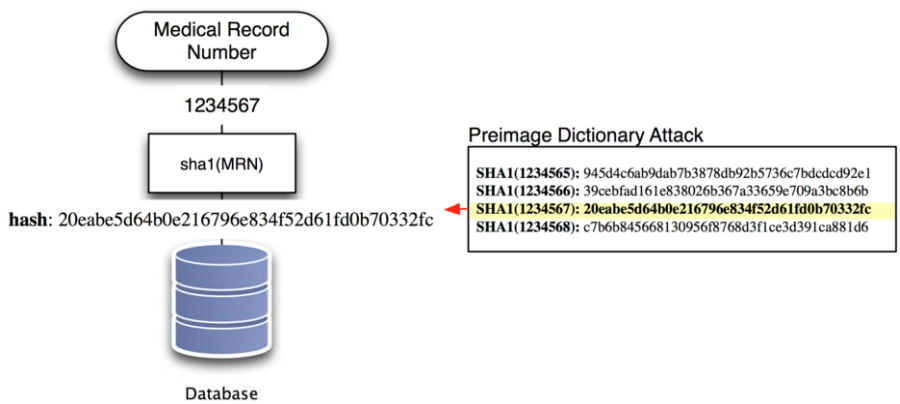

Figure 3 - Dictionary Attack on MRN's

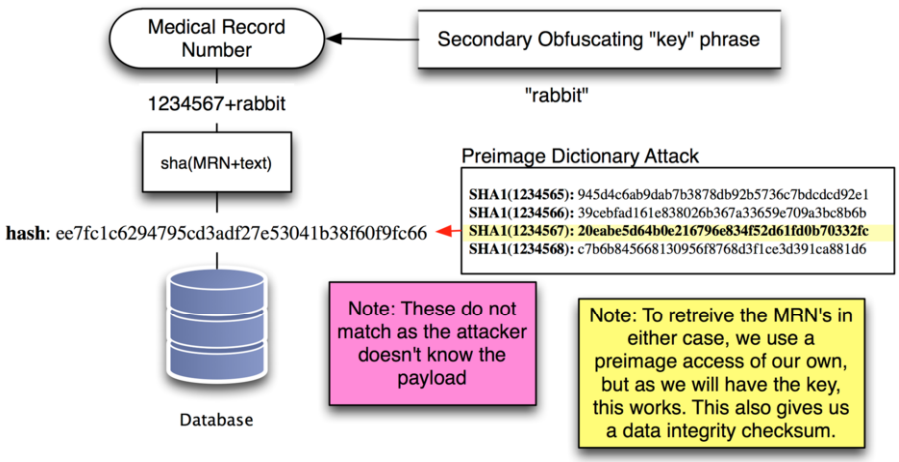

Figure 4 - SHA1 with extra payload

Our solution to solving this problem is to add an obfuscating payload to the medical record number. This payload key is also supplied by the KeyServer and is added to every predictable field on a per-column basis. For example, using "rabbit" as the payload key, MRN "*1234567*" becomes "*1234567rabbit*". For record retrieval we can then use our own "dictionary" knowing what the obfuscating package key was to match against. This is shown in Figure 4. If we wish to change the package key, we manually "decrypt" the column by performing our own mass dictionary attack and parsing the data back to MRN's and encrypting with the new package added. For data such as patient names, we can add this text to the start of every name, and programmatically subtract it after decryption.

While most password systems require the user to comply with various levels of onerous password change and complexity requirements, this makes users do things like write their password down next to their computers. Security breaches against passwords without access to the password file, are generally human-nature attacks such as finding the password written down or guessing familiar terms, which is not protected against by stringent password requirements. Even worse, stringent password requirements are not foolproof in themselves, and simply lower the penetration risk somewhat.[5]

However, we were additionally concerned about password file theft, which means protection against a dictionary attack. Since our passwords are stored as asymmetrical SHA1 hash values, we chose a different method. A simpler task is to take password security out of the hands of the human user, and make the file inherently highly resistant to preimage attack. Again an obfuscating payload makes a useful barrier to mass preimage attack.

Rather than forcing the user to remember these obfuscating elements, we can programmatically change their password on entry/storage on database entry to include these elements, but without access to the originating code, and knowledge of the obfuscating payload, decryption is unlikely. For instance instead of the password sent to the encryption algorithm being "*password*" it is "*passwordrabbit*" where *rabbit* is a secret key kept only within the system. The user is unaware of these changes. One downside of this, is that this package cannot be dynamically rewritten, as we have no ability to perform our own dictionary attack, since the system does not retain the passwords as entered by the user.

Discussion

We have successfully designed and deployed a highly secure clinical data repository using our novel KeyServer technology. The technology combines pre-existing and novel techniques into a layered protective barrier around compromise of patient data. We start with network security by use of encrypted connection with RSA-certificate signed servers. We then further the identification of clients via secure session management with IP address verification and separate local hardware identification of clients. Onto this we add loading of the client side keys into memory means that if the server is stolen, on restart the local keys are destroyed, along with column level encryption. Scalable security timing of master key changing and authentication calls using system generated encryption keys make preimage attacks highly unlikely. Finally adding additional payloads to predictable data such as passwords, names and patient identifiers, makes these more resistant to preimage attacks.

There are some potential disadvantages with this configuration. Firstly, unexpected server shutdown automatically voids all keys

from memory. Depending on the reliability of server side support services, this will either be likely or unlikely. In any event, the keys can always be reloaded from the US KeyServer. Another limitation is the absolute requirement for a reliable network connection between the client and US KeyServer. Multi-column encryption and decryption processes potentially could affect overall performance, however our experience is that this is negligible.

There has been published work done that has demonstrated a cryogenic attack at retrieving keys from computer DRAM chips is possible,[6] this is a level of attack, that we choose not to protect against. This level of sophistication is outside of the level of perceived threat that PHI is likely to be subjected to. If this threat becomes more realistic, the referenced article suggests one practical countermeasure to this technique which is writing the keys to memory with large amounts of garbage data around them greatly lengthening the time required for key reconstruction, but even this is vulnerable.

With some careful planning an EHR/CDR can be placed in relatively insecure settings, with a high-level of security surrounding data theft, even in the event of hardware theft. This is made possible through advanced security practices and distributing the security apparatus across international boundaries with the primary security codes being in a highly secure data center, with no ability of the remote system to recreate its own codes. Another key to this approach is a reliable method for local client proof of identity even if stolen and booted outside of its home environment; this is the key to prevention of stolen code and database being usable on any computer not in its predefined network environment even if network hardware and soft IP addressing is spoofed. We believe these methods are generally useful for cloud-based solutions in healthcare.

Healthcare System Evolution towards SOA: A Security Perspective

Vassiliki Koufi, Flora Malamateniou, George Vassilacopoulos, Despina Papakonstantinou

Department of Digital Systems, University of Piraeus, Piraeus, Greece

Abstract

Healthcare providers often face the challenge of integrating diverse and geographically disparate IT systems to respond to changing requirements and to exploit the capabilities of modern technologies. Hence, systems evolution, through modification and extension of the existing IT infrastructure, becomes a necessity. This paper assumes a healthcare systems evolution towards a service-oriented architecture (SOA) and places emphasis on the development of an appropriate authorization model and mechanism that ensures authorized access to integrated patient information through web service invocations.

Keywords:
Healthcare systems, SOA, Context-aware authorization.

Introduction

Healthcare delivery is undergoing radical change in an attempt to meet increasing demands in the face of rising costs. In this context, healthcare providers adopt new ways of delivering healthcare involving a major shift to information systems that enable authorized access to integrated patient information anytime, anywhere [7,9]. Thus, healthcare providers are faced with the challenge to safeguard their significant past investments in the development of large and complex information systems by modifying and extending them in response to changing requirements in addition to capitalizing on modern technologies [8]. To this end, a systems evolution process is often designed and implemented with the objective to achieve interoperability among diverse systems that may have been developed at different times and with different technologies. Such evolutionary processes are operating on legacy systems, are directed toward long-term user needs and are usually conducted in an iterative and incremental manner [7,10].

Contemporary system evolution processes are increasingly directed towards Service-Oriented Architectures (SOA) since such system architectures are thought to maximize IT support to business processes that are subject to constant change in response to a changing environment. In this respect, SOA allows users to rapidly build, reuse and reconfigure business processes as healthcare priorities, regulatory requirements or environmental conditions change [6,10]. Hence, it responds to the need of exchanging medical information between diverse systems on the web and can form an ideal architectural basis for evolving legacy healthcare systems [7,8].

In most cases, a SOA is not built from scratch but rather the functionality of legacy systems and their components are being wrapped to web service interfaces. Thus, as contemporary SOA is intrinsically reliant on web services, an evolution process towards developing a SOA often uses the transformation of legacy systems into web services as the first step. The SOA architecture assumed in this paper, as part of an evolution process, is based on an ESB/BPEL software infrastructure that enables legacy systems to be synthesized so that they serve as a unified whole. Hence, uniting legacy systems into healthcare processes involves exposing each system as a web service and, then, using BPEL to combine the web services into healthcare processes.

When the healthcare system envisaged as a result of an evolution process is SOA-based, developers are faced with the challenge not only to ensure that the evolved system supports the delivery of healthcare services within and across organizational boundaries but also to meet global security requirements that were not applicable when disparate systems were in place. Thus, developers are called upon to ensure that component sub-systems constituting a SOA can interact and exchange information subject to an appropriate level of privacy and disclosure regulations based on state of the art practices for access control [1].

This paper presents a security framework that addresses the authorization and access control issues arisen in an interoperable healthcare system that accrues from the evolution of legacy healthcare systems into a SOA-based system. The need to also evolve security has led to the development of a context-aware authorization model which is based on the role-based access control (RBAC) paradigm. This model is then used in a prototype interoperable, SOA-based healthcare system that has resulted from an evolution process to enable authorized access to integrated patient information during the execution of healthcare processes.

Motivating scenario

The basic motivation for this research stems from our involvement in a recent project concerned with defining a prototype SOA-based system architecture by evolving legacy healthcare applications. To illustrate the security aspects of the

adopted approach to systems evolution, a sample evolution project is described which is concerned with patient referrals among healthcare providers within the boundaries of a health district.

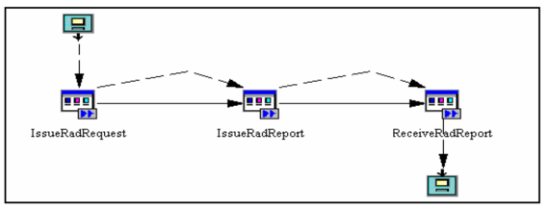

Figure 1- A high-level view of the healthcare process concerned with radiology orders.

The sample process considered here is concerned with patient referrals to a radiology department of a hospital. Suppose a healthcare delivery situation where a physician situated within a health district issues a radiological request for one of his/her patients. The request is submitted to a radiology department of a hospital which schedules the radiological procedure requested and notifies the requesting physician on the date and time scheduled. After performing the radiological procedure requested, the radiologist consults the relevant portion of the patient's record and writes a radiological report, incorporating both the radiological images and the associated text, which is sent to the requesting physician. Figure 1 shows a high-level view of the radiological process considered. This process consists of three composite tasks: *IssueRadRequest*, *IssueRadReport* and *ReceiveRadReport*.

A SOA-based evolution

The sample process described above involves two separate legacy healthcare systems which, in general, are based on different technologies:

- *Radiology Information System (RIS)*: A system that manages radiological requests and produces radiological reports.
- *Electronic Medical Record (EMR)*: A system where patient data is stored and managed.

To protect healthcare providers' investments, these legacy systems can become component applications of a loosely-coupled interoperable system (i.e. the system resulted from the evolution process). With regard to the sample healthcare process of Figure 1, all or parts of these legacy systems can be expressed as orchestrated web services (consisted of interconnected tasks) and the whole system can be a SOA implementation on an ESB/BPEL software infrastructure [4]. For example, the EMR system above may be converted into a number of web services and each web service may consist of a number of interconnected tasks. A detailed description of the system evolution approach adopted (including technical and operational requirements) is presented elsewhere.

To benefit from the advantages of SOA, the composition of two or more web services is implemented using BPEL which requires sophisticated solutions for securing web services [6]. Such an implementation may pose security problems not encountered in traditional, not SOA-based, systems. In particular, the authorization to execute a web service task built-in a SOA needs to be externalized and this authorization may be subject to certain contextual constraints that are extracted and evaluated from every request and for every application of the system [5].

An authorization perspective

Typically, role-based authorizations with regard to web service tasks and related data accesses are specified when the SOA is designed and the exact user-to-role and role-to-permission assignment relationships are decided. Context-aware authorizations are intended to provide more flexibility by taking context into account when deciding on the permission(s) that should be granted to users at run time [2,7]. Hence, these authorizations are bound to specific web service invocations and incorporate such constraints as those based on the data content, the user identity, the valid time and the location of attempted web service task accesses.

Table 1 - Extract of authorization requirements for the healthcare process of Figure 1

1	PHs may issue requests for radiological procedures on their patients. (IssueRadRequest)
2	RDs may issue radiological reports for patients on request by PHs. (IssueRadReport)
3	PHs may receive patient radiological reports issued by RDs only if requested by them. (ReceiveRadReport)

From a role-based authorization perspective, the healthcare process of Figure 1 involves two roles: the role of the physician (PH) and the role of the radiologist (RD). An extract of the authorization requirements regarding web service task execution and related data access privileges assigned to these roles is shown in Table 1. It is seen that the tasks "IssueRadRequest" and "ReceiveRadReport" can be executed by a user holding the role PH and the task "IssueRadReport" can be executed by a user holding the role RD. Also, during the execution of these tasks the users holding the roles PH and RD can have certain access rights on relevant data objects. In addition, the healthcare process of Figure 1 surfaces some additional requirements with regard web service invocations and associated task execution involved in data accesses. These requirements include the following:

- **Data content** – Some role holders should be allowed to exercise a set of permissions on web service invocations and task executions that result in accessing certain data objects only. For example, a physician is allowed to invoke the relevant web service and execute the "IssueRadRequest" task for reading patient records and issuing (write, edit and send) radiological requests only for his/her patients.

- **Permission propagation** – Some role holders should receive additional permissions on web service invocations and task executions that result in accessing certain data objects in order to effectively execute a task but these permissions should cease holding upon successful execution of the task. For example, for an effective execution of the "IssueRadReport" task with regard to a patient, in response to a request submitted by a physician, a radiologist should receive the permission to access the relevant web service and read a relevant portion of the patient's record but he/she should not be allowed to retain this permission after successful task execution. Thus, the permission for reading the patient's record, held by the patient's physician, is passed on to the radiologist who performs the radiological procedure requested for as long as is required to complete the execution of the relevant task.
- **Restricted task execution** – In certain circumstances the candidates for a web service invocation and associated task executions should be dynamically determined and be either a sub-group of the authorized users or only one, specific authorized user. For example, if the radiological procedure requested by the patient's physician is an MRI, then the radiologist who is allowed to perform it, and the one who can execute the "IssueRadReport" task, is among the radiologists holding the relevant sub-specialty. Also, the radiological report issued by the radiologist can only be read by the requesting physician who is allowed to execute the "ReceiveRadReport" task.

The authorization requirements of Table 1 suggest that permissions on web service invocations and task executions that result in certain data accesses depend on the process context. In particular, contextual information available at access time, like temporal, location or user/patient relationship or user/medical specialty relationship, can influence the authorization decision that allows a user to invoke a web service and perform a task.

Authorization model

Within a SOA resulting from an evolution of legacy systems there is a need to address authorization globally, while incorporating component system authorization policies in order to enforce the least privilege principle [2]. In turn, this requires ensuring that access permissions with regard to web services and associated tasks are only awarded dynamically, thus allowing users to assume the absolute minimum role required for web service invocations and task executions. Hence, there is a need to enforce context-aware authorization constraints regarding web service invocations and associated task executions that result in accesses to patient information.

The context

From a SOA authorization perspective, context can be defined as any information which is available at run time and is considered relevant to web service invocations and associated task executions that result in data accesses [5]. Thus, every SOA-based system may be assumed to be associated with a context which is defined as an evaluation of a set of pre-specified, domain-dependent and domain-independent context types. Domain-dependent context types are those related to the subjects and objects involved in the particular healthcare process under study as well as the relationships between subjects and objects (e.g. user and patient as well as the "proximity" relationship between them) while domain-independent context types are those related to the environment (e.g. time and location).

In a typical RBAC environment, roles are often defined as named collections of capabilities and privileges intended to perform healthcare functions [2]. In our context, roles are divided into two main classes: strong and weak. Strong roles correspond to existing organizational structures and define the division of work and the lines of authority based on job functions and seniority (e.g. "physician" and "radiologist"). On the other hand, weak roles are derived from strong roles and are subject to domain-dependent contextual constraints (e.g. "attending physician" and "attending radiologist"). For example, a radiologist can only assume the weak role "attending radiologist" when a physician has issued a request for performing a radiological procedure on one of his/her patients and the particular radiologist is assigned or chooses to respond to the request.

To alleviate users from the burden to change roles at run time, as required by access needs and the current work context, and to reduce the administrative overhead imposed, a rule-based approach should be adopted that enables automatic role changes (e.g. from strong to weak and vice versa) on the occurrences of specific events which are termed "role change events". These events occur when a web service invocation is initiated (initiation events) and result in granting the appropriate weak role to the current user; they terminate when the web service invocation is terminated (termination events) and result in revoking the current user's weak role. To achieve role changes, event occurrences automatically trigger the processing of relevant rules defined in the event-condition-action (ECA) format [3]. Hence, role change rules can be described as follows:

Definition (Role change). A role change is a 4-tuple (u, r_i, r_j, e_k) stating that a user u holding the role r_i receives the role r_j on the occurrence of the event e_k.

Authorization rules

To reduce the complexity of the authorization model, only positive authorizations are considered, so no explicit authorization conflicts occur. The dynamic authorization model proposed here extends the classic role-based access control (RBAC) for SOA-based authorization, while retaining its advantages, in that it addresses the issue of dynamically changing user roles at run time based on event occurrences. Hence, web service invocation and task execution authorization rules can be described as follows:

Definition (web service invocation). A role-based authorization for web service invocation is a 4-tuple (r, "invoke", WS,

$\{p_k\}$) stating that a user holding the role r is allowed to invoke web service WS subject to contextual constraints $\{p_k\}$.

Definition (web service task execution). Given an authorization for invoking web service WS by a user holding the role r, a role-based authorization for web service task execution is a 5-tuple (r, "execute", WS, T, $\{p_k\}$) stating that a user holding the role r is allowed to execute task T of web service WS subject to contextual constraints $\{p_k\}$.

Such authorization rules contain both domain-dependent and domain-independent contextual constraints. For example, on an attempt to invoke a web service, the contextual constraints are evaluated and applied in order to restrain accordingly the permissible actions of a user.

SOA authorization system

In a SOA environment, a typical authorization architecture involves a subject (e.g. a user) which wants to access an object (e.g. a service). The authorization architecture takes care of requesting authorization decisions and enforces them. To this end, it has to intercept user requests asking whether the user is authorized based on an evaluation of the applicable policies and building the authorization decision (deny/permit) upon that.

A SOA-based system accrued from rendering legacy systems interoperable should not violate any security enforced in these systems but it can itself enforce additional security. Hence, an implementation of a centralized authorization architecture can be made with due regard to the security policies that have been incorporated into the legacy systems.

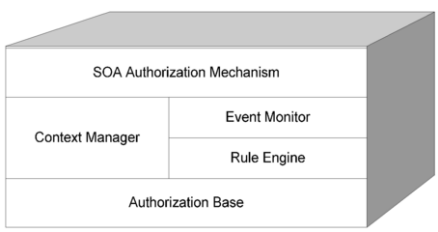

Figure 2- Authorization system architecture

Based on the authorization model defined above, an experimental SOA authorization system has been designed and implemented. This system enforces role-based authorizations that determine who (in terms of role) can invoke which web services, and can execute which web service tasks, and under what conditions. As shown in Figure 2, the architecture of the prototype authorization system consists of the following main components: the authorization base, the event monitor, the rule engine, the context manager and the authorization mechanism. The authorization base records all the elements of the model. The event monitor manages generated events and keeps track of the events that have already occurred in a healthcare process. The rule engine ensures that the rules set about invoking web services and executing web service tasks are enforced. The context manager collects the context information used in making access control decisions. The SOA authorization mechanism maintains user information and intercepts user requests (web service invocation or task execution) asking whether the user is authorized based on an evaluation of the applicable policies and building the authorization decision (deny/permit) upon that subject to contextual constraints.

A. Authorization base

The authorization base records users, roles (strong and weak), web services and permissions as well as user-to-role and role-to-permission assignments. Role-based authorizations are stored in the form of authorization rules with regard to web service invocations and web service task executions, most of which have been converted from legacy system authorizations to retain alignment between old and new system authorizations. Hence, source system security is conveyed. In addition, the authorization base contains role change event occurrences as well as the contextual constraints defined.

B. Event monitor

The event monitor records event occurrences into the authorization base and passes the event occurrence data to the rule engine that triggers the appropriate rule (e.g. for weak role granting/revocation). The event monitor is informed on event occurrences when a user attempts to initiate or terminate a web service invocation.

C. Rule engine

The rule engine stores weak role granting and revocation rules in ECA format, determines the appropriate rule when information on the occurrence of an event is received from the event monitor and triggers the weak role granting (revocation) action when the condition specified in the rule is satisfied. Weak role granting (revocation) amounts to recording (deleting) an entry in the user-to-weak role relationship table of the authorization base. Thus, the rule engine maintains the authorization base information up-to-date regarding dynamic granting/revocation of weak roles to strong role holders.

D. Context manager

The context manager, on occurrence of an event, determines the current work context and communicates the collected information to the rule engine which uses it when triggering the relevant ECA rule. The context manager is realized by a number of context agents which use middleware context collection services to monitor context and interact with the rule engine.

E. Authorization mechanism

The authorization mechanism accesses the permission relationships of the authorization base to enforce access control on users holding a role at the time of an attempted web service invocation or task execution. Thus, on an attempted web service invocation or task execution the authorization mechanism mediates between role holders and web services or tasks to determine whether the requested action should be permitted or denied.

Implementation issues

To illustrate the functionality of the proposed security model, a prototype SOA-based system was implemented that draws on the business rules and authorization requirements of the healthcare process depicted in Figure 1 and on the two legacy systems mentioned above.

Referring to the healthcare process of Figure 1, two web services have been developed: The one is a version of RIS concerned with radiological requests ("RIS_RadRequest" web service) and the other is a version of EMR concerned with medical record activities performed by either the physician or the radiologist ("EMR_RadPortion" web service). Thus, basically, the tasks depicted in Figure 1 belong to the "RIS_RadRequest" web service although these tasks include sub-tasks that are concerned with invoking the "EMR_RadPortion" web service to access medical record data.

Let a physician wishing to order a radiological procedure for one of his/her patients. Then, the following actions are performed with regard to security: On attempting to invoke the RIS_RadRequest web service, a web service invocation event occurs which is identified by the event monitor and is recorded into the authorization base while event occurrence data is passed to the context manager and to the rule engine. Then, the context manager evaluates the contextual parameters specified to determine the current context that constraints authorization rights (e.g. the patients that are currently attended by the physician) and passes this information to the rule engine. The rule engine identifies and triggers the relevant ECA rule to grant the weak role "attending physician" to the user, by inserting an appropriate entry into the authorization base, and passes the weak role to the authorization mechanism. The authorization mechanism consults the authorization base and grants to the user the restrained permissions for invoking the web service, performing the relevant tasks ("IssueRadRequest" and "ReceiveRadReport") and accessing the relevant patient's data only in order to issue a radiological request for one of his/her patients. Due to lack of space, a detailed description of the SOA authorization system implementation will be presented elsewhere.

Conclusion

Healthcare organizations are faced with the challenge to improve healthcare quality and reducing healthcare costs. To these ends, healthcare organizations often attempt to evolve their legacy systems by using innovative information technologies. However, for such a system to reach its full potential in supporting healthcare activities, authorization mechanisms must be in place that can conveniently and cost effectively regulate user access to information while providing confidence that security policies are faithfully and consistently enforced.

This paper presents an authorization model and system for enforcing authorization when migrating existing systems into a SOA. Based on the well known RBAC paradigm, a context-aware authorization model which is focused to the upper layers of SOA (i.e. the integration layer and the process layer) has been introduced and its practicability has been demonstrated using a prototype system based on a sample healthcare process.

Abstract

Healthcare applications that have access control, disclosure management and or privacy enforcement requirements may implement the respective solutions to these issues at the application level or at the database level or in both. Unfortunately, there are technical and non-technical factors that influence what can be done. In this paper we present a flexible, simple and novel approach to seamlessly imbuing current healthcare applications and their supporting infrastructure with security and privacy functionality, while being cognizant of these factors. This approach is called the Chain method. This paper will highlight the smaller design footprint, the increased ease of implementation and use of the Chain method, while demonstrating that it is as powerful and effective as traditional methods.

Keywords:

Privacy, Healthcare

Introduction

Globally, healthcare companies are increasing under pressure to provide technology, which delivers a core functionality, e.g. practice management, X-ray scanning, etc., and protects the sensitive information locked in their systems. Currently, a lot of healthcare vendors have significant investment in their existing product offerings, which tend to be developed with older technical building blocks and does not support the current social, legislative and technical requirements for privacy protection in medical systems.

The first step in enabling current healthcare vendors to augment their systems to address the current market demands, is the provision of non-intrusive technology that allows them to seamlessly handle arbitrary permissions. Unfortunately, these permissions are varied; ranging from storage access rights to "execute" rights for methods of individual classes. The focus of this paper is on the specification and enforcement of access rights to shared data resources, such as Electronic Medical Records (EMRs) and Personal Health Records (PHRs). We introduce novel technology – the Chain method [1] – which enables easy and non-intrusive definition and adherence to easily understood privacy rules.

Methods

Our methodology involved designing the information flow for the healthcare environment of our partner – the Kuwait Hospital, then implementing the Chain method behind a healthcare application at Kuwait Hospital. We then evaluated the technique against comparable technologies in the field.

What is the Chain Method?

The Chain Method [1] (hereafter referred to as *Chains* or *Chain*) is a new and novel paradigm for specifying and enforcing access controls on both applications and data; by formalizing the stakeholders, the acts that they perform and the entities that they act on. The intuition is that in modeling the actors, entities and their interactions (i.e. the private information handling model), one gets a more realistic view of the system's workflow. This model is then refined into a permissions matrix and then sent to an enforcement mechanism.

At the conceptual privacy level, Chains allow for the transformation from purpose-based systems into systems built on chains of limited acts. This is highly desirable because contemporary privacy research has lighted the fact that specifying or deriving purposes in the real world is a difficult problem [2]. A natural consequence of using Chains is that the approach doesn't need a huge number of purposes and doesn't potentially hide important user information from authorized users.

As briefly mentioned previously, the Chain method enables the simplification of the mapping/translation process from user actions to low-level implementation-level mechanisms. Chains leverage concepts from Role-Based Access Control (RBAC) [3, 4], where users have assigned roles and access purpose permissions are granted to roles associated with tasks or functionalities, not directly to individual users. In traditional RBAC, supporting dynamic changes in purposes may involve the assignment of a role to attributes with hierarchy inheritance characteristics, which allows an access purpose to be assigned

to a specific subset of users in the same role. In the Chain method, roles are assigned to acts.

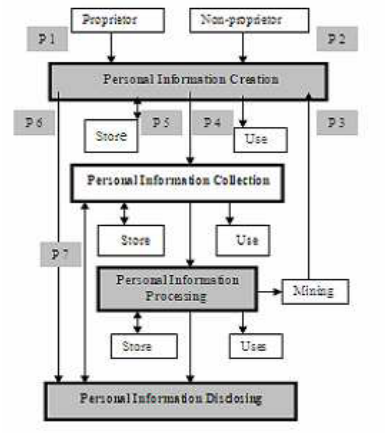

Figure 1-Personal Information Flow Model

The Chain method assumes that each purpose, i.e. conceptual task or function, can be translated to a series of actions (i.e. *chain of acts*) on personal information. The implicit assumption in the Chains is that any piece of personal information does not need more than a limited number of acts to be dealt with, such as creating, storing, processing and disclosing. This limited set can be used to design a lightweight and durable database that could safeguard personal information privacy [1]. The Personal Information Flow Model (PIFM) is a representation of the movement of information and the actions taken. The basic PIFM (Figure 1) consists of informational privacy entities and processes and is divided into a limited set of discrete actions. New personal information may be created at one or more points, e.g. P1, P2, and P3 in Figure 1, by proprietors or non-proprietors. The created information is used either at P4 (e.g. a decision for surgery needs to be made), P5 (e.g. receptionist stores patient information), or P6, where it is immediately disclosed (e.g. a physician explains to the patient his health case). Processing involves analysis and use of the personal information, e.g. mining for adverse drug reactions, longitudinal diagnostic analysis for rare conditions, etc.

Prototype

This work is the first practical instance of the Chain method. Using the concept of the Personal Information Flow Model, we built a system that involves the data owner, i.e. proprietor/patient, and healthcare entities and practitioners, i.e. doctors, nurses, clinics, hospitals (Figure 3).

Each of the labeled arrows represents specific actions that can be taken. In constructing the PFIM, we had to define a healthcare ontology (Figure 3) and integrate it with the (industry-agnostic) Chain method.

The classification that the ontology provides defined the meaning of each act. It also enabled the adjudication of the decision concerning the chain that a particular act should be added to. Finally, we specified the users that could access a particular chain or set of chains. The prototype is shown in Figure 4.

The ontology (Figure 3) was used by distributed semantic agents whose job it is to manage access and protect personal information. The actual interface to other systems and actors wishing to access personal information will use web services (Figure 5).

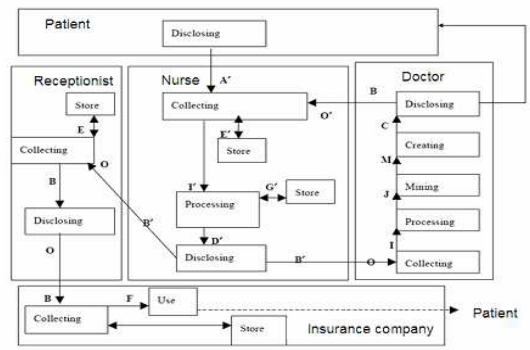

Figure 2- Healthcare PIFM for Kuwait Hospital

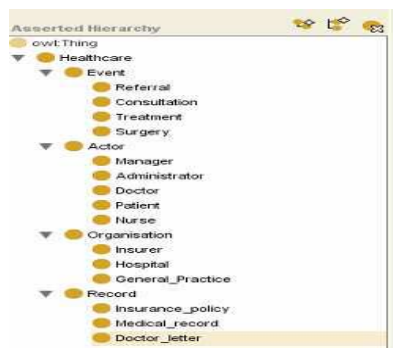

Figure 3- Healthcare Ontology constructed using Protégé OWL environment

These Personal Information Manager (PIM) agents assess information requests, potentially using other agents to verify the request and its circumstance, i.e. current state, using the ontology and analyzing the permitted acts based on the chain approach. This shared ontology is then be mapped onto a local ontology, where appropriate, to map onto the data store, where the personal information is actually stored. The benefit of this architecture is its flexibility to be applied easily to existing systems that store personal information and to manage the access using the shared ontology, while mapping it to the actual data store using a local lower level ontology as described in the ONAR approach [4].

Any request, whether by a user or by a system, in this framework will be dealt with in the following manner:

1. Authenticate the user (locally or through a trusted authentication server)
2. Verify the request to determine legitimacy using the ontology to establish whether the request is reasonable and should be acquiesced to (involves reasoning about the request and checking other systems for verification where needed)
3. Determine the location of information
4. Verify the acts and chains of acts for legitimacy
5. Extract the records
6. Execute the request

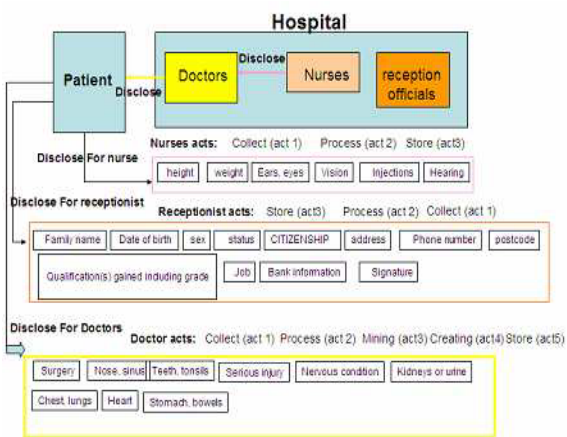

Figure 4- The Prototype

The database was designed based on our findings from a real HealthCare provider in Kuwait. After discussion with physicians, nurses and receptionists to better understand how the work in the hospital is performed, what are the problems of the existing database system they have are, and what are the requirements that should be added to their database system, we have designed the system as shown in Figure 5.

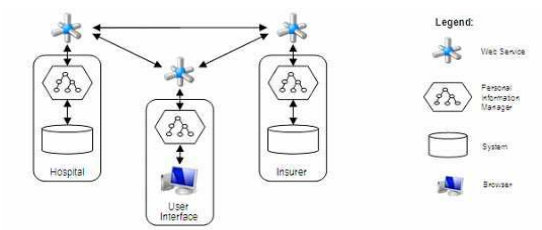

Figure 5- Designed System Architecture

The system in Figure 5 leveraged the chain ontology work and codified the requirements of the current system users.

Experiments

We developed two sets of experiments. The first is a user study, which is still ongoing. This test involves the system users at Kuwait Hospital providing feedback on their experience with Chains. The second is a comparative analysis with other similar technologies in terms of ease of and effort required for enforceability.

The first technology chosen for the comparative analysis was Role-based Access Control (RBAC) [3, 4]. In RBAC, a Role has a list of permissions. By placing a user in a Role, that user is granted access to the systems or resources associated with the Role. Users are assigned to one or more Roles, and each Role is related with a permission or set of permissions to IT resources. Using this method, a Role establishes the relationship between the users and the systems that they are authorized to access and provides a much more efficient way to decide who has access to what resources. An interesting consequence of RBAC is that organizations no longer have to work at the application or system levels, instead they can use roles to assign the appropriate permissions as a group. As a user's job tasks change they are removed from their old roles and placed in new roles based on their job title.

The second technology chosen was Task Based Access Control (TBAC) [6]. This technology is well suited for distributed computing and information processing activities with multiple points of access, control, and decision making such as found in workflow and distributed process and transaction management systems. TBAC varies from traditional access controls and security models in many respects [6]. Instead of having a system-centric view of security, TBAC approaches security modeling and enforcement at the application and enterprise level, which makes it more desirable in real world enterprises.

For our experiments on ease of and effort required for enforceability, we chose real privacy policies[1] found on the websites of the top 100 healthcare companies named in the 2009 Thomson Reuters study [7], as well as the privacy policy from Kuwait Hospital. The results were the same across the board.

For generality, we will walk through the process and show the results for a typical example, the OSF Healthcare System[2]. Given the following HIPAA policy statement[3] from their Web site:

> *"OSF may share your information with a medical care institution or medical professional for the purpose of verifying insurance coverage or benefits, informing you of a medical problem of which you may not be aware, or conducting an operations or services audit."*

We represent and implement it in RBAC, TBAC and Chains. A representational model of the above policy statement in RBAC is shown in Figure 6. We used the standard techniques for mapping from natural language to the each technology [1, 3, 4, 6].

[1] In this context, privacy policy here refers to a virtual combination of the privacy policy and the HIPAA privacy practices notice.
[2] OSF HealthCare is a multi-state corporation operating facilities in Illinois and Michigan.
[3] The full privacy policy is at http://www.osfhealthcare.org/hipaa

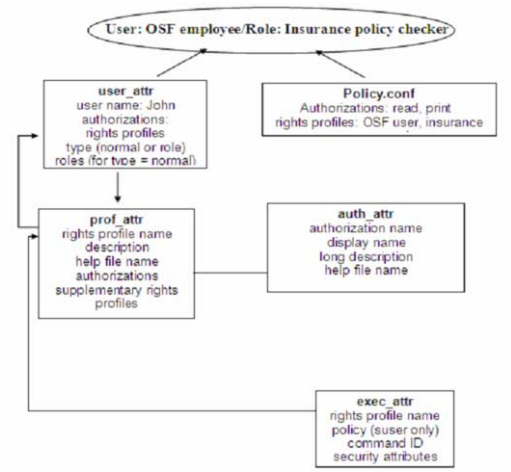

Figure 6- Policy in RBAC

Figure 7 shows the representation of the OSF policy statement in TBAC.

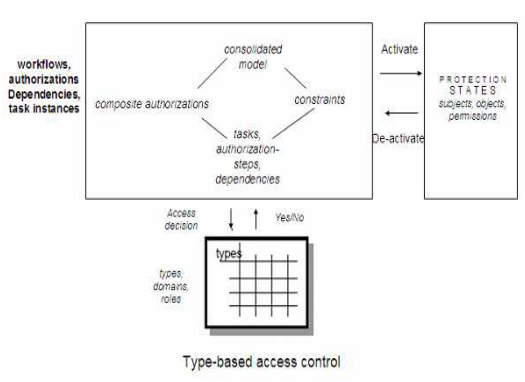

Figure 7-Policy in TBAC

Figure 8 illustrates the Chains representation of the OSF privacy statement.

As these representations will be required to be translated into a standard form, both for healthcare domain reasons and in order to do a fair comparison, each representation was transformed into OWL[4], which has a direct mapping into HL7 [8].

Representing the three models above in the OWL language, we find that the Chain model is the easiest to be translated as it contains less statements and simpler syntax.

[4] OWL (The Web Ontology Language) is a family of knowledge representation languages for authoring ontologies that is endorsed by the World Wide Web Consortium.

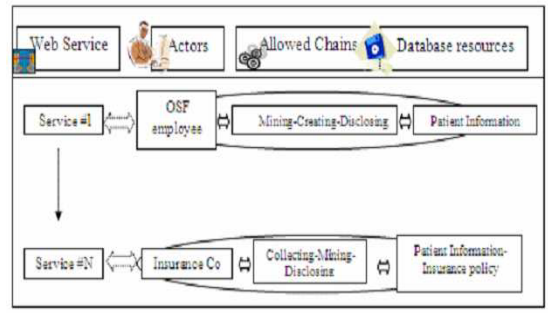

Figure 8- Policy using the Chain Method

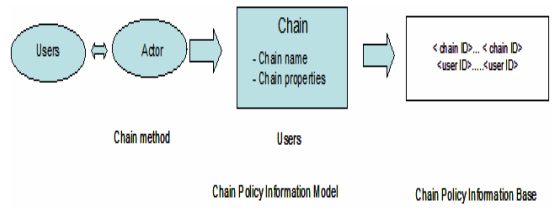

Figure 9- Chain model using OWL

Figure 9 shows that the result of the transformation process would be of the form:

<User ID>.... <User ID>
<Chain ID>.....<Chain ID>
……

Figure 10 shows the refinement process from the RBAC statements to OWL.

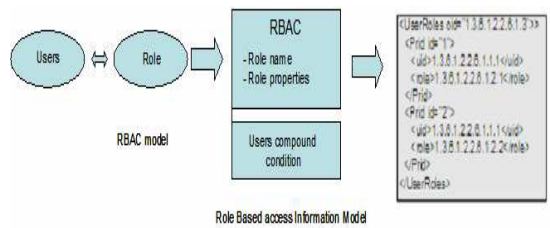

Figure 10- RBAC model using OWL

The resulting policy statement is of the form:

rbac:ssod a owl:SymmetricProperty, owl:TransitiveProperty;
rdfs:domain rbac:Role;
rdfs:range rbac:Role;
.....
<RoleName> rdfs:subclassOf rbac:Role.
<ActiveRoleName> rdfs:subclassOf
rbac:ActiveRole;rdfs:subclassOf <RoleName>.
<RoleName> rbac:activeForm <ActiveRoleName>

As TBAC is based on RBAC, the translation of the TBAC statements is similar to the translation of RBAC statements (Figure 10).

For ease of enforceability, we measure the number of tables that needs to be accessed in the determination of an access or disclosure decision. Table 1 shows that the number of required accessed tables in the Chain method is always the minimum (1), while, for this example (OSF Healthcare), TBAC and RBAC several orders of magnitude more. While the effort required may vary in TBAC and RBAC from policy to policy, the trend is that the effort is always more than Chains (and sometimes the same).

For the effort required in enforcement, this is measured by the work that has to be performed in evaluating the attributes and conditions in a statement (all other things, like low-level enforcement platform details, being equal).

Table 1- Ease of Enforceability

Access Based Method	Chain Method	TBAC	RBAC
Number of tables	1	8	5

Table 2 shows the re-thinking of the underlying representational model in Chains yields benefits in terms of the number of checks that have to be performed during policy enforcement.

Table2- Effort Required in Enforcement

Access Based Method	Chain Method	TBAC	RBAC
Number of attributes/conditions	2	4	5

Discussion

This paper is the first work in literature that has made a comparison between the three privacy preserving methods: Chain, RBAC and TBAC. This comparison was based on scientific criteria that have compared the number of tables, conditions and attributes required to design each of the methods. The chain outstands the two other methods with the small number of required tables and conditions. Also the comparison has shown the complicity of translating the RBAC and TBAC in OWL compared with the simplicity of the OWL sentences in the chain case. We also recognized that EPAL [9], Hippocratic Database (HDB) technology [10] and P3P [11] are related technologies in the field and that it is important to empirically compare them to the Chain method. But we need first to put the HDB and the Chain on same acting level (either to put them both on the application or the data level). This is one of our plans for future work.

Conclusion

In this paper, we have identified that the problem of defining, acquiring, inferring and consistently using purpose-based data disclosure technologies is difficult. We introduced the Chain Method – technology that allows easier specification of (security and privacy) policy at both the application and data level. We have prototyped the Chain method in a real healthcare provider and provided our initial results on the ease and effort involved in enforcement in a Chain-enabled system.

Acknowledgments

HIPAA Compliance and Patient Privacy Protection

Tyrone Grandison[a], Rafae Bhatti[b]

[a] *IBM Almaden Research Center, San Jose, California, USA*
[b] *Oracle Corporation, Redwood Shores, California, USA*

Abstract

Recent prosecutions of violations of the Health Insurance Portability and Accountability Act (HIPAA), and the amendments currently in process to strengthen the Act of 1996, has led many companies to take serious notice of the measures they must take to be in compliance. A company's privacy policy states the business' privacy practices and embodies the firm's commitments to its users and is normally a mandatory step in reaching legislative compliance. In the face of this, the patient has to decipher if the company's privacy practices are congruent with their thoughts on the level of privacy protection they should be receiving. This is the core of our investigation. In this paper, we explore the question "Is a healthcare entity's compliance with regulation sufficient to provide the patient with adequate privacy protection?" in the context of the United States of America.

Keywords:

Patient Data Privacy, Compliance, Legislation

Introduction

There is a significant body of evidence that shows that privacy breaches of healthcare data occur far more often than patients believe [1]. The prevailing perception, by most non-corporate healthcare stakeholders, is that the current measures (i.e. legal, social, technological and business safeguards) are weak and not effective [2]. In recent times, enforcement of the legal mandates articulated for covered entities[1] has been on the rise [3].

Though not as prolific as many would like, the record of convictions under HIPAA [4] provides hope. In the first HIPAA-related criminal case (2004) [5], a phlebotomist, Richard W. Gibson, employed by the Seattle Cancer Care Alliance, obtained a cancer patient's personal information from the health record and used that to fraudulently obtain four credit cards, charging $9,000 to the patient's name. That patient, Eric Drew, tracked down the perpetrator on his own, while fighting leukemia. Gibson pled guilty and was sentenced to 16 months in prison.

In Delaware, Linda Danyell Williams, an insurance representative employed by Hospital Billing and Collection Services in New Castle, was indicted in November 2006 for allegedly conspiring to steal the identities of more than 400 of the billing company's clients and selling the data to Richard Yaw Adjei, who used 163 of the stolen identities to file false and fraudulent tax returns, seeking refunds from the Internal Revenue Service. Williams pled guilty to two counts [6].

In 2007, Liz Arlene Ramirez, an employee at a doctor's office in Texas, pled guilty and was convicted of selling confidential medical information belonging to a Federal Bureau of Investigation Special Agent to someone she believed was working for a drug trafficker. She was sentenced to six months in prison [7].

In that same year, the U.S. Attorney Southern District of Florida obtained the first medical privacy criminal conviction after a trial [7]. In that same, Isis Machado, a front desk office coordinator at The Cleveland Clinic in Weston, Florida, improperly obtained Medicare information and other demographic information about Cleveland Clinic patients in Naples, Florida, and sold that information to her cousin, co-defendant, Fernando Ferrer, of Naples, for $5 to $10 each. Machado improperly obtained the patient information of approximately 1,130 patients. That data led to $7 million in fraudulent Medicare claims. Machado pled guilty to conspiracy and testified at trial against Ferrer. Machado was sentenced to three years probation, including six months of home confinement, and ordered to pay restitution of $2.5 million. Ferrer was sentenced to 87 months in prison, three years supervised release and ordered to pay $2.5 million in restitution.

In February 2008, CVS Caremark Corp. ("CVS" for short) agreed to pay $2.25 million to settle a federal investigation into allegations that it violated HIPAA privacy regulations when pharmacy employees threw items such as pill bottles with patient information into the trash [8].

Most recently (in May 2009) [9], California health regulators fined Kaiser Permanente's Bellflower Hospital to the tune of $250,000 due to the unauthorized access, by 23 workers, of the medical records of Nadya Suleman, after she gave birth to octuplets in January 2009.

[1] Covered entities refer to health plans, health care providers and health care clearinghouses.

This stream of legal activity is slowly bolstering patients' confidence in the protection of their data, i.e. insofar as the activities of regulators are concerned. Is this phenomenon encouraging healthcare firms to elevate patient protection in their own business functions? In this paper, we explore the legislative and technical sides of this patient privacy discourse.

Method

The baseline for regulatory compliance in the American healthcare industry is thought to be HIPAA [4], the new security and privacy requirements imposed by the Health Information Technology for Economic and Clinical Health (HITECH) Act [10] and the changes to HIPAA mandated by the American Reinvestment and Recovery Act (ARRA) [11]. We used these to measure legislative compliance.

However, as the HITECH [10] and ARRA [11] Acts are still open for public comment and not been implemented by organizations, they were removed from our study. A high-level summary of the five key principles in the HIPAA Privacy Rule are:

1. *Notification* - Patients should receive a notice of a covered entity's privacy practices.
2. *Authorization and Consent* - Written authorization is required for disclosures not permitted under the Privacy Rule.
3. *Limited Use and Disclosure* - Covered entities must use or disclose the minimum necessary PHI for a specific purpose and ensure the development and implementation of policies and procedures governing access and use.
4. *Auditing and Accounting* - Patients have the right to an accounting of all disclosures of their PHI for non-allowed HIPAA operations.
5. *Access* - Patients have the right, under most circumstances, to access the covered entity's designated record set. Covered entities must amend information that is inaccurate or incomplete.

The full descriptions of the principles can be found at the U.S. Department of Health and Human Services' website [4]. For completeness, we have to define *Protected Health Information* (PHI) as individually identifiable health information held or transmitted by a covered entity or its business associate, electronically, on paper, or orally.

For this project, a sample of 78 patients, commissioned from Amazon's Mechanical Turks[2] [12], were randomly selected and provided their expectations of privacy protection with regards to the principles above. The study population ranged from 23 to 68 and their county of residence covered 31 states. Each participant was given five options for each principle and asked to indicate the choice they associated most with their expected level of privacy protection.

As stated previously, a healthcare entity creates and publishes privacy documents, which describe their behavior (and implicitly establishes an agreement between themselves and their patients). A typical covered entity in our study provided an electronic copy of their HIPAA Notice of Privacy Practices[3], as required by regulation. Most organizations in our study also posted a separate Website Privacy Policy[4]. For our purposes, we use the terms "policy" and "privacy policy" to mean the virtual combination of both.

In order to answer our initial question, "Is a healthcare entity's compliance with regulation sufficient to provide the patient with adequate privacy protection?" we analyzed a sample set of privacy policies from twenty healthcare companies (chosen from the Thomson Reuters Top 100 Hospitals list [13]) with respect to patient expectations (obtained from our Amazon Mechanical Turks survey [12]). The companies in our study included Norton Healthcare, CIGNA Healthcare, West Virginia University, Interim Healthcare, Mount Auburn hospital, OSF Healthcare System, PharmaCare, Oakwood Healthcare, St Joseph's Hospital, AETNA, Blue Cross Blue Shield, Kaiser Permanente, Kindred Healthcare, United Healthcare, Camino Medical Group, Veterans Health Administration, Thomas Jefferson University Hospital, University of Michigan Health System, University of Chicago Hospital and St. Louis University Hospital. Table 1 shows the locations of the policies used.

Results

Generally, the surveyed companies structured their policies to convey information on the following areas: Collection of Information, Information Types, Information Use and Changes to Information. There were slight differences in terminology amongst the policies, but the higher level concepts were equivalent. We found the policies clear in their articulation of the information that they collect. This information falls into one of three classes: 1) *Protected Health Information*, which includes name, address, social security number, email address, licensure, certifications, education and employment history, etc. and is normally assumed critical for the delivery of care and the company's normal business functions, 2) *Derived Information*, which includes individual access history and usage patterns, which is gathered through cookies in order to improve their site and allow personalization or customization, and 3) *Aggregate Information*, which is statistical information, consolidated from IP addresses, computer information and locations (amongst other things), for promotion and marketing.

From the Mechanical Turks study, the top choices for each of the principles in the HIPAA Privacy Rule were:

1. *Notification* - Patients expect notifications sent to them of privacy practices' changes within days of the change.
2. *Authorization and Consent* - Patients expect authorization and consent for each non-authorized disclosure.
3. *Limited Use and Disclosure* - Patients expect healthcare payers and providers to enforce rules that ensure their business partners do not abuse their information.
4. *Auditing and Accounting* - Patients expect timely (a few days) response when they request an accounting of who touched their PHI.
5. *Access* - Patients expect to be able to see the information a healthcare entity has on them and they expect to be able to quickly correct any inaccurate information.

When analyzing each privacy policy, we examined the policy stipulations against the requirements of the HIPAA Privacy Rule and the expectations of patients. The results show that a all the policies were in a satisfactory compliance state with regards to legislation but fell short of patient expectations.

Each of the following sections goes into more detail on our findings.

Notification, Authorization and Consent

At the start of their policies, the healthcare companies either stated (1) that they do not collect personal information from web page visitors, but do collect web usage statistics in the aggregate form and if one wishes to register with them, then personal information will be collected or (2) that by accessing the companies' web pages you have consented to their privacy policy. Both cases lead to a situation where the patient is assumed to have implicitly consented to the privacy policy through the action of browsing the companies' web pages. It is debatable if this is in the spirit of the HIPAA Privacy Rule. However, it is clearly outside of patient expectations.

There was also an interesting trend present in the statements about the communication of policy updates to the patients. From the companies' policies, a majority of them were content with simply updating the policy on the website, and making it the responsibility of the user to check for policy changes. It is a general theme that privacy policy changes are communicated with very little concern for the patient. There were a few exceptions to the rule which actually indicated that they would alert the patient (via email, etc.) in case of a policy update.

Limited Use and Disclosure

For all the firms in the study, use and disclosure of information are associated with a purpose and specific purposes are defined for information. However, we found that all organizations defined very broad and all encompassing purposes, which may be used to exploit exceptions in the HIPAA Privacy Rule. For example, the policies mention collecting information for the purpose of "administering healthcare". They settled for a granularity so coarse that it could subsume a huge category of uses and disclosures of information. As a result, a whole host of activities, which the patient may not be in agreement with, could be interpreted as included within these purposes.

For disclosures to third parties and affiliates, it is common to see the phrase "we require the third parties to comply with Policy". However, there are two significant hurdles here. Firstly, a proposition to either "comply with policy" or to have "use limited by policy" is only meaningful if the policy is not broadly defined and implicitly inclusive of a wide range of business functions. Secondly, apart from business associate contracts with the third parties that perform services, requiring PHI, for them, there are no guarantees of the actual enforcement of policy on the third party. Ideally, covered entities should proactively monitor third parties to assure that they comply with the business associate agreements. However, the policies make no mention of the (general) terms and ramifications of such agreements.

None of the privacy policies surveyed provided a fine-grained list of roles or employee categories who have the authorizations to view specific categories of patient data. For internal use, the collected information is available to all "members of medical staff". This is the only requirement for being an "authorized" employee. Nowhere are the precise conditions for being "authorized" stated, nor is there any criteria specified under which any exception-based accesses may be granted (such as in "break the glass" scenarios). Overall, the counsel or consent of the patient is not incorporated in assigning more specific access privileges to employees.

Audit and Accounting

The privacy policies of all organizations advise that patients can obtain audit records for information disclosures. They also mention that protected health information may be disclosed to government and regulatory authorities for compliance with law. Although not explicitly stated on the websites, the literature from the medical community [14] suggests that most organizations advocate the use of audit trails of all actions pertaining to patient medical records to meet the audit reporting and accounting requirement. Our experience with clients indicates that audit trails do not record all the necessary context information, such as purpose and recipient amongst other attributes. More alarmingly was the tendency of corporate executives to turn off audit systems because of the storage and performance burden incurred when they ran.

Access

The privacy policies posted on all the websites in our survey indicated that patients have the right to access or update their personal information maintained by the company through phone or email or an online account. However, the response time was in the order of weeks and normally in written form.

Discussion

For each of the principle areas examined in our study, there was useful insight that we gained while examining the policies. Here we share some of these lessons.

Notification, Authorization and Consent

Current practices around issuing a notice and obtaining consent are not sufficient unless they provide the patient an opportunity to clearly and easily understand the policy and negotiate any objectionable provisions. This will continue to be a manually intensive task unless the policies are presented to the patient in a format that not only highlights the key segments in the policy, but also allows reasonable modifications to be made by the patient at his/her discretion. The use of P3P[5] technology, for example, may facilitate this task. Though recent studies have shown that privacy policies are unreadable by their target audience, irrespective of their format, [15] and that less than 26% of Internet users read privacy policies [16], we assert that the codification of policy would enable computer to analyze them and visualize potential problems, perhaps based on a specification of the user's concerns or hot buttons.

None of the websites actually published a policy in machine-readable form using an electronic privacy language, e.g. P3P, and only the natural language version is available online for manual review. This precludes anyone from performing automated interpretation and analysis.

[5] Platform for Privacy Preferences (P3P) enables Websites to express their privacy practices in a standard format that can be retrieved automatically and interpreted easily by agents (machines or humans).

Limited Use and Disclosure

While HIPAA requires organizations to obtain unambiguous authorization of the patient before use or disclosure of information for a purpose other than what it was collected for, and recommends adoption of the principle of minimum necessary disclosure, HIPAA-compliant policy can be constructed that allows organizations to design policies with broadly defined purposes. This concern has also been highlighted in the public media [17]. For instance, while "marketing" is identified as a purpose that requires authorization, various sub-categories are defined, such as "communications for treatment of patient", that are exempt from the rule, making it possible to disclose patient data for marketing under the assumed purpose. Therefore, it may be assumed that the levels of disclosure post-HIPAA will not necessarily shrink, and in fact a data disclosure previously considered a breach may now fall within the folds of the policy to which the patient has consented. Anton et. al. [18] observe a similar phenomenon, where the number of information disclosures increased post-HIPAA.

Audit and Accounting

The fact that current healthcare audit systems do not capture the required context information in order to provide an accounting was the most striking observation. Even though HIPAA requires organizations to account for all activity (including data disclosures) and provide detailed reporting for audit purposes, fulfilling this requirement by itself would still not be effective in improving levels of privacy protection unless measures are taken to compensate for shortcomings in the data disclosure and access rules in the privacy policy.

When the purpose or authorization is not established at a fine granularity before any disclosure or access is allowed, the burden falls on the audit mechanism to be able to capture any action that may actually constitute as a violation of the policy. Additionally, when an exception-based mechanism is in place that allows users to override normal access controls, the need for audit-based controls is further accentuated. While an argument can be made that the deterrent factor of audits is more suited to the healthcare sector because of the critical nature of the services provided, it should certainly not become an excuse for failing to do better.

Access

Meeting this requirement may not translate to adequate privacy protection for patient. There are several reasons for this. First, the ability of a patient to access or update personal information maintained by the organization provides no measure of how much information is actually protected unless the patient is also in control of the use and disclosure rules, and, based on our preceding discussion, this is not the case. Second, navigating the processes of information access and update can be simple or laborious for the patient depending on the organization. In some cases, data retrieval may be a matter of few mouse clicks online. In others, one may have to wait up to 60 days to receive a paper copy of one's information.

Further Observations

From our analysis, the language used in the privacy policies appears to be unnecessarily convoluted. This is corroborated by other researchers in the field [19, 20] for healthcare and finance. Given this, it will likely not be understandable by the average patient. In other cases, the language was clearly ambiguous. For example, one policy in the study states "…will not sell, license or transmit to anyone any personal information that members or practitioners provide to us online. We may disclose information obtained online to our partners involved in administering or providing services for our health benefits plans". These are possibly two seemingly contradictory, yet consistent statements that seem to have a nullifying effect on each other.

Conclusion

The overall message from our study was that even though the privacy policies cover enough ground to enable healthcare organizations to claim regulatory compliance, they are not adequate to communicate understandable privacy practices to the patient or provide adequate privacy safeguards. Even more importantly, current privacy policies do not reflect what patients think are in their best interest.

We believe that organizations must be required to make their practices more explicit and held accountable for any deviations from the stated policy. It is only a matter of time before gaining customer confidence and trust with regards to privacy concerns plays a more significant role.

Abstract

Introduction: The ubiquitous availability of medical or care data for authorized clinicians and nurses is expected to increase quality while reducing costs in the health care sector. The standardized, distributed provision of medical or care data is capable to support the vision of patient centered shared electronic health records (SEHRs). A main contribution to cross-institutional data exchange is provided by Integrating the Healthcare Enterprise (IHE). However, holistic implementations of IHE based eHealth infrastructures for SEHRs are currently rare and security and privacy regulations are not fully covered by existing IHE Integration Profiles. This work aims to point out our experiences and lessons learned from five years of development and the implementation of IHE compliant products.

Methods: Cross-Enterprise Document Sharing (XDS) describes the base components for exchanging medical or care data. A unique patient Identification is described by the Patient Identifier Cross-referencing (PIX) and the Patient Demographics Query (PDQ) Integration Profile. All interactions are logged in an "Audit Record Repository" deployed once per Affinity Domain and defined in the Audit Trail and Node Authentication (ATNA) Integration Profile.

Results: Based on the IHE Integration Profile XDS and other Integration Profiles high-level components for eHealth infrastructures and applications, supporting a holistic, secure concept and, based on these concepts, software products for a technical cooperative care infrastructure, has been developed. The products are practically evaluated in a project for setting up an IHE XDS Affinity Domain in the Austrian district of Tyrol and a number of lessons have been learned.

Keywords

Medical records, Medical record linkage, Data security

Introduction

The ubiquitous availability of medical or care data for authorized clinicians and nurses in a timely manner and in appropriate representation is expected to increase quality while reducing costs in the health care sector [1-3].

Currently health care institutions are experiencing a transformation in cross-institutional data exchange from proprietary solutions, mainly for point-to-point communication of selected medical data, towards a standardized provision of various document types including (radiological) images and multimedia content as virtual electronic patient records [4].

The standardized, distributed provision of medical or care data is capable to support the vision of patient centered shared electronic health records (SEHRs) [4]. As an extension to the exchange of medical or care data between health care providers, the patients with SEHRs are empowered to add content to their records (i.e. self assessments, medical diaries), to view audit events and to define security policies, as well as to access their own medical or care data [4, 6].

A main contribution to cross-institutional data exchange is provided by Integrating the Healthcare Enterprise (IHE), an international initiative which aims to support interoperability by widely accepted international standards such as Web services, HL7 and DICOM. Common workflows for standard-based sharing of clinical data are compiled as so called IHE Integration Profiles [7]. IHE Integration Profiles represent building blocks for the realization of holistic e-Health infrastructures (and other common clinical processes) in a broad sense [8].

Holistic implementations of IHE based eHealth infrastructures for SEHRs are currently rare and broad experience is missing. Apart from missing practical experiences with the implementation also the IHE frameworks shows some weaknesses. IHE describes the technical interoperability between systems of several vendors well, but does not focus on additionally re-

quired organizational interactions. Security and privacy requirements are only covered on a basic level by existing IHE Integration Profiles.

However, the importance of privacy aspects seems to vary between different nations in a European but also in a worldwide scope. This may have to do with historical events and possible data misusages in the past. Such strong privacy expectations in several regions require slight extensions of standardized IHE Integration Profiles.

Therefore our work aims at the identification and description of gaps between theory and practical experiences in implementing IHE Integration Profiles by pointing out our experiences and lessons learned from five years of development of IHE compliant products for the realization of a SEHR in Tyrol, the western part of Austria.

Methods

In order to ensure the highest possible degree of interoperability with other vendor's systems an IHE compliant architecture is a strict requirement. The design of the architecture followed standardized software engineering processes [9] incorporating architectural paradigms predetermined by the following IHE Integration Profiles relevant for SEHRs:

Cross-Enterprise Document Sharing (XDS) describes the base components for exchanging medical or care data between different institutions participating in an organizational framework called "Affinity Domain". XDS defines "Repositories" as data storage units which can reside locally in the institutions where data is produced. "Registries", deployed once per Affinity Domain, hold metadata about documents stored in the Repositories.

Registries serve as index services which allow predefined queries to find documents. Services used for registering Documents are called "Source" and services for retrieving documents "Consumer".

A unique patient Identification is described by the Patient Identifier Cross-referencing (PIX) and the Patient Demographics Query (PDQ) Integration Profile. The first allows mapping of locally used patient Identifiers to a unique Identifier per Affinity Domain, the latter provides services for identification of patients based on their demographic data.

As traceability of interactions is a key requirement for extended privacy aspects all interactions are logged in an "Audit Record Repository" deployed once per Affinity Domain and defined in the Audit Trail and Node Authentication (ATNA) Integration Profile. ATNA furthermore defines the use of Transport Layer Security (TLS) for encrypted communication and mutual authentication of services based on client certificates.

Apart from the use of IHE Integration Profiles the successful implementation of an e-Health infrastructure is also dependent on the fulfillment of a variety of other elements. To guarantee a high level of quality modern principles of software engineering were applied and intense testing was carried out through the whole process of development.

In order to assure compliance to IHE Integration Profile the software products has to be periodically tested at so-called Connect–a–thons, where different vendors are able to test and prove interoperability of their product with other vendor's software based on IHE Profiles. The products developed successfully took part in 4 Connect–a–thons.

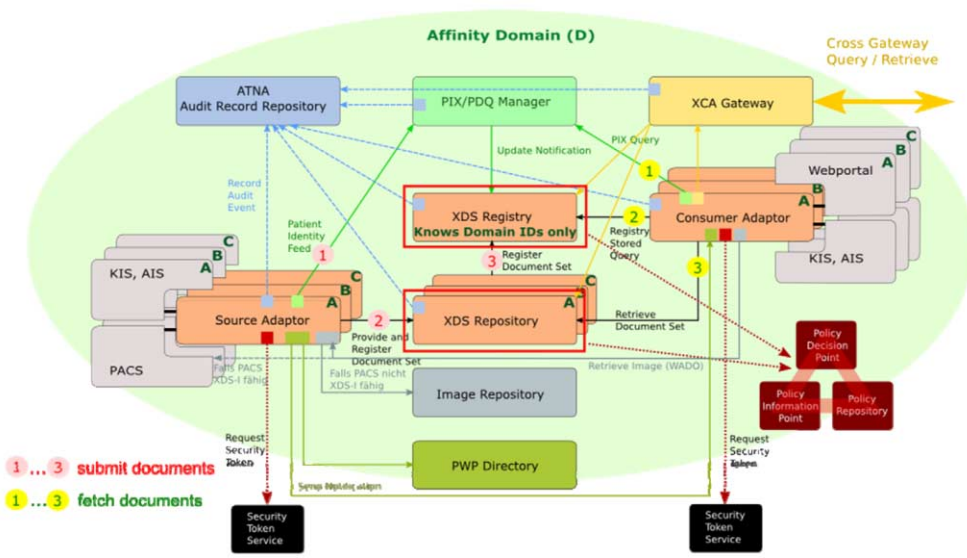

Figure 1 - Overview of sense Architecture based on several IHE Integration Profiles. Actors are depicted as boxes and Transactions as lines.

Results

Development of IHE compliant products

General considerations

Interoperability is required to support trans–institutional clinical data exchange in the context of SEHRs [10].

IHE describes the above mentioned building blocks for standardized e-Health infrastructures as so-called "Actors" and their interactions as so-called "Transactions". The IT-Infrastructure Technical Framework of IHE facilitates distributed data storage and also distributed index services. One of the main advantages is that medical or care data can reside in the institution, where they have been produced, and can be accessed by other institutions, provided that access rights are sufficient.

Based on the IHE Integration Profile XDS high-level components for eHealth infrastructures and applications, supporting a holistic concept for cooperative care, has been developed. Originally this development started five years ago as a research project [5] of universities in cooperation with industrial partners.

System Architecture for e-Health infrastructure

The software products are designed as modular components incorporating the Service-Oriented-Architecture (SOA) approach using Web service technology. Figure 1 shows an illustration of the architecture. The product family is called "sense® – smart eHealth solutions" owned by ITH icoserve technology for health care GmbH [11], which is a subsidiary company of a regional hospital holding company and Siemens. The products are available worldwide.

Workflow for transmission of documents

Workflow for registration of documents (cf. Figure 1, red numbers): Documents are submitted from the Clinical Information System (CIS) to the sense Source Adaptor which triggers the following IHE Transactions for (1) Adding patient identification to PIX/PDQ, (2) submitting the document to the Repository and (3) submitting metadata to the Registry.

Workflow for retrieval of documents (cf. Figure 1, green numbers): Documents are retrieved from the sense Consumer Adaptor which triggers the following IHE Transactions for (1) obtaining patient Identification, (2) querying the Registry and (3) retrieving the document from the Repository.

Java-based Web services offer a high degree of flexibility in implementation while supporting interoperability, as required by IHE, with other vendor's products, independent from platforms and programming languages. Therefore Apache Tomcat and Axis2 have been selected as application server and Web service runtime environment. For the sharing of clinical documents highly configurable services are deployed locally (sense® Localnodes) in health care institutions as well as centrally (sense® Communitynodes), operated for example by a large hospital, forming the XDS Affinity Domain as described above. Localnodes provide XDS Repositories as data storage and adaptors for the connection of existing, proprietary systems such as Clinical Information Systems (CIS) or GP's systems. Communitynodes provide XDS Registries as index services, a PIX/PDQ master patient index for unique patient identification and an ATNA audit record repository for central storage of audit events.

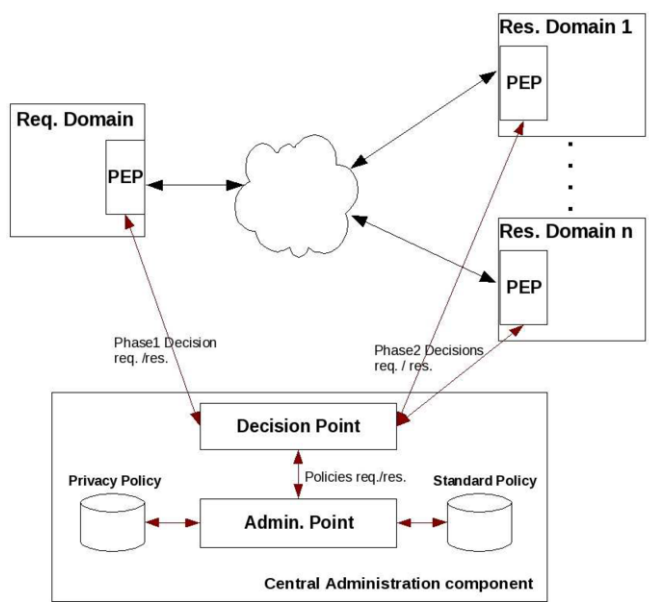

Figure 2 – Design of the security architecture

Security Concept

The sharing of patient data requires a sophisticated security concept reaching from Transport Layer Security (TLS) to provide authenticated and encrypted data exchange on Network Layer as well as an advanced authorization framework based on the Security Assertion Markup Language (SAML) [12] and extensible Access Control Markup Language (XACML) [13] on the application layer, which – in future – should empower the patient to decide who may access his health information.

The security concept [14] tackles privacy and access control in IHE systems from two perspectives: a Policy and an Enforcement. Two types of policies were defined: standard and privacy policies. While standard policies represent data security regulations in Austria, privacy policies enable – in future – citizens to define their own personal preferences and conditions. From the enforcement point of view, two phases' enforcement and decision making process was defined (cf. Figure 2). The difference between the two phases is the granularity. In the first phase the whole patient's record is considered as one virtual object and the enforcement is done at the requesting side. In the second phase a finer granular decisions can be taken for each part of the patient's record. Due to the fact that the parts of a patient's record are stored in different domains, the enforcement in this phase is done at the responding side, i.e. affinity domains that store parts of the requested record.

Implementation of a SEHR in Tyrol

Based on these components in the Austrian district of Tyrol a virtual electronic patient record with capability to future extension to a shared electronic health record has been set up.

Tyrol is located in the western part of Austria, with alpine topography. It has approx. 750.000 citizens, 12 hospitals with together approx. 4000 beds and 2.000 physicians (in- and outpatient).

Prior and during the implementation, a couple of important lessons have been learned, which are of interest to other similar projects:

- The financing and the assignment for projects related to e-Health is one of the most difficult tasks. The benefits are mostly in the public economics and less in the business economics. This means that public bodies are the main beneficiaries. This leads to the fact, that health care institutions are often not the buyers of such systems and are not willing to invest in such solutions.
- In general, the benefits of e-Health (infrastructures or applications like SEHRs) are not easy to verify. Big saving potentials with regard to macroeconomics are regularly published [1]. But health professionals do mostly not think in big numbers but in small steps assisting their personal work. Therefore it's very difficult to create acceptance amongst health professionals.
- In Tyrol, several independent health care providers requested in common a standardized e-Health infrastructure to improve cooperation. This common appearance at public bodies got the ball (for assignments) rolling.
- After assignments a working group for common coordination, consisting of all participating health care institutions has been established.
- The introduction of standards for medical document formats or metadata was one of the most labor intensive steps. With currently available technology such as CDA, a very fine–grained structure can be applied to clinical data. Structuring of clinical data influences the workflow of data capturing. This is an organizational rather than a technical challenge as health professionals must be motivated to switch from flexible free text to a rigid framework for data capturing.
- Austrian data protection regulations require a 2-level access control mechanism. The fist level requires that a current treatment relationship exists between physician and patient. The second level requires consent of the patient. In the consent document restrictions can be applied for institutions, departments, document type and time range. Level 1 is covered by a service, provided by the operators of the so called "e-card" (Austrian health insurance card). Level 2 requires extensions to the XDS Document Registry and an organizational framework.
- In order to support patient-controlled restrictions as described above, new queries had to be added to the Document Registry which allow filtering particularly for institutions and departments. Level 2 restrictions are currently not evaluated technically. Physicians querying for documents have to obey the patient's restrictions when setting search criteria in the user interface. In order to assure that those restrictions are actually applied all queries are logged to the ARR. Health care professionals participating in the SEHR have to obligate themselves to respect the patient's consent and to store the consent document paper-based or electronically. Furthermore health care professionals have to agree to periodic inspections of consent documents with the aim to prove that issued queries, logged in the ARR, match the consent of the patient given in the consent document. However in future versions of the software the patient's consent will be covered by access control policies.
- Early usability evaluation revealed that a seamless integration of the SEHR application in the Clinical Information System (CIS) or the GP's system is vital for end-user acceptance. A web portal solution is only the second-best choice. The concept of the sense Source and Consumer Adaptor proved to be important to facilitate the development effort for those systems as complex IHE transactions and the handling security validations is covered by the Adaptor services.
- Operating the SEHR in a dedicated physical network, strictly separated from the Internet improves security and therewith also end-user acceptance.
- Although IHE dramatically improves interoperability between different systems, test effort remains high.

This seems to be rather caused by semantic then by technical issues.

- End-user and system administrator training is a key factor for success and acceptance of SEHRs. The challenge is to create awareness of the sensitivity of retrieved data, which implies that restrictions issued by patients in the consent document have to be strictly obeyed.
- A professional project management from acquisition to routine operation of a SEHR is a vital success factor. E-Health projects are complex and risky as there are many players involved with partly distinct interests, level of technical understanding and organizational objections. Advanced project and also conflict management skill is required to reach the goal. However this is a time-consuming process.

Discussion and Outlook

IHE Integration Profiles leave details open for implementation, which is, from the economic point of view, expected to support the market. Technically this might lead to slightly different interpretation of the specification, which may prevent successful communication between different systems.

The concept of IHE is interoperability testing and not certification. This means that systems attested conformity to an Integration Profile can be further developed. This "snapshot" approach allows vendors to further modify and improve their systems even after conformity has been attested, which furthermore allows modifications carried out during the Connect–a–thon to be stabilized to a mature system. We however would like to create awareness that changes to a successfully tested system might lead to side effects that can, in the worst case, break interoperability.

Particularly the upcoming seamless integration of the security concept shows that especially in the health care sector technical challenges can be solved rather easy in comparison to organizational challenges such as a nation-wide role definition for medical personnel or such as required changes in medical or care workflows.

Interoperability between computer systems in health care seems to be adequately solvable using state-of-the-art technology such as Java and Web services. Semantic interoperability which should provide for identical, language independent interpretation of the submitted content is expected to remain one of the major challenges for the next years.

Desiderata for a Computer-Assisted Audit Tool for Clinical Data Source Verification Audits

Stephany N Duda, Firas H Wehbe, Cynthia S Gadd

Department of Biomedical Informatics, Vanderbilt University School of Medicine, Nashville, TN, USA

Abstract

Clinical data auditing often requires validating the contents of clinical research databases against source documents available in health care settings. Currently available data audit software, however, does not provide features necessary to compare the contents of such databases to source data in paper medical records. This work enumerates the primary weaknesses of using paper forms for clinical data audits and identifies the shortcomings of existing data audit software, as informed by the experiences of an audit team evaluating data quality for an international research consortium. The authors propose a set of attributes to guide the development of a computer-assisted clinical data audit tool to simplify and standardize the audit process.

Keywords:

Data auditing, Data quality, Software design

Introduction

Analyzing low quality study data produces meaningless results, which is why interventional clinical trials focus so heavily on data quality control [1]. Many international, multi-center research networks that pool and analyze observational data, however, do not report a similar emphasis on data quality assurance. Without methods to assess and improve data quality, studies using the resulting observational databases may generate false research conclusions based on unreliable information.

Data auditing is a proven method of assessing the quality of routine clinical care data that have been reused for research[2]. Unfortunately, most verification audits of clinical data use paper audit forms, which have been shown in general to be less effective and efficient than electronic tools [3, 4]. This work aims to identify the core weaknesses of paper forms when used for clinical data auditing, as motivated by a series of data monitoring visits to seven clinics participating in an HIV observational research network. The authors propose a set of functional requirements for a computerized audit tool that may simplify the audit process and encourage research networks to measure and improve the quality of their data.

Auditing is an established technique for evaluating and improving the quality of products, services, or information, and has been a staple of quality control activities for over a century [5, 6]. Audits take many different forms depending on the domain: in accounting, they identify fraud; in manufacturing, audits help assess both the quality of a product lot and the producer's compliance with Good Manufacturing Practice; and in information security, audits allow for the inspection of the security and reliability of computer systems and of the information they contain [7, 8]. In medicine, researchers have employed audit techniques to detect inconsistencies in terminologies, evaluate the quality of patient care and verify that medical services are properly documented, coded, and billed [9-11]. The U.S. Federal Drug Administration also requires auditing of many clinical trials to ensure that the operators of the trial are properly monitoring patient safety, accurately recording data generated by the study, and adhering to the study's protocol and Good Clinical Practice [12, 13].

Protocol-driven studies such as clinical trials often engage teams of clinicians and data managers to perform research data audits. These auditors compare research data to the source documentation, which often includes paper clinical charts, laboratory reports, or the contents of electronic medical record and laboratory systems at the study sites. Most tools to support clinical data audits are paper forms with lists and checkboxes, with various examples freely available online [10, 14, 15].

Although paper-based audits are still common in medicine, computer-assisted audit tools (CAATs) have improved the quality of audits in finance, manufacturing, and IT security by facilitating more thorough audits, generating more consistent documentation, and saving both time and money for auditors and auditees [16, 17]. CAATs can aid auditors during many stages of the audit process, from merging and analyzing data to generating audit reports. Auditors often use statistical or data extraction software as a CAAT in order to detect anomalous patterns in large data sets. Other software packages specifically designed for auditing (e.g., Audit Command Language (ACL) and Interactive Data Extraction and Analysis (IDEA)) even assist auditors in selecting the audit sample size and audit methodology [18, 19]. Each single-user ACL or IDEA license provides access to powerful data analysis tools, but also costs thousands of dollars. Less expensive audit-specific software includes TopCAATs, a Microsoft Excel audit plug-in, and Picalo, a Python-based, open-source data analysis and fraud

detection toolkit [20, 21]. Most of the advanced CAATs also require computer programming skills.

Unfortunately, these software packages focus on analyzing an existing, electronic dataset for errors and unusual patterns, rather than facilitating the comparison between the dataset and a physical source document. Indeed, in many accounting and security audits, the electronic database *is* the source document and no other records exist. As a result, these advanced software packages are not helpful for auditing paper source documents. Furthermore, the cost of tools such as ACL and IDEA makes purchasing them unfeasible in resource-limited settings.

Motivation

Data Audits at Seven HIV Clinics

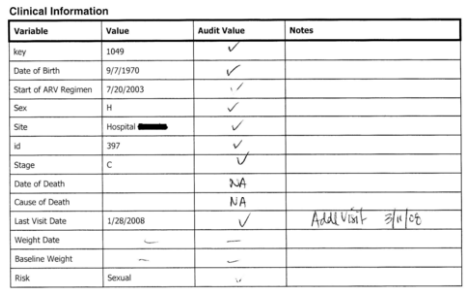
The Caribbean, Central and South America Network for HIV research (CCASAnet) is one of seven collaborative research groups participating in the International Epidemiologic Databases to Evaluate AIDS (IeDEA) [22]. CCASAnet brings together researchers from HIV clinics in Argentina, Brazil, Chile, Haiti, Honduras, Mexico, and Peru to create an HIV observational database using routine patient care data. The project's data coordinating center (DCC) at Vanderbilt University conducts Good Clinical Practice-based audits on datasets submitted by CCASAnet member sites to identify sources of error in data collection, abstraction, and representation, and help the DCC determine the structure, quality, and reliability of the submitted data.

Between March 2007 and April 2008, a two- or three-person team including at least one physician and one informaticist visited each member clinic to compare the on-site medical documentation to the contents of the electronic database that the site previously submitted for analysis. The audit team used a multi-page paper audit form to record the results of the database-to-clinical record comparison. Data on the form were divided into categories such as demographics, clinical visit data, antiretroviral regimens, and laboratory results.

Two items per data element were preprinted on the form: the variable name (e.g., birth date, date of death, viral load result), and the database value for that variable. The team used the blank "audit value" field to record whether a data element was present in the source documents and whether the source value was correctly represented in the database. A small notes field – as well as the margin of the paper – was used to record additional information or possible causes of the error. Figure 1 shows a sample page of a completed audit form.

At the end of an audit visit, the auditors presented their preliminary findings during an exit interview with the site investigator and staff. After returning to the DCC, the audit team produced a report describing its findings and recommendations, which was sent to the site for review and comment.

The audit team inspected 184 records and 4223 unique data elements during seven audits. The average time between the end of an audit and the completion of the audit report was 101 days which meant the site data personnel rarely received immediate, implementable recommendations on how to improve data quality.



Clinical Information

Benefits of a Computer-Assisted Audit Tool

Feedback on data quality is most effective when it is communicated shortly after the audit takes place, but the use of paper audit forms makes generating reports a challenge [6]. In post-audit debriefings, the auditors identified several causes for delays in producing the audit report, including difficulties with

- handling multiple audits and reports simultaneously,
- reading other auditors' handwriting,
- interpreting underspecified notes without the presence of the source documents,
- deciding how to handle partially completed audit forms,
- classifying errors during post-visit audit form reviews,
- assessing whether an error was clinically meaningful,
- consulting with other auditors abut error classifications or unclear information,
- sharing a single set of original audit forms among a team of auditors,
- tabulating errors,
- double-checking other auditors' error tables,
- calculating error rates,
- composing a thorough and detailed audit report, and
- formatting error tables for the final document.

A computer-assisted audit tool that replaces the paper forms could help standardize the audit process and increase the timeliness and reproducibility of audit results. A CAAT for clinical data auditing could guide users through the process of importing their study data, selecting records to audit, recording and categorizing data discrepancies, and generating audit results. The audit findings would be immediately available in an electronic format that could be used to generate tables or to feed corrected data back into the source database.

Key Attributes of an Audit Tool

To improve the audit process, computer-aided software for source document verification should provide flexible functionality in five main areas: networking, audit data management, error categorization, audit decision support, and results reporting. The audit team's experiences that motivated these requirements are described in the text. The requirements are outlined as desiderata in Table 1.

Requirement 1: Networking

Paper forms functioned as an excellent sharing tool during audits. Although each auditor worked independently on a set of records, difficult cases or records with cascading errors often required a group review in which the source document and audit form were passed around the table. A suitable CAAT should facilitate the same real-time communication between multiple auditors and allow collaborative editing of a shared database, in settings where Internet access is not guaranteed. CCASAnet data audits, for example, often take place in the record storage or meeting rooms of clinics in resource-limited settings, where auditors work collaboratively on complex records. An effective paperless audit tool needs to accommodate multiple users manipulating a single copy of the data. However, because of the unreliability of local network connections, a useful tool should take advantage of portable routers or alternate network structures, such as wireless ad hoc networks between auditor laptops.

Requirement 2: Audit Data Management

Preparing paper audit forms in advance of each audit was a laborious, multi-day task for the audit team and the CCASAnet data manager. An audit tool that allowed users to import preformatted datasets could reduce the preparation time significantly. A standard XML data specification would permit auditors to load a copy of the audit data, as provided by the study data manager, before the audit begins. A standardized import/export format also allows the audit results to be routinely converted for use in statistical software packages.

Although the ongoing CCASAnet audit program evaluates the accuracy and completeness of HIV-related clinical and laboratory data, the proposed audit tool should be able to accommodate datasets with different medical content, such as data collected for studies of cancer or tuberculosis. The software's internal representation of the audit data, therefore, must be flexible enough to adapt to different content types. Such types include not only standard data representations, such as integers, character strings, or Boolean variables, but also the frequent irregular data forms that the audit team catalogued, such as malformed, partial, and approximate dates, miscoded values, and integer variables with character content (e.g."<400").

Requirement 3: Standardized Assessment of Errors

CCASAnet's paper-based audit process relied heavily on memory, interpretation, and opinion, and was difficult to replicate and standardize across sites. Indeed, when the DCC undertook a reevaluation of the audit findings in mid-2008, the authors had a difficult time applying a standard error categorization system devised for the task, as the original paper forms had required auditors only to describe errors, not to classify them according to a formal error taxonomy.

A robust audit tool should assist auditors in assessing and classifying errors during the audit visit, rather than weeks afterward when the source documents are no longer accessible. The auditor should be able to import the most appropriate error categorization scheme for a given audit task, as errors in HIV data, for example, may be distinct from errors in cancer or tuberculosis data. The tool should also accommodate complex error classifications that prompt auditors to evaluate data errors on multiple axes, including the type of error, the severity of the error, the clinical relevance of the error, and the probable direct cause.

Requirement 4: Audit Decision Support

Selecting the number and type of records to audit is a challenge for novice auditors. The audit team consulted a statistician in advance of each audit, but a useful CAAT could provide basic guidance on sample size calculations and selecting records for audit, using selection metrics that have been described in the literature.

The system should also allow the auditor to import an optional rule set that would guide the automatic classification of errors based on the data class and error type. A mismatched weight value of 37.5kg in the clinical record vs. 38kg in the database, for example, is likely to be a rounding error of limited clinical significance. This functionality could be useful in labeling complicated errors of drug prescription and discontinuation.

Requirement 5: Results Reporting

The CCASAnet team found that preparing a post-audit report from paper audit sheets required time-consuming counting, description, tabulation, and confirmation of all the data discrepancies. Both auditors had to count the variables in each record, group any recurring errors, double check final numbers, and tabulate the results manually, which delayed preparing the final report. Software support for generating tables, graphing data, and displaying trends based the results of the audit could simplify the post-audit work and help auditors detect patterns of errors across records or data falsification that might be overlooked in manual review. Furthermore, such tools could help auditors adjust their sampling of variables during auditing to focus their efforts on evaluating variables that appear more prone to error.

By automatically generating tables of error rates and lists of specific errors, a computerized audit tool would assist auditors in preparing a summary for the exit interview and the final post-audit report. Audit support software should also provide basic quality improvement suggestions for the site based on patterns of error in the audit data and established user-imported rules.

Table 1- Obstacles encountered during clinical data audits and corresponding desiderata for computer-assisted audit tools.

Obstacles Encountered during Audits	**Solutions / Desiderata for a Computer-Assisted Audit Tool**
Challenge: Collaboration	**Solution: Networking**
Auditors need to work collaboratively on the same copy of a record.	Real-time Collaboration: networked laptops for auditors, shared databases, web-based systems
Audit sites may have no network infrastructure.	Portable Network Infrastructure: peer-to-peer networking, portable server and router
Challenge: Audit Data	**Solution: Audit Data Management**
Paper audit forms take a long time to prepare and validate.	Import Functionality: one-click import of data and data descriptions (metadata) from research database to CAAT, instant generation of basic electronic audit forms
Copying audit results from paper forms into a spreadsheet for analysis is time-consuming.	Export Functionality: export of audit results into structured data formats such as XML
Datasets may contain different medical content (e.g., HIV, Tuberculosis, or cancer data).	Metadata Management: customizable import interface, customizable display of data on screen, data dictionaries for special topic areas (HIV, TB, Cancer)
Data may violate syntactic rules; auditors may need to record corrected values.	Reasoning About Data Types: representing simple and complex data types, data syntax rules, codification of mismatch between research data and native records, handling malformed data
Challenge: Types of Errors	**Solution: Standardized Assessment of Errors**
Errors are not categorized and described clearly on paper forms, making it difficult to analyze and report error types and rates.	Representation of Error Types: hierarchical ontology of errors, clear operational descriptions of error types, specification of domain of error types (applies to specific variables within the audit record or applies to entire record), specification of error labels and default values and whether closed or open world assumptions apply
Auditors discover new and unexpected types of errors during the audit process.	Error Scheme Evolution: support for versioning and collaborative authoring of error schemes, interface to edit error schemes while in use
Some audits require different error classification schemes that are better suited to the data.	Error Scheme Management: storage, import, and export of audit-specific error terminologies
Challenge: Audit Design	**Solution: Audit Decision Support**
Auditors are unsure how many records should be audited to produce meaningful results.	Statistical Dashboard: guidance for sample size calculations, identification of grossly problematic records, pre-selection of records via statistical sampling
Challenge: Analyzing and Presenting Results	**Solution: Results Reporting Tools**
Tallying and tabulating errors by hand is a time-consuming and error-prone task for auditors.	Automatic Report Generation: software support for generating tables and graphs
Manual approaches may miss subtle patterns of data error.	Real-time Trend Detection: automatic checks for patterns of error suggesting data falsification, systematic errors

Discussion

When an audit process lacks standardization, different auditors may produce different audit reports given the same source record. Without standardized quality measures, the changes in an organization's data quality cannot be compared from year to year, nor can audit results be compared from site to site. Flexible audit support tools that have the attributes described will simplify and standardize auditors' work, thereby increasing an audit's potential benefit.

The CAAT recommendations described here stem from audit experiences at HIV clinics in Central America and the Caribbean. The perspective of a single international research network, however, may limit the diversity of experiences that

informed the five suggested requirements. Indeed, these recommendations may represent a necessary but not sufficient set of features needed for a successful paperless audit tool.

Future work will focus on developing a prototype CAAT for audits of HIV, tuberculosis, and cancer data. If the tool proves to be useful within CCASAnet, other similar networks could use it to evaluate the quality of their data, standardize their quality control activities, and identify areas for process improvement.

Conclusion

The quality of routine clinical care data should be assessed before such data are included in observational databases. Current paper-based audit techniques can be both inefficient and inconsistent. Computer support tools may be able to simplify and standardize the preparation for and execution of a source document audit, if certain criteria for such a tool are met.

Complexities in securing sustainable IT infrastructures in Hospitals: The many faces of Local Technical Support

Lone Stub Petersen

Participation and Technology, Department of Development and Planning, Aalborg University

Abstract

This paper contributes to an understanding of the complexity of support work and stress the need for local technical support in hospitals in order to maintain a sustainable infrastructure of information systems (IS) and information technology (IT). Given this complexity it is pointed out that a naïve trust in formal stylized models of support organization is problematic. With an increasing number of critical systems in the hospitals technical support is becoming an essential service needed for maintenance, acute failure of systems and help with the everyday use of hardware and software. In order for the health informatics technologies and systems to work, the healthcare institutions need strong IT organizations to support and maintain the IS/IT infrastructure on which these technologies and systems rely. Through a qualitative study of IS/IT support at hospitals I have examined the work and competencies of the service level in the IT organization. On this basis I recommend a nuanced understanding of the complexity of the work of these local technical supporters. I contrast this to the understanding of the organization of IT support through rationalized, formal, 'best practice' models that emphasize centralization and cost-effectiveness through single point of contact. It is argued that there is a need for local technical supporters in hospitals with organizational and local knowledge because a) the local circumstances are key to supplying effective support and b) the supporter supply pro-active support that aid to secure the sustainability of the IT infrastructure.

Keywords:

Technical support, Local, Maintenance, Health informatics, Organization.

Introduction

Sustainable and appropriate use of information systems is not just based on the system design and the way the systems are implemented even though this is important and is the focus of a wide range of research in the field of IS and Health Informatics. An important factor to the functioning of an information system is the way the systems are supported, and as Pentland states "[…] an unsupported product is hardly considered a product at all"[13]. The focus on and importance of supporting systems within the healthcare sector is also central in the strategy from the Danish public organization SDSD (Connected Digital Healthcare in Denmark): "The increase in digitalization results in an increase in demands of the IT solutions on the related operations. IT solutions that are applied in the healthcare sector are often of vital importance to the treatment of patients. It is therefore of critical importance that the solutions of IT operation are handled professionally in order to produce a high level of reliability of operations."[2]

If the technical background (the IT infrastructure) is not working, the best information systems in the world won't do much good. Besides, a large amount of the cost of IT is related to the work carried out after installation [5][[8]. In spite of this there have been very few studies related to the topic of supporting systems in healthcare within the Health Informatics field.

The empirical basis of this article is a study of the IT organizations providing services to the Danish hospitals. These have changed to a large extent since 2007 where the Danish regions, which are responsible for the hospitals, were reduced from 13 to 5. The structural changes were followed by a focus on a new way of perceiving the regions. The new ideal was seeing the regional organization as a corporate group (in Danish; 'koncern'). One of the implications of this change in Region North Jutland and the other regions was that the IT departments began a centralization of services.[17] The organization of the IT departments was further inspired by and based on an English public IT organization model called ITIL, that focus on streamlining the IT organization in a centralized and uniform way in order to increase service and reduce cost. This has proven difficult for a number of reasons, some of which will be addressed in this paper.

Analytical framework

What is support?

Technical support consists in the maintenance, repair and other services done in relation to securing the function of hardware and software: "Technical support is a post-sales service provided to costumers [or users in organization] of technology products to help them incorporate a given product into their work environment."[1] Technical support is the backbone in securing sustainable infrastructure on which the IT systems of the hospital rely. Support can both be organized as both an internal or external service.

Levels of support/service

The support structures of IT organizations are often divided into levels. There are different ways of defining the levels. One way is to divide them into front-end and back-end support. The front-end support is further divided into helpdesk and product support as illustrated in Figure 1.[8]

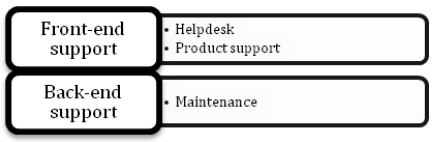

Figure 1- Levels of support

The front-end support is where support has contact with the users or costumers. The first level is the first point of contact for the user and preferably the only one in terms of cost-effectiveness. There are a number of reasons why this structure is preferred. One is to reduce the amount of trivial tasks solved by experts; another is to secure a simple structure for support with easy, one-way contact and tools for managing the technical problems.

ITIL methodology and centralization

Information Technology Infrastructure Library (ITIL) is a paradigm used by or inspiring all the IT organizations of the Danish regions[17], though many have found problems with implementing the paradigm in the organization. ITIL describes different IT practices and provides descriptions of checklists, tasks and procedures that are considered best practice. The focus within ITIL is on the needs of the clients, and on clearly and effectively defined responsibilities and processes for different service tasks within the IT organization. [6][16]

ITIL also divide support work into three levels that determine the level of escalation of a specific problem (incident). First level support is defined by first contact. On this level of support the problem is registered and clarified and attempts are made to solve the problem immediately. This level is also responsible for the communication about the status of the problem to the users. If the problem is too complex (require a higher level of expertise), the task is escalated/transferred to the second level, the expert technical support. The purpose of this level of support is to patch up the more complex problem as quickly as possible. The difference between the first two levels is based on the level of expertise and therefore the cost of the service provided. The second level is, in contrast to the third, generalists in the technical field. The third level of support is the escalation of a problem to highly specialized experts in a specific field. This is often external provides of software or hardware, but can also be internal providers such as server and network maintenance.

Technical support can both be done remotely or as local technical support. In both cases there are a number of tools used for both administering and getting the job done. According to ITIL an incident management tool is essential for recording and managing incident information. A tool like this is also used in Region North Jutland.

Support as interaction and design

Mira Kajko-Mattsson states that "Today, we do not have maintenance models (standards) appropriately reflecting the diversity of maintenance activities. What we have is a very general standard model mainly applicable with perfective maintenance at the third support level."[8] A number of attempts have been made to describe the complexity of support activities. Two of these approaches are described below. One concerning support as mending social situations and another viewing support as design.

According to Julian E. Orr, support is often seen as the diagnostic, repair and maintenance of machines. But this is actually not the whole picture. He points out that "[…] machine problems may actually be problems in the social relationship between costumer and machine, and large parts of service work might better be described as the repair and maintenance of social settings."[15] As illustrated in figure 2 the technician can be seen as a mediator or someone engaged in the reconfiguration and repair of the relation between the user and the machine.

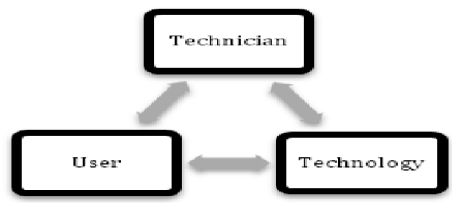

Figure 2- The technical support reconfigures the relation between the user and the technology

This approach sets focus on the fact that being a technical supporter is also being concerned with social relations and consulting the costumer on the interaction with technology.

Another approach to drawing the more complex picture of local support work is to perceive the support activities as a form of local design.[9][10] The concept of local design points toward the constructive features of doing support work. The constructive features of the local support work helps the design of relation between costumers/users and technology in order to secure it "[…] works for people in a context of values and needs, to produce quality results and satisfying experience" [20][9] Anne Marie Kanstrup argues that the local supporters are "[…] domain experts with enough computer knowledge to be able to install, maintain, support, etc., hardware and software in the organization. And they are capable of supporting and teaching other members in the organization with regards to the use of software applications in an efficient way because they take their point of departure in 'the system, the users, and the context all together'."[9] This perspective contributes to an understanding of the importance of a variety of competencies and of having local knowledge along side the technical in order to provide qualified support and systems design.[14]

Methods and Materials

My empirical study is based in the qualitative field and places its studies on a cross between grounded theory and processual research[12][19]. The study of IT support was set up to inquire into the work of IT supporters, but also to uncover features of IT support that could be subject to further inquiry. IT support was in this study taken in the broadest sense as all support of IT systems, involving hardware, software and people-ware.[11] The study is based on 10 interviews (clinicians, secretaries in clinical practices and IT professionals), 6 days of observation of technical IT supporters work and study of reports and other texts. Also an organizational analysis was carried out about the structure of IT support in the organization.

Results

The technical support organization

In Region North Jutland the support organization is build on inspiration from ITIL though the structure is not fully implemented, and is not intended to be. In a document concerning the forming of the regional organization it is written that 'the core in IT maintenance and support will be the implementation of a framework for processes (ITIL) as a means of securing that the appropriate services are delivered to the business at the appropriate price and agreed upon quality.'[3]

IT in Region North Jutland is organized as a centralized function in the organization managing support, maintenance and development projects and tasks across the nine hospitals in the region. The way the Region North Jutland has implemented ITIL in relation to support is by formalizing procedures for contact, escalation and feedback of incidents. This is organized around a problem handling IT tool (software).

The support organization is divided into levels. The first level and front end support is the Virtual Service Desk. On the second level (technical) we have backend support where the service can be done either on-site or remotely through different tools, e.g. remote access to computers. The third level is internal support or repairs of servers and networks or external help from the manufactures of hardware and software. Thus we see that their IT support (in figure 3) is structured similar but not identically to the general model described above.

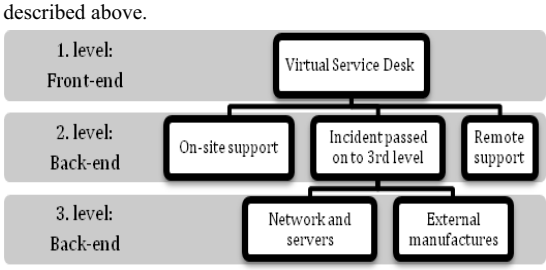

Figure 3 - The structure of technical IT support at Region North Jutland

The virtual service desk is the single point of contact for support. The costumer calls a number and is redirected to the supporter on duty that day. Costumers can call the service desk with acute problems, but must send an e-mail if they e.g. need new hardware or other non-acute services. When service desk receives a call or e-mail they will either solve the problem immediately or escalate the problem to second or third level of support. The hospitals need to call the service desk in order to get in contact with the local supporters. Not even the secretary at the front desk has the phone number to the local technical supporter.

The work tools of the supporters

When using ITIL and IT Service Management strategies, IT organizations usually use problem handling software for logging and managing the incidents. This is also the case for Region North Jutland. They use a system for logging, distributing and acceptance of IT problems/tasks. The system is also used for management of the work of the IT professionals. Most problems are logged in the problem handling system by the supporters at Service Desk, some come in via e-mail with non-acute requests and the local supporters also log some problems that need solving at a later point.

Some of the problems that arise in the local support work stem from the need for completeness from a management/system point of view, not from the usability of the system for managing and distributing tasks. This gives an added workload that seem unnecessary from a work perspective. Lucy Suchman describes this problem through the concept and discussion of visibility of work.[18] The visibility of tasks through an IT system can both mean legitimacy, rescue from obscurity or other aspects of exploitation but it can also create reification of work, opportunities for surveillance, or increase group communication and burdens on the work process. In relation to the problem handling tools these can both prove an effective tool for managing the support services and become a burden to the local supporter given the amount of tasks he needs to solve 'on the fly' while performing other tasks. Even though some supporters expressed uncertainty towards what tasks to log in the problem handling tool, most supporters thought the system was useful for getting a picture of the tasks that need addressing and managing the work.

In addition to the problem handling tool the supporters used a wide range of different, mostly digital tools for managing and performing their work, though I do not have the space to describe these in the present paper. (See figure 4, seond column.)

The work tasks of the supporters

Support of the IT infrastructure is important, but the way of organizing the process is not always as simple as suggested by the formalized ITIL model and the organization model of the support structure in Region North Jutland. This will be illustrated by the following description of the typical work procedures of the supporters.

Roughly two days a week is used on on-site support, solving problems locally in the hospital. Every local supporter also needs to do Service Desk support for half a day once a week. The rest of the time is used on remote support, maintenance of

old equipment and preparation of new equipment. Also supporters participate in projects related to implementation of new technologies in the hospitals.

Because the service desk takes all the calls from costumers the supporter can do his work with fewer interruptions. But this does not mean that he will not be interrupted. When doing on-site support there are often requests for additional help and the supporter is often stopped in the hallways. Despite these interruptions and departures from the plan, the supporters generally expressed a high level of satisfaction with the complexity of their job.

Between levels of support

Though the organizational mode used for managing the support of IT/IS in hospitals is focused on centralization, there are a number of reasons why this can prove difficult. In the explorative study it was evident that the local technical supporters were not just local expert technicians. Their work was also composed of taking tasks 'on the fly' and enquiring about problems they are aware of. In this way their practical work procedures do not fit the model. The supporters can be said to be between levels. They are both IT professionals solving technical problems and tasks takers, taking and solving tasks as they emerge.

Another way in which the local technical supporters did not fit the model is the multitude of tasks they are part of. As described by Orr [15] the technical support task is not just focused on solving a technical problem, they are actually repairing and maintaining a social setting and as described by Kanstrup [9] they are also designing the workplace. This was also supported by the empirical study. In the study a multitude of roles, skills and knowledge emerged as part of the everyday work of the supporter. (Illustrated in Figure 4)

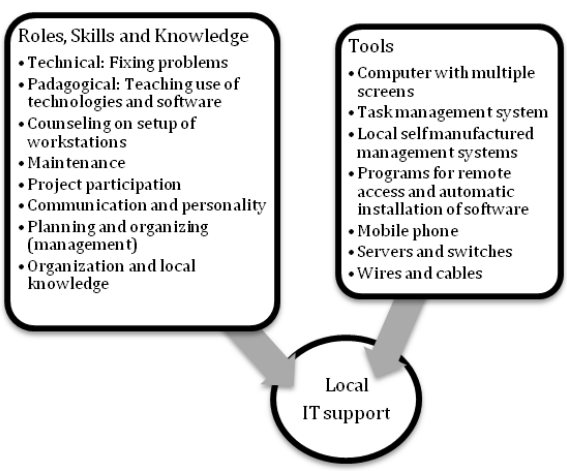

Figure 4- Examples of the multitude of roles, skills, knowledge and tools needed by the local technical supporters.

Meeting the costumer

Generally the customers/users were satisfied with the support they got. However, the problems they mentioned in interviews were generally related to a) problematic communication with supporters, b) insufficient number of local supporters, b) lack of relevant updates to all involved parties when a task was solved, and d) getting more complex support tasks done.

Most of the staff interviewed expressed the desire for knowing their supporter personally. The reasons mentioned for this were e.g. that it made communication easier, because they could continue to build on an understanding that was already established. Another reason was that the supporters generally need a certain amount of knowledge about the clinical practice in order for them to help resolve the technical problems. Even though there are a lot of changes in the support staff, the clinicians thought that the relationship to the supporters was build rather quickly and was needed for securing proper support and solutions of their technical problems.

It was also enlightening to look at the everyday work practice of the clinicians. Their work is characterized by being mobile and structured around the face-to-face communication between clinicians, patients and other staff. The mobility of the work implies that the majority of the clinicians seldom have their own workspace, but share computers and other office related tools among the staff of the wards. The distribution of work is done on daily and weekly meetings. And most of the critical information is documented in writing, but is supplemented and passed on to others in speech. Technical problems are often passed on to secretaries or leading nurses because solving these problems require a break in the work flow. This is also the reason why some technical problems are just left as they are and 'work-arounds' are implemented.

In order for the supporter to communicate efficiently with the clinicians they need to somehow fit in with the practice. It can be argued that this is done best by fitting in with the way clinicians generally communicate, that is face to face. The fact that clinicians often let secretaries or leading nurses pass on their technical problems is likely to lead to misrepresentations of the problems or the omission of certain details that will complicate the solutions of the problems. All in all this view on the daily practices shows that the possibility to have face to face communication with a local supporter would be preferable in order to solve technical problems efficiently. To have a competent person with knowledge and awareness of the local setting fixing the problems is likely to help satisfy the costumer/user.

Discussion and Conclusion

In this paper it is argued that the local supporters, with the multitude of skills, roles and tools at their disposal are needed in order to keep the IT infrastructure of the hospital in working order. They are not just needed in order to fix technical problems, but also as maintainers and designers of the interactions with and around the many technological products in hospitals today. The contribution of this paper to the field of health informatics is an attempt to a) set focus on the complexity of local support work and b) to emphasize the need for this kind of support work as a means to keep the hospitals running with as few technical problems as possible.

The problem when using relatively stylized models like the ITIL model is that the complexity of the job can be forgotten or that the significance of the local circumstances of the job is can be overlooked or neglected by the top level managers. In the case of Region North Jutland there were made efforts of centralization where the local supporters were taken away from the local setting. This was reversed due to protests from the staff of the hospitals in the region. One of the reasons for this, as argued in this paper, is that the supporter is not just solving technical problems, but is also an integrated part of making the work with and around IT systems seamless. The local supporters, with their specific multitude of roles, knowledge and tools, are an important part of securing this repair, maintenance and design of the social setting of users and technologies. The work done by the local IT supporters cannot be centralized because of the complexity of competencies and tasks needed to keep the IT infrastructure running smoothly.

On the basis of this analysis I recommend a general caution towards using general models and seeking centralization in relation to technical support of IT/IS in hospitals. I recommend that we use models that emphasize the close-knitted working relationship between supporters and users as not only a potentially valuable local resource, but also an essential part of having/using information systems at all.

Acknowledgments

This study was supported by and conducted with the help of the IT department and a special thanks goes to IT support manager Klaus Larsen and the local IT supporters in the hospitals of Region North Jutland.

Citizen Centric Architecture Approach - Taking e-health forward by integrating citizens and service providers

Yong Han, Timo Itälä and Matti Hämäläinen

Software Business and Engineering Institute, Helsinki University of Technology, Finland

Abstract

In this paper, two related research problems will be discussed in the development of e-health services: First, an architectural approach is needed to provide a holistic view for solving the ICT challenges in e-health development. Second, solving the needs of the citizens should be the focus of the architecture solution. To overcome these problems we suggest a Citizen Centric Architecture (CCA) approach for providing a holistic and appropriately balanced view of the integration. Naturally, enterprises' information systems and citizens' information systems are the key elements of CCA. In addition, for solving the topology challenge brought by a large number of involved parties, a role of trusted third party is proposed to provide an environment for the information exchange and service mediation among the various parties. We believe this approach will enable the large scale growth in citizen centric e-health services that is poorly facilitated by the prevailing models: the improved integration of information will attract more citizens and health care service providers, which in turn, improve the health care information and quality of service.

***Keyword*:**

E-health, Information integration, Citizen informatics, Health care service provider.

Introduction

The term e-health is used to refer to a range of ICT enabled health care services and related businesses. It is in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies [1]. Successfully implementing e-health is believed to have many benefits both for health care service providers and for citizens.

Not surprisingly, e-health faces numerous challenges from social, economical and organizational reasons [2]. According to Eysenbach [1], challenges for the health care information technology industry are mainly (1) B2B: improved possibilities for institution-to-institution transmission of data; (2) B2C: the capability of consumers to interact with their systems only; (3) C2C: new possibilities for peer-to-peer communication of consumers. Haux has also stated the future of health information systems should go from health care professionals to patients and consumers [3]. In other words, achieving e-health would not only require the successful integration of range of health information systems, more important, it should enable the integration of information between service providers and citizens.

As user generated content and consumer health informatics are becoming more relevant in e-health, there is an increasing need of integrating information between citizens and health care service providers. However, current research work related to health information integration has mainly focused on the side of professionals (B2B), with little attention to supporting B2C and C2C communication. Health care, as any other business, needs an architectural solution to guide the changes in all key areas: business models, process design, information management, applications and information infrastructure. Therefore, this paper tries to find out what would be the architecture approach for supporting e-health development, which would solve those appearing challenges.

Methods

The research methodology applied here is design-science, which aim at creating relevant artifacts to bridge the theory and the practice [4]. We start from analyzing the citizens' needs in e-health information systems, and then further investigate current architectures from the perspective of how well they support integration. We aim at designing an artifact, which visualizes the architecture approach needed to support future e-health development.

Step 1: analyzing citizens' needs in e-health

The integration challenges in e-health service development from citizens' point of view can be analyzed by using the B2B, B2C and C2C scenarios as starting point:

- B2B: Most of the citizen's information is in the service providers' hands and it is fragmented into a number of service providers' information systems. Thus, B2B integration is important also for citizens, as it creates integrated access for their own health data. Without proper integration among the organizations neither a service provider nor citizen him/herself can access up-to-date and comprehensive information, which in turn may cause errors in clinician decisions and create many other problems.

- B2C: While the service providers can have a good and specialist view on citizens' health in their respective areas, the people themselves naturally know their own life situation, experiences and expectations best. Possibility to combine the relevant health related information that citizen can provide and the information for the service providers in easily accessible form would both help to serve citizens needs better and to help clinicians and other providers to improve the experienced quality of service. Meanwhile, citizens want to be more proactive and they increasingly seek health information on the Internet [5]. One of the trends is transforming the relationship between physicians and patients [6] as more self-care enables both to reduce health care costs and improve the efficiency. However, without good support of B2C integration this will be hard, if not impossible to achieve.
- C2C: In addition people to interacting with their health service providers they also have the desire to share their experiences, express themselves and seek support from others with common interests. The rapidly development of Internet technologies has enabled them to do it online using tools like SNS, discussion groups, wikis, and blogs to share health knowledge, stay informed and rate health care services etc [7].

In summary, an appropriate and multi-perspective architecture vision should help provision of the key integration needs listed above from the citizens' point of view. In the following we will discuss this extension in the context of the common enterprise architecture frameworks.

Step 2: extending the scope of Architecture

Architecture has been defined as "The fundamental organization of a system embodied in its components, their relationships to each other, and to the environment, and the principles guiding its design and evolution" [8]. An Enterprise Architecture (EA) is used for dealing with the increasing complexity and improving the communication among stakeholders related to information systems in an enterprise. So architecture should help to define highest-level concepts of system integration. Enterprise architecture is normally divided into layers. The most popular way of dividing layers is: business architecture, information architecture, application architecture and technology architecture [9].

Architecture issues have mostly been discussed in the scope of enterprise. In the context of IT, an enterprise can be a whole corporation, a division of a corporation, a government organization, a single department, or a network of geographically distant organizations linked together by common objectives [10]. Therefore, it differs from individuals or citizens. As shown in Figure 1, we can classify architecture issues into two main categories according to the needs of integration: integration inside an enterprise and integration between enterprises (B2B).

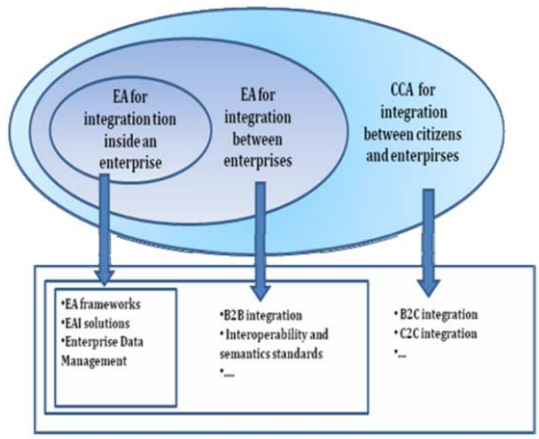

Figure 1- Extension of an enterprise architecture based on the needs of integrating citizens' information

- Architecture for integration inside an enterprise: The development of an architecture starts from the integration needs inside the enterprise. Since Zachman's Framework [11], many EA frameworks have been developed for solving increasing complexity caused by fragmentation of information systems. Integration inside one enterprise usually happens vertically along each layer, so that lower layer provides consistent functions needed by the higher layer.
- Architecture for integration between enterprises: More and more the integration between businesses has raised needs in architecture solutions for achieving better collaboration between enterprises. Integration should happen horizontally in each layer among the organizations to support the business process [12]. Sometimes those two cannot be clearly distinguished. Topics like Business Process Management (BPM), Data Warehouse design, EAI implementations consider both the integration inside the enterprise and among enterprises.

A fundamental principle that can be applied to architecture is: "Always design a thing by considering it in its next larger context - a chair in a room, a room in a house, a house in an environment, an environment in a city plan [13]." With the growing amount of citizen generated information and increasing demand of citizen empowerment, extending the scope of architecture is the natural result of an architecture evolution. As figure 2 shows, while the current architecture issues remain, the extended architecture is meant to solve the integration between service providers and citizens, as well as the integration among citizens or communities of citizens.

Results: Citizen Centric Architecture

Health care service in its essence is all about people. Citizens are the final ones who determine how well the service providers have done their work, i.e. what value have they actually

produced. When the healthcare information systems cannot support the communication of B2C and C2C, the goal of better quality of service would be hard to reach. The observation that the world of health information is still managed in very unbalanced way, putting too much focus in the world of enterprises (or service providers) and ignoring the needs of citizens serves as a good starting point for improvement.

Based on the study we propose to add the citizens into the current scope of Enterprise Architectures, the extended architecture would be called Citizen Centric Architecture (CCA). Also, a Dual Model is sketched for visualizing the integration between citizens and health care service providers. As showed in figure 2, the Dual Model contains two basic elements: Service providers' information and systems and the citizens' information and systems that should work in complementary and harmonious interaction.

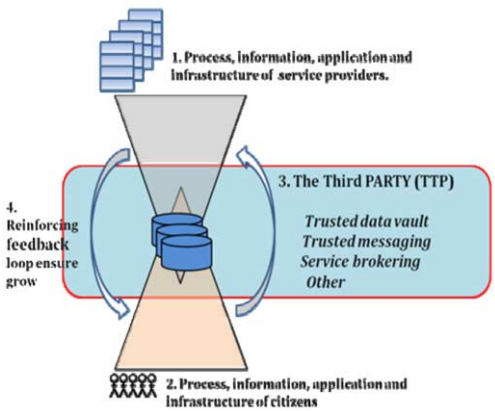

Figure 2- Dual Model of Citizen Centric Architecture

In addition, as CCA is meant to integrate a large number of citizens and service providers the issue of integration topology becomes especially challenging. Integration topology is needed when the design of integration context should specify the locations, structure, and channels to connect all the elements together to form a coherent whole [14]. When the number of parties is increasing the preferred topology is to use a hub in the middle to minimize the number of connections. Therefore, one new element is introduced for connecting many service providers and many citizens together: the "Trusted third party".

Enterprise Information Systems:

Citizens typically use more than one health care service provider in their life. Thus, having access to integrated health care information is the fundamental requirement for clinicians to make the correct diagnoses [15]. In health care, achieving interoperability among health care information systems still has a long way to go. Existing systems are experiencing transition from integration of hospital information system into interoperability of health information systems [3,16]. Promoting Electronic Health Record (EHR) is one of the big steps forward for automating and streamlining the clinician's workflow [17]. Many standards of EHR have been developed for improving the level of interoperability.

Citizen Information Systems:

For achieving citizen empowerment and communication with various service providers and communities, an information management system which could help them to own, create, manage and share information with commonly available and easy to use formats and tools is vital. With the tools and approaches knows as Web 2.0, the user/citizen-generated content has become popular and the idea widely accepted. Service consumers have also become producers.

Similarly, in health care the focus is starting to shift from service providers' side to citizens' side [18]. Citizens need to have better information support in order to be more active in their own care. The counterpart of EHR in the citizen's world is the Personal Health Record (PHR) that is being promoted to help citizen to become more active in their own cares [19]. Some have used the term PHR 2.0 to refer to applying Web 2.0 into the PHR systems [20].

The third party

When the number of involved parties grows large, the benefits of having a third party acting as a hub or intermediary become obvious. For the service providers the third party provides a flexible integration mechanism with least amount of risks, provided they are experienced as trustworthy and providing value for money.

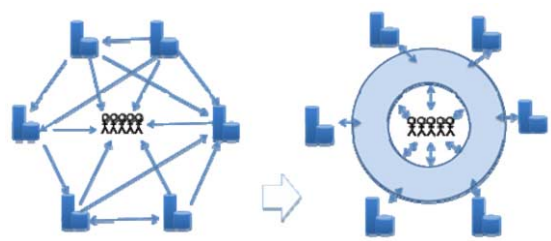

Figure 3- The third party minimizes the connections and builds a trusted and community platform

For the citizens, the third party can provide substantial help in a variety of activities and lowering the barrier of use. These include locating the relevant services and information sources, setting up explicit or implicit contracts with them for service use, integrating them, providing a single point for authentication, and also providing payment services both for providers and users.

In addition to the intermediary services it is also well positioned to provide the citizens an environment for storing, managing and sharing their own information.

The third party needs to follow two principles in order to build smooth communication and interactive collaboration between the service providers and citizens:

- Trusted environment: There are two key steps in creating a trusted environment. First, the service providers and citizens should be able to trust the third party. They need to consider it to be safe to transfer their data in the platform offered by the third party. Second, the third party should build the trusted relationship between the service providers and the citizens.
- Community environment: With the success of Web 2.0, people have experienced the power of social networks in enhancing collaboration and communication. This is also one of the ultimate goals of e-health. In CCA, the third party can take the responsibility of building community environment and enable social relationships among the professionals and the citizens. It has been already suggested that Web 2.0 approach and tools should be adopted into health systems [21].

Achieving growth by reinforcing feedback loop

Adequate volume and penetration in the population is vital to success, as in any other citizen service that requires network effect. Economically, only when the scale of integration is up to certain degree, the communication between citizens and service providers would benefit the society. Further, from dynamic point of view, a right solution for bridging the communication is needed to ensure the growth of the number of users over time. That is, the more citizens and service providers join in, the more benefit each party would achieve. That, again, would attract more citizens and service providers to join. While the motivation of the suggested CCA approach and dual model has been described above as enabler of citizen centric health services, we believe that the trusted third party is essential in creating the reinforcing feedback loop and such services to become reality in a large scale.

Discussion and Conclusion

The contribution of architecture research to health care service would have strategic significance on providing a high level solution for advancing the ICT revolution in healthcare sector. "It is increasingly difficult to practice modern medicine without information technologies [22]." While applying architecture frameworks and approaches for alignment of business and IT have been common in other sectors, it has not been much realized and discussed in the health care sector. Thus, this research may have deep implication for further development of e-health.

Realizing that solving the needs of citizens is the foundation of e-health development, the scope of the architecture need to be extended to integration of the citizens' information. In Dual Model, the role of citizens' and their information is given equally important position as that service providers'.

The benefits of CCA can be summarized into:

- Improving the two-way communication between citizens and service providers and providing an environment for service and information integration, management and sharing, facilitated by the trusted third party as a vital element of CCA.
- Stimulating and enabling necessary changes in service providers' current architecture at various layers. With CCA service providers can efficiently reach, utilize and mange the information generated by citizens and use it to improve the quality of service and reduce the costs.
- The third party can offer a secured platform for citizens to organize and manage their own information. In addition to being able to create their own content, more power and responsibility will be transferred from health care service providers to citizens' hands. They can collect information from different service providers conveniently, manage and distribute it as needed providing benefit to all parties.
- Enhance the citizens' capability to communicate with all relevant entities, including also other individuals and communities with common interests, in addition to the service providers. CCA is meant to facilitate processes, information, applications and infrastructure to be designed for citizens. This would help them to identify and locate the needed services, be empowered to manage the service process, and eventually to improve the quality of their own life.

Current Dual Model cannot yet provide explicit methodology of establishing an integrated platform among health service providers and citizens. At this early phase, Dual Model serves as the purpose of providing a high-level guidance in long term and encourages further research work in Citizen Centric Architecture, which can be generally applicable in any industry and service domain.

In last recent years, several PHR tools such as HealthVault by Microsoft, Google Health etc have launched to the market. However, the adoption of those applications was not smooth and fast as expected. Missing a comprehensive architectural approach would be a partial reason, as one single application solution is not enough to build an interactive communication among millions of service providers and citizens.

As stated, research works about architectural approach are not many in the domain of healthcare services. Possible future works related to CCA are plenty. What we would like continue is to conduct empirical investigations in order to better evaluate and validate CCA approach. As CCA changes both citizens and service providers' workflow, modeling and analyzing the process changes are necessary works in future study. Last but not least, to put CCA into real use, a feasible business model of CCA should also be further explored.

Acknowledgments

This work is a part of MyWellbeing research project in 2008–2009, funded mainly by Tekes, the Finnish Funding Agency for Technology and Innovation, and a consortium of 10 companies and public organizations.

Abstract

This paper describes the building of an HL7-based Information Model Ontology (IMO) that can be exploited by a domain ontology in order to distribute querying over different clinical data repositories. We employed the Open Medical Development Framework (OMDF) based on a model driven development methodology. OMDF provides model transformation features to build an HL7-based information model that covers the conceptual scope of a target project. The resulting IMO is used to mediate between ontologically queries and information retrieval from semantically less defined Hospital Information Systems (HIS). In the context of the DebugIT project - which scope corresponds to the control of infectious diseases and antimicrobial resistances – Information Model Ontology is integrated to the DebugIT domain ontology in order to express queries.

Keywords:

Information systems, Knowledge, Software design, Semantics, Information systems/methods.

Introduction

An important limit of most existing surveillance systems in healthcare is that they rely on local clinical data repositories based on proprietary data models without any semantic interoperability. The main objective of the DebugIT (Detecting and Eliminating Bacteria UsinG Information Technology) project [1], a 7th EU Framework Program, is to build an interoperability platform able to share heterogeneous clinical data sets from different European hospitals for the monitoring and control of infectious diseases and antimicrobial resistances. In this context, Semantic Web technologies are used to aggregate and query heterogeneous distributed clinical data in a unified view via ontologies. In particular, SPARQL[1] are Semantic Web services implemented to interface local clinical data repositories with ontologies.

A challenging issue is to ease the querying process between proprietary information models (IM) and domain ontologies. Indeed, it seems easier, as a first step, to map proprietary IMs to "mediator" ontologies that are instantiated by information entities. The binding of a domain ontology to an IM ontology has then to be done in a second step [2] in order to improve the coverage of the domain ontology.

This paper describes the methods and tools for building an HL7 IM based ontology that serves ensuring coverage of the conceptual scope within DebugIT by amending the DebugIT domain ontology (DCO)[2] with new "information entity" concepts. In this way the Information Model Ontology (IMO) ensures ontological coverage needed to query heterogeneous clinical data repositories while still largely complying to HL7.

Background

Healthcare standardization efforts

One major contribution of the standardization bodies in the health care domain (Health Level 7 (HL7)[3], CEN TC251, International Health Terminology Standards Development Organization (IHTSDO)[4], etc.) is to define the domain knowledge (reference business models, reference IMs, reference health care services and reference terminologies/ontologies) to enable semantic interoperability.

HL7 is an important standard for encoding clinical information. Its Reference Information Model (RIM) has been developed through a consensus process including harmonization activities. The RIM is the general structure that guarantees the coherence of the complex set of HL7 version 3 models that may be used in many contexts to describe particular administrative or clinical health care information. Besides IMs, HL7 also provides a controlled vocabulary that has been developed for coded properties of the HL7 IMs. Vocabulary specifications often refer to standard biomedical terminologies such as SNOMED CT.

Model-Driven Architecture for ontology building

A new generation of Hospital Information Systems (HIS) integrate more and more standard IMs linked to biomedical terminologies, using state-of-the-art software development process methods, such as the Unified Process or Model-Driven Architecture (MDA) proposed by the Object Management Group (OMG)[3]. MDA defines a software development approach based on modeling and automated mapping of models [5]. Consequently, an increasing number of development frameworks are available allowing the use of MDA approaches into the HIS development process [6, 7, 8].

Only few of them provide the use of MDA associated to a healthcare standard into the HIS development process and investigate the use of ontologies mapped to information models [9, 10]. But, according to us, none of those development framework allow to build ontologies. Moreover, the use of the MDA approach for designing an ontology development platform is addressed by recent initiatives such as the OMG's one. Although ontologies and the Model-Driven Architecture (MDA) are approaches largely developed in parallel, many authors have attempted to bridge these modeling approaches [11, 12]. A software tool called DUET[4] enables the importing of DAML ontologies into IBM Rational Rose and ArgoUML and the exporting of UML models into the DAML ontology language. The tool is actually implemented as an add-in for IBM Rational Rose and as a plug-in for ArgoUML. It is freely available. XPetal[5] is a freely available tool implemented in Java that transforms mdl, the IBM Rational Rose model format, to the RDF and RDFS ontologies [13, 14].

In a previous work, we have developed the Open Medical Development Framework[6] (OMDF) that is a UML editor that supports adaptation of HL7 IMs according to local constraints. In this paper we present an additional extension that supports the building of an IM ontology.

Material

Conceptual scope of the DebugIT project

The objective of the DebugIT project is to aggregate clinical data, stored in different hospitals, in a unified system dedicated to the control of infectious diseases and antimicrobial resistances. The infection control scope of the stakeholders of the project is delineated via several queries. At the current stage, nine queries are being tested, e.g "percentage of patients with a given infection type (e.g urinary tract infection) by a given pathogen (e.g E.Coli) resistant to a given antibiotic (e.g trimethoprime (TMP)". The DebugIT data catalog includes 58 items covering the conceptual scope of the queries considered within the project. As a typical feature of IMs, it mixes information artifacts with references to real-world entities and is divided into four domains: microbiology lab results ("CULTURE") (11 items), antibiotherapy ("PATHOGEN TREATMENT") (7 items), patient data ("PATIENT DATA, PATIENT TREATMENT, PHYSIOLOGY & LAB FINDINGS") (31 items) and encounter ("EPISODE OF CARE") (9 items). Those items have been used as a resource in the development of DCO.

HL7 information models

We considered the January 2009 version of the HL7 ballot as the standard IMs source [3]. This ballot version includes 1285 IMs (e.g Administrable Medication or Result Event) that are available in the section Universal Domains, including 30 domain chapters (e.g. Clinical Statement, Laboratory, Medication, Orders, Pharmacy, etc.).

Open Medical Development Framework

The OMDF is a methodology and a platform dedicated to medical artifacts development. It uses the Model-Driven approach in the sense that it takes platform independent UML models and exports them into various output format. We have extended the functionalities of the UML editor Topcased[7] by integrating the following features: i) import of selected HL7 models, ii) model adaptation, iii) model transformation into various languages (html, sql, c#, etc.).

The "HL7 model import" functionality takes XML files provided by HL7 content information relating to the previously selected models to transform HL7 IM into UML [15]. The "models adaptation" function allows the designer to select the relevant classes to keep in the intended model. Only classes inheriting from "Entity", "Role" and "Act" of HL7 RIM are presented to the designer; other kinds of classes can be considered as structured relations. Relations are added automatically whenever two classes involved are part of the selection, thus simplifying specialization, aka model scope refinement, by the designer. The last feature, "model transformation" is the result of the integration of the Atlas Transformation language (ATL) engine[8]. This engine allows to implement a transformation (from one model to another) by describing the transformation process in an ATL file.

Method

We have extended OMDF in order to use the model-driven development methodology for designing an HL7-based ontology in the specific context of DebugIT. The ATL transformation engine of OMDF allowed the transformation of an IM in XMI syntax into an IM expressed in OWL syntax, which was then "ontologized" using Protégé and DCO. The Eclipse Modeling Framework for Semantic Web[9] was used to define the ATL syntax mapping file. For example, the UML classes will be mapped with OWL classes.

We followed a 3-steps methodology to derive the IMO from HL7 IMs.

Identifying relevant sub-models

We investigated relevant standard IMs in the following HL7 Domains: Common Message Element Type, such as i) for encounter "EPISODE OF CARE", ii) for patient administrative data "PATIENT DATA", iii) for microbiology lab results "CULTURE", iv) for antibiotherapy orders "PATHOGEN TREATMENT", and v) for patient clinical data "PATIENT DATA & TREATMENT". We organized meetings with medical experts, business analysts and designers in order to browse the HL7 IMs of the chosen HL7 domains and select sub-models that covered the conceptual scope of the DebugIT domain.

Each HL7 domain is characterized by a representative model (Domain Information Model - DIM). We first compared the DebugIT catalog to each DIM to validate the choice of HL7 domains. Since the DIM frequently provides overly abstract information to be aligned directly with a data catalog, we then looked for more specific models within each domain. We evaluated the relevancy of a model according to the rate of mapping between the properties of the classes of the model and the items of the DebugIT data catalog.

Designing a DebugIT conceptual information model

The scope of DebugIT covers more than one HL7 domain (e.g. Laboratory, Order, etc.) and sometimes addresses more specific information. Therefore, we have been using OMDF to i) aggregate selected models into one model, ii) specialize this model to retain only the information relevant in the DebugIT conceptual scope.

Deriving IMO and completing DCO

We used OMDF in order to automatically transform the DebugIT conceptual IM into an OWL file. The problem with automatically generating OWL models from representational formalisms with different expressiveness is that the syntactical transformation may lead to semantically invalid statements. Therefore the target representation must be manually validated and if possible adapted aka "ontologized".

The initially exported OWL file is a semi-formal ontology in the sense that its semantics does not use DL expressiveness. The auto generated list of concepts, properties and attributes needs to be formalized manually.

The OWL file is edited into Protégé environment to add constraints on properties and classes. Then DCO is imported into the same OWL file to be completed with IMO's concepts by hand.

Experimenting queries using the ontology

Evaluating an ontology can be divided in two parts: verification and validation [16]. Verification refers to a technical process that aims at checking the correctness of the ontology. It deals with the formalization of the ontology and may be guaranteed by a reasoner. For instance to check the consistency of our ontology, we used a reasoner included into the Protégé editor (FaCT++[10]).

While the ontologization enabled us to use a classifier to check the logical consistency, the adequacy must be checked manually by a domain expert. An ontology is valid if it is useful to execute the task it has been built for.

The queries defined in the scope of the DebugIT project have to be expressed by IMO and DCO. As a matter of fact, the validation of IMO consists in testing the queries defined for the scope of the project.

Results

DebugIT HL7-based information model

OMDF enables us to design the conceptual model describing the information entities needed for the DebugIT project according to the HL7 standard. At this stage, this model is available as XML Metadata Interchange or HTML file. The six relevant HL7 IMs are: A_Encounter universal (COCT_RM010000UV01); Result Event (POLB_RM004000UV01); Composite Order (POOR_RM200999UV); Common Observation (POOB_RM410000UV); Adverse Reaction (REPC_RM000022UV) and A_BillableClinicalService Encounter (COCT_RM290004UV06). The IM includes 61 classes and 262 properties. The classes consist in Entity type classes (n=7) such as "Natural", "Person" or "Organization"; Act type classes (n=22) such as "ObservationEvent", "ObservationCluster", Role type classes (n=9) such as "Specimen", "Derived Specimen", "Patient", "Assigned Organization"; Participation type classes (n=10) and ActRelationship type classes (n=13). We have been able to express the totality of the DebugIT data catalog in the resulting HL7-based model. There is a one to one mapping with an HL7 property in 84% of cases. Seven per cent of the items were expressed using more than one HL7 property. For 4 items (9%), more than one item corresponded to one single HL7 property in the HL7 source IM. For example, EncounterStay.effectiveTime represents two items (admission date and discharge date).

The DebugIT HL7-based ontology

The OMDF extension enables us to get all the information we need about concepts and relations (cardinality, lexical information items as comments or definitions, domains and ranges for the properties) as shown in figure 1. The ontologization was done as follows : i) restructuring the concepts by adding subsumption properties between IMO concepts and concepts from DCO. So we imported and used classes as "clinical administration activity" "InformationEntity" "LegalEntity" or "PatientRole", ii) it is important to add constraints on the concepts and relations. "Admitter" and "Discharger" are both defined as linked to the concept "AssignedPerson" by a property. Nothing in the ontology states that a discharger is different from an admitter so that the reasoner defines both concepts as equivalents. So we have to create a disjointness axiom between those two concepts. The current version of the DebugIT HL7-based domain information includes 40 classes and 41 properties (10 Object properties and 31 Data properties). We used the reasoner (FaCT++) included into the Protégé editor. It took around twenty iterations the FaCT++ reasoner to obtain a consistent ontology. After each step, constraints were adjusted manually. Then, medical experts validated the completeness of IMO using the ontology to express the nine example questions defined in the DebugIT project. Figure 2 shows a sample of this validation process. It represents one of the queries expressed by IMO's concepts and properties.

Conclusion

Large-scale data integration efforts to support clinical and biological research are greatly facilitated by the adoption of standards for the representation and exchange of data. As part of the DebugIT project dedicated to multi-institutional sharing of disparate data on infectious diseases, we have explored the potential of the standard HL7 information models (IMs) for representing medical information entities and makes them usable through ontologies. We adopted state-of-the-art software development methods, such as the MDA approach proposed by OMG and have used the Open Medical Development Framework, developed in our laboratory, to support software designers and developers in adapting (importing and specializing) relevant HL7 IMs and transforming IMs into ontologies than can be mapped to domain ontologies.

We found that HL7 was a valuable source of artifacts and knowledge such as domain use cases, IMs and vocabularies. In our study, 100% of the DebugIT data catalog has been covered

by the standard IMs selected in the HL7 Ballot. We experienced that HL7 IMs, though available in a specific format not handled by the UML modeling tools, could be converted to UML and used to build an IM ontology. HL7 IMs include many explicit comments about the meaning of classes and/or properties that are carried on from conceptual models to an OWL file, across all the transformations performed with Open Medical Development Framework. We experienced that the syntactical transformation that occurs while automatically generating OWL models from other representational formalisms may lead to semantically invalid statements. Indeed, the IMO derived from HL7 IMs does only yield a semantic network like OWL file including both information entities and real-world entities. Manual adaptation and validation are required so that this IMO conforms to the ontological assumptions of OWL. A potential outcome of this effort is an example of how epistemological assertions, as occurring in information models, can be modeled within an ontological framework. Thus, using one single representation formalism, our proposal brings together HL7 information models and philosophically founded ontologies. At this first stage of the DebugIT project, we focused on integrating HL7 and not CEN TC251 artifacts to the MDA approach. CEN TC 251 also provides reference models (the openEHR Information Model [17]) and defines in additional constrained models how the general reference model is used to describe particular administrative or clinical health care information. Although, integrating specific plug-ins dedicated to the use of HL7 artifacts, the Open Medical Development Framework is not structurally dedicated to HL7 standards and we will develop specific extensions dedicated to support CEN TC251 IMs as long as these IMs conform to a meta-model conforming itself to the Meta Object Facility (MOF).

Acknowledgments

This work was funded by the EU 7th FP project DebugIT (ICT-2007.5.2-217139).

Foundations for a Nursing Services Reference Model

Liza Heslop[a], Keith Toh[b], Evelyn Hovenga[a]

Abstract

The Nursing Services Reference Model (NSRM) is presented as a theoretical position and discussion paper. The aims are to describe the components of the NSRM concept, to explain why such a model needs to be developed and to explore methodological issues in the development of a NSRM. The concept is important to address as it may illuminate a most pressing problem faced by the Australian health care industry where the content and activity of nursing practice is not embedded as computer processable data in health information system structures. Digital documentation of nursing content and activity is urgently needed to enable reliable electronic processing of nursing services. However, it is necessary, prior to this, to develop a reference model that describes the range of nursing services in an unambiguous manner.

Keywords:

Nursing information systems, Health knowledge management, Reference models, Operations management, Acute health services.

Introduction

The content and activity of nursing practice in the Australian health care industry is not embedded as computer processable data in health information system structures. Two key conceptual matters must be addressed for this to occur. There is a need for standardisation of nursing service description at an abstract business level as well as standardisation of clinical nursing language in terms of computer processing of digital documentation. While these conceptual matters persist and remain unaddressed, the imbalance continues at a business level where nursing services have not made the same pace of development as other fields such as supply chain management which are advanced in terms of the standardisation of service models e.g. Supply Chain Operations Reference Model [1-3].

Reference models are proven methods for communicating business information to stakeholders, strategists, policy makers and business analysts. Two examples of such models include the SAP reference model [4] and Scheer's model for production planning and control systems [5]. The Service Reference Model of the Australian Government Architecture (AGA) contains seven service reference models, including, for example, Customer Services, Business Management, and Back Office Services [6]. It does not include a service reference model for nursing services, which is a critical part of the Australian health and social infrastructure. Nurses represent the largest health workforce in Australia. Conservative estimates suggest the acute services nursing workforce continue to represent greater than 30% of total inpatient costs [7]. In addition, public hospital unit/ward nursing costs alone constituted 24% of the national average case cost identified in round 12 of the National Hospital Cost Data Collection Round 12 (2007-08), and critical care, operating room and emergency services, where nursing costs are very significant, constituted a further 25.6% [8].

The concept we wish to develop is a Nursing Services Reference Model (NSRM) to fill the previously identified gap. The NSRM is separate to diagnostic taxonomies which also lack integration into clinical nursing practice in Australia. For example, the nursing taxonomy with most development is an outcome of two decades of research by the North American Nursing Diagnosis Association (NANDA) where more than 100 nursing diagnoses form a taxonomic structure that reflect patient responses to actual or potential health problems. A NSRM is a different concept and comprises a standard business structure which documents the business activity of nursing practice in a manner that will support management of nursing service delivery and represent nursing activity in business system structures. It forms the basis for knowledge resources, data types and structures.

The proposal for a NSRM is also in line with the IT Infrastructure Library (ITIL) Framework [9-10] in relation to the definition of a service catalogue. Based on ITIL, the service catalogue is used as a starting point for the implementation of the Service Level Management process. Carefully planned and documented IT Service Management (ITSM) processes are becoming an increasingly important component in the delivery of higher customer satisfaction.

At a consultation workshop titled "S*tudying the redesign of patient care*"[1] participants voiced powerful opinions about the current state of health knowledge management and indicated

[1] Hosted at Victoria University (VU), Melbourne, Australia on the 20th of July 2009. Attendees comprised 25 targeted participants including researchers from within VU, key policy advisors, regional health services officials, representatives of the Victorian Government Department of Health (DoH) , the Australian Nursing and Midwifery Council and executive nursing and information communictaoin technology members from Western and Melbourne Health service providers including their health service redesign teams.

that support would be received for several projects (for example, the NSRM project) by peak health professional bodies in nursing, health informatics and health service officials at many levels of industry and government.

This paper is based on a critical reflection upon the workshop results and what is needed to develop a NSRM. The NSRM we propose will be informed by an international standard: The International Standards Organization (ISO) 'Health informatics - integration of a reference terminology model for nursing' (ISO/FDIS 18104). This ISO standard helps researchers to recognize that nursing data cannot stand alone [9]. It requires integration within clinical records. Also, the NSRM model we propose will be developed within the Australian Government Reference Model of the Australian Government Architecture (AGA). If the model can be situated in this context, the language for nursing services has potential for recognition alongside other health agency services in Australia. This work follows related projects, especially, of health informatics standards development, health terminology and electronic health records including knowledge management and ontology documented in the following references [11-18].

No reference model exists for nursing services in Australia and we could only source very limited international literature on reference models to support nursing practice. Destrebecq et al [19] from Italy refer to an 'old reference model' to allow for classification of tasks performed by nurses in three areas-nursing activities without chances of delegation, nursing activities that could be assigned to aids, and activities beyond the competence of nurses. They made a comparison between data collected and the reference model. The study has limitations for international audiences as the detail on the reference model was not provided. An example of the application of reference model for heatlh services more generally is provided by Huber-Bloder et al [20] who report a reference model with comprehensive hierarchical specifications for the domain layer of a hospital information system and its enterprise functions.

The development of a reference model would form the basis for the further development of an ontology (containing links to terminologies and bindings) for the nursing domain of knowledge. The nursing activity domain is wide-ranging and diverse; nurses practice in settings ranging from acute to community care as well as private and public services. For this project, our research team will focus on clinical public hospital nursing. The proof of concept or theoretical work to be achieved is to fit the NSRM with the many information /workflow processes where each process is associated with a specific aspect of nursing care.

The Nursing Services Reference Model

As part of the e-Government Strategy (released in March 2006), the Australian Government Information Office (AGIMO) defined a vision for increasing the effectiveness of service delivery and established the requirement for a 'cross-agency services oriented architecture' [6]. A crucial part of this was the development of a set of high-level reference models that provide a common language and classification scheme for business and technology (see Figure 1).

Figure 1 - Business Management Services of the AGA [6]

The development of the NSRM concept was proposed with the recognition that service improvement efforts would be supported through the considered application of ICT. It has been recognised that ICT will play an increasing role in terms of patient care. In proposing the NRSM, we wanted to ensure that technology plays a subservient role to the needs of service provision and therefore, the establishment of the NRSM was proposed as a means to push the "nursing business architecture" in front of technology architecture.

The development of the NRSM concept was influenced by the Service Reference Models of the AGA, in terms of granularity and abstraction of the service types. Development of the model will be informed by the AGA to enable the eventual acceptance of the NRSM as part of the Service Reference Models of the AGA. National adoption would be a longer process and would depend upon funding to support further development and application of the NSRM. The proof of concept NSRM model will be developed and tested as a valid model that fits with international standards (through the ISO) and Australian Government standards (through the AGRM and AGA). Methodologies will be developed during the development for testing validity. Generally, the model of validation will be based on consultaion and feedback incorporating elements developed by others who have adopted this approach. See, for example, Mohpatrea et al [21]; Colton and Hatcher [22]; and Tracey et al [23].

In parallel to this, the study of service management practice in the industry brought forward the ITIL Framework. The official definition of an ITIL Service Catalogue is: "A database or structured Document with information about all Live IT Services, including those available for Deployment. The Service Catalogue is the only part of the ITIL Service Portfolio published to Customers, and is used to support the sale and delivery of IT Services. The Service Catalogue includes information about deliverables, prices, contact points, ordering and request Processes" [24].

The initial NRSM concept was developed on this basis as the foundation for service management in the nursing sector in Australia. As an applied discipline, nursing uses knowledge in the service of solving problems of human health and caring. Nursing care also has complex management dimensions.

Integration within the AGRM and AGA will establish a national consistent approach with reference models of other clinical domains such as medicine and allied health. Hence, relevant entities of the Australian Commonwealth Government will benefit through improved understanding of ICT investment via access to repositories of standards, principles and templates derived from reference models. Improved design and delivery of nursing infrastructure ICT capability will improve business services to Australian citizens.

A high level start point for the clinical component of the NSRM is shown in Figure 2. The basis for this is that effective nursing is always organized and systematic, that prioritizes patient assessment and management.

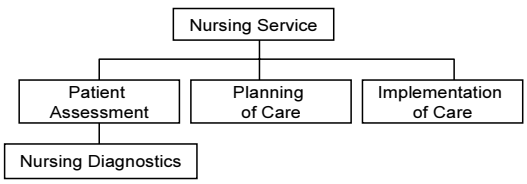

Figure 2 - High level classification of nursing services

The fundamental elements of the model are as follows:

- ***Assessment.*** An integral and ongoing aspect of the nursing service.
- ***Planning and Implementation.*** The formulation and implemention the care.
- ***Evaluation***. Determining whether the action taken has met the identified needs.

A challenge immediately emerged, where the nursing service includes more entities beyond procedures/techniques necessary for care and actually includes day to day personnel management and training/mentoring activities. Furthermore, delivery of the nursing services also includes significant multidisciplinary interactions with doctors, consultants and other specialists, going beyond the administrative domain (see Kelley et al [25].

It emerged from the workshop that there are other categories, for example in "Implementation of Care", the category of "Respite services" was put forward, which tends to be provided on a short-term basis because of the emergency absence or need for routine or periodic relief of the primary caregiver. They are provided in an individual's home, other community residence or in other community sites. Examples include assistance with activities of daily living such as: bathing or showering, toileting, and routine personal hygiene skills.

Further, in developing the NSRM, consideration must be given to other relevant areas of work to reflect the interdependency with behavioral sciences to allow room for the inevitable expansion of nursing practice.

It was clear to the participants of the initial consultations that the NSRM would have to capture monitoring health status and physical condition, assistance with medication and other medical needs. This also included assistance with preparation and eating of meals.

The NRSM must also include the holistic and effective nursing care, including health promotion and health screening. It must also include service descriptors relating to "housebound" care, where for reason of their diagnosis patients are best supported in their own environment by the skills and expertise of the nurses.

Another issue that emerged was the level of abstraction in describing aspects of services that were generic across the entities described in Figure 2. This is shown in Figure 3.

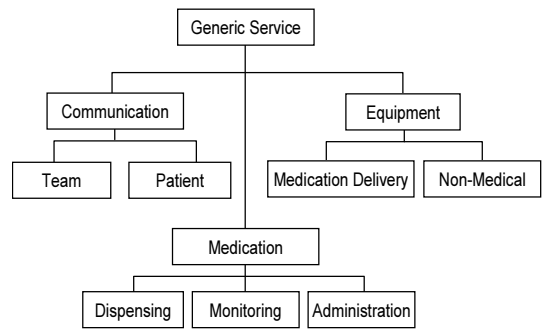

Figure 3 - Generic service descriptions

Communication

Communication (team) is generic, related to the exchange of information among the patient care team about a patient and patient care issues. Communication (patient) relates to the exchange of information from the patient care team or the health care facility to patients. This aspect will be common across assessment, planning and implantation of care.

Equipment

This relates to the physical infrastructure and may be categorized into medication or non-medical. Examples of non-medical include hospital lighting, privacy, physical safety and noise abatement. Medication delivery equipment identifies the services provided in terms of ensuring availability, reporting of malfunctions, maintenance, design, training and operations.

Medication

This category is related to a patient medication that originates in the dispensing process. Administration is related to patient medication that originates with administration of medication to a patient. Monitoring is related to a patient medication that originates after a drug is administered to a patient.

Future application of a NSRM with a common nursing data structure will enable formal recognition of nursing services from which an evidence base can be built to inform understandings of the nursing infrastructure including funding and provision of nursing services, and for the connection and integration of nursing care services across the health system.

Discussions

Given the importance of the nursing domain of care provision, the lack of a reference model at a national level in Australia has a major impact on research and development of health service systems including using source data to monitor, measure and evaluate nursing performance. Also nursing data cannot be shared within and between healthcare agencies.

Nursing work is complex and has many interconnections with medicine, allied health and community services. Nurses must increasingly deal with information and share their information with multi-disciplinary teams. Nursing services are largely documented upon paper-based records. Nurses have multiple files and documents to deal with for specific nursing aspects of patient care. For example, these files might be paper-based documents related to assessments of neurological observations, input of figures related to fluid balance management which forms part of managing an intravenous infusion, and pain management records.

Systemic change is necessary to accommodate the content of nursing records within information systems to fulfill interdisciplinary needs. Interdisciplinary professionals must access nursing files and records daily to make decisions about patient care. Design of digital systems will be enhanced by a sound description of nursing services in the form of a NSRM. Effective digital nursing data flow within and between healthcare agencies enables the use of these data both as contributions to electronic patient records and for the purpose of managing nursing workflow efficiency, nursing workload allocation, costing, and effective nursing service and performance management.

These different areas of work should be underpinned by a standardized and widely accepted structure or framework for describing nursing services. The Australian Government has recently announced its intention to fund hospitals federally based on activity (casemix) data. This means there must be a mechanism to consistently identify the nursing service contribution to ensure that these services are adequately funded to achieve desired outcomes. The NRSM should be sufficiently mature and embody the goals and descriptions of nursing services and can then be looked at as a reference for the various purposes discussed above.

Conclusions

The development of the NSRM is in the infancy stage, but it is in the opinion of the authors that this forms the first critical step to achieving the same degree of maturity in definition which will be comparable, eventually, to SCOR or the Service Reference Models of the AGA.

A Nursing Services Reference Model (NSRM) concept will be developed within the context of Australian government ICT architecture frameworks and international standards development organization (ISO TC125) as a research endeavour towards achieving a sustainable health care system.

This paper arises from dialogue between senior health care officials, health care managers and academics interested in the complex health knowledge management needs of contemporary health care organization. These discussions have continually underscored the importance of dialogue between the service and academic sectors. Such collaboration is necessary if the evidence from studies on reference models are to be effectively linked to initiatives in practice that to enhance the quality and safety of patient care. Development of a NSRM will involve key nursing stakeholders to build consensus on requirement analysis. The methodology when formally developed will include critical inputs from stakeholders and a project reference group. We will work with peak groups in nursing, health informatics and relevant government entities supporting the AGA to achieve levels of rigor acceptable to these groups.

Acknowledgments

The authors extend their thanks to Victoria University for the support for the project. We also acknowledge the participants from VU, regional health services officials (Western and Melbourne Health), representatives of the Department of Health Services (DoH), the Australian Nursing and Midwifery Council (ANMC) and colleagues from the University of Melbourne. Particular mention is made of Karen Parent from the Vancouver Health Care Authority, BC, Canada, who attended and persevered during a period of bereavement.

The Health Service Bus: An Architecture and Case Study in Achieving Interoperability in Healthcare

Amanda Ryan, Peter Eklund

School of Information Systems and Technology, University of Wollongong, Wollongong, Australia

Abstract

Interoperability in healthcare is a requirement for effective communication between entities, to ensure timely access to up-to-date patient information and medical knowledge, and thus facilitate consistent patient care. An interoperability framework called the Health Service Bus (HSB), based on the Enterprise Service Bus (ESB) middleware software architecture is presented here as a solution to all three levels of interoperability as defined by the HL7 EHR Interoperability Work Group in their definitive white paper "Coming to Terms". A prototype HSB system was implemented based on the Mule Open-Source ESB and is outlined and discussed, followed by a clinically-based example.

Keywords:

Interoperability, Systems integration, HL7, SNOMED CT.

Introduction

A main challenge in the field of health informatics is to enable shareable and computable information [1]. Taylor defines three "grand challenges" for health informatics: reading and writing patient records; creation of medical knowledge; and access to medical knowledge [2]. The key to all these challenges is interoperability, which is defined in the next section.

In [3], a conceptual framework for interoperability in healthcare was outlined based on the Java-based Jini Architecture. Following that work, due to some limitations of the Jini Architecture, an improved framework called the *Health Service Bus* based solely on Enterprise Service Bus technology but following the same principles was developed and is presented here.

Definition of Interoperability

The definition of interoperability in healthcare was the focus of research conducted by the HL7 Interoperability Work Group, a part of the Electronic Health Record Technical Committee. The result of this study was the observation that there are in fact three definitions of interoperability in the e-health industry [4]. In practice, these definitions correspond to three hierarchic levels of interoperability.

The first is *technical* interoperability, which involves communicating data between different applications and systems over a network. Messaging is the best solution to this type of communication problem [5], and is the approach taken here, as the Health Service Bus is built on a messaging core.

The second level, and the most difficult to achieve, is *semantic* interoperability. This pertains to messages not just being received, but that meaning can be transmitted from the sender to the receiver and be understood in the same way by both. Semantic interoperability is about the meaningful exchange of information in association with its context. It evolves beyond communicating message structure into also communicating the intent or meaning of data, so that the information will be understood in precisely the same way by both the sender and recipient [6].

The third level is *process* interoperability, which refers to social or workflow engineering aspects of interoperability.

The ESB-based solution to interoperability in healthcare proposed addresses all three levels of interoperability as defined in [4], as will be shown.

Methods

The methods employed in this work follow the paradigm of *design science*. Design science is a method of information systems research which seeks to extend the boundaries of human and organisational capabilities by creating new and innovative artefacts, which fall into four product-types: *constructs*, *models*, *methods* and *implementations* [7,8].

The work presented here as a solution to interoperability in healthcare is a model of an implementation, using distributed methods from the field of enterprise integration. The main method from that field employed here is that of the *Enterprise Service Bus*.

Enterprise Service Bus

Enterprise Service Bus (ESB) is a term coined at Stanford University to describe a specific middleware software architecture. An ESB provides a loosely-coupled, highly distributed approach to enterprise integration.

An ESB has a standards-based messaging engine, which is event-driven and provides foundational services for more complex software systems [9].

Standards-based integration is a fundamental concept of ESB and thus makes a fitting solution in the standards-filled realm of health informatics. ESB solutions can also be implemented incrementally, so there is no need for downtime to completely

swap over to a new architecture – it can be done one department at a time as it is deemed necessary or convenient.

The Health Service Bus (HSB) presented here is essentially an ESB using health standards within its messaging formats.

Service Containers and Endpoints

In an ESB, all applications and services that are connected to the bus are considered abstract endpoints. The underlying implementations of these endpoints can be diverse, but the abstraction of treating them as the same provides a powerful paradigm for higher-level tools to assemble endpoints into process flows – a part of process interoperability.

A service container is a physical implementation of an endpoint and provides the service interface to the ESB. The traits of service containers lead to the distributed nature of ESB [9]. Figure 1 shows a generic endpoint.

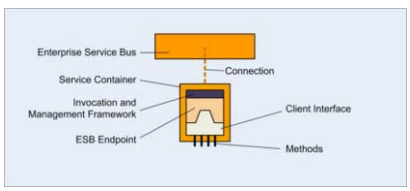

Figure 1 – A Generic ESB endpoint

Service containers should handle configuration, fault handling and management data – called the "Invocation and Management Framework". As Figure 1 shows, the endpoint connects to the client via an interface, which should be separate from the actual methods in the service connecting to the bus. This means that services can be changed over time, as long as their interface to the bus remains the same.

Mule Open-Source ESB

Mule, owned by MuleSoft, is the world's most widely used Open-Source ESB [10]. Like Jini, Mule is Java-based and provides a messaging framework which can use a variety of message formats. In Mule, application functionality is wrapped as a service, which includes a service component (business logic), routers (where to send the message), and configuration settings. This is consistent with the standard for ESB service containers and endpoints, and also provides process interoperability.

Results

HSB Prototype Implementation

A prototype HSB implementation was set up using the Mule Open-Source ESB, and making use of various services connected to the bus.

A client application for entering patient observations was developed for testing the prototype HSB. A SNOMED CT XML database, developed during a previous project was given a Web Services front-end and hooked into the HSB, allowing the Observations Application timely access to the SNOMED CT terminology.

Translation Services were also developed based on XSLT transforms to translate HL7 V3 messages to HL7 V2 and OpenEHR. The structure and content of these messages provides the level of semantic interoperability in the HSB. The actual XSLT transforms are discussed in [11].

The translation service was also set up with a Web Services front-end for connecting to the HSB. Figure 2 shows the components of the Mule HSB prototype.

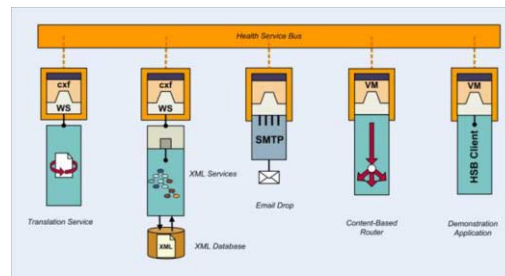

Figure 2 – Components of the Mule HSB prototype

As well as the services discussed, a content-based router is also included, and an email drop for reporting errors. The "HSB Client" shown in Figure 2 refers to the Observation Application, and the "XML Services" and "XML Database" combined make up the SNOMED CT XML Service.

Translation Service

Ontology mapping between different health standards (HL7 V2, HL7 V3 and OpenEHR) led to the development of XSLT stylesheets for translations between these standards in the instance of patient observations messages, as discussed in [11]. These XSLT stylesheets form the basis of the translation service connected to the HSB.

The functionality provided by the translation service allows for direct translation between HL7 V3 and HL7 V2, and from HL7 V3 and OpenEHR. Translation between HL7 V2 and OpenEHR may also be achieved within 2 steps – from V2 to V3 and then V3 to OpenEHR or vice versa.

SNOMED CT Terminology Service

The "XML Services" and "XML Database" in Figure 1 together refer to the SNOMED CT terminology service.

A subset of the SNOMED CT terminology was converted to XML for use as the basis of a terminology service which was connected to the HSB, based around the concept of *Vital Signs*. This encompasses Observations data, which is the example data used the HSB prototype.

SNOMED CT is distributed as data delimited into fields, with each record on a new line. To convert the SNOMED CT concepts to XML, each concept is converted to an XML node called "concept", with each field of the concept represented as one of its child nodes. For example, compare Table 1, which shows the concept "Sensation of blocked ears", to its XML representation, below.

Table 1 – Example SNOMED CT Concept

Concept ID	Status	Fully Specified Name	CTV3 ID	SNOMED ID	Primitive
103281005	0	Sensation of blocked ears (finding)	XU0sM	F-F5612	1

```
<concept>
    <conceptId>103281005</conceptId>
    <status>0</status>
    <fullySpecifiedName>
            Sensation of blocked ears (finding)
    </fullySpecifiedName>
    <CTV3Id>XU0sM</CTV3Id>
    <SnomedId>F-F5612</SnomedId>
    <isPrimitive>1</isPrimitive>
</concept>
```

The SNOMED CT relationships and descriptions pertaining to the concepts in the subset were also converted to XML in a similar manner. These XML records were then stored in a native-XML database, which provides a richer data model than a traditional database and makes the data self-describing, by way of the XML tag names [9]. The XML database can be queried over the bus by sending messages to its Web Services front-end.

Email Drop Service in the HSB

The purpose of the email-drop service is for automatically sending emails to a designated address when errors occur on the HSB. A service container is configured containing an endpoint which simply connects to an SMTP server and sends an email with a given subject and message to a defined address. The other services on the HSB are then configured to automatically use this service whenever an error occurs.

Content-Based Router

A *content-based router* examines the contents of a message and then routes it based on information contained in the message [5]. In the HSB, messages are routed based on who the messages are addressed to. HSB clients register their names with the router when they first connect to the bus. Messages between HSB clients are then sent through the router, which will pass them on to the appropriate party. The end-to-end example at the end of this section will demonstrate the router.

Patient Records in the HSB

Continuous patient records are stored in an XML database connected to the HSB. The format of the records is OpenEHR.

The format of most messages transmitted on the HSB is HL7 V3, so the translation service is used here to translate messages from the HSB into OpenEHR for storage in the database. The observation structures in HL7 V3 and OpenEHR are similar, making this translation simpler than expected. The "observation" sections of HL7 messages are translated to OpenEHR observations and then stored in the relevant patient's record.

Figure 3 shows the process of storing the observations in the patient's record. The setup of the EHR XML database is the same as the SNOMED CT database – the "XML Parser" in Figure 3 corresponds to "XML Services" in Figure 2, XML databases are shown in both Figures 2 and 3.

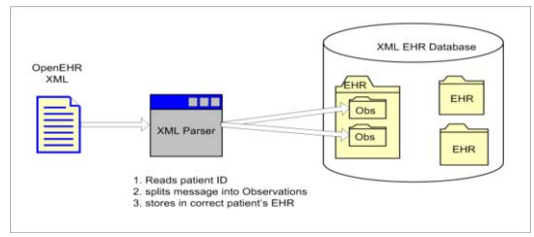

Figure 3 – Patient records stored in an XML database on the HSB. Observation Entries are stored in a patient's EHR.

Total Interoperability in the HSB

All three levels of interoperability (based on the definition in [4]) are achieved in the HSB.

Technical Interoperability

Technical interoperability is achieved in the HSB by the central HSB structure, specifically the messaging bus core. The messages sent "over the wire" are actually XML based on health standards, which brings us to semantic interoperability.

Semantic Interoperability

Semantic interoperability is achieved in the HSB by the content of the message sent within the framework and how they are processed. The messages are XML based on HL7 V3 models, which are themselves based on SNOMED CT constructs. The mapping from SNOMED CT to HL7 to obtain these models is covered in [12] and [13].

Process Interoperability

The level of process interoperability is achieved by the inherent nature of the HSB. Features such as intelligent routing and monitoring facilities which are part of ESBs contribute largely to process interoperability.

End-to-End Example

Figure 4 shows an end-to-end messaging example from the Mule HSB implementation. The HSB client wishes to send a message on the bus to another HSB client.

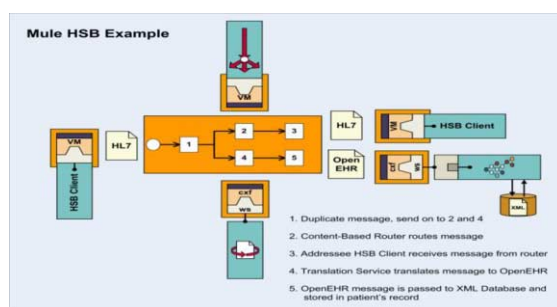

Figure 4 – End-to-end example of the Mule HSB implementation.

Step 1 is to duplicate the message and send it on to both the content-based router and the translation service. All observations messages sent from the HSB client Observations Applications are recorded in the OpenEHR database in the respective patient record.

Step 2 is the content-based router, which routes the message as described previously and sends it on to the receiver (Step 3).

Step 4 is the translation service, which translates the HL7 message into OpenEHR and passes it on to the EHR database (Step 5), where it is stored in the database as described previously.

Discussion

The prototype HSB demonstrates how ESB concepts can be applied to healthcare and is useful as a proof-of-concept. However, a large scale health information system is more complicated than this.

The HSB is scalable in that ESB is a highly distributed enterprise integration solution in that services that can work together are actually separated due to loose coupling principles and can be scaled independently from one another.

In terms of vertical scalability, a service container may manage multiple instances of a service; and in terms of horizontal scalability, several service containers may be distributed across multiple machines for the purpose of handling increased message volume [9].

Figure 5 shows an industry-level example between several healthcare facilities. Each entity has its own set-up and can communicate within itself and also to all other entities in the network through the HSB. For example, the Aged Care Facility has three desktops with a packaged patient administration application installed on each. The three computers can communicate with each other, and the Aged Care Facility as a whole can also communicate with other entities in the care network.

Previous Work

Bicer et al's *Artemis Message Exchange Framework* (AMEF) aims to mediate between healthcare information systems with differing messaging standards using Web Services and OWL[14].

A prototype demonstration mapping HL7 V2 to HL7 V3 is shown by the authors in [14]. This involves ontology mapping of the HL7 V2 and V3 XML schemas to each other using a mapping tool the authors have developed called *OWLmt*. Existing applications are then wrapped as Web Services and the messages they exchange are mediated through OWLmt

The HSB is different to AMEF in that it is a complete integration solution, encompassing message mediation, terminology services, patient records, management and monitoring and whatever else is required to be plugged into it; whereas AMEF concentrates solely on message mediation with some Web Services.

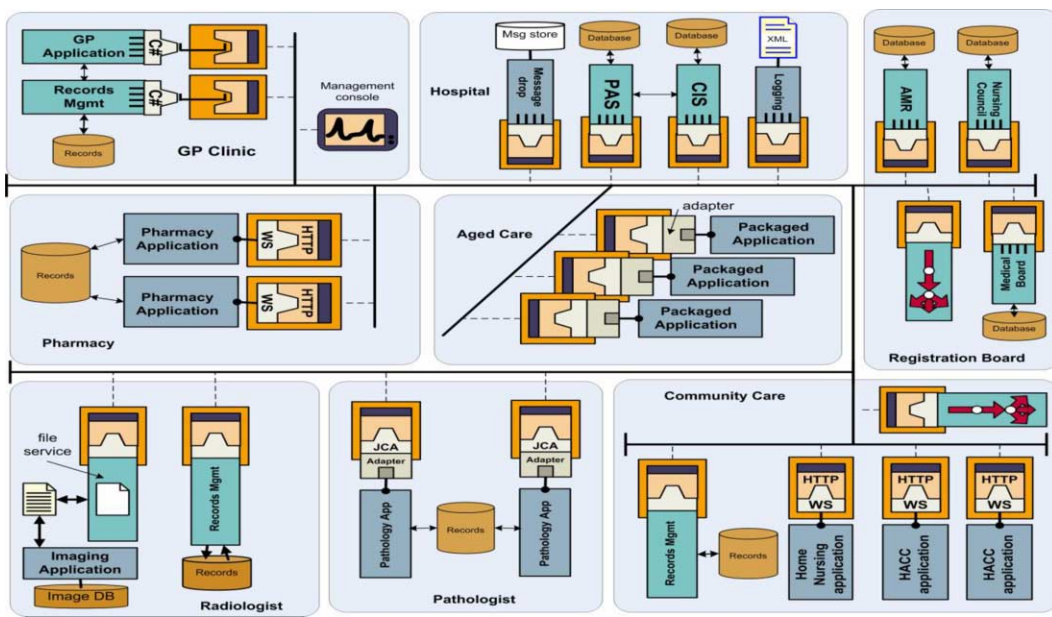

Figure 5 – Industry-based example HSB, covering eight different entities in a healthcare network.

Conclusion

ESB is a powerful technology for standards-based integration, which provides am excellent solution for communication in healthcare. The HSB solution achieves all three levels of interoperability, as defined by the HL7 Interoperability Work Group – technical, semantic and process – thus providing an architecture for a complete interoperability solution.

The small proof-of-concept HSB using Mule ESB Open-Source software shows that the solution has potential to be adapted to a larger industry-based solution.

Applying a User Centered Design Methodology in a Clinical Context

Hajar Kashfi

Division of Interaction Design, Department of Computer Science and Engineering,
Chalmers University of Technology, Gothenburg, Sweden.

Abstract

A clinical decision support system (CDSS) is an interactive application that is used to facilitate the process of decision-making in a clinical context. Developing a usable CDSS is a challenging process; mostly because of the complex nature of domain knowledge and the context of use of those systems. This paper describes how a user centered design (UCD) approach can be used in a clinical context for developing a CDSS. In our effort, a design-based research methodology has been used. The outcomes of this work are as follow; a customized UCD approach is suggested that combines UCD and openEHR. Moreover, the GUI developed in the design phase and the result of the GUI evaluation is briefly presented.

Keywords:

Clinical decision support system, User centered design, Usability, UCD, Prototype, Design and development process, Iterative design, *open*EHR.

Introduction

Errors that occur in a clinical process are mostly due to cognitive limitations of humans, the potential to forget knowledge in the health care flow. Information systems have the ability to decrease such errors by supporting clinicians in this process e.g. by reminding them of important factors to be considered for the current case or to alert them of adverse drug-drug interactions [1]. A Decision Support System (DSS) is an interactive application that is supposed to facilitate the process of decision making for decision makers. This support is done by mapping or compiling existing data to useful information that can be used as a clue for making the best decision [2]. Clinical Decision Support Systems are those DSS:s that are used in the clinical domain. CDSS:s are intended to help clinicians in the process of decision making. Services supported by CDSS:s include diagnosis, alerting, reminding, treatment suggestions, and patient education. Based on a thorough literature review done on around 140 papers about CDSS, it is clear that CDSS:s have the potential to improve care [3].

Usability of CDSS

ISO 9421 [4] defines usability as the "Extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use." Poor usability is the one of the reasons for why CDSS:s have not yet gained a broad acceptance. While there have been many efforts in developing CDSS:s, very few of those systems have been accepted in real clinical environments. Studies show that user interfaces have an impact on acceptability of CDSS:s in a clinical context. The success of a CDSS has a direct relation to the way its graphic user interface (GUI) has been designed [5].

CDSS:s are meant to reduce clinical errors, nevertheless, because of improper design of those systems, other kinds of errors may occur by using them [1,6]. Studies reveal that clinical information systems with low usability not only do not improve patient care and reduce clinical errors, but also may have the opposite effect [7, 8].

Involving Clinicians in the Design Process of CDSS:s

Not just in the clinical domain, but in every other domain experiences show that by involving users in the design and development process of a system, the system will be more usable for the intended users [9-12].The design approach which emphasizes on involving users in the design is called User Centered Design process(UCD) [9, 10]. Accordingly, one can not develop a CDSS which addresses clinicians' needs in a clinical context without a design process in which end users, clinicians, are involved actively [13]. To make a CDSS a usable product, we should consider not only user needs that reveal functional requirements of the system, but also non-functional or usability requirements as well as characteristics of the clinical environment in which the system will finally be applied.

In this paper, we present issues related to user-centered design of a CDSS for Dry Mouth, an oral disease. The main reason for selecting Dry Mouth is that our end users expressed a need for a CDSS for this disease.

Methods

The research method we applied in our work is a design-based research method [14]. For this purpose, our collaborators in Sahlgrenska Academy[1] suggested the design and development of a CDSS for an oral disease named Dry Mouth. "Dry mouth or Xerostomia is the abnormal reduction of saliva and can be a

[1] http://www.sahlgrenska.gu.se/english

symptom of certain diseases or be an adverse effect of certain medications"[15]. Treatment of Xerostomia is related to finding its cause(s). There are five main categories for Xerostomia: Drug-induced, Disease-induced, Radiation-induced, Chemotherapy-Induced, and cGVHD-induced [15].

The reason for suggesting Dry Mouth was that the dentists and dental hygienists are commonly the first clinicians to face the complaints by patients regarding this disease; hence, they should be aware of it and its problems to prevent the deleterious consequences of this disorder. However, according to our expert panel, finding cause(s) of Dry Mouth is a challenge for dentist and dental hygienists, and needs to be supported by a clinical application. The decision support process we aim for includes these two main steps (1) finding the cause(s) of disease based on the patient's medical records (2) suggesting related materials and treatment options, based on results from the first step. Since this system is intended to be used integrated with an existing Clinical Data Entry application [16], data entry forms are not part of the Graphical User Interface (GUI), however we have to provide users with options to edit existing data. Finally, users need to be able to enter their own comments; including diagnosis or treatments to the system.

The Design Process

The approach we use in this design process is UCD. UCD focuses on the end users, their needs and the context in which the system will be used. The main goal in this method is user satisfaction. UCD has an iterative nature. It means that during the design and development process, at several points, prototypes are delivered to users for evaluation and improvement.

As depicted in Figure 1, the idea of UCD is a circular design process including analysis, design, prototyping and getting user feedback. End users are in the heart of this design process and should be involved in all steps. Users are asked about what they expect the application to do for them and what priorities they have in doing their tasks using the intended application. Users have the chance to specify their needs as detailed as possible e.g. which colors do they prefer or what are their time limits running a specific task using the application.

On the other hand, informaticians can communicate with users to extract vital information about their current situation and their future needs e.g. what users like about the way they are currently doing their tasks or what would they like to be changed [11]. Finally, *task analysis* and *evaluation* [9-10] should be done based on the gathered information.

The Importance of Involving Clinicians in the design

Domain knowledge plays the main role in complexity of clinical applications. Clinical tasks may not be complex by themselves but what makes the clinical application development so complicated is that most of the clinical processes are unstructured. They are done in clinicians' mind and based on their expertise. Moreover, clinical knowledge is ever-changing.

Hundreds of data items are involved in a clinical decision making process. After all, concepts in clinical domain are not easy to understand for informaticians and they face difficulties communicating with clinicians or studying literature to get enough domain knowledge to be able to model it and to develop an application.

Extracting domain knowledge in the clinical domain has always been a bottleneck in the development process of such systems and a challenge for informaticians. Therefore, in the clinical domain, we need to involve clinicians in designing the Information model or more precisely domain concept models to be used for information modeling. One of the recent approaches that focuses on involving users in domain concept modeling is *open*EHR [17].

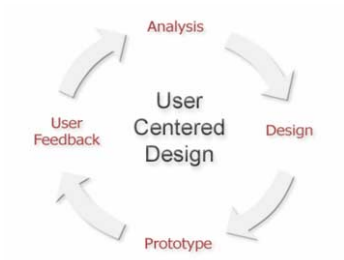

Figure 1- User Centered Design Process[2]

The openEHR Approach

*open*EHR is an open standard specification that emphasizes on the role of clinicians in organizing domain knowledge in form of different clinical concepts such as observation, evaluation, instruction and action [17].

In the *open*EHR approach, clinicians are in charge of defining the specification of clinical knowledge to be used in information modeling. This approach suggests a two level architecture for clinical applications to separate knowledge and information levels in order to overcome the problems caused by the ever-changing nature of clinical knowledge.

While the main emphasis of *open*EHR is on semantic interoperability of medical records, we found the approach highly compatible with UCD. Therefore, we applied *open*EHR to facilitate involving clinicians in the design and to ease domain concept modeling and communicating with our end users.

From an UCD point of view, *open*EHR is very helpful. This approach recommends the utilization of expert knowledge not only just by consulting clinicians but also by letting them design concept models based on what they have in mind. By applying *open*EHR, we can communicate better with our end users since clinical concepts recommended by *open*EHR are understandable for clinicians.

UCD Principles Applied in The Project

There are number of principles that are recommended in UCD [18]: *Multidisciplinary design team, Understanding users and context, Active user participation, Early prototyping, Continuous evaluation,* and *Holistic design*. Besides Holistic de-

[2] Copyright 2009, Kevin Bury Design

sign, we have been concerned about the other principles, as explained below.

Project Team

Our development team is a multidisciplinary team consisting of an interaction design expert, two computer scientists with different backgrounds (AI, Software Engineering), a domain expert (specialist in dentistry), a programmer, and a nurse. However, more end users and experts are involved in different steps in various time periods.

Intended Users, Tasks and Context of Use

One of the main principles in UCD is to define users and the context of use [10].

Users: In this project, direct users are dentists who work in an oral medicine clinic. We used narrative explanation of some typical end users, *personas,* [7] to find more about our end users' characteristics. Since the output of the CDSS will be a treatment decision, patients are our indirect users. Nonetheless, patients will not use the system directly.

Tasks: Based on literature review and interviews with end users and domain experts, we defined the tasks listed below as the main tasks that dentists carry out with regard to Dry Mouth: (1) Information Overview (2) Information manipulation, (3) Requesting related actions like laboratory tests, (4) Diagnosis, (5) Referring to guidelines and other clinical evidence, (6) Recording the results.

Context of use: Dentists will use the application while they are visiting a patient in the clinic. They will use it in presence of the patient, at the same time they are communicating with the patient and in a setting with a limited amount of time.

Users' priorities/Usability goals: The goal is to develop a system, which fits to the dentists' workflow as much as possible; experiences show that clinicians should not need to change their clinical workflow while using a CDSS [18]. It is also important to consider that not all clinicians are experienced in using information systems. On the other hand, because of their occupations, they do not manage to spend much time on learning a new application. Based on this information, we set up our usability goals such as: Effectiveness, Efficiency, Safety, Learnability, etc.

Iterative GUI Design and Evaluation

During the design, we have been using both low fidelity and high fidelity prototypes. From those, we can name sketches designed and improved during brain storming sessions for collecting functional requirements and usability requirements together with our expert panel. In this step, conceptual design of the application was done. These sketches were later translated to some power point prototypes. Afterwards, low fidelity prototyping tools were used to visualize the design solutions. Finally, a Java based GUI has been developed to make the final usability tests more realistic and reliable.

Iterative Domain Concept Model Design

The domain concept modeling started with brain storming sessions in which our expert panel (experts in Dry Mouth) were asked to think about Dry Mouth and its related concepts based on this question: *What do you want to know about a patient who visits you because he/she suffers from Dry Mouth?;* and to put as much information as possible on a paper. Later, our expert panel has been asked to prepare a questionnaire based on this question: *What do you ask from a patient who visits you because he/she suffers from Dry Mouth?*

Questions on the questionnaire were then categorized based on *open*EHR concepts; in other words, their logical relation e.g. is the question related to patient history or is it a lab result? In the next step, simple diagrams were created based on the questionnaire. For this purpose, a mind-map application[3] was used to make it possible for our expert panel to simply understand and edit the created diagrams.

GUI and Domain Concept Model Evaluation

For the GUI evaluation, we used the evaluation methods applicable in early stages of the project. Two main methods we have been utilizing so far are *Heuristic Evaluation* and *Usability Tests* [9]. Based on the results from the evaluations we improved the GUI in several stages. One of the resulting GUI screens is showed in Figure 2.

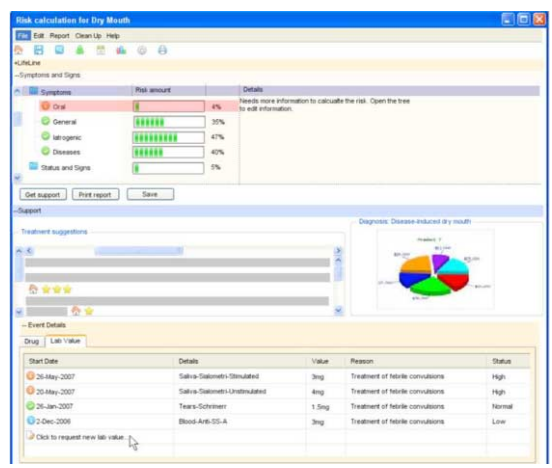

Figure 2- GUI Prototype

Iterative design of the domain concept model includes evaluations of the current model based on the literature and experts' opinions, and story-based assessment. Information modeling diagrams were improved several times based on the experts' opinions. Several experts were involved in this process to minimize the subjectivity of the design and to be as broad as possible in collecting knowledge. A sample mind map is depicted in Figure 3.

[3] http://www.xmind.net/

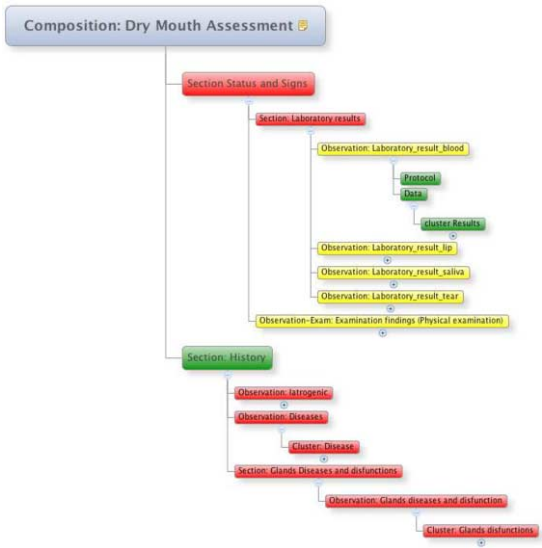

Figure 3- Information modeling

Results and Discussion

UCD emphasizes that users' needs should be reflected in the GUI design and that the GUI design should influence the design of the rest of the system [12]. On the other hand, *open*EHR emphasizes the domain concept modeling as the starting point. But how much does the domain model reflect the end users' needs? By using the *open*EHR approach without considering other aspects like usability issues, we may end up developing highly adaptable systems with comprehensive information models, which are not usable.

In this project, we tried to benefit from the strengths of the two of approaches and to introduce an adaptation of UCD in a clinical concept keeping an eye on the *open*EHR approach.

The Customized UCD Approach for *open*EHR Based CDSS Development

As references suggest "The actual contents of the UCD process, the methods used, the order of activities, etc, must be customized and adapted to the particular organization and project based on their particular needs" [19]. So it was not a surprise to see that we need to apply a customized version of UCD in this project.

As shown in Figure 4, the main idea of UCD is used in the process but in three different cycles. One is a general cycle to develop the whole application. This main cycle contains a cycle to develop the Domain Concept Model; and a cycle to develop the GUI. So the process includes two main steps in parallel (1) Iterative development of the domain concept model (2) Iterative development of the GUI. For the first step, several specialists in dentistry (expert panel) and for the second step, both domain experts and general dentists (end user panel) were involved.

GUI vs. Domain Concept Model

During the iterative design process we noticed that the impact of the domain concept model on the GUI is inevitable. Decision about the components to be shown on the GUI is directly related to the output from the domain concept modeling. Any changes in the domain concept model should be checked from the GUI point of view. Therefore, as depicted in Figure 3, in each iteration, there should be an input from the left hand side process (domain concept model) to the right hand one (GUI). In other words, after each domain concept modeling iteration, the necessity of a new iteration for GUI design should be checked.

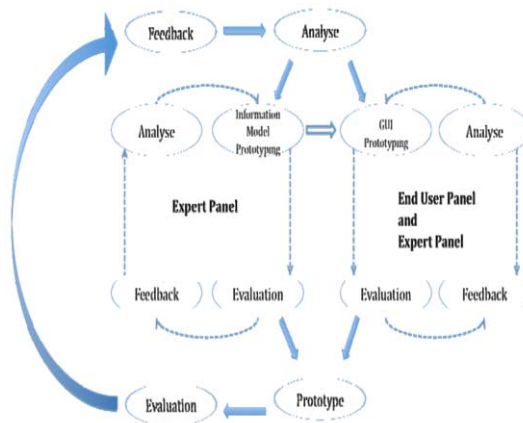

Figure 4- Customized User Centered Design Process

Characteristics of the Customized Approach and prblems

The recommended approach has several characteristics:

- This approach considers active involvement of the end users and domain experts in designing and evaluating the domain concept model and the GUI
- In the suggested approach new GUI and Domain Concept modeling iterations will be performed until the end users are satisfied with the results.
- In this approach, the effect of the domain concept model on the GUI has been considered as explained before.
- The approach helps overcoming the knowledge extraction bottleneck by applying clinical concepts suggested by *open*EHR for communicating with clinicians and providing an opportunity for them to model domain knowledge based on their expertise.
- This approach inherits the idea of the knowledge and the information level separation suggested by *open*EHR in order to make developed applications highly adaptable.
- Finally, the approach is applicable for developing not only *open*EHR-based applications but also all kinds of

clinical applications e.g. OWL based ones. Important issues to be considered while applying the approach are (I) the parallel iterative UCD of the domain concept model and the GUI, and (II) the effect of the domain concept models on the GUI.

We also faced some problems during the design phase. In design and implementation of CDSS:s a big challenge is choosing a knowledge representation and reasoning. Our experience showed that, selecting the representation and reasoning method have to be done in parallel with the information modeling and the GUI design, otherwise, the changes forced by this selection causes modifications in the GUI design which is more cost effective to be known in the early stages of the GUI design. Secondary, the classical bottleneck of knowledge acquisition in clinical domain still exists. While applying the suggested methodology decreases difficulties in mutual understanding of clinicians and designers, it cannot eliminate the bottleneck problem totally, especially for the cases that reasoning should be done by applying knowledge intensive methods.

Acknowledgements

Scincere thanks go to Ian McNicoll, Soren Lauesen, and Dowen Birkheld for evaluating domain concept models and the GUI. Many thanks also go to Mats Jontell, Marie Lindgren and Göran Falkman, our team members; and to my love Mohsen Nosratinia, and to Anna Gryszkiewicz for proofreading this paper. The author would also like to express her gratitude to Olof Torgersson under whose supervision this work has been done as a part of the author's PhD study. The project was funded by the Swedish Governmental Agency for Innovation Systems (VINNOVA), grant 2006-02792, as a joint project between Chalmers University of Technology and Sahlgrenska Academy, and is in progress at the time of writing this paper.

Bridging the HL7 Template – 13606 Archetype gap with Detailed Clinical Models

William TF Goossen, Anneke Goossen-Baremans

Results 4 Care B.V., Amersfoort, Netherlands

Abstract

The idea of two level modeling has been taken up in healthcare information systems development. There is ongoing debate which approach should be taken. From the premise that there is a lack of clinician's time available, and the need for semantic interoperability, harmonization efforts are important. The question this paper addresses is whether Detailed Clinical Models (DCM) can bridge the gap between existing approaches. As methodology, a bottom up approach in multilevel comparison of existing content and modeling is used. Results indicate that it is feasible to compare and reuse DCM with clinical content from one approach to the other, when specific limitations are taken into account and precise analysis of each data-item is carried out. In particular the HL7 templates, the ISO/CEN 13606 and OpenEHR archetypes reveal more commonalties than differences. The linkage of DCM to terminologies suggests that data-items can be linked to concepts present in multiple terminologies. This work concludes that it is feasible to model a multitude of precise items of clinical information in the format of DCM and that transformations between different approaches are possible without loss of meaning. However, a set of single or combined clinical items and assessment scales have been tested. Larger groupings of clinical information might bring up more challenges.

Keywords:

Archetypes, Templates, Information modeling, Detailed clinical models, Concept representation

Introduction

Huge efforts are ongoing in the specification of clinical data elements. In particular clinicians, regulatory agencies, health statisticians, institutions for quality control, among others, invest in clinical data standards [1-4]. The idea of two level modeling has been taken up in healthcare information systems development [5]. Two level modeling is in particular of interest for the electronic health record, the electronic exchange of patient data for continuity of care, and aggregation purposes.

There is ongoing debate whether one approach should be taken, or that alternatives are equivalent. Most efforts consist of data item specification, definitions of each element, and unique coding to determine the semantics. In particular the interaction between the information model and the terminology model is of interest because several standards that model information, such as the Health Level Seven (HL7) [6] and the ISO 13606 [7] apply external terminologies like Snomed CT [8], LOINC [9] or others. These clinical information models, templates, archetypes, clinical data elements, and Detailed Clinical Models (DCM) aim at three parts [10]:

1. Formalizing, organizing, structuring or standardizing clinical data elements to allow semantic interoperability,
2. Modeling these data elements independently of the technical implementation itself, and
3. Applying these data elements and models in different technical implementations [11], such as electronic health records, electronic messages, data warehouses / data repositories, and clinical decision support systems [12].

A fourth area of concern of such models is quality control and governance. The latter is not content oriented, but establishes what quality measures are necessary and how the ongoing maintenance is guaranteed for current and future use.

The question this paper addresses is whether Detailed Clinical Models (DCM) can bridge the gap between HL7 templates and 13606 archetypes and allow specification of concepts for use in both HL7 and 13606 standards.

Methods

In existing comparisons between HL7 templates (TM) and 13606 archetypes object model (AOM), the comparison is based on the 'whole' approach, including the full extent of the reference information models used [13, 14]. We discuss the information view only. Bointner and Duftschmid compare the TM and AOM models and find many differences e.g. in inheritance of characteristics, definition of semantics of reference model instances rendering them incompatible [14]. Their findings are consistent with earlier discussions in the standards organizations themselves. However, we see this as the effect of object modeling using a top down approach that is based on the whole standard, and starts with the Reference Information Model downwards.

When the starting point is the clinical relevant concept such as represented in the scientific literature and/or in clinical practice documentation, records and guidelines, the comparability can be improved. This however, requires a bottom up approach on the conceptual level. One example of such compari-

son is presented by Cuggia et al, where they compare the Apgar score representations in both HL7 v3 and OpenEHR archetype [15].

In the CEN/ISO mirror panel of NEN, the Netherlands, the two approaches HL7 v3 and 13606 have been part of ongoing debate for many years. Based on a bottom up approach we were able to further disentangle the clinical concept modeling from the technical modeling and to identify adequate levels of equivalence [16]. This allows comparing data element – by data element based on review of medical knowledge on the specific topic. The underlying assumption is that data elements that medically must be similar for safe patient care should remain the same despite the applied modeling and despite their technical representation.

In other words: if a patient has a coronary heart disease, a receiver of information should not see diabetes type 2 in the problem list. Or, if a Glasgow Coma Scale (GCS) is assessed, or a body temperature is measured, then the results of such observations must be exchanged without loss of meaning, leading to appropriate care by the receiver of information.

In order to bypass all technical constraints that might block a full comparison, the Detailed Clinical Modeling approach [10] has been taken to model a Top 10 of frequently used clinical concepts (height, length, temperature, pulse, respiration, blood pressure, Apgar score, Barthel index, Braden scale and Glasgow Coma Scale). Six are variable based; four are assessment scales with a well established meaning.

We identified these levels of comparison as appropriate:

1. Data types; that is the use of different types of data such as free text, (coded) value sets and physical quantities, [17] including their units of measurements [18].
2. Encoding; that is the manner in which each approach refers to external terminologies [8, 9] for the semantics of each data element.
3. Concepts; that is the level of the clinical concept, the unit of thought.
4. Meaning is created by combining concepts, including component data elements and linking this with the context and knowledge for use in health care.
5. Electronic communication, i.e. the exchange of clinical data between systems, which is a technical level.
6. Cooperation, which discusses expectations based on exchange of information, which is an organizational level.
7. Workflow around the data elements and concepts.
8. Agreements between stakeholders.
9. Maintenance and management of the instances of models.

For this comparative analysis the Top 10 of frequently used clinical concepts where modeled in Unified Modeling Language, are represented in HL7 v3 via a mapping to the Clinical Statement Pattern, and are also modeled into an archetype using an archetype editor.

In the analysis, the search is for equivalence on the level of information modeling, applying rules from data element standards, terminology standards and information model standards. In addition, where appropriate, we applied specific knowledge about the content. E.g. when a scale is represented, the psychometric measures of reliability and validity require that scientific rules are applied as well.

Materials

Results indicate that it is feasible to compare and reuse information models for single or combined clinical data elements and for assessment scale from one approach to the other. This works when specific limitations are taken into account and precise analysis of each data-item is carried out. In particular the HL7 template approach and the ISO/CEN 13606 and OpenEHR archetypes reveal more commonalties than differences. When compared against DCMs, it becomes even easier to transform from one to the other formalism.

In the area of data types, level 1 comparison, DCM, HL7 v3 and ISO/CEN 13606 use the ISO 21090 standard for data types. All examples show that the data types as expressed in the DCM could be expressed in both the HL7 v3 Clinical Statement Pattern (CSP), TM and in the AOM (Table 1).

Table 1- Data type level: example blood pressure

Clinical knowledge	Clear understanding is clinically important, e.g. 120 80 37 68 only make sense as 120 / 80 mm Hg 37 OC, and 68 /min
DCM	Data type PQ, unit mm Hg
HL7 v3 message using ISO 21090	<value xsi:type="PQ" value="165" unit="mm[Hg]"/>
OpenEHR archetype Partly ISO 21090	value matches { C_DV_QUANTITY < property = … units = <"mm[Hg]"> > }

For encoding data elements, level 2, DCM, HL7 v3 and archetypes can refer to external terminologies, or use internal coding. In order to achieve interoperability however, only the external codes offer equivalence. E.g. HL7 internal vocabulary deals with the mechanics of the messaging, where an archetype uses an internal numerical order for each element, called ontology. Latter has no reference to external ontologies in the medical domain. The linkage of DCM to terminologies suggests that to some extent data-items can be linked to terms present in multiple terminologies. Table 2 gives some examples of data element coding from the Top 10 of items, represented in DCM and mapping to TM and AOM.

Table 2- Coding level: blood pressure

Clinical knowledge	Systolic Blood Pressure: The maximum pressure that is build in the aorta when the left ventricle contracts.
DCM	Blood pressure as Observable Entity, using both Snomed CT and LOINC codes as presented above.
HL7 v3 message using	SNOMED CT <code code="271649006" codeSystem="2.16.840.1.113883.6.96" displayName=" systolic blood pressure"/> LOINC: <code code="8480-6" codeSystem="2.16.840.1.113883.6.1" displayName=" BP Systolic "/>
OpenEHR archetype	ontology > ["at0004"] = < text = <"systolic"> description = <"the systemic arterial blood pressure in systolic phase"> term_binding = < ["SNOMED-CT"] = < items = < ["at0004"] = <[SNOMED-CT(2003)::163030003]>

On the concept level 3, Cuggia et al (2009) [15] illustrated that the Apgar Score can be expressed in both the TM and AOM formats. Similarly, the Glasgow Coma Sale (GCS) can be modeled. The GCS consists of three categories: eye opening, best motor response and best verbal response. The GCS is scored by documenting the number representing the best response that could be observed with the patient. Here DCM, in which concepts can be represented by one or multiple individual data elements, potentially ensure uniformity across standards concerning composition, format and structure. See Table 3 for the concept level comparison of the Glasgow Coma Scale.

Table 3- Concept level: example Glasgow Coma Scale

Clinical knowledge	This scale is used to measure the level of consciousness of a patient with respect to verbal, motor and eye movement reactions. It has a total score summated from the three underlying observations.
DCM	Each data element is described as is the relationship between data elements. The derivation into the total score is expressed and class models can be drawn, including defining the hierarchical relationships.
HL7 v3 message using	Class representation for each of the score items and component relationships to identify hierarchical relationship with total score. Each class represented for instance by a LOINC and/or Snomed CT code: LOINC 9269-2 Glasgow Score Total, SNOMED CT 281395000: GCS eye opening sub score.
OpenEHR archetype	Node representation does allow identifying the three observations as a single data item and the total score. Also the fact that the total score is derived is defined. Each can be linked to an external code system as illustrated in table 2.

Level 4 Meaning. Figure 1 illustrates HL7 v3 classes forming the context for GCS, including the total score and the underlying components of Eye Opening, Motor and Verbal. In the code attribute the codes from external code systems can be specified. In the example LOINC codes are used, but also other codes can be included as synonyms. Figure 2 similarly represents (excerpts from) the GCS in AOM formalism.

Meaning is about the interaction between the (often intrinsic) knowledge model of clinical concepts, the information model representing it in technology, and the terminology model revealing its semantics. Both Standards do have a generic structure where concepts fit. In HL7 v3 this is the so called Clinical Statement Pattern (CSP). This is a RIM derived choice box pattern allowing 1 – n data elements to be represented and linked together with the component relationship. Figure 1 is in fact a roll out of that CSP. Similarly, the 13606 standard has the Entry component (Figure 3). DCM examples for e.g. blood pressure and GCS apply a full class diagram in which the concept is modeled, each component is represented in a class, each value is represented as a class diagram and the set of values and the code bindings are both represented in classes. An example is presented in Figure 4. This full modeling allows a full mapping to either a HL7 CSP / TM and to an Entry in AOM.

Figure 2- Glasgow Coma Scale concepts as in AOM.

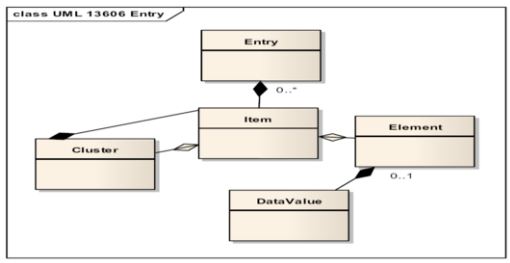

Figure 3- Entry part of 13606 RIM.

The entry level in 13606 RIM seems to equal the CSP function in HL7 v3 Models. Comparing this reveals a difference of the Reference Models between 13606 RIM and HL7 RIM. The first is, although generic, representing the 'whole' picture, where the HL7 v3 RIM requires a second step to create a so called Domain Message Information Model, of which the CSP is an example. Thus if we are to compare how a concept fits in the overall model, the 13606 Entry is the equivalent level to deal with a single data element or a concept (e.g. one (set of) observation(s) as CSP in HL7 v3 or one (or more) item(s) in 13606). This way the same level of comparison is achieved between TM and AOM. Concepts partly get their meaning from the structure they are embedded, which cannot lead to full 100% comparability of the reference models differ.

In HL7 v3 it is possible to represent the step in workflow (level 7) for each data element via the HL7 moodCode attribute that is inherited in each instance from the HL7 v3 RIM Act class. For instance, it is possible to order a blood pressure measurement (HL7 RQO or request mood), plan it (HL7 INT or intent mood) and document it (HL7 EVN or Event mood). In AOM such a workflow definition or modeling of a care process is absent. In DCM, the actual use of data elements, e.g. their creation, the phase in a care process and where relevant more aspects of workflow are expressed. Also general guidelines for the correct interpretation of values are included, offering the option for appropriate follow up.

Levels 5, 6, 8 and 9 would require a technical, organizational and managerial discussion, which is out of scope for this study. It is a more human and organizational issue to discuss the technical tools to be used, the cooperation between care professionals, getting agreement on formalisms and maintenance issues. However, on level 7 of comparing TM and AOM, it is possible to model processes and determine workflow support. For instance in health care it is quite common that particular observations are requested, planned and carried out. For observations this can lead to entering a value (score, text, value from list) into the EHR and exchange that.

Discussion and Conclusion

This work proves that it is feasible to model items of clinical information in the format of DCM and that transformations between different approaches are possible without loss of meaning. In particular, DCM expresses clinical concepts that can be represented in TM and AOM. However, the sample of data elements that has been tested includes single data elements or small scale groupings of elements and assessment scales. Larger data sets and groupings of clinical information might bring up more challenges, and perhaps reveal potential conflicts between the terminology model and information model.

The comparison from a bottom up approach following the levels indicated reveals many commonalties. At the first level of data type specification we find no differences, as long as the standards themselves adhere to ISO 21090. When the standards create additional data types, they will render semantic interoperability hard to achieve.

At the second level of coding, we see agreement between TM and AOM in the option to bind individual clinical data elements to codes from external terminologies. In Table 2 we see a difference in the Snomed CT code applied for blood pressure systolic. However, this is partly a matter of choice. In the HL7

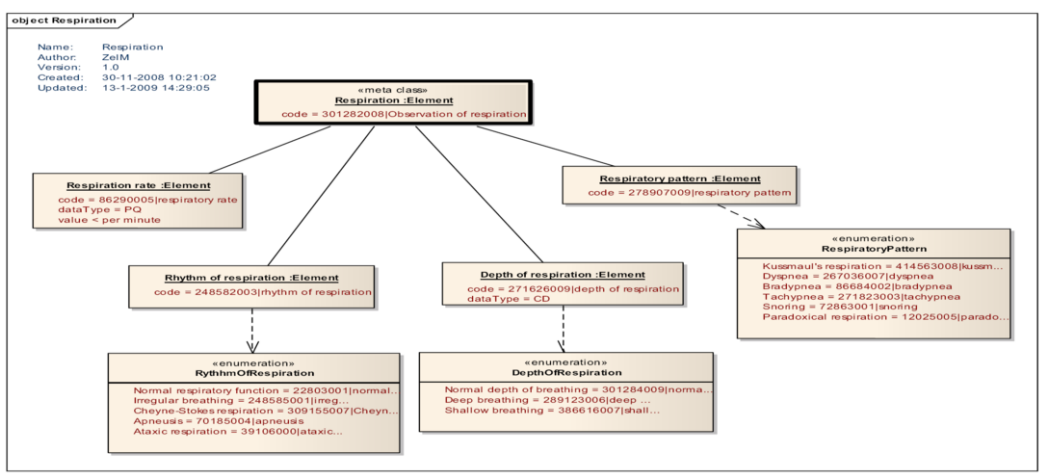

Figure 4- DCM model of respiration

example, which is similar to the DCM, the Snomed code for Observable Entity is used, referring to a field name in EHR. In the archetype example the clinical finding code is used, pointing to the actual finding on examination and the value entered. This illustrates the depth of knowledge necessary to model clinical information and to options that have to be set for actual implementation. It can be argued here that the AOM is more accurate in using the clinical finding, compared to the HL7 example. However, DCM, TM and AOM allow any choice. It can be recommended to use guidelines for code use such as Terminfo in HL7 [6] to sort this out. A difference between TM and DCM and AOM is that the latter currently does not support multiple external code systems as synonyms in the definition.

At the third level of concept, TM, AOM and DCM can define all relevant data elements, their relationships, their binding to coding, and the derivation of results. Although the representation formalism does look different, and obviously is handled different in an EHR system or an HL7 v3 XML message, the concept representation in DCM, TM and AOM remains intact for the clinical concept aspects. Only the hierarchical aspect cannot be defined in AOM itself, and needs some external mechanism. Class models applied in DCM would serve as such.

Meaning, level four of our comparison, is often discussed from the viewpoint of the reference information model of 13606 and/or HL7 v3. In fact HL7 v3 RIM is a generic structure with building blocks requiring a domain specific modeling exercise before it becomes meaningful. One format in HL7 is the CSP [6] that is used in several HL7 domain message information models or D-MIMs and message models derived from that. In the 13606, the RIM does represent the whole model used for the EHR communication [7]. The exercise with DCM examples Glasgow Coma Scale en blood pressure illustrate that these can be modeled against either the CSP in HL7 v3 and the Entry class in 13606. From this bottom up approach the commonalties become apparent, although it is not a 100% fit. Differences still remain in the hierarchical representation of concepts and in the workflow options that are both present in HL7 v3 and currently not in the AOM.

Comparisons of standards work can have different approaches, depending on the focus of the researcher carrying this out. With the bottom up approach is it feasible to stay very close to the original clinical concepts and relate these to terminologies, and different information models. Criteria from terminology use, information models, and the clinical knowledge need attention in order to get the necessary quality on the details. Use of DCM seems to bridge the gap to some extent at the very granular level indeed. However, transforming DCM into HL7 v3 TM and 13606 AOM does require transformations and careful attention for adequate concept representation and prevention of loss of meaning on the clinical side and appropriate application of the formalisms on the technical side. The overall approach is very promising; it reveals proof for the validity and the core asset of DCM: allowing specification of semantics and reuse of investments, independent of technology or standard.

Abstract

Controlled randomized clinical trials and meta-analyses show that stroke patients benefit from access to specialized Stroke Units, in terms of mortality, disability and dependency. However, many issues relating to stroke diagnosis and therapy and to the organization of stroke care remain to be solved and little is known about what interventions make Stroke Units more effective. It is also agreed that compliance with clinical practice guidelines improves health outcomes for these patients, but little is known about the relative weight of the different guideline recommendations. Over the last decade, many hospital- or population-based stroke registers have been set up with the aim of identifying specific key indicators able to monitor the quality and adequacy of acute stroke care. Registers seem to be adequate tools for collecting the data needed to analyze care processes, providing data useful for both national healthcare planning and scientific research. In this paper we applied data mining techniques to data collected within the stroke register of the Lombardia region in Italy. From our analyses both expected and unexpected results have been found: not always compliance to recommendations is related to a good patients' outcome.

Keywords:
Data mining, Stroke care, Clinical practice guidelines.

Introduction

Stroke is a leading cause of disability and death in developed countries. Since many years, national scientific communities work to support specialists with the most appropriate approach to stroke care. In Italy, the Stroke Prevention and Educational Awareness Diffusion (SPREAD, www.spread.it) collaboration, active since 1998, involves multidisciplinary experts coming from 36 different organizations together with representatives of patients' associations. The goal of SPREAD is to make available clinical practice guidelines (GLs) for stroke management, from prevention to acute and post-acute phase. These GLs are a set of practical recommendations periodically revised (we are now currently at 5th edition) and based as much as possible on the best available scientific evidence: according to the strength of the supporting evidence, recommendations are labelled with decreasing degrees from A to D.

In previous works, we described how these GL recommendations have been translated in logical (IF-THEN) rules and integrated within an existing electronic patient record (EPR) through a careflow management system [1]. The result has been a real-time decision-support system based on clinical evidence, which has been implemented in our hospital. Moreover, a module has been implemented, called RoMA (Reasoning on Medical Actions) [2], able to detect non-compliances with GLs. In principle non-compliances could be weighted with the recommendations degree. RoMA is a flexible tool that can be integrated with different databases, such as different EPRs. It has been used on about 500 cases to evaluate adherence to SPREAD GL before and after the implementation of the decision support system [1], showing its effectiveness.

In order to obtain more significant statistics with respect to the analysis of a single EPR, RoMA has then been used to analyze the bigger amount of data collected in the Stroke Unit Network (SUN) register, still with the aim of verifying GL compliance and its correlation with patients' outcome. The results so far obtained show that good compliance improves the clinical outcome. However, this is an *overall* result, correlating the outcome with the total number of non-compliances, while no result exists about the influence of every single recommendation, or set of similar recommendations, on the outcomes.

Therefore, there are several open questions:

1. Which are the recommendations more related to a good/poor outcome? Is it possible to make some inference on the importance of the recommendations with low scientific evidence degree?
2. Which is the most effective organisational setting for a Stroke Unit? Which facilities, among those distinguishing a Stroke Unit from a regular ward, are more influential on the outcome?
3. Which are the major patterns of non-compliance, i.e. is it possible to individuate predictors of non-compliance for the different SPREAD recommendations?

4. Are these patterns more related to clinical or organisational factors?

As shown in [3], data mining techniques can be profitably used in this area. Thus we used decision trees and rule extraction methods on the SUN register data to try answering some of the above questions.

The paper organisation is the following: the next section illustrates the data available in the register; then the GL recommendations are illustrated together with data necessary for testing the compliance; then we describe the data mining techniques used; eventually, analyses and results are shown.

The Stroke Unit Network Register

The SUN register is part of a web-based network connecting 36 Stroke Units and Neurological Departments in the Lombardia region, Italy, with the aim at improving the quality of stroke care in the acute and post-acute phase. The SUN website facilitates storing homogeneous data, debating among specialists and sharing research projects and results.

The data collected within the SUN register can be split into different categories as shown in Table 1.

First, there are general information about patient's demographics, admission modalities, stroke type and severity scales.

In the second category there are patient's clinical data such as risk factors for cerebro-cardiovascular diseases and medical complications that arise during the hospital stay.

In the third category there are indicators of the care process. Some of them describe diagnostic patterns: whether or not ECG, neuroimaging and other basic tests have been performed in the emergency room, and all the instrumental tests performed during the hospital stay. Timing of each performed test is also recorded. Others are indicators of good medical assistance: again, both type and timing of every assistance procedure are stored. Finally there are indicators of therapeutic procedures, both for the acute phase and for the early clinical phase, treatment for comorbidities (diabetes, hypertension, etc.) and counselling for healthy lifestyle.

The fourth category is composed by outcome indicators, among which the Rankin scale, collected both at discharge and at three months follow-up.

Moreover, each clinical centre is provided with a description of the hospital to which it belongs (e.g. rural or not, university-related or not), of its organisation (e.g. human resources), and diagnostic facilities (e.g. presence and 24h availability of a service).

The register is provided with procedures for data quality control both in real time and in batch.

The register and its database have been designed and implemented during 2006, while the patients' recruitment started in January 2007. At January 2009, the register contained 5079 cases of ischemic strokes, which represent our study population.

The guideline recommendations

As we are dealing with a disease register, we must point out that it contains less data, for an individual patient, with respect to a clinical chart, which reports much more detail. That means that we have fewer data fields available for testing GL compliance. On the other hand, a register allows a quick collection of a high number of patients, from a high number of clinical centers, thus allowing sounder statistics.

The information needed to assess the GL compliance has been matched with the data model of the SUN register in order to obtain IF-THEN rules as a formal representation of recommendations. The IF part of a rule is called *eligibility condition*, while the THEN part is the *action*. Three examples of this matching procedure are reported in Table 2. We remark that such a matching is not a trivial task, and it requires the collaboration of physicians in order to interpret the text, often ambiguous, of the GL, and to include some "hidden" knowledge that is not explicitly written in the GL, because part of the cultural background of any physician (e.g. which tests belong to a given diagnostic work-up, which diseases belong to a certain category, etc) or simply because obvious (e.g. the patient must be alive at a certain time for being evaluated).

Table 2 – Examples of matching the Register data with GL recommendations, in order to assess compliance

Recommendation	GL section	Register data used
5.5(D) - After a TIA or a stroke, transthoracic echocardiography (TTE) is recommended only when a heart disease is clinically suspected.	Diagnostic work-up	Alive at 3 days, TTE execution, myocardial infarction, atrial fibrillation, coronaropathy, heart failure, arrhythmias, prosthesis
9.7(D) - A non-contrast CT scan is recommended as soon as possible in the emergency care: to allow the differential diagnosis between ischaemic and haemorrhagic stroke, and with non-cerebrovascular lesions; to detect possible early signs of infarct.	Acute stroke:hospital admission (diagnostic procedures)	Time of stroke onset, time of hospital admission, time and setting of the neuroimaging execution
12.6a (B) - After stroke or TIA, lowering of high blood pressure is recommended, preferably using agents active on the renin-angiotensin system, calcium channel blockers and diuretics.	Secondary prevention	Alive at discharge, hypertension as risk factor or complication, antihypertensive therapy at discharge

The overall procedure result was that compliance can be verified for 12 recommendations of the acute phase and 4 of the secondary prevention phase, subdivided according to their scientific degree as follow: 2 with grade A, 4 with grade B, 1 with grade C, 8 with grade D and 1 only supported by experts consensus. While, in general, a guideline can contain recommendations that either suggest or advise against an action, all the 12 recommendations are of the first type and the non-compliance is defined as a case where the eligibility condition is satisfied and the action has not been performed.

The rules obtained have been used within the RoMA tool to assign every patient with a 1/0/null flag for any recommendation, representing non-compliance/compliance/no-eligibility respectively.

Data mining techniques

To analyze the impact of non-compliance to clinical GL on patients' outcome, we herein chose to exploit Data Mining (DM) techniques besides the classical statistical analysis that is the most frequent approach in these cases. The reason why DM can be useful is that it provides some tools to model the possible paths that lead to the outcome in a way that can be easily visualized and interpreted also by clinicians. These motivations led us to the choice of a specific DM algorithm, i.e. Classification Trees.

Classification Trees are a classification algorithm that works by recursively partitioning the examples space on the base of the most discriminant feature to predict the outcome (also known as class variable). Besides providing a method for class prediction, classification trees can be also a useful instrument for data exploration and understanding. Each branch of the extracted classification tree not only leads to the class prediction (in the leaves), but also identifies a clinical path that can be usefully considered for results interpretation. Each branch of the tree can be in fact seen as a classification rule where the body of the rule is represented by the conditions that characterize the patients belonging to that branch, while the head of the rule is the outcome. Such a representation is very suitable to identify the patterns that can lead patients to a particular outcome.

For Classification Trees construction we used the algorithm that is implemented in the Orange Data Mining Suite [4], choosing Gain Ratio as attribute selection criterion. Moreover, we set a minimum number of 100 patients in the leaves in order to avoid an excessive expansion of the tree obtaining too small and not significant patients sets. As we will see in the following paragraphs, we herein exploit classification trees mainly to analyze and discuss with our clinical partners about the clinical paths that lead to a certain outcome. For these reason the Orange widget "Classification Tree Graph" was very useful for results visualization and presentation.

Besides Orange, also S-Plus (Tibco Software Inc., Palo Alto, CA) was used for more classical statistical analysis such as logistic regression.

Analyses and Results

In order to produce results easily interpretable, different types of analyses have been performed using subsets of variables instead of using all the variables together, and continuous/ordinal variables have been discretized as follows:

Age: <=45years, 46-79, >=80

NIHSS scale: 0-7, 8-14, >14

Rankin pre-stroke scale: 0-1, 2-3, 4-5

Rankin scale at discharge/follow-up: good (0-2), bad (>2, including death). This binary value has been chosen as the main patients' outcome.

Delay between stroke onset and hospital admission: <=3 hours, 3-6, 6-24, >24.

The analysis has been performed using 5079 cases. The outcome at discharge was good for 2737 patients and bad for 2342, while the outcome at follow-up, where 2739 patients were available, was good for 1826 patients and bad for 913 (*good* and *bad* defined as illustrated above). On the average 3760 patients were eligible for each recommendation (range: 109 to 5079) and the average non-compliance rate was 36% (range: 0% to 80%).

The compliance flags, produced by the RoMA tool for the above mentioned 16 recommendations, have been used as explanatory variables for the health outcome, the discretized Rankin scale both at discharge and at 3-months follow-up. Age, gender, and severity at admission, that are known to be correlated with health outcomes, have been included in all the analyses as correction factors.

In the next paragraphs we show some results from different types of analyses. For sake of space, only the most significant results are shown.

Non-compliance vs outcome

In principle, GL compliance should be correlated to a good outcome, mainly when recommendations are based on scientific evidence deriving from clinical trials. This is not guaranteed in the real-world setting indeed, because the clinical routine can be very different from the *ideal* conditions in which trials are conducted. As an example, about short-term outcome, we obtained the classification tree in Figure 1. The tree has been derived considering the *Rankin scale at discharge* (good/bad) as outcome and the *non-compliance/compliance* to the set of recommendations of the acute phase as features. Figure 1 suggests that, after considering stroke severity represented by NIHSS and Rankin scales, that resulted the most discriminant variables, and age and gender (not appearing in the tree because not discriminant), the non-compliance to the recommendation 5.15 (namely *Transcranial Doppler is a complementary examination in patients with a recent TIA or stroke. It may provide additional information on patency of cerebral vessels, recanalization and collateral pathways; grade D*) is the most important to determine poor outcome in patients with less severe initial status. This is in agreement with the current physicians' feeling that this examination is very important to drive the subsequent diagnostic work-up, despite its low degree of scientific evidence.

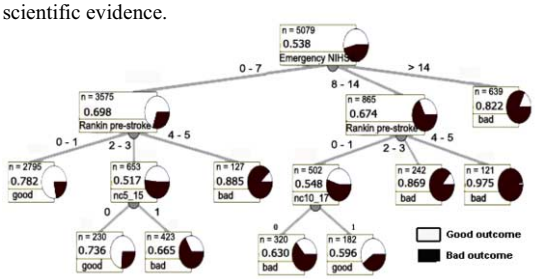

Figure 1 – The classification tree for the identification of the recommendations that are most related to the health outcome. "nc X" means "non-compliance with recommendation X". Bottom lines in the leaves indicate the majority class of the outcome (dichotomized Rankin scale), and the numbers represent the sample size (top) and the proportion of cases belonging to the majority class (middle).

On the contrary, in patients with a slightly more severe initial status (NIHSS 8-14), compliance to recommendation 10.17 (namely *Early mobilisation and hydration are always indicated to prevent Deep Venous Thrombosis. Graded compression stockings as well as intermittent pneumatic compression are recommended in combination with anticoagulation or as an alternative when anticoagulation is contra-indicate; grade D*) seems to be not as beneficial as expected (see Figure 1 again, bad outcome in 63% of compliance cases, and good outcome in about 60% of non-compliance cases) . The result is in agreement with a recent publication [5] that raised some doubts among such prevention procedures, which mainly consist in using graduated compression stockings. This is a very interesting exploitation of data mining, showing that a continuous monitoring of the collected data can anticipate and support some literature results, providing early indications for both GL developers and users.

The results shown in Figure 1, both for recommendation 5.15 and 10.17, are confirmed considering long-term outcome (Rankin scale at three-months follow-up). Among the 4 questions mentionned in the Introduction, the analyses just described are related to question #1.

Another type of analysis, still related to question #1, has been performed using every single recommendation, with the usual correction factors, as predictor of the health outcome. This analysis has been run through logistic regression, using age as a continuous variable. The rationale for this investigation is that some clinical trials enroll only a subset of the entire population (only males, only less than 80years, etc.) and the results are then extended to the entire population. Otherwise, a trial may involve unselected population, but lack of the so-called "subgroup analysis" may hide important distinctions about the treatment effect in different patients subsets. Therefore, we investigated whether some recommendations do not hold for the whole sample of our patients.

An interesting result has been obtained running logistic regression with recommendation 12.6a (hypertension treatment, see text in Table 2) as explanatory variable. In particular, the presence of a non-compliance to this recommendation resulted to have a negative correlation with the outcome (i.e. patients with non-compliance had better outcome). In order to gain a deeper insight into this result and since also the age variable turned out to be significantly correlated with the outcome in the logistic regression, we tried to stratify the patients sample on the base of their age. The main goal of this step was to see whether there exists a group of patients where this behavior is stronger. We created two age groups relying on the median of the age distribution (75 years) and we obtained a significant negative correlation between non-compliance and outcome with an odds ratio of 0.25 for the population of older patients with mild/severe impairment. Results on the younger patients group were instead not statistically significant.

After discussing this result with medical partners, they realised that it could be sensible, because the antihypertension treatment may induce a too high reduction of blood pressure, thus compromising the cerebral autoregulation mechanisms and causing secondary damage from cerebral hypoperfusion. This can be even more possible for elderly people living alone. For these people it is in fact difficult to monitor drug assumption and provide for prompt dosage correction if needed. The bad effect of lack of blood pressure response (and thus hypoperfu-

sion) in stroke was already described in [6], but the study was limited to the acute phase. After finding the result described above, a literature search was performed and our finding has been strengthened [7,8].

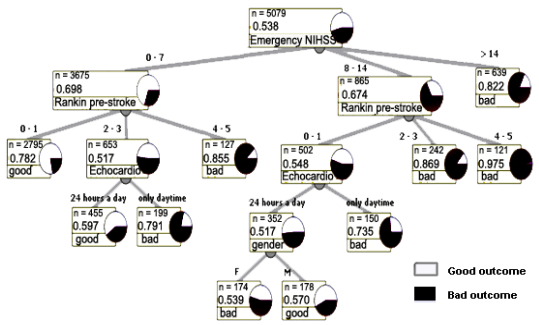

Figure 2 – The classification tree for the identification of the organizational variables that are most related to the health outcome.

Organizational setting vs outcome

To answer question #2 of the Introduction, an analysis has been performed using organisational variables, again besides considering severity, age and gender. Among the resources that characterize the medical units in terms of diagnostic facilities, only the possibility of performing echocardiography over the 24 hours was found to be related to the health outcome, as shown in Figure 2. Note that the result holds only for a subset of patients with moderate impairment.

Conclusion

Our study demonstrates that data mining techniques are a useful tool for (a) continuous monitoring of GL recommendations when implemented in the real-world clinical routine, (b) promoting discussion among GL developers and users and (c) suggesting priorities for equipping stroke units with diagnostic and treatment facilities. In particular, the results obtained in this work stimulated useful discussion among clinical experts, rising doubts on the general applicability of GLs and providing a feedback to the SPREAD GL developers themselves. Interestingly, the debate fostered a deeper literature search, that eventually strengthened our findings. From another point of view, when data-mining techniques show unexpected results, these can suggest further clinical research. It must be stressed, in fact, that data mining cannot replace clinical trials, but only give suggestions for their planning.

About the support to organisational issues, we observed that transcranial doppler examination leads to a better outcome, both at short and long-term. This suggests this equipment, still rare, should be highly recommended: its initial cost will be very likely justified by long-term cost-saving. Similarly, enough personnel to ensure 24h echocardiography should be provided in every hospital that treats stroke patients.

In a near future further analyses will be performed in order to answer also questions #3 and #4 enumerated in the Introduction. In particular, individuating predictors of non-compliance and organisational pitfalls could allow to enact the opportune correction actions to modify the incorrect behaviours and to enhance clinical settings.

Acknowledgments

We are grateful to all the participants of the SUN project for providing data in the stroke register.

Automatically Detecting Medications and the Reason for their Prescription in Clinical Narrative Text Documents

Stéphane M. Meystre, Julien Thibault, Shuying Shen, John F. Hurdle, Brett R. South

Department of Biomedical Informatics, University of Utah, Salt Lake City, Utah, USA

Abstract

An important proportion of the information about the medications a patient is taking is mentioned only in narrative text in the electronic health record. Automated information extraction can make this information accessible for decision-support, research, or any other automated processing. In the context of the "i2b2 medication extraction challenge," we have developed a new NLP application called Textractor to automatically extract medications and details about them (e.g., dosage, frequency, reason for their prescription). This application and its evaluation with part of the reference standard for this "challenge" are presented here, along with an analysis of the development of this reference standard. During this evaluation, Textractor reached a system-level overall F_1-measure, the reference metric for this challenge, of about 77% for exact matches. The best performance was measured with medication routes (F_1-measure 86.4%), and the worst with prescription reasons (F_1-measure 29%). These results are consistent with the agreement observed between human annotators when developing the reference standard, and with other published research.

Keywords:

Pharmaceutical preparations, Drug prescriptions, Natural language processing, Program evaluation, Knowledge bases.

Introduction

Computerized physician order-entry (CPOE) and E-Prescribing systems are becoming widely available in the healthcare system [1], and provide detailed information about the medications prescribed and managed with these systems, but a substantial proportion of the medications actually taken by the patient are still only mentioned in narrative clinical text documents in the patient electronic health record. These medications were prescribed in another institution or private practice, were bought over-the-counter, or were prescribed before the introduction of CPOE. Their mention in narrative text format makes them inaccessible for decision-support, research, or any other automated processing. These functionalities require coded data, and as a possible answer to this issue, Natural Language Processing (NLP) can convert narrative text into coded data. Techniques for automatically encoding textual documents from the electronic health record have been evaluated by several groups, as described in Meystre et al. [2]. Examples are the Linguistic String Project [3] and MedLEE (Medical Language Extraction and Encoding system) [4]. Other systems automatically mapping clinical text concepts to standardized vocabularies have been reported, such as MetaMap [5]. MetaMap and its Java™ version called MMTx (MetaMap Transfer) were developed by the U.S. National Library of Medicine. MetaMap has been shown to identify most concepts present in MEDLINE titles [6] and has been used for Information Retrieval [7] and Information Extraction [8].

When extracting information from narrative clinical text documents, the context of the extracted concepts plays a critical role. Important contextual information includes negation (e.g., "denies any chest pain"), temporality (e.g., "...fracture of the tibia 2 years ago..."), and the event subject identification (e.g., "his mother has diabetes"). NLP systems such as the LSP [3] or MedLEE [4] include negation analysis in their processing, but research focused explicitly on negation detection started only a few years ago with algorithms like NegEx [9].

The automated extraction of information from clinical text documents has been the focus of several competitions — called "challenges" — these last few years. Prominent ones were organized by the i2b2 (Informatics for Integrating Biology and the Bedside) National Center for Biomedical Computing. These "challenges" took the recent application of NLP to clinical research a step further by providing a de-identified corpus of clinical narrative text documents and by stimulating new developments in this domain. The i2b2 "challenges" started in 2006, with an automated de-identification challenge [10], and a smoking status detection challenge [11]. The obesity challenge was organized in 2008 [12]. The latest "i2b2 challenge" was organized in 2009 and focused on the extraction of medications, details about these medications, and reasons for their prescription. A corpus of 1249 clinical text documents (discharge summaries from Partners Healthcare in Boston, MA) has been semi-automatically de-identified and re-identified with realistic surrogates, and then split into a training corpus of 696 documents, and a test corpus of 553 documents. Only 17 documents in the training corpus were annotated by the organizing team for medications and prescription details; all other documents in the training corpus were not annotated.

For this challenge, we built a new NLP application based on the UIMA (Unstructured Information Management Architecture) framework [13]. This new application, called Textractor, and its evaluation using the first part of the reference standard are presented here.

Materials and Methods

Architecture and development process

Text analysis functionalities developed for Textractor are implemented as modules organized in a pipeline, as depicted in Fig. 1. The whole analysis pipeline is implemented in the UIMA framework. UIMA provides a development model that enforces the use of XML description files for maintainability and interoperability, as well as tools to test and visualize the text annotations realized by the system.

The pre-processing phase starts with the analysis of the document structure. Each document is broken into sections using regular expressions to match section titles or subtitles. Some sections that typically contain mentions of medications that should not be extracted by our system are filtered out (e.g., "Family history" sections mention drugs taken by family members, "Allergies" sections mention drug allergies that should not be extracted for this i2b2 challenge). For each section of interest, the text is split in sentences using an OpenNLP [14] module based on the maximum entropy principle. The whole text is then tokenized, and a part-of-speech (POS) tagger is applied to the set of tokens. The POS tagger is also based on an OpenNLP module, with a supplementary logic to treat sections where the end of the sentence cannot be inferred without knowledge of the section content structure.

During the second phase, medications and details about them (dosage, duration, frequency, route, reason for prescription) are extracted. We use MMTx to extract medications and possible reasons for their prescription. MMTx was developed to extract data from MEDLINE abstracts, and acronyms are less common in paper abstracts than in clinical documents, and are the principal source of ambiguity for our system. Examples of acronyms ambiguous to MMTx are "Dr." (detected as diabetic retinopathy), "Mr." (mitral regurgitation), "M.D." (mental depression), etc. For disambiguation, we expand abbreviations and acronyms before feeding MMTx with each sentence of the document to parse. A list of abbreviations and acronyms and corresponding full terms from the APL system [15] was expanded for this purpose. MMTx (version 2.4.C) is used to extract UMLS Metathesaurus [16] concepts related to drugs and health conditions. More specifically, the system implements the MMTxAPILite class and uses the default dataset (complete 2006 UMLS Metathesaurus) and settings. The following semantic types were used to extract medications: Amino Acid, Peptide, or Protein (aapp), Antibiotic (antb), Biologically Active Substance (bacs), Carbohydrate (carb), Hormone (horm), Organic Chemical (orch), Pharmacologic Substance (phsu), Steroid (strd), Vitamin (vita), and the following semantic types for possible prescription reasons: Disease or Syndrome (dsyn), Congenital Abnormality (cgab), Finding (fndg), Pathologic Function (patf), Sign or Symptom (sosy), Therapeutic or Preventive Procedure (topp). Since MMTx lacks context analysis (e.g., Insulin will be extracted in "…glucose management didn't require insulin …"), a context analysis step is also required after the extraction. Context analysis is based on an improved version of NegEx. This algorithm uses regular expressions and lists of terms to analyze negation (a concept can be affirmed, negated, or possible). Our implementation uses a variable window to analyze the context of each concept (instead of the 5 tokens fixed window originally used in NegEx) and infers the context from a larger set of base phrases. Finally, medication attributes (dose, frequency, duration, and route) are extracted with a set of regular expressions.

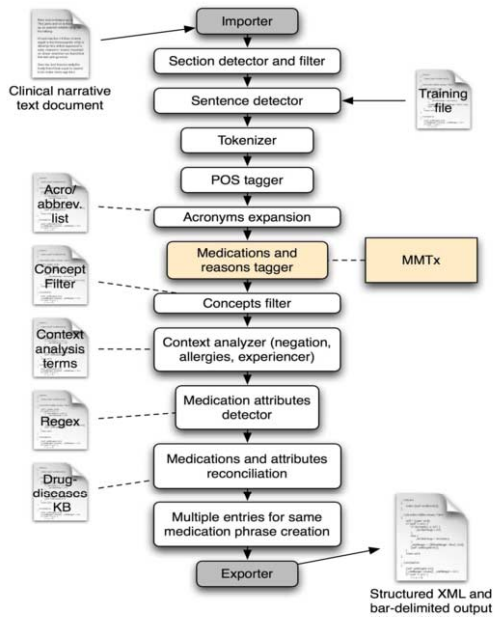

Figure 1- Components of Textractor for medications extraction

During the last phase, extracted medications are combined with medication attributes to build the prescription annotations. Each medication is combined with attributes that follow (or sometimes precede) it according to a set of rules. For example, in "Rheumatology suggested starting colchicine 0.6 mg b.i.d. for two days"…, the medication *colchicine* is followed by a *0.6 mg* dose, a *b.i.d.* frequency, and a *for two days* duration that are combined with the medication. Reason for prescription annotations are more complicated. As mentioned earlier, possible reasons are extracted with MMTx. They are then linked with the corresponding medication using a few rules and regular expressions that recognize possible reasons preceded by expressions like "because of …", "due to …", "… was treated with", etc. For the prescription annotations that do not have any reason attribute after applying this logic, we complement the search with the use of a drug-disease knowledge base. This knowledge base was built from existing databases that include the Pharmacogenomics Knowledge Base

(PharmGKB; available at www.pharmgkb.org), the Comparative Toxicogenomics Database (CTD; available at ctd.mdibl.org), and the UMLS Metathesaurus. The final knowledge base contains about 750 paired relationships of medication and disease, with their CUIs, and their relationship type. If a possible reason is found in a window of ± 2 lines of a medication (as defined for the i2b2 challenge) and is related to this medication according to the knowledge base, then it is added as the reason attribute for this prescription.

Finally, multiple prescription annotations are created for a single medication if the associated attributes describe multiple values or reasons (e.g., "Tylenol 650 mg p.r.n. pain or headache" becomes two *Tylenol – 650 mg – p.r.n.* annotations, one with the reason *pain*, and the other with the reason *headache*).

Reference standard creation

As mentioned previously, part of the reference standard (251 documents) was built by all teams participating in the challenge. Each document was annotated by one member of two different teams participating in the challenge with a member of a third team adjudicating disagreements in a second step. This process produced a final reference standard created by the challenge teams that could be used for evaluation purposes. Assigning annotation tasks to challenge participants is one of the novel approaches for this i2b2 challenge.

For our own annotations, we created an annotation schema using an open source annotation tool called Knowtator [17] and based on the annotation guideline provided by the i2b2 challenge team. Knowtator is a Protégé [18] plugin tool that uses the unique knowledge representation capabilities of Protégé to develop complex annotation schemas. Our annotation schema treats medication as the parent class and all other related information as child subclasses. Each medication class has an associated slot attribute describing whether the annotated mention was found in a list or in narrative text, and a complex slot attribute used to link annotated subclass information with the parent medication class. Using the Knowtator tool and this annotation schema, the span of medication mentions can easily be annotated and linked with associated spanned mentions of dose, route, frequency, duration, and reason.

Our team was assigned 40 reference standard documents for annotation. From these documents, each member of our team was assigned 10 documents to annotate using the guideline and the Knowtator annotation schema (10 documents were annotated by two of us, for subsequent agreement analysis, as described below). The logic for annotation tasks for each mention of medication in the clinical texts was as follows: a) identify the parent class medication; b) determine if the identified mention is in the context of a list or narrative test; c) identify associated subclass mentions of dose, route frequency, duration, and/or reason; d) link the subclass mentions with the parent class medication; e) identify the next medication mention (Figure 2).

Due to the complexity of this challenge, we felt it was necessary to evaluate the performance of human beings on annotation tasks related to this challenge. We evaluated reliability (task consistency) of the team annotation task using a subset of 10 documents from the assigned document set. Two team members annotated each of these documents. Logical pairings were created so that each annotator was evaluated against every other annotator on our team. Task consistency was evaluated using inter-annotator agreement, as published by Roberts [19], using the formula for the Inter Annotator Agreement (IAA): IAA = matches / (matches + non-matches).

We report IAA for class, subclass and slot attribute agreement for instances where class matched with an overlapping span, or where class and span matched exactly.

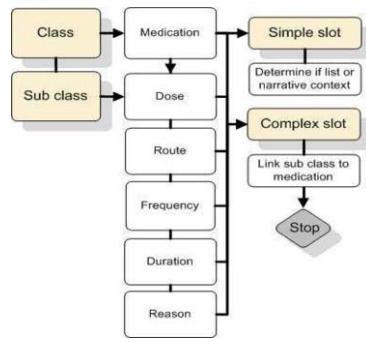

Figure 2- Annotation task logic process flow diagram

Medication extraction evaluation

Evaluation for this "i2b2 medication extraction challenge" is realized with exact matches (i.e. the extracted phrase corresponds exactly to the reference standard) and with inexact matches (i.e. the extracted phrase overlaps with the reference standard) separately.

Exact matches evaluation is done at the instance level, and metrics are recall (number of correct distinct instances extracted / all instances in the reference standard), precision (number of correct distinct instances extracted / all instances extracted), and the F1-measure (a harmonic mean of recall and precision, with a weight of 1 [20]). Instances that are not mentioned are ignored.

Inexact matches evaluation is realized at the token level (i.e. words or character groups separated by a white space). Metrics are also recall, precision, and F1-measure, but recall and precision are calculated differently (recall = number of correct tokens extracted / all tokens on the reference standard; precision = number of correct tokens extracted / all tokens extracted).

Exact and inexact matches evaluations are done separately for each class (e.g., all doses or all medications) and also for each full prescription annotation (i.e. medication, prescription details, and reason for the prescription if present), and then averaged at the document level or at the system level (i.e. over all medications extracted). For the example in Table 1, these metrics would be: exact recall = 3/5 (3 correct instances extracted and 5 instances in the reference standard); exact precision = 3/5 (3 correct instances extracted and 5 instances extracted); inexact recall = 5/8 (5 correct tokens extracted: toprol, 50, mg,

p.o., b.i.d.; 8 tokens in the reference standard); inexact precision = 5/6 (5 correct tokens extracted: toprol, 50, mg, p.o., b.i.d.; 6 tokens extracted).

Table 1- Medication extraction example

Medication instance extracted					
Medication	Dose	Route	Frequency	Duration	Reason
toprol	50 mg	p.o.	b.i.d.	Nm	Asthma
Reference standard					
Medication	Dose	Route	Frequency	Duration	Reason
toprol xl	50 mg	p.o.	b.i.d.	3 weeks	Nm

nm = not mentioned

Results

The testing corpus of 553 documents was made available for three days in August 2009, and each participating team could submit up to three runs. We analyzed this corpus with three slightly different configurations of Textractor: the first included the 15 UMLS semantic types cited above, the second had fewer prescription reason semantic types (aapp, antb, carb, horm, orch, phsu, strd, bacs, vita and dsyn, patf, sosy), and the third fewer medication and prescription reason types (antb, phsu, vita and dsyn, patf, sosy).

Local evaluation details and results

The results of our first configuration of Textractor, with the part of the reference standard annotated by the participating teams, are presented here in Tables 2 and 3. System-level results were averaged over all medications extracted by the system; patient-level results were averaged at the level of documents (since we had one document per patient).

Table 2-Results of the exact match evaluation

Information	**N**	**Syst R**	**Syst P**	**Syst F**	**Pat F**
Medication	8882	0.752	0.769	0.761	0.759
Dose	4432	0.758	0.910	0.827	0.811
Route	3417	0.813	0.921	0.864	0.842
Frequency	4074	0.781	0.890	0.832	0.824
Duration	545	0.329	0.395	0.359	0.347
Reason	1529	0.185	0.679	0.290	0.259
OVERALL	22879	0.720	0.830	0.771	0.760

Syst = system-level results; Pat = patient-level results;
R = recall; P = precision; F = F1-measure
N = number of instances of each class in the reference standard

Table 3- Results of the inexact match evaluation

Information	**N**	**Syst R**	**Syst P**	**Syst F**	**Pat F**
Medication	8882	0.766	0.782	0.774	0.784
Dose	4432	0.785	0.921	0.848	0.830
Route	3417	0.798	0.927	0.858	0.837
Frequency	4074	0.736	0.924	0.820	0.817
Duration	545	0.326	0.481	0.388	0.398
Reason	1529	0.145	0.697	0.240	0.244
OVERALL	22879	0.693	0.837	0.758	0.750

This corpus included 251 documents and took Textractor an average of about 24 seconds to analyze each document. Most of the time was spent extracting concepts with MMTx, and even when limiting the semantic types and skipping sections of the document for MMTx analysis, the concept extraction phase represented most of the execution time.

Annotation task reliability evaluation

For the 10 documents we used to evaluate task consistency, overall inter-annotator agreement for class and span exact matches (or with matching using overlapping span) was the highest for identification of mentions of medication 85.9% (92.4% partial match), and the lowest for identification of duration 16% (29.3%) (Table 4). Slot attribute agreement for overall exact match to determine if the medication was mentioned in a list or in narrative text was 62%, and 63% for linking subclass attributes with the parent medication class.

Table 4- Inter-annotator agreement (all values are percentages)

Annotation class/subclass	**N**	**Exact match IAA (class match, Span match)**	**Partial match IAA (class match, span overlap)**
Medication	303	85.9	92.4
Dosage	109	88.4	88.4
Route	119	76.5	81.0
Frequency	88	73.3	89.9
Duration	16	16.0	29.3
Reason	59	31.3	73.1
OVERALL	694	78.5	86.6

N = number of annotated instances of each class

Discussion

This evaluation showed that the NLP application we developed for this task – Textractor – performed satisfactorily. The reference metric for this challenge, the system-level overall F_1-measure, reached about 77% for exact matches. Performance was good for medication attributes like dose, route, and frequency, with recalls around 80% and precisions around 90%. Results were not as good for durations, with recall and precision between 30% and 40%, and for reasons, with a recall below 20%, and a precision below 70%. These two attributes are very difficult to define precisely and also resulted in low agreement when analyzing our own manual annotations. The exact match IAA is equivalent to the F_1-measure when scoring one annotator against the other (i.e., treating one annotation as reference and the other as test), and in our case, this agreement only reached 16% with durations and 31.3% with reasons for prescription, in similar ranges than the measured performance of Textractor.

Our results are also consistent with other published similar research, such as the MERKI system [21] with measured precisions of 83.7% for dose, 88% for route, and 83.2% for frequency. What distinguishes our work from MERKI is its foundation on an open-source pipeline, a more comprehensive test set, and broader multi-reviewer evaluation scheme.

The adoption of UIMA as a firm ground for our developments gave us several advantages: efficient development tools to test and visualize the results of the system, good integration with

Eclipse [22], use of standard XML description files for maintainability and interoperability, and easier integration of existing developments (e.g., OpenNLP tools). We also integrated MMTx in UIMA, and benefited from its good UMLS Metathesaurus concepts indexing. However, the significant pre- and post-processing required to use this application with clinical text, its relatively slow performance, the impossibility to adapt it for multi-processing, its planned phase-out by the NLM, and its lack of an API will lead us into the development of a new concept extraction tool integrated in UIMA.

For our annotations, considering the complexity of this annotation task, we were not surprised to see that exact span matching had much lower agreement compared with overlapping span matching for all classes of annotated information. Prevalence of annotated classes varied widely across the 10 documents used to assess annotator agreement at the class and subclass level. The high variability in the observed agreement could be partly explained by this small sample. A more formal evaluation of both reliability and validity of annotation tasks across the challenge in general would show interesting results and would help define how to deal with some of these issues.

The automated extraction of information from biomedical text is still a relatively new field of research, and the extraction of information from clinical text is even newer [2]. The potential uses of information extracted from clinical text are numerous and far-reaching. In the same way the Message Understanding Conferences have fostered the development of information extraction in the general domain, similar competitive challenges for information extraction from clinical text, such as the "i2b2 medications extraction challenge," will undoubtedly stimulate advances in the biomedical field.

Acknowledgments

We would like to thank the i2b2 challenge team for the development of the training and testing corpora and for the excellent organization of this challenge.

Extracting Medication Information from French Clinical Texts

Louise Deléger, Cyril Grouin, Pierre Zweigenbaum

LIMSI-CNRS, Orsay, France

Abstract

Much more Natural Language Processing (NLP) work has been performed on the English language than on any other. This general observation is also true of medical NLP, although clinical language processing needs are as strong in other languages as they are in English. In specific subdomains, such as drug prescription, the expression of information can be closely related across different languages, which should help transfer systems from English to other languages. We report here the implementation of a medication extraction system which extracts drugs and related information from French clinical texts, on the basis of an approach initially designed for English within the framework of the i2b2 2009 challenge. The system relies on specialized lexicons and a set of extraction rules. A first evaluation on 50 annotated texts obtains 86.7% F-measure, a level higher than the original English system and close to related work. This shows that the same rule-based approach can be applied to English and French languages, with a similar level of performance. We further discuss directions for improving both systems.

Introduction

The information contained in Electronic Health Records (EHRs) may take the form of coded data or may be written in free text. Free text is indeed the easiest and most natural way for physicians to convey information [1]. It cannot, however, be used as is by health information systems [1,2]. It is also time-consuming for clinicians to read narrative sections in order to find relevant information. Natural Language Processing (NLP) techniques — more specifically information extraction methods — have therefore been proposed to gain easier access to this information [3]. Among the useful types of information to extract from narrative reports is information related to treatment such as medications [4–9].

Within the framework of the i2b2 NLP2009 challenge[1], we developed a medication extraction system for English narrative patient records. This system extracts and links medications with related information such as dosage, mode of administration, frequency, duration and reason for treatment. According to Harris [10], "The structure of each science language is found to conform to the information in that science rather than to the grammar of the whole language". This was exemplified further by Borst *et al.* [11] when they designed a system for analyzing French discharge summaries starting from Sager's [12] original system designed for English. In contrast, Friedman *et al.* [13] highlight the differences found when developing systems for two distinct domains (clinical and biomolecular), although both in English. Closeness or distance of information structure is thus stronger than closeness or distance in languages. If the same principle applies to the language of medications, it should then be possible to transfer our initial English medication extraction system to one for French medications with limited modifications. In this paper, we test this hypothesis and report the implementation of a similar system to deal with medications in French medical records.

This work is part of the AKENATON project which addresses information extraction in the domain of telecardiology. In this context, extracting information from clinical texts would allow physicians to link more easily automatic alerts to patient data, including coded data obtained from electronic health records and that obtained from free text. Medications are one type of useful information to be extracted in this regard.

This paper is structured as follows. We begin by a review of existing work. We then describe our corpora of clinical texts and detail the implementation of our system. We finally present its evaluation and discuss the results.

Related work

A few approaches, all dedicated to English, have addressed medication extraction from free text.

Some approaches focus on extracting a specific type of medication information, such as drug names or dosage. Levin *et al.* [4] developed a system based on lexicons (drug names and medical abbreviations) and regular expressions to extract drug names (generic or trade names). In order to deal with misspelled drug names, the authors used a phonetically based matching module, thus allowing them to increase the extraction by 7%. Also centering on drug name recognition, Sirohi *et al.* [5] studied the importance of determining the best lexi-

[1]https://www.i2b2.org/NLP/Medication/

con list to use in order to improve the quality of drug name extraction. They used the commercial software FreePharma and experimented with filtering criteria to refine drug lexicons, more specifically to eliminate ambiguous entries or to take into account abbreviated forms. Shah and Martinez [6] focused on recognizing dosage from the free-text field of a database of patient records specifying dosage instructions. The extracted information is then classified according to an existing format, which includes daily dose, frequency, units, duration. This system does not detect drug names, as they are contained in a structured field of the database.

Other approaches aim at extracting a more complete set of information elements related to medications. The first system specifically designed to extract drug and dosage information was that of Evans *et al.* [7]. The authors defined a model of the drug-dosage information to be extracted that included drug name, dose level, route, frequency and necessity. They detected this information using a set of extraction rules relying on lexicons (both general and specialized) and NLP steps including stemming, part-of-speech tagging and semantic category assignment. In their system, a drug name was extracted only if associated with at least one related piece of information (*e.g.* dose, frequency, duration, etc). More recently, Gold *et al.* [8] built Merki, a parser for extracting a similar set of information. The process consists in identifying drug names using a lexicon as a first step, and in applying regular expressions to detect associated elements as a second step. Xu et al. [9] used a more detailed drug model and detected medication information performing semantic tagging and parsing.

Materials and Methods

Development and test corpora

The corpora used in this experiment consist of a total of 17,412 French EHRs from the cardiology unit of a French University Hospital, written between 2004 and 2006. They include discharge summaries, consultation reports and surgical reports. This set is divided into two corpora: a development corpus of 17,362 documents which we used to implement our system and a test corpus of 50 documents which we manually annotated to use as a gold standard. The test corpus contained 253 medications, plus the associated information elements.

A rule-based approach to medication extraction

Our approach to medication extraction is rule-based, as is often the case in information extraction. A set of lexicons define the relevant vocabulary, and a set of extraction rules encode the grammar of medication expressions.

Lexicons

Lexicons associate linguistic information to words. Here, each lexicon entry is associated to a semantic category which corresponds to one of the target information types: drug, dosage, mode of administration, frequency, duration, and sign or symptom which is the reason for prescription. We group these entries into three lexicons according to the sources of information used to compile them. The first two are acquired from external sources, while the third is mostly obtained from a development corpus: a *drug lexicon*, used to recognize drug names; a *list of signs and symptoms*, to detect reasons; a *list of abbreviations and expressions*, which is used by the extraction rules to identify information related to medications: dosage, mode of administration, frequency, and duration.

System outline

The system first segments the text into sentences based on typographical clues, *i.e.* certain types of punctuation (here we considered only full stops). We use these punctuations to determine sentence boundaries, while also taking care of exceptions, mainly periods which occur in abbreviations ("etc.") or within numbers ("1.5").

Then, the first stage of our extraction algorithm iterates over the sentences to recognize drug names. The process consists in a lexicon look-up. A drug is extracted when an exact match is found between the text and an entry of the drug lexicon. This stage terminates when the text has been completely scanned.

The second stage starts by dividing each sentence into subparts according to the detected drug names. That is, each resulting text span is composed of a medication name and the text which follows that name. We call this process drug span segmentation. The underlying assumption is that most information associated to a drug occurs in the text span which follows the drug name.

The second stage of the algorithm thus consists in looking for information related to medications within each of these text spans. If needed, we also extend the search to other parts of the sentence in which a drug name occurs, especially to the text closely preceding the drug name, in order to deal with cases where a piece of information does not follow a drug name. This second stage relies on lexicons and on a set of extraction rules implemented by regular expressions.

French implementation of the system

The system was originally designed for English in the context of the i2b2 challenge. The above-described principles and outline apply to both the English and French versions of the system. We do not detail the specificities of the English system any further and we focus on the French implementation from now on. This version was modified and extended to take into account the specificities of the language and the corpus.

Corpus study

A first study of the corpus highlighted structural similarity between French and English EHRs. At the document level, information is generally structured as follows: illness and social history, allergies, medications on admission, examinations, and discharge medications. At the local level, drug names are often followed by related information (dosage, frequency, mode of administration, etc.) in the same sentence. These shared patterns point to the same direction as previously observed by Harris [10] and Borst *et al.* [11]. They give positive signs that our hypothesis could be valid, and that it might thus be possible to obtain a localization from English to French with limited modifications.

Lexicons

Three French lexicons were constituted according to the three previously defined types. The *drug lexicon* was compiled from the Internet using drug lists provided by three different sources: Vidal[2], Eureka Santé[3] and Doctissimo[4]. We also completed these lists with drug names not found in these sources, namely drug name abbreviations ("*avk"* for "*anti-vitamine K"*, *i.e. oral anticoagulants* in English), common orthographic and grammatical variations of names ("*bétabloquant"*, "*bêtabloquants"*, *i.e. beta-blockers* in English), and drug names mentioned in the records but absent from the Internet sources since they are not used anymore nowadays. Finally, we added substance names from the Biam database[5]. The resulting lexicon is composed of 33,371 drug names.

The *list of signs and symptoms* was obtained by querying the UMLS (version 2008AA) for French terms with the *Sign or Symptom* semantic type. It contains 3,988 entries.

The *list of abbreviations and expressions* was adapted from the English list, by translating existing entries and adding new ones when necessary. This list includes 68 abbreviations and expressions for 4 types of elements: dosage, mode of administration, frequency, and duration (see Table 1).

Table 1 – Excerpt of the list of abbreviations and expressions

Entry	Attribute
mg	DOSE
iv	MODE
h	FREQUENCY
heure (*hour*)	FREQUENCY
semaine (*week*)	DURATION

Since we can easily access such kind of information for French, there was no problem in creating these lexicons. Nevertheless, a small amount of post-processing of the lists was performed to remove entries that were ambiguous (for instance, *eau* (*water)* was listed as a pharmacologic substance) or too general (e.g. *"mal": pain*, *illness, disease,* in the signs and symptoms list); this should allow us to reduce over-extraction and thus increase precision.

Extraction rules

The extraction rules were designed using both the initial English rules and examples from the development corpus. For each item to be extracted (*i.e.* dosage, mode, frequency, duration and reason), regular expressions are applied in combination with a lexicon look-up. The list of abbreviations and expressions is used to detect dosage, mode, frequency and duration, while the purpose of the lexicon of signs and symptoms is to identify reasons. Examples of extraction rules are given in Table 2, where uppercase words represent semantic categories as obtained through lexicon lookup.

Table 2 – Example extraction rules (FREQ = frequency)

Rule	Sample matched phrase
[0-9]+[.,0-9]* DOSE	2,5mg
[0-9]+ DOSE [0-9]/[0-9]	2 cp 1/2 (*2 tabs 1/2*)
[0-9]+ FREQ / FREQ	3 fois / j (*3 times a day*)
[0-9]+ FREQ / [0-9]+	5 jours / 7 (*5 days out of 7*)
Pendant [0-9]+ DURATION	pendant 3 semaines (*for 3 weeks*)

These rules were either adapted from the English ones or rewritten based on the corpus study. The adaptation of the rules was often almost direct. For instance, the first rule of table 2 corresponds to the English rule *[0-9]+[.0-9]* DOSE*. In this case, a comma has simply been inserted in the expression since figures such as 2.5 are usually written as 2,5 in French. The last rule of Table 2 also shows a basic modification of the initial English rule *for [0-9]+ DURATION*: here, the English word *for* has been translated by the French word *pendant.*

The implementation of this French system was performed in a relatively short period of time: about 10 hours, of which approximately 1/3 was devoted to lexicon compilation and 2/3 to the adaptation and development of rules. Preparing the gold standard was comparatively a more time-consuming task (approximately 10 hours to annotate the 50 documents).

Evaluation

We evaluated our system against the test corpus, in terms of recall (the ratio between the number of correct extractions and the number of expected extractions), precision (the ratio between the number of correct extractions and the total number of extractions), and F-measure (the weighted harmonic mean of recall and precision, with a weight set to 1 to give recall and precision the same importance) computed at different levels: an horizontal level which assesses all information as a whole (drug names and their associated information) and specific levels (referred to as the vertical level) which evaluate each item separately (medication, dosage, frequency, mode, duration, reason), as per the i2b2 medication extraction guidelines.

Results

Table 3 shows that the F-measure is high on the horizontal level, as well as on the levels of medication, dosage, frequency and duration, but rather low for mode and reason.

[4]http://www.doctissimo.fr/html/medicaments/articles/medicaments_loupe.htm
[5]http://www.biam2.org/ (last update: May 2001).

Table 3 – Evaluation of French medication extraction (n = number of instances to be extracted, R = recall, P = precision, F = F-measure)

	n	R	P	F
Horizontal	257	0.839	0.896	0.867
Medication	257	0.887	0.934	0.910
Dosage	110	0.891	0.907	0.899
Mode	6	0.500	0.750	0.600
Frequency	122	0.795	0.858	0.825
Duration	4	0.750	0.750	0.750
Reason	23	0.391	0.563	0.462

Table 4 – Example extracted medications (an "nm" label is used when the information item is not mentioned in the text)

Original text	Extracted medication
nous conseillons donc la mise en place d'un traitement par Durogésic et débutons ce jour les patch de 25 µg/72 h *we thus advise treatment with Durogesic and start today patches of 25 µg/72h*	medication="durogésic" dose="25 µg" mode="patch" frequency="/72 h" duration="nm" reason="nm"
Paracétamol 1 g = x 4/j si douleur *Paracetamol 1g = x 4 a day if pain*	medication="paracétamol" dose="1 g" mode="nm" frequency="x 4/j" duration="nm" reason="douleur"

The results obtained by our localized French medication information extraction system are higher than those of the original English system[6]: at the horizontal level, we obtained an F-measure of 0.867 in French and of 0.773 in English. At the vertical level, medication name extraction yielded the best results for French (0.910) while it was only average for English (0.798). Dosage extraction also yielded much better results in French: 0.899 against 0.804 in English. Frequency detection was equally good for both systems (0.825 and 0.827). Reason extraction produced the worst results also for both systems: 0.462 in French and 0.299 in English (this was a common feature to all systems participating to the i2b2 challenge as well). There is a high difference in favour of the English system, however, regarding the extraction of the mode of administration: while it is the best type of information we extracted in English (F-measure of 0.836), we obtained a low F-measure in French (0.600). This difference is essentially due to the fact that there are very few occurrences of modes in the French corpus (only 6 occurrences over a total of 257 medication sets of information to extract).

Table 4 gives examples of medication information extracted by our system.

Discussion

Our system achieved good results for French, even higher than those of our initial English version. It should be noted, however, that this cannot constitute a fully accurate comparison between the two systems, mainly because we evaluate the French system on a much smaller reference corpus (annotating records is indeed time-consuming) than that used in the i2b2 challenge. It gives a fair indication, though, as to the quality of the system. Results are also close to existing systems working on English. Gold *et al.* [8], for instance, obtained a precision of 94.1% and a recall of 82.5%, and Xu *et al.* [9] reported F-measures over 93% for drug names, strengths, routes and frequencies. Our system is most comparable to these two works because we identify similar types of information. They do not extract, however, reasons for administration.

There is room for improvement, especially for the extraction of reasons. We mainly relied on proximity to associate signs and symptoms to prescriptions. However, more sophisticated Natural Language Processing modules, such as a part-of-speech tagger or a syntactic parser, could also be applied to the texts. Syntactically parsing the text is an interesting direction to investigate, as it would allow us, for instance, to identify prepositional and noun phrases and grammatical relations, which would be useful to link reasons to prescriptions more accurately. Another way to improve reason identification would be to rely on a knowledge base associating drug names with the symptoms they treat (*e.g. simvastatine* and *Zocor* for *hypercholestérolémie*). Based on this known association, if the reason *hypercholestérolémie* (or other signs or symptoms related to this one) is found in the neighborhood of *Zocor* or *simvastatine*, we could give it a more important weight: this might help improve the precision of reason detection.

Originally, the program was designed within the framework of the 2009 i2b2 challenge. Therefore, the pieces of information to extract are those defined in the challenge. We transposed our program from English to French using the same definition of the items to be extracted, namely the following six types of information: drug name, dosage, mode, frequency, duration and reason. However, when processing the corpus, we were confronted with the ambiguity of some types of information. *Dosage* refers both to the drug dose the patient has to take ("Previscan **1 cp** par jour": *Previscan **1 tab** a day*) and to the drug concentration ("Plavix **75 mg**"). Sometimes dose and concentration are both mentioned (e.g. "Levothyrox **150 µg 1 cp**": *Levothyrox **150 µg 1 tab***), in which case both pieces of information were extracted as dosage. It might be interesting, however, to separate them. Another ambiguity due to the chosen representation of information concerned *Frequency*: it can refer to the frequency with which the patient has to take the medicine ("Coversyl 8 mg**/jour**": *Coversyl 8*

[6]The English system was evaluated against a set of 256 annotated records. Those are the official results of the i2b2 challenge.

*mg **a day***) as well as to the time of day when the drug should be taken ("Symbicort 1 bouffée **matin et soir**": *Symbicort 1 puff **in the morning and in the evening***). In this last example, we can deduce the frequency from the time (2 times a day), but we cannot deduce the time from the frequency. Grouping information into one type makes identification easier, but it would also make sense to represent each type of information separately.

It could also be interesting to extract additional information related to medications. Useful information would be, for instance, *temporal markers (i.e.* is the time of medication administration in the past, in the present, or in the future?*), events* (*i.e.* is the medication being started, stopped, or continued?), and *certainty (i.e.* is the medication suggested or compulsory?). These were considered by the i2b2 challenge at first, but later dropped to simplify the task. An interesting direction for future work would be to process such information.

Finally, the current output representation is the exact strings of words found in the input texts. Further work will address normalizing these strings into canonical forms: *e.g.* unique identifier for each drug, unique preferred form for *tab* and *tablet*, etc.; a task similar to that described in [14]. This will enable us to merge them with coded data obtained from EHRs.

Conclusion

In this paper, we presented our experiments to localize an existing medication information extraction system from English to the French language. This localization kept the same target information items and semantic categories. It was based upon the compilation of French lexicons and the adaptation to French of the regular expressions used to extract the different items. This last part represents most of the work, since it implies re-writing a certain number of rules. Nevertheless, the work done for English gave us pointers to the types of rules to define, so that we believe our approach saved time compared to creating a system from scratch. Also, the French medical texts exhibited some similarity to the English texts, which made the transposition of some of the rules almost direct.

An evaluation of this localization over a corpus of 50 French EHRs provided better results than those obtained by the English systems at the i2b2 challenge.

This work shows that in the case of a specific sublanguage, that of prescriptions, the same approach can be successfully applied to two different languages, English and French.

Acknowledgments

This work was partially funded by the Akenaton project under grant number ANR-07-TECSAN-001and by the Quæro project. English deidentified clinical records used first were provided by the i2b2 National Center for Biomedical Computing funded by U54LM008748 and were originally prepared for the Shared Tasks for Challenges in NLP for Clinical Data organized by Dr. Özlem Uzuner, i2b2 and Suny.

Abstract

Due to the overwhelming volume of published scientific papers, information tools for automated literature analysis are essential to support current biomedical research. We have developed a knowledge extraction tool to help researcher in discovering useful information which can support their reasoning process. The tool is composed of a search engine based on Text Mining and Natural Language Processing techniques, and an analysis module which process the search results in order to build annotation similarity networks. We tested our approach on the available knowledge about the genetic mechanism of cardiac diseases, where the target is to find both known and possible hypothetical relations between specific candidate genes and the trait of interest. We show that the system i) is able to effectively retrieve medical concepts and genes and ii) plays a relevant role assisting researchers in the formulation and evaluation of novel literature-based hypotheses.

Keywords:

Text Mining, Annotation networks, Gene ranking, Candidate gene study

Introduction

Current biomedical research is starting to increasingly rely on automated literature analysis. Text Mining (TM) and Natural Language Processing (NLP) provide algorithms and techniques for automated summarization and analysis of textual content, so that it is possible to extract and interpret the information contained in literature databases and repositories. This task is particularly important in the early stage of any study, when gathering the available knowledge about the problem of interest is crucial in formulation of initial hypotheses and planning of the next research tasks. Several TM systems exists which can help us expose relevant biomedical literature [1] in order to retrieve available knowledge which is relevant to user's interest, like finding all publications about a disease candidate gene. The challenge is to broaden and deepen this search to expose possible other useful information for proposal of novel hypotheses [1 - 3]. For instance, an added value could be the suggestion that the candidate gene is often related to another gene, which has not been previously considered.

We describe the tools that we are developing to provide such kind of support. In particular, we focused on genetic studies, in which a set of initial hypotheses of genes-disease association is made on some candidate genes, so that the first step is to explore the recent literature to confirm their possible role in the disease mechanism. We extracted the concepts of interest (genes and medical terms, like pathologies) using a structured knowledge base like Unified Medical Language System (UMLS), by which we derived genes/disease annotation. Then we implemented a similarity metric that is based on a relevance measure of the terms for each gene. In this way the approach identifies which terms are shared between genes. The results of such analysis can be summarized as a graph in which the proximity of the nodes reflect how tightly related are these terms according to the available literature.

We tested our tools for the INHERITANCE research project, which aims to translate basic knowledge of the aetiology and pathophysiology of genetic dilated cardiomyopathies (DCM) into routine clinical practice and to identify novel therapeutic strategies. We show how our automated literature analysis strategy was able to both correctly reconstruct the available knowledge and support researcher's new hypotheses formulation and evaluation.

Materials and Methods

The analysis method we propose aims at derive a literature-based gene annotation by extracting UMLS terms related to diseases from the abstracts of the publications referencing each gene. The overall analysis consists of 3 main steps:

- querying PubMed via Web Services to retrieve the most recent literature about specific genes/diseases
- automated extraction of concepts (genes/disease) from PubMed abstracts based on NLP techniques
- construction of annotation/co-citation networks to interpret available knowledge and suggest new hypotheses that can be tested.

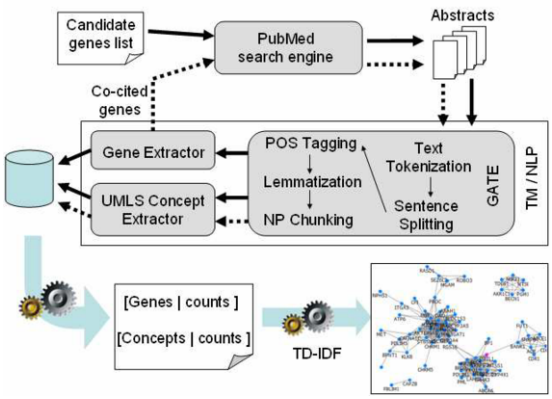

Figure 1 – Schematic representation of the analysis pipeline

The literature searching engine

The first module we developed is a searching engine which exploits the NCBI Web Service implementation of the Entrez Programming Utilities (EUtils) [4]. EUtils are software tools that provide access to Entrez data outside of the regular web query interface, in order to retrieve search results in another environments. In particular, the Web Service implementation, which enables developers to access Entrez Utilities via the Simple Object Access Protocol (SOAP). The modules query PubMed to retrieve scientific papers dealing with the genes of interest in XML format, so that their title and abstracts can be automatically processed and analyzed .

Abstracts text mining

The system is aimed at extracting both medical concepts (diseases, in particular) and genes, from titles and abstracts of articles obtained from PubMed databases. To work out this task, we have implemented a text extraction system that relies on a language processing environment called GATE [5]. The text analysis is handled through seven different steps, scheduled in a pipeline-like architecture. The first five steps are typical of many text mining systems and are in order: Text Tokenization, Sentence Splitting, Part Of Speech (POS) Tagging, Lemmatization and Noun-Phrase (NP) Chunking. The last two modules of the pipeline, i.e. the UMLS Concept Extractor and the Gene Extractor, have been designed specifically for our purposes.

The *Text Tokenizer* operates in two stages: the simple identification of parts of text separated by blank spaces and the management of the language-dependent exception to the basic rule.

The *Sentence Splitter* separates the sentences within the text. The so-called "ANNIE POS *Tagger*" module assigns each previously identified token to the grammatical class (POS) that it belongs to. The *Lemmatizer* derives the lemma belonging to every token. The *Noun-Phrase-Chunker* is aimed at identifying noun phrases (NP) within the text. The NP identification has proven its usefulness in many text mining tasks, because most searched concepts are contained in NPs [6].

The *UMLS Concept Extractor* module accomplishes the task of extracting medical concepts from the text. It relies on the resources available within the Unified Medical Language System (UMLS) [8], one of the National Library of Medicine (NLM) projects. In particular we exploited the UMLS Metathesaurus, a large database containing health-related concepts coming from many different source vocabularies. Among the different sources, our systems relies on the main ones: MTH (the official vocabulary of the Metathesaurus) and MSH (Medical Subject Headings), both provided by the NLM [9]. The module starts its analysis generating a set with all the possible substrings of each noun phrase in the document. For each token contained in the noun phrase those substrings are generated considering the token itself and its lemma. At this point the module sends a query to the database storing the concepts for each string. When a positive matching arises, the system makes another query aimed at identifying the official name of the found concept and creates a new annotation on the document.

Finally, the *Gene Extractor* finds the genes names present in the analyzed text. The identification is related to the whole abstract document, as the exact position of the name in the phrase is not what we are seeking. As well as the UMLS Concept Extractor, also the Gene Extractor relies on a database, which is directly derived from the Entrez Gene NCBI's database [10] (we consider human genes only). The module starts evaluating each token found by the Text Tokenizer in order to discard strings which do not fit with a standard gene representation (for example a string candidate to represent a gene must have almost one capitalized letter and can't be composed only by digits). Once the set of candidate strings is defined the Gene Extractor sends a first query to the database for each string, trying to find the string between all official genes names and their synonyms. When a match with an entry is found, a second query is sent in order to find out the official name of the gene previously identified.

Once that articles titles and abstracts have been retrieved for each candidate gene contained in the initial set (11 and 18 genes for Hypertrophic Cardiomyopathy and Dilated Cardiomyopathy respectively, see Results section for more details), these textual resources pass through the text mining pipeline just described. The analysis is therefore the same for titles and abstracts, but the results are kept separate in order to preserve the possibility of a further separate management of the results. From the first set of abstracts analysis, the system exploits the output of the Gene Extractor in order to build a new, larger, set of co-cited genes which are cited together with the first candidate ones. Then, for each gene of this augmented set, we retrieve articles titles and abstract from PubMed; all of these textual resources pass again through the analysis pipeline, now

ending with the UMLS Concept Extractor. By now the system is able to associate an array to each gene belonging to the larger set. The array contains the name of the diseases cited in the articles titles and abstract relative to the gene and, for every disease, the number of citation occurrences. At this point all the arrays are passed to the annotation measure and analysis module described in the next section.

Annotation networks

Our final aim is to derive a literature-based gene annotation by extracting UMLS terms related to diseases from the abstracts and the titles of the publications referencing each gene. Information about each gene in our study can be therefore represented by a gene annotation profile *A*, composed by a set of UMLS terms indicating diseases or symptoms and the counts of their occurrences in PubMed entries.

Formally, for the g^{th} gene, A_g is a feature vector which contains a set of tuples $a_{gj} = \{t_{gj}, f_{gj}\}$, with t_{gj} being the annotation term (i.e., a UMLS term) and f_{gj} the frequency the term appears in the annotation (i.e., the total number of times that the UMLS term t_{gj} is included in the papers citing gene *g*, with *j* ranging from 1 to the number of annotation terms found to be relevant for gene *g*). To expose the important terms for each gene, we applied a TF-IDF (Term-Frequency Inverse Document Frequency) transformation. TF-IDF is a popular technique used in Vector Space Model approaches [11] for the preprocessing of textual documents. Within this model, documents are represented by vector of features where each term is weighted according to its importance in the document. For a term *t* found in a document *d* of a document corpus *D*, the TF-IDF weight is computed as:

$$TF - IDF(t,d) = TF(t,d) * IDF(t) \tag{1}$$

where TF(*t*,*d*) is the term frequency in the document *d*, and IDF(*t*) is defined as:

$$IDF(t) = \log\left(\frac{|D|}{DF(t)}\right) \tag{2}$$

where |*D*| is the number of documents in the document corpus and DF(*t*) the number of times a term *t* appears in all documents.

Since we represent a gene by a vector of UMLS terms, the documents correspond in our case to genes and |*D*| is the total number of genes. As a result of this weighting scheme, a term indicating a disease is considered as an important annotation for a gene if it occurs frequently in the publications related to that gene. On the other hand, terms about diseases or symptoms that are not specific for a gene are rated as less important due to their low IDF. The weighted annotation profiles were then normalized.

One of our purposes was to test if the proposed gene annotation method is able to find groups of similarly annotated genes that are in fact known to be similar as they play an important role in the same disease. In addition, we aimed to find other genes related to cardiomyopathies. For these reasons, we needed a similarity measure that reflected the degree of gene similarity in terms of their feature terms and weights. To compute the similarity between the annotation profiles of two genes *g1* and *g2*, we resorted to the cosine similarity between the TF-IDF vectors W_g as follows:

$$sim(g_1, g_2) = \frac{W_{g1} \cdot W_{g2}}{\|W_{g1}\| * \|W_{g2}\|} \tag{3}$$

A similarity of 1 means that g1 and g2 have exactly the same terms and weights, while a cosine value of zero means that the two annotation vectors are orthogonal and had no match. To have a graphical visualization of the groups of similarly annotated genes we created gene association networks, where the genes are the nodes of a network and they are linked if their similarity is greater then a threshold (in our case set to 0.7).

The information coming from our literature-based annotation was used to build three types of gene annotation profiles: i) *Titles*, including for each gene only the terms extracted from the titles of the gene-related PubMed entries; ii) *Abstracts*, including only the terms extracted from the abstracts of the publications. iii) *Titles+Abstracts*, obtained by including all the terms from Titles and Abstracts and for each of them adding the corresponding weights resulting from TF-IDF.

Finally, we developed a Python procedure to process the gene annotation profiles, to evaluate the pair wise similarities and to create network files in a standard format. A network has been created for each of the annotations (Titles, Abstracts, Titles+Abstracts). The networks were visualized using an interactive network exploration module provided by the software Orange [12]. Giving information about gene names and attributes to this software, it is possible to show gene symbols next to each node, underline the genes of interest and make a zoom on a specific region. The software allows the selection of some nodes of interest (in our case the genes related to cardiomyopathies and their annotation-similar genes) in order to visualize their attributes. Giving as input data the weighted annotation vectors to Orange, we were also able to visualize in a table (see Figure 2 in Results section) the terms rated by TF-IDF scheme as the most important terms for our genes of interest and for their annotation-neighbors.

Results

We tested the strategy and tools described above to analyze data concerning Hypertrophic Cardiomiopathy (HCM) and Dilated Cardiomiopathy (DCM), which are the pathologies being studied in the Inheritance Project. HCM and inherited DCM are most commonly transmitted as an autosomal dominant traits is and they have been associated to mutations in a number of genes that encode for one of the sarcomere proteins. 11 loci (relative to genes *TNNT2*, *TTN*, *MYBPC3*, *ACTC*, *TPM1*, *MYH7*, *MYH6*, *MYL2*, *MYL3*, *TNNC1*, *TNNI3*) are known to be associated to HCM and 18 associated to DCM (*TNNT2*, *TTN*, *MYBPC3*, *ACTC*, *TPM1*, *MYH7*, which are the same as for HCM, together with *ABCC9*, *CLP*, *CTF1*, *DES*, *DMD*, *DSP*, *LDB3*, *LMNA*, *MVCL*, *PLN*, *SGCD*, *TAZ*) [13]. We used the two lists as starting set of candidate genes that we

want to investigate[1]. Through the search engine and the extractors modules we retrieved 1409 concepts and 866 other genes that are co-cited in the 30 most recent abstracts dealing with each of those initial genes and the 15 most recent abstracts for each of the other genes. For brevity, here we present and discuss the results of the Titles+Abstracts analysis, as it is the more informative combination we obtained[2]. The computed networks involve a great number of genes and other medical terms which are cited together with the initial ones, as well as all genes/medical terms related to the derived genes. Thus, we identified the spatial distribution of the initial sets, which have been highlighted in different colors: blue nodes are the six common associated genes, the orange ones are HMC related genes, the pink ones are the DCM related genes and the green filled ones are genes not mentioned in the known list but with an high co-citation index with the term "cardiomyopathy" (Figure 2).

TNNT2	**Hypertrophic Cardiomyopathy** - Hyperostosis, Diffuse Idiopathic Skeletal - **Cardiomyopathy, Dilated**
TTN	Respiratory Distress Syndrome - **Hypertrophic Cardiomyopathy** - **Cardiomyopathy, Dilated**
MYBPC3	**Hypertrophic Cardiomyopathy** - **Cardiomyopathies** - Heart failure
ACTC	**Hypertrophic Cardiomyopathy** - **Cardiomyopathies** - **Cardiomyopathy, Dilated**
TPM1	**Hypertrophic Cardiomyopathy** - **Cardiomyopathy, Dilated** - Exanthema
MYH7	**Hypertrophic Cardiomyopathy** - Myopathy – **Cardiomyopathy, Hypertrophic, Familial**
PRKAG2	**Cardiomyopathies** - Ischemia - **Hypertrophic Cardiomyopathy**
ANKRD1	Myopathy - Muscular Dystrophy - **Cardiomyopathy, Dilated**
TCAP	Muscular Dystrophy – Myocarditis - **Cardiomyopathy, Dilated**
PPIF	Muscular Dystrophy – Swelling - **Cardiomyopathy, Dilated**
...	...

Figure 2 – Most important terms for some of the genes of interest and for their annotation-neighbors

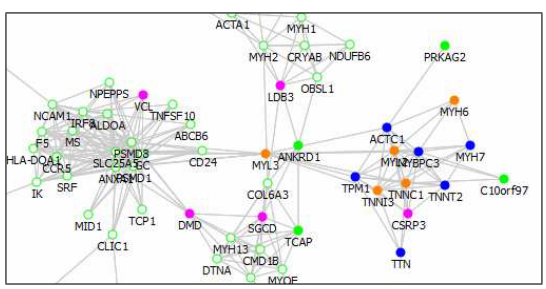

Figure 3 – Zoom on the HCM network . Blue nodes are the six common associated genes, orange nodes are HMC-related genes, pink-nodes are DCM related genes and the green-filled nodes are genes highly co-cited with the term cardiomyopathy

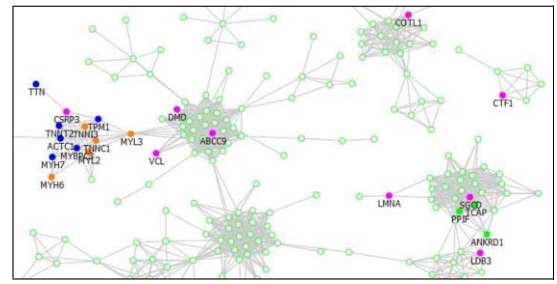

Figure 4 - Zoom on the DCM network

Figure 3 shows a snapshot of the region including the labeled genes for the network computed starting from the HCM related genes, while Figure 4 shows labeled genes for the network computed starting from the DCM related genes. Both of them are discussed in the next session.

Discussion

In this study we exploited the available knowledge about the genes which are known to be associated with the trait i) in order to perform an internal validation of the knowledge extraction capability of our tools, and ii) as a "background" to which new hypotheses of association can be compared.

In the first case, the results shown in the previous section confirm that the annotation networks built with our approach are able to reconstruct the existing knowledge, as the genes involved in cardiomyopathy are always clustered together. In particular, the six core genes (labeled with blue nodes in the figures) are always tightly connected, and the other genes related to HCM (highlighted in orange) always belong to the same clusters. This result gives a sufficient confidence that the algorithms have been properly set up to be able to extract evidence that we already know to be true. Similarly, networks show how the genes specifically related to DCM are on the contrary not so strictly linked to the HMC genes cluster, but they tend to be more scattered away from it. This also reflects the fact that current knowledge does not allow differentiating treatments on the basis of the different subtypes of DCM. Medical and interventional treatment strategies for DCM coincide with those optimised and indicated in the guidelines of scientific societies for HCM, congestive heart failure and atrial or ventricular arrhythmias or conduction disease. On the other end, the spatial distribution confirms the researcher hypotheses that DCM genetic mechanisms should be quite different from HCM ones.

Finally there are also some genes (green-labeled in figures) which are closely connected to the other known genes. Then, as the consideration made above gives us a good confidence

[1] Our elaboration took into account also synonyms of the gene names reported in [13]. In particular, our figures use ACTC1 for ACTC, COTL1 for CLP and VCL for MVCL.

[2] Titles are too shorts, and lead to very low connected network; however we kept the importance of the presence of a gene name or medical term in the title to strengthen Abstract-only results

that the literature analysis can properly extract knowledge, the new genes (green-filled nodes) related to the known ones may be interpreted as new candidate genes which could be further investigated.

Conclusion

In this paper we described a method for automated analysis of scientific literature. The tool is based on presentation of concepts in the association network, where concepts are related with respect to their similarity manuscript annotations in the most recent publications. We show how we can effectively retrieve medical concepts and a list of problem-related genes using this tool, which can play a substantial role in assisting researchers in the formulation and evaluation of literature-based novel hypotheses.

Our analysis investigates the data on the most recent published manuscripts, because the main interest is on the new findings, which have not yet been included in secondary databases that keep track of validated biological associations (e.g. OMIM, GAD, etc). The results depend on the abstracts content specificity. Our case study showed that the graphical representation can greatly facilitate results inspection, and the network tool is completely integrated with a data mining suite which provide a variety of other modules that can be used for further investigation of the subset of interesting genes.

The text mining process is comparable with the many already available tools, and a performance evaluation and comparison in term of precision and recall over a significant dataset is still ongoing. Nevertheless, our systems presents some peculiarities: i) the knowledge base on which the term recognition relies consists in whole terminological databases, while in general other systems use ad-hoc and manually cured collection of terms (moreover, this gives the system a greater modularity and scalability); ii) the similarity networks are based on a *weighted* measure of term's importance for a gene, and iii) the networks are able both to represent the current knowledge and to guide the hypothesis generation process.

The main assumption underlying the interpretation of the annotation similarity networks is that they associate concepts that are often referred to in the same manuscript and for this reason may have similar manuscript-based annotations. Notice that this does not (necessarily) correspond to a statistical or biological association between genes and diseases, but may nevertheless suggest a possible relation.

Abstract

Part of speech taggers need a considerable amount of data to train their models. Such data is not readily available for medical texts in Portuguese. We evaluated the accuracy of a morphological tagger against a gold standard when trained with corpora of different sizes and domains. Accuracy was the highest with a medical corpus during the complete training process, achieving 91.5%. Training on a newswire corpus achieved 75.3% only. Furthermore, an active learning technique has been adapted to the POS tagging task. The algorithm uses a POS tagger committee to isolate the sentences with the highest disagreement indexes for manual correction. However, the method was not able to reduce training and tagging times when compared to a random selection strategy. We encourage that future works employ some effort in order to annotate a small amount of random data in the domain of study, which should be enough for higher accuracy rates.

Medical records, Natural language processing, Part of speech tagging.

Introduction

Natural language processing (NLP) has been studied and applied on a broad range of domains and languages across the world. An important use case is the automatic mapping of narrative EHR content to biomedical terminologies such as SNOMED CT [1], which provides the basis of clinical decision support systems. NLP tools are used for sentence and token boundary detection, acronym recognition and expansion and syntactical analysis of sentences. POS tagging is essential in this process to identify each token part of speech class and to assign the corresponding tag (e.g., V for verb, ADJ for adjective, etc.) to the term. This task can easily be addressed by a set of language-independent tools publicly available via the internet. These tools need only to be trained on a previously tagged corpus in order to build a language-dependent model.

English medical corpora are widely available, but Portuguese corpora are less common. Although pilot projects (like the one conducted by the Interinstitutional Center for Research and Development in Computational Linguistics in São Paulo University [2]) built tagged newswire corpora, the usage viability of these models on different domain, e.g. medicine, is still under discussion.

Hahn and Wermter [3] assessed the performance of POS taggers trained on the NEGRA corpus of German newspaper texts when applied on a German database of medical documents called FRAMED. They concluded, "POS taggers cannot only be immediately reused for medical NLP, but they also — when trained on medical corpora — achieve a higher performance level than for the newspaper genre".

However, they also cite the work of Campbell and Johnson [4], which came to an opposite conclusion: POS taggers trained on newspaper data cannot be used on the medical domain without a new training process on a medical corpus.

In this paper, we want to give our own answer to this question, focusing on discharge summaries written in Portuguese, which is the focus of our main project. We also evaluated an active learning approach to accelerate the construction of a gold standard for the medical domain.

Materials and Methods

Newspaper and Medical Corpora

We used both a newspaper and a medical corpus in order to study this question. The newspaper corpus, named *MAC-Morpho*, is a compilation of 1,167,183 texts published in the *Folha de São Paulo* newspaper during the year of 1994. The corpus was compiled by the *Lácio-Web* [2] project from NILC-USP.

The medical corpus contains two collections of discharge summaries from the Clinical Hospital of Porto Alegre, Brazil. 2,453 discharge summaries cover the whole range of clinical specialties during one month (June 2007) and 5,617 discharge summaries were taken from the cardiologic department, covering a time span between June 2002 and May 2007. The corpus has been obtained from a partnership program between the Pontifical Catholic University of Paraná and the Federal University of Porto Alegre and has not been made publicly available due to privacy concerns.

In order to minimize efforts and keep compatibility between the corpora, we used only a fraction of the entire corpus. Lezius [5] argued that many German taggers were successfully

trained on corpora variable from 20,000 (more common) to 200,000 (rarer) tokens. Based on that, we used a fraction of randomly acquired 120,000 tokens from each corpus.

We then extracted one out of ten sentences available in the corpora to produce a gold standard for each domain. After that, we collected some statistics from the final corpora, which we show on Table 1.

Table 1 - Corpora sizes

Corpus	Corpus Fraction	Sentences	Tokens
Newspaper	Gold	495	13,810
	Training	4,533	123,019
Medical	Gold	595	12,451
	Training	5,964	123,018

In the next step, we evaluated the newspaper and medical models on the medical gold standard over a set of iterations where training corpus size was continually increased.

Active Learning Strategy

We further analyzed an active learning strategy proposed by [6] to build a tagged medical corpus in Portuguese. The active learning approach, commonly applied during the training process of syntactical classifiers, is used there as a method for corpus construction. In our work, we employed a *committee-based* approach, which uses a committee of POS taggers to select the sentences with the highest disagreement indexes and thus indicate priority in manual correction.

In order to accomplish that goal, we first calculated the *sentence disagreement index* $D_{sent}(s)$ for each sentence without manual correction on a given iteration. That index equals to the average of the *token disagreement indexes* $D_{tok}(t)$ seen on a sentence. Ranged 0 to 1, those indexes show how inconsistent are the results of a tagger committee on a token or on a sentence view. Equations 1 and 2 were proposed by [7] and show those relations mathematically using a measure called *vote entropy*. Here, $\frac{V(l_i,t)}{k}$ is the ratio of k taggers that gave the tag l_i to a token t and $|s|$ is the sentence size.

$$D_{tok}(t) := -\frac{1}{\log k}\sum_{l_i}\frac{V(l_i,k)}{k}\log\frac{V(l_i,k)}{k} \quad (1)$$

$$D_{sent}(s) := \sum_{j=1}^{|s|}\frac{D_{tok}(t_j)}{|s|} \quad (2)$$

We created an *OpenNLP* [8] model for each training iteration and evaluated it on a gold standard that has been previously tagged, revised by domain specialists and isolated from the training corpus. We stored the measured accuracy and an average of $D_{sent}(s)$ indexes observed on the non-revised sentences in a relational database. We also stored the number of tokens that had been manually corrected for graphical analysis.

We ran the entire procedure three times, one for each methodological direction: (a) heterogeneous tagger committee, (b) homogeneous committee, and (c) homogeneous committee with optimal initial set. The use of different approaches aims at reducing errors due to a set of distinct taggers (approach b) and a non-optimal initial set of sentences (approach c).

In the first approach (a), we used a heterogeneous committee that combines a rule-based tagger (*Brill Tagger*) with four statistical taggers (*OpenNLP*, *MXPOST*, *TreeTagger* and *QTag*). Performance has been evaluated based on the model created for *OpenNLP*, which is the tool used in our other projects. We chose the initial collection of sentences randomly.

In the second approach (b), we applied a homogeneous committee composed of *OpenNLP* tagger trained on five different subsets of data. Nevertheless, we measured accuracy based on a model trained on all data available per iteration. The initial set was randomly chosen as in the first approach.

Finally, in the third approach (c) we also employed selection by homogeneous committee, but with an optimal non-real initial set. We chose the best sentences for training based on a model trained on data available on the entire corpus. The aim of this approach is to test the hypothesis that the initial set of sentences influences all subsequent iterations.

Results

Newspaper and Medical Corpora

Figure 1 shows *OpenNLP* accuracy evaluated on the medical gold standard according to the number of tokens used in the training process. The red and the blue lines express the results for the medical and the newspaper corpus used for training, respectively.

Active Learning Strategy

Similarly, Figure 2 shows *OpenNLP* accuracy for different training set sizes. Now, however, we compare active learning strategy (red line) with a simple strategy, like random selection (blue line). In both cases, the gold standard and the training corpus belong to the medical corpora.

Figure 3 shows the $D_{sent}(s)$ average observed in the subset of non-trained sentences for the heterogeneous committee-based approach. As in Figure 2, blue and red lines express, respectively, the active learning and random selection strategies. Flattening seen on the line beginning convey the need of a minimal amount of data to correctly train the taggers. Additionally, the abrupt dip in the end indicates process conclusion, when there were no more sentences available for training.

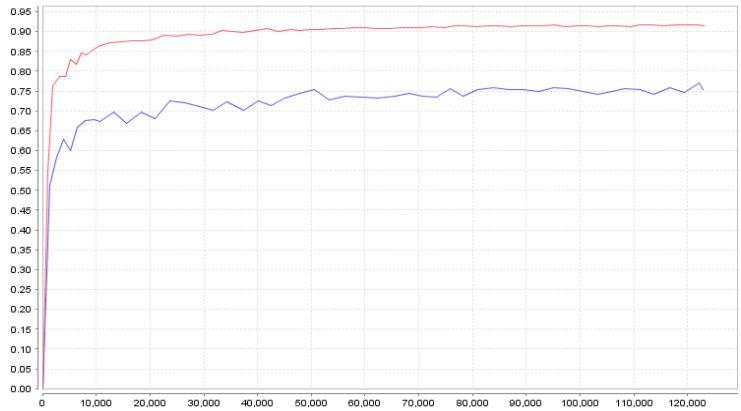

Figure 1 - Learning curves on the newspaper corpus (blue line) and on the medical corpus (red line), evaluated on medical data.

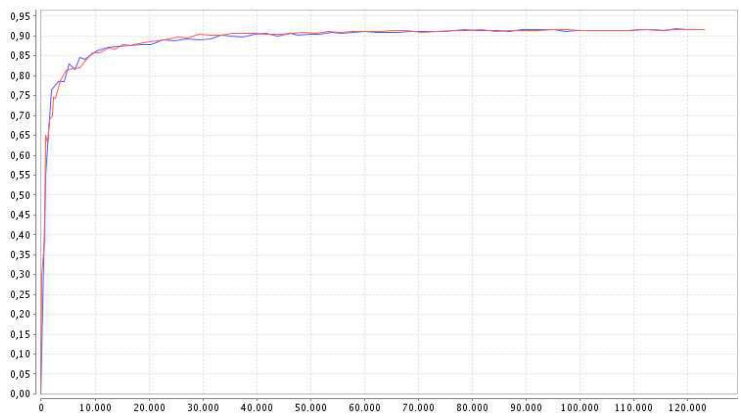

Figure 2 – Learning curves of active learning-based selection (red line) and random selection (blue line), trained and evaluated on medical data.

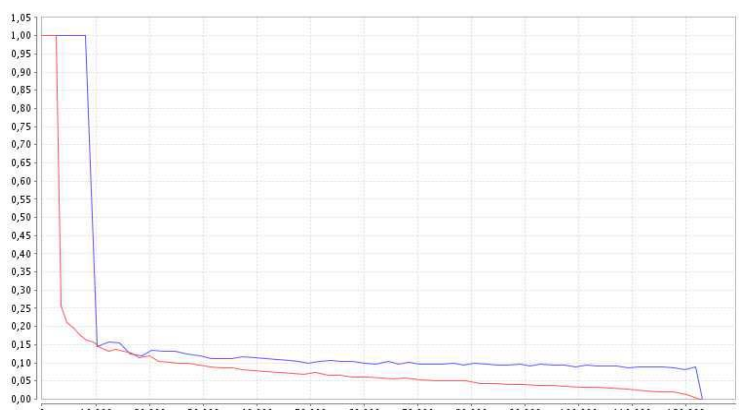

Figure 3 - Sentence disagreement index for active learning-based selection (red line) and random selection (blue line).

Discussion

When testing different approaches for active learning as proposed above (see "Materials and Methods"), we found similar results to those presented before. We then realized that active learning strategy should be adapted for POS tagging task in order to significantly reduce the manual tagging effort.

However, our results lack some statistical rigor. For example, a more precise result would have been found if we had run the random selection process at least three times. Nevertheless, our experience shows that data would have been similar and would not have affected conclusions presented here.

Despite that, a rigorous study would require the same initial set for random and active learning selections. The initial set influence was tested as described in the third approach presented above. We found that even an optimal initial set did not produce better active learning results.

Nonetheless, we could have tested other methodological approaches. The first one would be plotting learning curves as a function of number of sentences, not tokens. The second one would use 3/4 of the data available per iteration for the training process of each tagger, as proposed by [9]. Anyway, based on our experiments, we are certain that those variations would not considerably affect the conclusions of our work.

Conclusion

Our work confirm Campbell and Johnson [4] results: taggers trained on newspaper data cannot be readily used to tag medical data. At least in Portuguese, an *OpenNLP* model trained on a collection of 4,533 sentences (123,019 tokens), randomly chosen from the *MAC-Morpho* corpus of Brazilian newspaper, tags correctly only 75,3% of tokens from a collection of 595 sentences (12,451 tokens) arbitrarily chosen from a corpus of discharge summaries in Portuguese.

Comparing *OpenNLP* learning curves in the newspaper and in the medical corpus, we noted that newspaper data is more heterogeneous and more grammatically complex than medical data. Not only is the learning process in newspaper data slower and more sinuous than on medical data, but also the sentences are longer on that domain.

Considering that accuracy rates around 96.4% are expected [10], we encourage a domain-specific corpus to be build. However, our implementation of the active learning strategy for corpus construction [6] reached different results. We could not reduce manual correction effort by means of active learning when compared to a simple strategy like random selection.

Settles and Craven [11] reported similar results on a larger study with eight corpora from different domains. They realized that *vote entropy* is biased toward querying shorter sentences, which in our work showed as little or no value.

Our work showed additionally that manual tagging of around 30,000 tokens is enough to build a probabilistic POS tagger that accounts for an accuracy of 90% in the medical domain in Portuguese. Using a four times bigger sample, the tagger reached an accuracy index of 91.5%, which assures *OpenNLP*'s feasibility to annotate Brazilian hospital discharge summaries with POS tags.

Acknowledgments

We would like to thank Ana Carolina Peters, Claudia Seiko Yokoyama and Priscilla Koppe for their effort in corpus construction. We also thank Edson José Pacheco for his collaboration.

Our work is funded by the International Bureau of the German Ministry of Education and Research (BRA 07/022) and the Brazilian National Research Council (CNPq).

Abstract

Risk factors discovery and prevention is an active research field within the biomedical domain. Despite abundant existing information on risk factors, as found in bibliographical databases or on several websites, accessing this information may be difficult. Methods from Natural Language Processing and Information Extraction can be helpful to access it more easily. Specifically, we show a procedure for analyzing massive amounts of scientific literature and for detecting linguistically marked associations between pathologies and risk factors. This approach allowed us to extract over 22,000 risk factors and associated pathologies. The performed evaluations pointed out that (1) over 88% of risk factors for coronary heart disease are correct, (2) associated pathologies, when they could be compared to MeSH indexing, are correct in about 70%, and (3) in existing terminologies links between risk factors and their pathologies are seldom recorded.

Keywords:

Natural language processing, Semantics, Medical informatics, Risk factors, Public health informatics, Terminology.

Introduction

Risk factors jointly refer to behaviors, environmental conditions, diseases or genetic backgrounds – considered in an ample way – that actually increase people's chance of manifesting a given disease. Discovering risk factors to design prevention strategies is an important biomedical challenge. Indeed, it is an active research field, with major contributors coming from biology, epidemiology and public health programs. Within these programs, research proposes statistical studies of large populations in order to reveal risk factors for many health conditions and pathologies (*i.e.* cardiovascular diseases [1, 2], hypertension [3], atherosclerosis [4, 5], cancers [6, 7], mortality within older people population [8-10], to cite but a few). Despite this extensive activity, traditional risk factors for coronary heart disease for instance actually account for only 50% of the risk [11]. For biomedical professionals, this research assumes pushing back the frontiers of medicine and biology. Learning about risk factors not only benefits preventive healthcare; it may directly impact on patients. Indeed, accumulated and organized clinical knowledge may help counteracting disease progression, hence improving life quality in patients. The last few years have seen the proliferation of websites intended to centralize and organize widely scattered medical and healthcare information. A major concern of health information collected from the Internet, is the very quality of the data [12-14]. The Medline database [15] provides biomedical researchers/practitioners with instant access to extensive and high quality scientific literature. Yet, the huge amount of indexed peer-reviewed articles, currently over 18 million, hinders reliably sampling and selecting all relevant papers. Our central goal is to exploit the Medline repository and to extract risk factors and their associations to health conditions.

Background

Currently, genetic and medical information in bioscience papers is often exploited in a manual, expert fashion. Hence, increasing attention is being paid to the automation of natural language processing (NLP) and information extraction (IE) in biological and medical realms, as testified by the BioCreAtIvE[1] and TREC Genomics[2] challenges dedicated to extraction of gene and protein names, their interactions and functions from biomedical literature; or by I2B2 challenges[3] dedicated to extraction of various kinds of information (i.e., smoking status, signs and symptoms, medication) from clinical records. However, to our knowledge, little work has focused on risk factor extraction.

As a matter of fact, existing approaches for risk factors study are mainly issued from the data mining area. Thus, an important issue faced by these works is the large number of variables to be considered [10]: indeed, current state-of-the-art statistical algorithms are often unable to manage them. For example, data

[1] biocreative.sourceforge.net
[2] ir.ohsu.edu/genomics
[3] www.i2b2.org/NLP

mining methods have been applied to ICD-9 codes to predict groups of people with similar risk factors [16], or to data from insurance companies to get estimators of claim costs [17]. Let us mention also a KDD challenge[4] held in 2004 which addressed data mining in biomedicine, albeit confined to social subgroups of patients, the main goal being to identify atherosclerosis risk factors (and their combinations) and to monitor the evolution of these risk factors as well as their impacts [18].

A rare work related to the processing of narrative biomedical literature [19] combines manual and automatic meta-analysis-like methods for extracting facts on risk factors related to breast cancer. Findings are consistent with published studies: there is a positive association with alcohol consumption, but a negative association with former smoking.

In this paper, we attempt taking a further step from the above-mentioned approaches. Our objectives are massive extraction of risk factors from available literature and establishing their relation(s) to the corresponding pathologies. Also, this will allow providing comprehensive information on risk factors, which seems to be a missing resource currently.

Material and Methods

Material

Bibliographical database Medline

Our rough working material is Medline database, which currently hosts over 18 million citations - mainly from life sciences and biomedical research. We exploit the totality of these data, focusing on titles, abstracts and *MeSH* indexing within each citation.

Bibliographical database Medline

MeSH [20] thesaurus has been created for information storage and retrieval, and is currently used for indexing Medline database. Its descriptors are organized in a hierarchical structure, whose most general level are very broad headings such as A *Anatomy*, C *Diseases*, L *Information Science*, F *Psychiatry and Psychology*, etc., with 16 such headings in total. Within *MeSH*, we exploit headings and their notations, and thus can rely on their semantic types.

Snomed CT

Snomed CT [21] is another terminological resource of the biomedical area. The goal of the *Snomed CT* nomenclature is to provide a conceptual basis for organizing and, more particularly, for exchanging clinical data. This is a multiaxial terminology. Its terms are organized within 15 hierarchies, such as: *Clinical finding/disorder*, *Procedure/intervention*, *Environment or geographical location*, *Social context*, *Organism*, *Substance*, *Pharmaceutical/biologic product*, etc. *Snomed CT* terms are structured within a dense network of semantic relationships belonging to synonymy, hierarchy, or transversal relationchips. Among this last category, we distinguished three more precise relationships, which in our opinion may be linked with the risk factor notion: has causative agent, due to and associated with. Thus, associated with represents a clinically relevant association between concepts without either asserting or excluding a causal or sequential relationship between the two, while due to is used to relate a clinical finding directly to its cause. In this example from *Snomed CT*: *acute pancreatitis due to infection* is a *acute pancreatitis* due to *infectious disease*, infectious disease belongs to the causative agent axis and allows to identify a direct cause of a disease. Other *Snomed CT* examples state that: (1) *bacterial endocarditis* has causative agent *bacterium*; and that *fentanyl allergy* has causative agent *fentanyl*. Within *Snomed CT* we exploit these three relationships which, as far as we know, may correspond to the only resource providing an explicit and controlled information on risk factors and associated health conditions.

Methods

Bibliographical database Medline

The aim of the preprocessing step is to annotate Medline citations with linguistic information and to prepare the step of information extraction task (identification of risk factors, of pathologies and of relations between them). We use the Ogmios platform [22], suitable for the processing of large amounts of data and tunable to specialized areas. The following tasks are performed through the platform: segmentation into words and sentences, POS-tagging and lemmatization with the Genia tagger [23], term extraction and recognition[5]. These tasks, and especially the term extraction task, are performed in order to correctly tokenize and identify textual units relevant to the searched information. Thus, the next step of information extraction is performed on POS-tagged, lemmatized and term-tagged text.

Information extraction

The proposed method is designed for accessing several types of information within Medline citations. First, we aim at detecting and extracting risk factors, and as a matter of fact, this implies dealing with specific syntactic structures, such as coordination and enumeration. In the following examples, risk factors are underlined, related pathologies and health conditions are in bold, and pattern-related elements in normal font letters:

1. Risk factors for ***survival*** were *age* and *severity of aortic stenosis* ... (PMID 8705769)
2. ...a *high intake of calcium* and *phosphorus* is a risk factor for the ***development of metabolic acidosis***. (PMID 1435825)
3. ...had more than one of the common risk factors for ***cerebrovascular accidents***, including *hypertension*, *advanced age*, *hyperfibrinogenemia*, *diabetes mellitus*, and *past history of cerebrovascular accident*. (PMID 1560589)

We process such syntactic structures with specifically designed syntactic patterns, where the trigger is a mention of *risk*

[4] lisp.vse.cz/challenge

[5] search.cpan.org/~thhamon/Lingua-YaTeA

factor and the enumeration sequence (punctuation and coordination conjunctions).

Another aspect of the information extraction task consists into establishing an explicit link between risk factors and the corresponding pathologies and health conditions. We propose to use two sources for accessing such information:

- Information extracted from abstracts and titles. In this case, this information is accessed through another set of dedicated lexico-syntactic patterns, such as *risk factors for* in the previous examples.
- *MeSH* descriptors provided by the Medline indexing. In this case, we analyze all the descriptors associated to a given citation, we then match them to the *MeSH* thesaurus and select only those which belong to the heading of diseases *C*.

Evaluation

We have to evaluate various aspects of the obtained results. Our main concern is the quality of extracted information for both risk factors and associated pathologies. We propose to tackle this as follows: (1) For a given pathology, we evaluate quality and exhaustiveness of the extracted risk factors. (2) As, for certain risk factors, we have at our disposal the associated pathologies provided by two sources (information extraction and *MeSH* indexing), we propose to compare these two pathology-related data. (3) Finally, we take advantage of the causal and associative relations encoded within *Snomed CT* and compare them with the information extracted from Medline titles and abstracts. We compute the precision, i.e. ratio of correct extractions among all the results relevant to a given evaluation. All these evaluations are performed manually, as no dedicated and comprehensive gold standard is available.

Results and Discussion

Building and preparing the material

Within the Medline database, we selected those citations which contain singular or plural forms of the terms *risk factor* and *factor of risk* in abstracts or titles. This allows to reduce the whole Medline material to a reliable and homogenous subset of citations. The resulting corpus contains 187,544 citations (over 42 M word occurrences). This corpus of Medline citations have been processed through the Ogmios platform. *Snomed CT* tables were accessed through the UMLS resource [24] version 2008AB, and we could extract 154,130 pairs of registered relations between a pathology and its causative agent or another pathology. 92,807 of these relations are provided by has causative agent, 25,309 by due to and 36,134 by associated with relationships. 120 of these relations are provided by more then one relationship within *Snomed CT*.

Extraction of information on risk factors and pathologies

Patterns for information extraction from abstracts and titles were built manually on few positive examples, and then generalized and applied on the whole set of data. We distinguish three kinds of patterns (in the examples below, **<NP-RF>** indicates noun phrases corresponding to risk factors, **<NP-P>** to pathologies, ? and * for optional and recurrent elements):

1. Patterns for extracting risk factors and pathologies (n=5). This example of pattern: **<NP-RF> as a risk factor for <NP-P>** allows to discriminate this sentence: *Hypocalcemia at parturition as a risk factor for left displacement of the abomasum in dairy cows,* and to propose that *hypocalcemia* is a risk factor of *displacement of the abomasum*.
2. Patterns for extracting risk factors (n=12), among which we have a pattern for enumeration: (other)? risk factors? including **<NP-RF>(, <NP-RF>)* ((,)? and <NP-RF>)?** . From the sentence *The relationships between impaired fasting glucose, other risk factors including blood pressure, and mortality have never been clearly investigated* it extracts that *blood pressure* and *mortality* are risk factors.
3. Patterns for extracting pathologies (n=3), among which **(potential)? risk factors? for <NP-P>**, which detects in the sentence *A risk factor for poor pregnancy outcome, a population-based screening study* the health condition *poor pregnancy outcome*.

In order to get complete information on associations between risk factors and pathologies, elements extracted by patterns (2) and (3) are combined. In this way, we assume that each citation corresponds to a semantically coherent unit and that elements from its different sentences are strongly related between them. These patterns allowed us to extract information from 10,445 PMIDs. Pattern (1) extracted 313 pairs {*risk factor*; *pathology*}. Combination of patterns (2) and (3) provided 15,398 pairs more. Finally, 5,873 risk factors extracted by pattern (2) could not be associated with any pathology within abstract or title. *MeSH* indexing was analyzed and allowed us to extract 5,106 different pathologies and health conditions within the axis C related to diseases. Exploitation of the proposed approach generates triplets {*risk factor*, $pathology_{text}$, $pathology_{MeSH}$}, where the first element is always informed, the two other elements may remain empty.

We extracted 21,584 triplets, among which 17,620 pairs (14,895 of which are unique) are provided only by information extraction patterns, while 5,717 pairs (4,412 of which are unique) contain *MeSH* descriptors as pathology.

Evaluation

Analysis of the extracted risk factors for coronary heart disease

Coronary heart disease (CHD) is the most common form of disease affecting the heart and is an important cause of premature death all around the world. A medical doctor performed a qualitative evaluation of results on this disease. This evaluation appears to be encouraging: among 1,102 extractions, only 128 (11.62%) are rejected, while the remaining set is considered to provide helpful information. First of all, well known risk factors (such as *hypertension*, *smoking*, *diabetes*, *age*, *obesity*, *hypercholesterolemia*, *hyperlipidemia*, *family history*) are frequently detected in the literature and extracted. Amusingly, *work* was detected to be a risk factor for CHD in the

following sentence: *Passive smoking at work as a risk factor for coronary heart disease in Chinese women who have never smoked*. Obviously, this is an error due to an insufficient analysis of syntactic dependencies (the right risk factor is *passive smoking*). Such chunking and segmentation problems at sentence, term or word levels can appear but correspond usually to a minor problem. Another positive aspect of the method is that for several risk factors, it detects also synonyms: {*smoking; cigarette smoking; smoking history; importance of total life consumption of cigarettes*}, {*hyperhomocysteinemia; hyperhomocysteinaemia; homocysteine; plasma homocysteine*}.

Comparison between MeSH-indexed and extracted pathologies

In 291 cases, our approach generated a complete triplet {*risk factor, pathology*$_{text}$, *pathology*$_{MeSH}$}. In order to evaluate precision of the extracted pathologies, we propose to compare them with pathologies provided by *MeSH* indexing. This evaluation has been performed by a computer scientist and pointed out the following cases (in the given examples, pathologies are given in this order {*pathology*$_{text}$; *pathology*$_{MeSH}$}): 42 extracted pathologies are identical to *MeSH* indexing, 32 are their synonyms ({*breast cancer; breast neoplasms*}, {*coronary artery disease; coronary disease*}, {*cataractogenesis; cataract*}, {*postsurgical pain; pain, postoperative*}), 28 are lexically included ({*alzheimer; alzheimer disease*}, {*unsuspected anaphylaxis; anaphylaxis*}, {*hemorrhagic stroke; stroke*}, {*wound infection; surgical wound infection*}), 101 have a close semantic relation ({*poor pregnancy outcome; fetal growth retardation*}, {*development of alcohol disorders; alcoholism*}, {*stroke; cerebrovascular disorders*}, {*osteoporosis; bone diseases, metabolic*}, {*central retinal vein occlusion; vision disorders*}), 7 have a broad semantic relation ({*tardive dyskinesia; dyskinesia, drug-induced*}, {*squamous cell carcinoma of the skin; carcinoma, squamous cell*}) and 91 are not related semantically. Thus, among the set of 291 generated triplets, only 91 extracted pathologies (31%) appears to be not relevant, while nearly 70% are identical, or have a close or broad semantic relation with the *MeSH*-indexed pathologies.

Comparison of extracted risk factors with three* Snomed CT *associative relations

The evaluation question is whether relations extracted from abstracts and titles are already registered within *Snomed CT* and related through three causative relationships: has causative agent, due to and associated with. In order to analyze this aspect, we looked for those *MeSH*-indexed pathologies which are also involved in these three *Snomed CT* relationships. This evaluation is performed by a computer scientist. We obtain a set of 22,730 propositions, related to 168 various pathologies. We analyzed 20 pathologies (3,100 extractions, about 25% of the whole set), such as: *acquired immunodeficiency syndrome*, *kidney diseases*, *heart diseases*, *alcoholic intoxication*, *epilepsy*, and *cytomegalovirus infections*. Only 19 extractions (0.6%) were considered as already recorded within *Snomed CT* or very close to the recorded relations. For instance, within the sentence:

> *...how patients with abundant alcohol consumption as a risk factor develop the chronic alcohol abuse episode of care...* (PMID 10414608)

abundant alcohol consumption was extracted as risk factor for *alcoholism* C0001973, which is very close to the relation registered in *Snomed CT*: *drinking alcohol* (C0589068) has causative agent *alcoholism* (C0001973). Other comparable extractions: {*asbestos fibres* (C0003947); *asbestosis* (C0003949)} in *Snomed CT*, while in citations we obtain {*asbestos exposure*; *asbestosis* (C0003949)}; or {*cytomegalovirus group* (C0010825); *cytomegalovirus infections* (C0010823)} in *Snomed CT* and {*cytomegalovirus; cytomegalovirus infections* (C0010823)} in text. Remaining extractions share little common aspects with the analyzed *Snomed CT* associative relations. One reason is that the precision of these extractions is not perfect; but a more specific reason is that *Snomed CT* does not specifically record this type of information, although risk factors may occur among the *Snomed CT* relations. Thus, for *acquired immunodeficiency syndrome* we extracted several risk factors, i.e.:

> *bisexuality* (C0005639), *bisexual* (C0178515),
> *blood transfusion* (C0005841),
> *intravenous drug abuse* (C0086181), ...

which are *Snomed CT* concepts but have no associative relations to *acquired immunodeficiency syndrome*. The situation is similar with other illnesses: *family history*, *age*, *race*, *smoking*, *hyperlipidemia*, *diabetes*, *hypertension*, *sedentary life style, weight control*, *stress* and many others are extracted as risk factors for *heart diseases* but are not recorded as such in *Snomed CT*. This implies, not surprisingly, that the creation and maintenance of specific dedicated and comprehensive resource for risk factors, would be most welcome.

Conclusion

We presented an experience in extracting information linked to risk factors from Medline citations. The proposed approach relies on NLP and IE methods and is based on lexico-syntactic patterns. It allows extracting risk factors and the associated pathologies. We perform several types of evaluation by medical and biological experts and computer scientists. Evaluation of the precision of risk factors extracted for coronary heart disease shows that they cover a large range of risks, and that only 11.62% of them are incorrect, while the remaining 88.38% are correct. Comparison of the associated pathologies extracted from abstracts with pathologies provided by the *MeSH* indexing prove to be identical or semantically related in about 70%. These two evaluations are very positive. Finally, a comparison of pairs {*risk factor*; *pathology*} extracted from citations and those proposed by associative relationships within *Snomed CT* allowed us to observe that *Snomed CT* is not dedicated to the recording of this type of information, although some of the pathologies can be related to their risk factors in this terminological resource.

We have several perspectives for this work. Methodologically, we will design and apply other patterns for detecting and extracting information on risk factors. For instance, triggers like

predictor, *precursor* are not taken into account currently. We also plan to apply other methods, *i.e.* machine learning and text mining. From a knowledge representation viewpoint, a more precise categorization of risk factors within homogenous groups will be performed. Thus, we can distinguish groups related to environmental, social, clinical, behavioral, and other risks. Besides, this categorization can even be mentioned in abstracts:

> *Demographic risk factors (age, sex, and ethnicity), clinical risk factors (diabetes mellitus, increased cholesterol, antihypertensive medications, history of congestive heart failure, myocardial infarction, hypertension, and neurological deficits), and behavioral risk factors (smoking and heavy drinking) were controlled for statistically.* (PMID 11973166)

Another perspective is related to characterizing the extracted information itself. Thus, some of the extracted elements may occur in modal or negative contexts, which reduces their reliability. Otherwise, geographical, demographic or other variables for risk factors exist. For instance, for a given pathology, common risk factors in North America or Europe may be of less (or no) relevance to other geographical areas. Such characterization may well deserve more focus.

A Qualitative Approach to Signal Mining in Pharmacovigilance using Formal Concept Analysis

Agnès Lillo-Le Louët[a], Yannick Toussaint[b], Jean Villerd[b]

[a] *Centre régional de pharmacovigilance, Hôpital européen Georges Pompidou, Paris, France*
[b] *LORIA – INRIA Nancy Grand Est, Vandœuvre-lès-Nancy, France*

Abstract

"Pharmacovigilance is the process and science of monitoring the safety of medicines, consisting in (i) collecting and managing data on the safety of medicines (ii) looking at the data to detect 'signals' (any new or changing safety issue)" [1]. Pharmacovigilance is mainly based on spontaneous reports: when suspecting an adverse drug reaction, health care practitioners send a report to a spontaneous reporting system (SRS). This produces huge databases containing numerous reports and their manual exploration is both cost and time prohibitive. Existing techniques that automatically extract relevant signals rely on statistics or Bayesian models but do not provide information to the experts about possible biases lying in the data, nor about the specificity of a signal to a particular patient profile. Our extraction method combines numerical methods from the state of the art with a qualitative approach that helps interpretation. We build a synthetic representation of the database that is used to (i) identify unexpected patterns and biases (ii) extract potentially relevant signals w.r.t. patient profiles (iii) provide traceability facilities between extracted signals and raw data.

Keywords:

Adverse drug reaction reporting systems, Data interpretation, Data collection, Drug safety, Public health informatics, Information storage and retrieval, Artificial intelligence, Formal concept analysis, Data mining

Introduction

The huge and constant increasing size of spontaneous reporting systems (SRS) precludes case-by-case human analysis. Indeed, in 2008 more than 20,000 new cases were added to the French pharmacovigilance system; the WHO database contains more than 3 millions of reports. This has lead to the development of data mining algorithms (DMAs) that automatically extract signals, i.e. potentially relevant adverse drug reactions for further investigations by experts in pharmacovigilance [2].

Two main approaches to extract signals are known, both of them are based on statistical criteria: (i) the frequentist approach which establishes pertinence threshold with respect to disproportionality measures between occurrences of a drug and an adverse effect (AE), and (ii) the Bayesian approach based on probability distribution models. Most of the debate has focused on the advantages and drawbacks of these approaches and on the fine tuning of their respective measures and thresholds.

DMAs only deal with co-occurrence of drugs and AE and produce quantitative indicators. For this reason, [3] throws them back into question arguing that a drug-AE pair is, in itself, rarely sufficient to assess whether a potential signal has been generated. Indeed, using DMAs, experts have to evaluate each extracted drug-AE pair and its statistical measures with no way to estimate to what extent these measures are reliable. They also ignore if there are some demographic population restrictions or the presence of concomitant medications.

Moreover some biases in SRS databases degrade quality of the DMA results: the number of patients that take a particular drug without AE is not known (no control sample) and fields in the database are not always fully or properly filled. Experts ignore if some of the detected signals are due to biases since they have no way to evaluate the presence of specific biases or noise in the case database when they evaluate detected signals.

We argue that DMAs should provide experts disproportionality measures as well as qualitative information in order to explain or to trace the reasons why each signal has been generated. We claim that a symbolic classification method such as Formal Concept Analysis reaches this goal providing (i) a synthetic view of the database (ii) a search space for candidate signals (iii) an environment to navigate among results (iv) and a potential noise detection method.

Materials and Methods

This section presents first Formal Concept Analysis which builds a partial ordered structure called lattice. Then, we highlight some mathematical properties of the lattices used to achieve the (i) to (iv) previous goals.

Table 1 – Binary relation between objects in rows (cases) and attributes in columns (age bracket, gender, AE, drugs)

	demographic attributes					adverse effects										drugs				
	<18	18-60	>60	M	F	e1	e2	e3	e4	e5	e6	e7	e8	e9	e10	d1	d2	d3	d4	d5
#1		×			×				×		×				×		×			×
#2			×	×			×		×	×	×	×	×				×	×		
#3		×			×	×	×		×				×	×					×	×
#4	×				×	×	×						×				×	×		
#5		×		×		×		×			×	×		×	×	×				

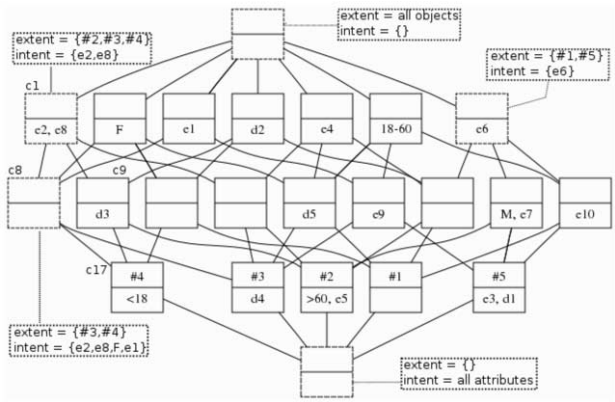

Figure 1 – Concept lattice representing the binary relation given in Table 1

Basis on concept lattices

A **formal context** [4] is a triplet (G,M,I) where G is a set of objects, M, a set of attributes and $I \subseteq G \times M$ is a binary relation and for any $g \in G$ and $m \in M$, $(g,m) \in I$ if the object g has the attribute m. Two derivation operators, both denoted $'$, link objects and attributes:

for $O \subseteq G$ and $A \subseteq M$, $O' = \{a \in A \mid \forall o \in O, (o,a) \in I\}$, $A' = \{o \in O \mid \forall a \in A, (o,a) \in I\}$. The compound operators $''$ are closure operators over 2^G and 2^M.

A **concept** c is a pair (O'',O') where $O \subseteq G$. $O'' \subseteq G$ is called the **extent** of c and $O' \subseteq M$ the **intent** of c. Both intent and extent are closed sets which intuitively means that the extent of c is the exact set of objects which share all attributes in the intent and no other attribute, and dually between the class of attributes versus objects. The set C of concepts is partially ordered: for any $c_1=(O_1,A_1)$ and $c_2=(O_2,A_2)$, $c_1 \leq c_2 \Leftrightarrow O_1 \subseteq O_2 \Leftrightarrow A_1 \supseteq A_2$. The structure $L(C,\leq)$ defines a lattice, called **concept lattice**.

Applied to pharmacovigilance, objects are cases and attributes are drugs $(d_1 \ldots d_5)$, AE $(e_1 \ldots e_{10})$, and demographic attribute such as gender (M,F) and age bracket $(<18,\ldots,>60)$ of the patient (see Table 1). In the resulting concept lattice, shown in Figure 1, concepts are represented by boxes in which the upper (resp. lower) part contains the extent (resp. intent).

A reduced labeling scheme is used so that each object/attribute appears only once in the lattice. An attribute (resp. object) label appears in the highest (resp. lowest) concept that contains it in its intent (resp. extent). A concept labeled with an attribute a is called the attribute-concept of a denoted $\mu(a)$: for instance, $c_1=\mu(e_2)=\mu(e_8)$. Therefore, the intent of a concept is made of all attributes whose attribute-concepts can be reached from the concept on an upward-heading path while extent is recovered in a dual way. For example, considering the concept c_8, its intent contains all the intent labels of its ancestors $\{e_2,e_8,F,e_1\}$, and its extent all the extent labels of its successors $\{\#3,\#4\}$.

The lattice as a synthetic view of the database

The concept lattice gives insights into the case database. We illustrate this point by few examples: $c_8 \leq c_1$ since $\{\#3,\#4\} \subseteq \{\#2,\#3,\#4\}$ and $\{e_2,e_8,F,e_1\} \supseteq \{e_2,e_8\}$. This means that among the cases containing adverse effects $\{e_2,e_8\}$, some of them (but not all) are women (F) who also suffer from e_1. By definition, the intent of a formal concept is a closed itemset[1] and the lattice contains all possible closed itemsets as intents. Thus $\{e_2,e_8,F,e_1\}$ (intent of c_8) is a closed itemset but $\{e_2,e_8,F\}$ is not closed as there is no concept with this exact intent. This means that there is no case

[1] Here, the data mining term *itemset* denotes a set of attributes.

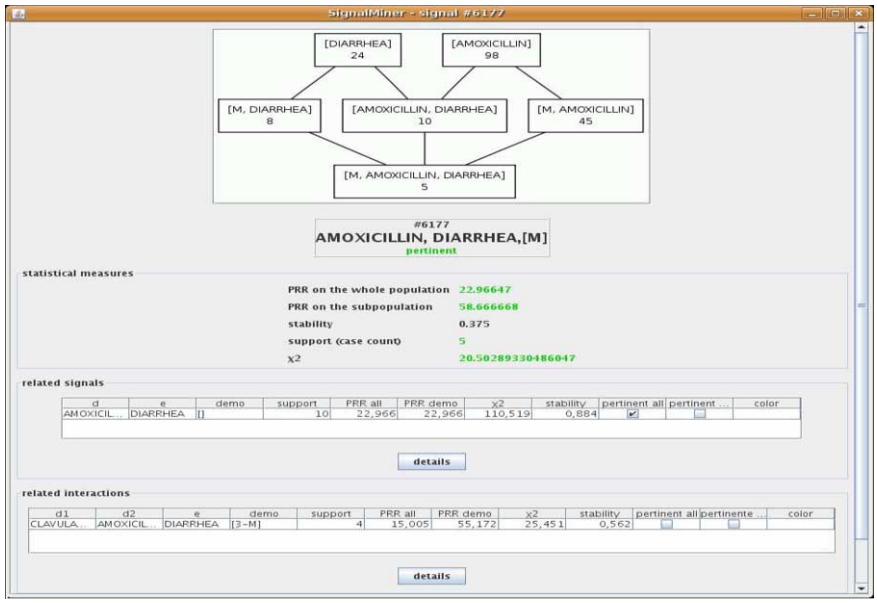

Figure 2 – graphical user interface showing the (amoxicillin, diarrhea, M) signal

in the database where a woman suffers from e_2 and e_8 without suffering from e_1. The concept c_9 with $\{e_2, e_8, d_3, d_2\}$ as intent shows that every patient who took d_3 also took d_2 and suffers from e_2 and e_8, since $c_9 = \mu(d_3)$.

Thus, through the relations existing between labeled concepts, the lattice reveals correlations between attributes: for instance "d_3 is always taken with d_2", "d_1 is only taken by men", "all and only elderly suffer from e_5"...

A search space for candidate signals and interactions

The lattice is used to identify necessary conditions for both signals (1 drug, 1 AE) and interactions (2 drugs, 1 AE). A necessary condition for a signal to occur is when the intent of a concept contains a pattern (d, e), i.e. it contains exactly one drug and one AE. Such a concept is called a "signal-concept". Note that the intent of a signal-concept may be $\{d, e\}$ or $\{d, e, X\}$ where X is a set of demographic attributes. We note signal-concepts c_{de} or c_{deX}. Similarly, the intent of an "interaction-concept" contains the pattern (d_i, d_j, e). Let us call c_{ij} (or c_{ijX}) an "interaction-concept" with the pattern (d_i, d_j, e). If its related signal concepts c_i with the pattern (d_i, e) and c_j with the pattern (d_j, e) exist in the lattice, by construction, then $c_i \leq c_{ij}$ and $c_j \leq c_{ij}$. The absence of c_i means that d_i and e never appears together without d_j. Thus the lattice defines the search space for candidate signals and interactions. It also links interactions to their related signals.

Statistical measures are then computed for each signal-concept c_{de} or c_{deX} in order to evaluate its pertinence with respect to the British Medicines and Healthcares products Regulatory Agency (MHRA) interestingness criteria [2]. We adopted three criteria for raising hypotheses regarding signals: number of cases ≥ 3, $\chi^2 \geq 4$, and PRR ≥ 2. If the three criteria are successful, the signal-concept c_{de} (resp. c_{deX}) generates a **potential signal** (d, e) (resp. (d, e, X))

For the first criterion, the number of cases is actually the extent's cardinal of the concept. The lattice contains all the information needed to compute the contingency table and therefore the two later measures [5].

Considering a signal-concept c_{de} without demographic attribute, the PRR is computed as follows:

$$PRR(d,e) = \frac{P(e|d)}{P(e|\bar{d})} = \frac{P(de)P(\bar{d})}{P(d)P(\bar{de})} = \frac{|de| \cdot |\bar{d}|}{|d| \cdot |\bar{de}|} \quad (1)$$

where $|a|$ denotes the number of cases that has attribute a.

Considering a signal-concept c_{deX} with a set of demographic attributes X, the PRR is computed as follows:

$$PRR(d,e,X) = \frac{|(de)_X| \cdot |\bar{d}_X|}{|d_X| \cdot |(\bar{de})_X|} \quad (2)$$

Formula (2) provides a PRR that takes demographic attributes into account by restricting the scope to the concerned population. Hence, $|(de)_X|$ denotes the number of patients in the X subpopulation that took d and suffer from e.

An interaction-concept with the pattern (d_i, d_j, e) becomes a **potential interaction** if it satisfies the three following criteria[2]: number of cases ≥ 3, PRR ≥ 2 and the interaction's PRR

[2] The PRR value of an interaction (d_1, d_2, e) is computed as follows: $PRR(d_1, d_2, e) = P(e|d_1 d_2) / P(e|\ not(d_1 d_2))$

has to be greater or equal to each PRR of the two related signals if the signal-concepts of these signals exist in the lattice. The later criterion means that an interaction must "override" its related signals. When it is the case, its related signals are removed from the set of potential signals.

However, related signal-concepts may not exist in the lattice. We proved that it is not worth computing the PRR for non-closed signals (d_i,e) since it is always less or equal to the PRR of the interaction (d_i,d_j,e).

Navigation through results

The user interface makes the most of all the previous observations. Experts can see what kind of relation exists between drug(s) and AE, for instance "all patients that took drug d_i suffer from e". They may access to a set of potential signals and interactions, along with their statistical measures. Each signal and interaction is linked with its concept in the lattice and a subpart of the lattice can be visualized to help experts in their interpretation task.

Figure 2 shows the user interface illustrating a signal d,e,X where d=amoxicillin, e=diarrhea, X={male}. A subpart of the lattice is shown, which contains the concepts c_{deX}, μ(d), μ(e), and all concepts on the paths from c_{deX} to μ(d) and μ(e), here c_{de}, c_{dX}, and c_{eX}.

Concepts are labeled with their intents and the number of objects in extent. Through this graph, experts can observe the distribution of cases in the database: 24 patients suffer from diarrhea (μ(e)), 98 took amoxicillin (μ(d)), 10 took amoxicillin and suffer from diarrhea (c_{de}), and among them 5 are men (c_{deX}).

Then, experts can compare PRR values for both signals c_{de} (denoted "PRR on the whole population") and c_{deX} ("PRR on the subpopulation") and understand why, in this exemple, PRR(d,e,X)>PRR(d,e). It can be seen that 5 men took amoxicillin among the 8 men that suffer from diarrhea; *i.e.* almost all of them. Unlikely, only 10 people took amoxicillin among 24 people who suffer from diarrhea, *i.e.* less that half of them. Thus, the demographic attribute M makes the signal stronger according to PRR values.

In addition, it is possible to compare the strengths on two subpopulations. The same signal on the female population shows a lower PRR (13.38). Hence, we have |(diarrhea, F)|=16 and |(amoxicillin, diarrhea, F)|=5. So the weight of amoxicillin takers within women suffering from diarrhea is lower compared to men, and compared to the whole population. Thus, examining the lattice allows experts to understand why a signal is stronger on given population.

A potential noise detection method

Trimethoprim and sulfamethoxazole come together in marketed drugs, thus a unique concept μ(trimethoprim) = μ(sulfamethoxazole) should exist in the lattice. It is not the case in Figure 3 since only one case has been badly filled in the database. The stability ratio [6] of a concept can capture such a situation. It quantifies the ability of the concept to remain existent after deletion of objects in its extent. Here a low stability can be used to identify concepts in the lattice resulting from noise in the database.

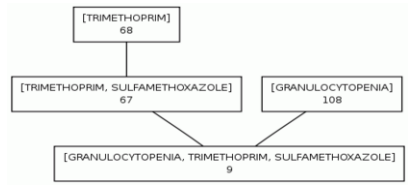

Figure 3 – an interaction example containing noise

Results

We applied our method on a subset of the French national SRS database. This subset contains 3249 cases, 976 drugs, 573 AE, and demographic attributes such as gender and age, divided in 3 brackets (<18, 18-60, >60). The resulting lattice contains 13178 concepts, among which 6788 contains at least 3 cases in the extent. The 2812 candidate signal-concepts led to 565 potential signals and the 836 candidate interaction-concepts to 102 potential interactions. Note that the exhaustive search performed by existing method would generate more than 500,000 candidate signals and more than 270,000,000 candidate interactions.

In the worst case, the lattice contains 2^n concepts where n is the minimum of the number of objects and the number of attributes. In practice and especially with SRS databases, the number of closed itemsets is much lower than 2^n and even lower than the number of candidates for exhaustive search.

Table 2 shows the distribution of the 565 signals by pattern. Interestingly, we observe that signals can be divided in four distinct categories, depending on the weight of the demographic attributes. Only 29% of the signals have the pattern (d,e), the rest of the signals have at least one (49%) or two demographic attributes (22%). The validation of such attributes *a posteriori* by manual review of all signals shows a good relevance. In the majority of cases, the demographics attributes associated to the couple drug/effect constitute a known risk factor or probable risk factor. For example, cases of Pulmonary Hypertension associated with the use of appetite suppressants amphetamine-like were observed in women, aged 18 to 60.

Secondary, all the signals were classified into 5 categories (see Table 3). Categories (1),(2) contain true positives, (3),(4) false positives and (5) unknown potential signals. Table 3 shows that our method generates few false positives that are discussed in the next section. 27 signals were classified as unknown, i.e. not reported in the literature, but interesting enough for investigation by experts.

Table 2 - distribution of the 565 potential signals by pattern

signal pattern	count (%)	example
drug, effect	160 (29%)	cefazolin, thrombocytopenia
drug, effect, gender	132 (23%)	furosemide, gynecomastia, male
drug, effect, age	148 (26%)	abciximab, thrombocytopenia, > 60
drug, effect, gender, age	125 (22%)	levofloxacin, mental confusion, female, > 60

Table 3- Classification of the 565 potential signals

category	signals
(1) known (in reference documents)	502 (89%)
(2) known (in a similar form)	24 (4%)
(3) the AE is the origin of the medication	3 (1%)
(4) due to concomitant drug	9 (2%)
(5) unknown potential signal	27 (5%)

Discussion and perspectives

In this section we discuss the efficiency of our qualitative approach, especially for handling demographic attributes. Then, we present future directions about preventing false positives.

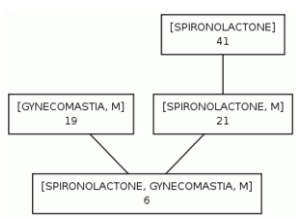

Figure 4 – a signal containing a masculine AE

The lattice helps experts in interpreting PRR variations depending on demographic attributes as shown before for (`amoxicillin, diarrhea`). Moreover, in some situations where an AE is specific to a population, *e.g.* `gynecomastia` (see Figure 4), handling demographic attributes in the PRR computation is the only way to obtain a meaningful measure.

False positives (contained in categories (3) and (4)) are common in signal detection. In the following, we give directions for preventing false positives from category (4). The signal (`hydrochlorothiazide, cough`) is detected because these drug and AE often appear together. However in these cases, `cough` is actually caused by ACE inhibitors taken concomitantly with `hydrochlorothiazide`. Since there are several `ACE inhibitors` d_i, each association $(d_i, \texttt{cough})$ appears less often than the association (`hydrochlorothiazide, cough`). Therefore, only this later signal is detected. A solution would be to introduce drug therapeutic families, such as ACE, as attributes, with $(o, \texttt{ACE}) \in I$ for each case o containing an ACE inhibitor. Then signals of the form $(\texttt{ACE}, \texttt{cough})$ would be detected, where `ACE` is a drug family, even if each signal (d, e) where d is an ACE inhibitor is too weak to be detected.

In this paper, we have presented a novel automated signal detection method that focuses on the qualitative aspects of the extracted signals. The pivot structure is a concept lattice that allows experts to identify unexpected situations in the case database, and provides information to the experts about why each signal has been detected. Besides our symbolic approach, we have implemented disproportionality measures which are commonly accepted in pharmacovigilance. Our first results based on an extract of the French database are very encouraging: our method has a very good relevance and the signal pattern includes demographic attributes. Further research will focus on (i) improvements for preventing false positives (ii) the scalability of our approach and its efficiency on a bigger database.

Abstract

Variations in International Normalized Ratio's (INR) are closely related to bleeding and thrombosis incidents in patients on oral anticoagulation treatment. This study investigates predictive factors that affect INR values. Data sampled with relatively high frequency allows for detection of local INR variations, and hence also allows detection and evaluation of predictive factors where time is taken into consideration. Univariate linear regression was applied and different models were reduced into a final predictive model. F-tests were utilized to test whether or not a model reduction would benefit INR predictions, in terms of decreasing observed variance. In addition to an INR submodel, the final model includes individual interaction from the last three days change in mean warfarin intake and three days change in mean vitamin K intake. Prediction residual error was mainly reduced by the INR submodel, while the warfarin model and the vitamin K submodel did not benefit predictions to same extend compared to the INR submodel. However, more studies on the temporal aspects of the effect of warfarin seem to be relevant.

Keywords:

Anticoagulation, Linear regression model, Time series model, Vitamin K, Prediction model.

Introduction

Oral vitamin K antagonists such as warfarin and other coumarin derivatives are prescribed to an increasing number of patients enrolled for lifelong therapy with underlying disorders such as heart valve replacement, atria fibrillation and venous thromboembolism. Despite well-described clinical benefits, use of warfarin is known to be associated with adverse effects, in particular haemorrhage, if too much warfarin is given. The dosage of oral anticoagulation agents should be based on minimizing both the risk of thrombotic events and the risk of bleeding [1].

Three different types of patient management exist. One is "usual-care" where patients visit the hospital-based or the GP every 4-6 weeks to have a blood sample taken to have the so-called International Normalized Ratio (INR) measured. The INR represents a patient's coagulation time compared to a normal healthy individual. An INR value of 1 is normal and, for example, a measured INR value of 2 means that blood coagulation takes twice as long compared to the normal coagulation. In the "usual-care" warfarin dosage is recommended by the doctor based on current and historic INR values. Some patients are able to take part in the management of oral anticoagulation treatment (OAT) by handling a Point-of-Care (PoC) device and measure INR values themselves. Patients assigned to "self-testing" will report this INR value to a responsible clinician who prescribes the dose of warfarin. Patients educated in "self-management" will both handle INR measurement by a PoC device, and are allowed within a preset range to change warfarin dosage. In the latter two mentioned groups, measurements of INR values are most frequent: once every week or two.

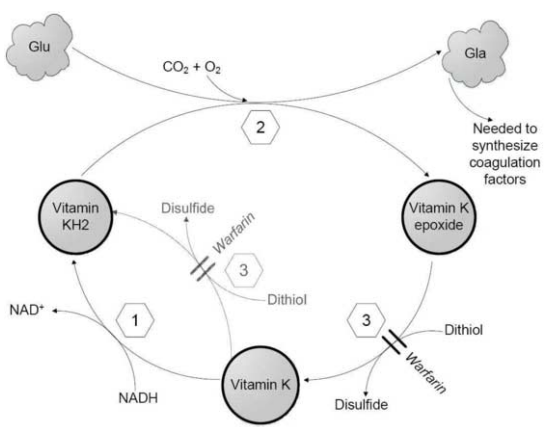

Figure 1- Vitamin K is reduced either by a NADH dependent reductase activity reaction ‹1› or a reductase reaction dependent on the conversion of dithiol into disulfide ‹3› (shaded). The carboxylation reaction ‹2›, which converts Glu (glutamate residues) into Gla (gamma-carboxyglutamate residues, aka Gla-residues), is driven by a vitamin KH2 dependent carboxylase activity, which simultaneously converts vitamin KH2 into vitamin K epoxide. The last step in the vitamin K cycle reaction ‹3› is a reductase of vitamin K epoxide dependent on conversion of dithiol into disulfide. The two reactions indicated by ‹3› are inhibited by anticoagulants as warfarin, thus dietary vitamin K sources are necessary to maintain haemostasis. Adopted from [7].

Maintaining patients within the desired therapeutic range presents a challenge due to at least three factors: (1) a target INR value restricted by a relatively narrow therapeutic range; (2) an interindividual variation of the effect of oral vitamin K antagonists, and (3) changes in dietary intake of vitamin K.[2-4] A change of 0.7 INR in two consecutive measurements has been shown to be clinically relevant for OAT.[5]

Fluctuations in vitamin K intake through dietary sources have shown clinical relevance, and must be regarded as a major independent factor that interferes with anticoagulation stability.[6] Based on known physiology the interactions between INR, warfarin, and vitamin K are well described; an overview is provided in Figure 1.

Since they are based on accessibility of Gla-residues the amount of functional vitamin K dependent coagulation factors will decrease if warfarin is administrated; this leads to an increase in INR value.

Disregarding the complexity of the vitamin K cycle, a novel approach to describe the course of action of INR values is proposed in Equation (1), where INR_t denotes the INR measurement at time t.

$$INR_t = \alpha(INR_{history}) + \beta(Warfarin_{history}) + \gamma(Vitamin\ K_{history}) \quad (1)$$

where α, β and γ are arbitrary coefficients. Due to the slow-acting physiological systems involved, one must take time into consideration, e.g. warfarin has a half-life of 36 hours. Warfarin and vitamin K interaction will have carryover effect from previous intake(s), affecting the current INR value. Being able to take into account such different predictive over-coagulating and under-coagulating factors could potentially decrease bleeding risk or decrease risk of thrombosis in patients assigned to an outpatient setting of OAT.

The purpose of this analysis is to utilize quality data to assess interactions between current and previous INR values, warfarin administration changes, and changes in dietary vitamin K intake. Such interactions might reveal important predictive factors for variation in INR values.

Methods

We have built models predicting the current INR value from available information. This is performed in three steps:

- Information on previous INR measurements
- Additional information on warfarin intake
- Additional information on vitamin K intake

The first model provides information on the serial correlation structure of individuals that are well regulated with respect to warfarin and vitamin K intake. Having established a prediction model solely based on historic INR values, the inclusion of warfarin intake in such a model provides information on the time-span of the effect from warfarin on INR. Further, it will provide information on between-subject variation of sensitivity to warfarin treatment. Finally by also including vitamin K intake in the model, it is possible to assess the time-span of the effect from vitamin K. Again, the between-subject variation of sensitivity can be assessed. The analysis also provides empirical knowledge to judge to which amount these three predictive variables reduce the unexplained variation.

Materials

All patients included in this study referred to Medicinsk Ambulatorium, Brædstrup Sygehus. Approval from the Danish Data Protection Agency was obtained prior to onset of the data acquisition program. Clinicians at the facility enrolled suitable patients to be included in a data collection protocol, and the study was conducted in the period from June 2008 to February 2009. Patients were asked to fill out a daily scheme for a one month period. Schemes included information (among others) on INR value, diet, and warfarin intake. Data were entered into Microsoft Excel ®. Nutrition data was evaluated to calculate vitamin K content. The vitamin K assessments were performed by using the USDA National Nutrient Database for Standard Reference.

Data Analysis

A retrospective statistical evaluation of variability in INR values was performed. The current INR value is predicted from previous values in a regression model, and hence the approach is auto-regressive time series modelling. However, as the data is characterized by being shorter time series from a number of independent individuals, the statistical methods applied are mainly univariate linear regression analyses rather than the classic approach developed by Box and Jenkins [8].

Prediction model based on previous INR values

Prediction of the current INR value at time *t* for the *i*th subject is given in Equation (2).

$$INR_{i,t} = \alpha_{i1}\, INR_{i,t-1} + \alpha_{i,2}\, INR_{i,t-2} + ... + \alpha_{tv}\, INR_{i,t-n} + \varepsilon_{i,t}, \quad (2)$$

where the lag time is n, $\alpha_{i,k}$ are weights in a weighted average of previous INR values, and $\varepsilon_{i,t}$ is the residual uncertainty (prediction error). We assume that $\varepsilon_{i,t} \sim N(0,\sigma^2)$. It should be noted that in this model we assume variation between individuals in weights. Reductions of this model could be:

I. Reducing the lag time of influence
II. Reducing the interindividual variation

Reductions in lag time must be performed in descending order, and likewise, reductions in interindividual variation should be done in descending order of lag time.

Prediction model based on previous INR values and changes in warfarin intake

The preceding model is now expanded by adding intake of warfarin. Assume that an individual is in steady state and dependence of previous INR values is described by $\alpha(INR_{history})$. In this case changes in warfarin dose will affect the prediction of INR. The absolute change in warfarin intake from previous days is, however, not a sophisticated way of modelling the effect from warfarin. This is mainly due to the nature of warfarin administration: the advised dosage pattern of warfarin is rarely fixed in terms of tablets per day. A normal pattern could be; 2, 2, 3, 2, 2, 3, 2 tablets per day for one week. If the absolute change in previous warfarin intake is modelled as change

from one day to another, the effect from previous changes would be negated due to this pattern of changes (i.e. positive change always followed by a negative change and vice versa). Hence, it is decided to model changes in warfarin intake based on the difference from the mean intake of the last day's change as in Equation (3).

$$INR_{i,t} = \alpha(INR_{history}) + \beta_{i,1}\,\Delta W_{i,t-1} + \ldots + \beta_{n,1}\,\Delta W_{i,t-n} + \varepsilon_{i,t}, \quad (3)$$

where $\Delta W_{i,t-1} = W_{i,t} - W_{i,t-1}$ is the change in warfarin intake compared to change in mean warfarin intake from t days. Again we model potential between-subject variations in sensitivity toward vitamin K antagonist treatment.

Vitamin K based model

Expanding the model to incorporate intake of vitamin K is done similar to the intake of warfarin, see Equation (4).

$$INR_{i,t} = \alpha(INR_{history}) + \beta_i(W_{history}) + \gamma_{i,1}\,\Delta K_{i,t-1} + \ldots + \gamma_{n,1}\,\Delta K_{i,t-n} + \varepsilon_{i,t} \quad (4)$$

where $\Delta K_{i,t-1} = K_{i,t} - K_{i,t-1}$ is the current change in vitamin K intake compared to mean intake from t days. The reduction of this model follows the same rules as the previous model. However, the reduction in interindividual variation may be performed in two steps; 1) reduction in weights modelling potential between-subject variation, and 2) reduction to weights specific to a grouping into individuals who take, and who do not take supplementary vitamins including vitamin K. The latter approach is based on Schurgers et al. who reported a threshold of 150µg/day of vitamin K supplements for having a clinically relevant effect. [9] For this reason, the vitamin K model was tested with two types of interaction: vitamin K supplements interaction and interindividual interaction.

Results

A total of 30 patients accepted to be contacted, six declined to participate. Out of the 24 patients going into the study, 18 patients completed the data collection protocol (Table 1), equivalent to a 25% dropout rate.

Results from model reductions are reported in three steps:

- Reduction of lags on previous INR measurements and individual interaction
- Reduction from INR model including reduction from information on warfarin intake and individual interaction
- Reduction from INR model and warfarin model including reduction from information on vitamin K intake and individual interaction as well as vitamin K supplement interaction

A lag of four days, meaning four historic values relative to the current INR value was selected as appropriate, taking the amount of data per individual into account.

Table 1- Outline of 18 patients receiving warfarin

Characteristics	Number (%) or Mean ± SD
Age (years)	56 ± 15
Females	8 (44%)
Days in study	27 ± 1.78
INR value	2.5 ± 0.5
Warfarin intake [mg/day]	6 ± 2.5
Vitamin K intake [µg/day]	59 ± 105
Patients on daily vitamin K supplement	7 (39%)
Indication for OAT	
Heart valve replacement	9 (50%)
Deep venous thrombosis	3 (16%)
Atria fibrillation	4 (22%)
Coronary prosthesis	1 (6%)
Thromboembolism	1 (6%)

Analysis of INR model

The initial model holds both the main effect from INR with four lags and the interaction effect from INR and the individual with four lags. The interindividual variation between patients is not significant ($p = 0.99$), and only lag 1 is significant, lag 2 to lag 4 having a p-value > 0.87. The final INR model applied in the next step, where warfarin will be included is given in Equation (5).

$$INR_{i,t} = \alpha\, INR_{i,t-1} + \varepsilon_{i,t}, \quad (5)$$

with the within-individual Standard Deviation (SD) = 0.25 and α=0.99. The regression parameter does not differ significantly from 1 ($p = 0.96$), and hence the model describes the within-individual variation in INR by independent increments with a day-to-day SD of 0.25. Likewise, α is set to 1.

Analysis of INR and warfarin model

The first noticeable result is the importance of individual interaction with a p-value <0.00005; hence further testing will be including interaction from individuals. The warfarin model is deduced from successively testing the difference in warfarin intake from the last two, three or four days mean warfarin intake. The final INR and warfarin model is provided in Equation (6).

$$INR_{i,t} = INR_{i,t-1} + \beta_i\,\Delta W_{i,t-1} + \varepsilon_{i,t}, \quad (6)$$

with a SD = 0.54 and average value $\beta = 0.52$.

Analysis of INR, warfarin and vitamin K model

The addition of vitamin K information to the model and results for reduction of INR variation are described in the following. As no interactions from vitamin K supplement will

benefit the model (p = 0.1182), further testing of model reduction related to vitamin K information will be done without vitamin K supplement.

Reduction of lags on mean intake of vitamin K is done successively by removing one lag of the time, starting from fourth lag. There is no clear indication of a beneficial model provided by this reduction method. However, utilizing lag two including interindividual interaction will be a beneficial model compared to the full interaction one, with a successive p-value from F-test between the two of p=0.8338. Hence, the final model will be as in equation (7).

$$INR_{i,t} = INR_{i,t-1} + \beta_i \Delta W_{i,t-1} + \gamma_i \Delta K_{i,t-2} + \varepsilon_{i,t}, \quad (7)$$

with a SD = 0.22, average values $\beta_i = 0.51$ and $\gamma_i = -8.16*10^{-4}$.

Model control

The serial correlation structure of the model was checked by Durbin-Watson statistic (D-W = 2.074) and autocorrelation plots of residuals indicating mutually independent residuals. Hence, it is concluded that the suggested correlation structure is adequate. However, negative lag 1 autocorrelation suggest a possible improvement by adding white noise on top of independent INR increments. The normality assumption was checked by visual inspection of QQ-plots of residuals and found adequate. Variance homogeneity was assessed by scatter-plots of residuals versus fitted values, and no indication of heterogeneity was found.

Relative benefit of each independent variable

Significance tests between different models have shown what will benefit reduction of variance in INR predictions. By assessing the relative magnitude of each independent variable, it is revealed how much variance each variable explains. Each contribution to residual error reduction relative to total variation on INR is given in the following list:

- Contribution from the INR model 95.7%
- Contribution from adding the warfarin model 15.6%
- Contribution from adding vitamin K model 7.5%

Discussion

This paper reports the outcome of utilizing univariate linear regression models on quality OAT data.

The data is characterized by a close recording in terms of interval between observations; however the dataset is small in terms of number of individuals. The advantage is that it is possible to model and study the day-to-day dynamics of INR, warfarin and vitamin K. The disadvantage is that the group is small and selected. Hence, only qualitative and not quantitative results generalize to a larger population.

The model analysis directs the potential monitor/decision support system towards a state space model [10]. One virtue of the state space approach is that it is modular and flexible. It is possible to model the dynamics of a recommended dose of warfarin, the actual warfarin intake, intake of vitamin K and the INR level, true as well as measured. By use of the Kalman filter [11] it is possible to make inference on the recommended warfarin dose (in order to keep INR within the therapeutic interval) and to predict future INR values. This approach has been used to monitor pregnancy [12] and monitor post-surgical cancer patients [13]. By using the state space approach, it will be possible to suggest an optimal dose of warfarin given past values of INR, warfarin and vitamin K. Also the suggested dose can be adjusted for expected future intake of vitamin K.

The results from warfarin modelling showed the importance of individual interactions. This is in accordance with the fact that sensitivity to warfarin therapy often is associated with an interindividual dosage. In addition it was shown how the current warfarin intake was not a significant predictor for the current INR, while information from past days intake was able to explain INR variation. This is good in accordance with the pharmacological properties of warfarin that has a half-life of 36 hours in the plasma, and for this reason have a long-lasting effect on INR values. To further elaborate the utilized approach, one might include screening for polymorphisms of the enzyme (CYP2C9) involved in warfarin metabolism. Genetic variants in CYP2C9*2 and CYP2C9*3 have been shown to require lower maintenance dose of warfarin. In addition, patients with these variations are associated with an increased risk of over-anticoagulation.[2] Further, warfarin dosage variation is closely related to CYP2C9 and vitamin K epoxide reductase complex subunit 1 (VKORC1) and account for up to 30% of the variability in warfarin dose among European-Americans, and 10% variability among African-Americans.[16] Currently, screening for CYP2C9 variants before initiating coagulation therapy is an ongoing discussion in the literature, as this may allow clinicians to develop even more individual dosing protocols to reduce the risk of adverse drug effects.

While one could be tempted to neglect both the warfarin and the vitamin K model, the frequency of INR measurement from each individual must be taken into consideration. These patients are trained to aim for a target INR value by adjusting their dose of warfarin. In a regular setting, INR measurements would be done once a week and not every day. This additional information by more frequent measurements has earlier been reported to be related to an increase in Time in Therapeutic Range (TTR). [14] This will directly raise the contribution from the INR model to explain variance on the behalf of the other models. The indeed small contribution to explain variance from vitamin K model is also associated with the amount of intake. As vitamin K is found in a limited diversity of food, the daily intake is associated with large variations. Mean intake is 59.26µg/day with a SD of 104.62 µg. These large day-to-day variations in vitamin K intake may partly be the explanation of the low contribution from this model in terms of explaining variance in INR values.

In contrast to the findings in the present study, a recent study based on a physiological model of the vitamin K cycle, and tested on 157 days of data from 5 patients, has indicated that, for days with a high dietary intake of vitamin K, adding information on dietary vitamin K seems to significantly improve the accuracy of INR predictions [15]. Other studies have also shown a much larger effect of vitamin K intake than what can

be deduced from the 7.5% contribution from the vitamin K model in the present study [3, 6].

While it from a clinical point of view is to be expected that information on the intake of the anticoagulation drug, warfarin, is important in order to predict future INR values, more studies on the temporal aspects of the effect of the drug seems to be relevant. Furthermore, the vitamin K intake has to be further studied in order to assess its importance.

Acknowledgements

We acknowledge the staff from Medicinsk Ambulatorim, Brædstrup Sygehus for their effort in recruiting patients to this study.

Abstract

This article describes the challenges of implementing SNOMED CT into electronic clinical documentation systems for discharge summaries, synoptic operative notes and ambulatory documentation. Four significant implementation challenges were identified throughout these projects, which required collaboration between specialists across several disciplines to resolve. The challenges included: designing the graphical user interface for selecting SNOMED CT values, gathering and validating template specifications that use SNOMED CT subsets, handling SNOMED CT subsets and extensions, and, creating algorithms and the technological infrastructure to generate fast, meaningful, non-redundant search results. Our experiences suggest that, while the usage of SNOMED CT in tertiary care settings is promising, collaboration between specialists from multiple disciplines is needed to utilize their unique project management, data modeling, technical, and clinical skills in overcoming implementation challenges.

Keywords:

SNOMED CT, Electronic documentation, Synoptic notes and algorithm.

Introduction and Background

The Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) is an emergent data standard that provides the core clinical terminology for electronic health information systems and is endorsed by the International Health Terminology Standards Development Organization (IHTSDO) [1]. In the January 2009 release, SNOMED CT contained more than 350,000 concepts with unique meanings and formal logic-based definitions organized into hierarchies. [2] SNOMED CT was identified "as the most suitable choice of terminology for 24 priority clinical information groupings (or subdomains) of the core interoperable [Electronic Health Record (EHR)]." [2] With the demands to adopt EHRs across healthcare, it is increasingly important to implement SNOMED CT enabled information systems to facilitate interoperability between systems and allow consistent, reliable and comprehensive methods of capturing clinical information.[1,3]

This paper describes the implementation challenges faced when implementing SNOMED CT and the need for collaboration and expertise across several disciplines.

Methods

The University Health Network (UHN) is a tertiary care academic health centre comprised of three teaching hospitals in Toronto, Ontario. The Health Informatics Research and Medical Informatics departments at UHN have implemented SNOMED CT in several electronic documentation projects. The usage of SNOMED CT allows UHN to capture synoptic clinical data specific and adaptable enough to meet the complex needs of clinical documentation. It also provides the foundation for system interoperability with other SNOMED CT-enabled applications; it avoids the issues associated with retrospective mapping to SNOMED CT from a locally maintained vocabulary list [4]; it allows the capture of synoptic data in line with an international standard; it allows UHN to leverage future institutional benefits of the Cross-mapping mechanism to international classifications.

Electronic Discharge Summary

In 2006, SNOMED CT was used to capture diagnoses in the electronic discharge summary. The project focused on building a tool to address known discharge summary deficiencies and improve the continuity of care, clinician communication and accuracy of patient data.

Synoptic Operative Note for Ovarian Cancer

The ovarian cancer synoptic operative note uses SNOMED CT for modeling diagnosis, finding, tumour, and surgical procedure data, as part of the requirements set out by the Canadian Partnership Against Cancer Synoptic Reporting Tools Project. The goal of the project is to establish a shared national surgical outcomes database for ovarian cancer and other disease sites via pan-Canadian collaboration. [5]

Ambulatory Documentation Application

The ambulatory documentation application uses SNOMED CT to model diagnoses, physical exams, chief complaints, findings, procedures, and diagnostic tests. The application was built to provide four surgical clinics (General Surgery, Orthopedics, Plastics and Urology) with a method to document consultation and follow-up notes, reduce transcription volumes and improve access to usable electronic data for patient care, research and organizational planning.

Challenges

Creating an implementation of SNOMED CT that could leverage the comprehensiveness and hierarchy of the clinical terminology identified four significant challenges that required consultation and collaboration with specialists across a spectrum of disciplines:

1. *Designing the graphical user interface for selecting SNOMED CT values*: The graphical user interface (GUI) had to be simple, usable and intuitive. The complex relationship structures of SNOMED CT are not inherently simple to navigate.
2. *Gathering and validating template specifications that use SNOMED CT subsets*: SNOMED CT uses its subset mechanism to group meaningful concepts together. Collecting, mapping and validating the SNOMED CT terms requires additional work.
3. *Handling SNOMED CT subsets and extensions:* SNOMED CT uses its extension mechanism to allow the creation of terminology and subsets specific to local, national, or organizational needs that are missing in the core SNOMED CT content. [6]
4. *Creating algorithms and technological infrastructure for generating fast, meaningful, non-redundant search results:* GUI's involving search functionality required an effective method of navigating SNOMED CT's hierarchies to create fast and meaningful search results in real-time.

Results

Challenge 1: Designing the graphical user interface for selecting SNOMED CT values

Clinicians worked closely with the project teams to provide the functional and data requirements which directed the GUI design. Concerns were raised regarding delays to clinical workflow and the impact to medical practice. Designing a GUI that is simple, intuitive and fast-performing was difficult given the complexity of SNOMED CT. The intended clinical usage and user base of an implementation influenced the choice of interface; a multi-disciplinary application favoured a search-based interface while an application intended for a specific disease or medical specialty favoured clinically focused sets of checkboxes customized to the most common and clinically relevant options.

Electronic Discharge Summaries

To address the needs of multiple clinical services, a simple keyword-based search was implemented to select diagnoses. All disorder SNOMED CT values were copied to a local relational database for executing the search. The challenges encountered included:

1. The project and technical team initially lacked the expertise required to extract only disorder values from SNOMED CT.
2. Three iterations of the UI were required until users were satisfied with its ease of use; the interface required users to wait while the search was executed.
3. Users were frustrated with scrolling through a repetitive list of synonyms that potentially did not contain the desired search result.

34961 discharge summaries that had a value saved for most-responsible diagnosis have been created between September 2007 and October 14th 2009. In 15431 (44%) of these cases the user was able to find and select the appropriate SNOMED CT code using the basic keyword search. In 19530 (56%) of the cases the user entered free text to describe the diagnosis. Preliminary analysis showed that 50% of free text values actually had matching SNOMED CT terms, which suggested deficiencies with the GUI.

Synoptic Operative Note for Ovarian Cancer

Disease-specific subsets of SNOMED CT concepts were used to populate standard form fields such as radio buttons and checkboxes. Disadvantages of this design include:

1. Several iterations of the design were required to determine the ideal set of SNOMED CT values
2. Any clinical scenario not modeled by subset values is captured as free text.
3. Additional resources were needed to collect and map specifications specific for ovarian cancer to SNOMED CT.

260 operative note reports were created between June 2008 and October 2009. Data was entered using form fields encoded from SNOMED CT subsets a total of 8851 times. In 8572 (97%) of these occurrences, the user was able to select a synoptic SNOMED CT code; in 279 (3%) of these occurrences, the user was forced to enter free text.

Electronic Ambulatory Documentation

For this project, an interface which combines search functionality with SNOMED CT subset values was created. Developers created a web server at UHN that applications could query to search for SNOMED CT terms and subsets. This server implemented a faster, more intelligent search algorithm and real-time calculation of related concepts. For example, if a clinician indicates that bone tenderness was during a head exam, searching for a list of anatomical site options should give precedence to bones in the head. This project is currently in a

pilot phase, and data completion rates could not yet be measured.

Challenge 2: Gathering and validating template specifications that use SNOMED CT subsets

The subset mechanism enables concepts to be grouped together for "a particular language, dialect, country, specialty, organization, user or context". [6] Existing, published subsets could not address the specificity requirements of our projects. Project analysts worked with clinicians to determine the desired template specifications and the associated mapped SNOMED CT values. For example, an analyst worked with gynecological oncologists to create lists of the procedures, diagnoses, findings and tumour locations relevant to ovarian cancer. These mappings required validation for semantic correctness by a SNOMED CT specialist.

Process Challenges

Collecting, mapping and validating the SNOMED CT terms was time-consuming and project timelines had to accommodate the additional work required. (Table 1) This process involved continual communication with clinicians to identify, refine and verify mappings.

Table 1-Summary of work to gather SNOMED CT Specifications

Project	Ovarian Cancer Operative Note	Ambulatory Documentation
# of analysts	1	5
# of subsets	38	138
# of mapped concepts	276	1254
# of work hours	50	480
# of incorrect mappings	34	65
% of incorrect mappings	12%	5%

Short forms used by clinicians were a frequent cause of incorrect ontological mapping. These short forms are meaningful to clinicians, but are ambiguous or lack specificity for others without medical experience. For example:

1. In orthopedics, the term "SLAP tear" is a short form for describing a tear to the labrum.
2. In ovarian cancer, the term "lesser sac" is a short form for describing the omental bursa. The term "left adnexa" is used to describe the left uterine adnexa, but it could also refer to the left ocular adnexa.

Challenge 3: Handling SNOMED CT subsets and extensions

Out of the 1530 concepts mapped, 211 terms were not found in the January 2009 release of SNOMED CT (Table 2). These were split primarily into two categories:

1. Terms that lacked a higher degree of detail. Example: "left femur" as opposed to solely "femur".
2. Terms that were extremely specific to a specialty or service such as "Surgical repair of facial fracture" or "Debulking of tumour for symptom relief".

SNOMED CT lacked the synonym preferred by UHN clinicians for 101 concepts. (Table 2) Examples include "ovarian cancer" instead of "cancer of the ovary", and "Abdominal ultrasound" instead of "Ultrasonography of abdomen".

Table 2-Summary of SNOMED CT mapping problems

Project	Ovarian Cancer Operative Note	Ambulatory Documentation
# of mapped concepts	276	1254
# of missing synonyms	43	58
% of missing synonyms	16%	5%
# of missing concepts	43	168
% of missing concepts	16%	13%

Supplemental codes beyond SNOMED CT can be created to capture these outliers by using the mechanisms of extension and post-coordination. Canada Health Infoway (CHI) is responsible for managing a pan-Canadian extension and submitting new concepts to be evaluated and incorporated into the SNOMED CT core content. This process results in a delay for new SNOMED CT concepts to be approved and included in future releases. For project timelines it was essential to implement a form of local extension mechanism and to not be dependent on the approval process. Designing a local mechanism required the following considerations:

1. The vocabulary specialist was required to validate against adding semantically incorrect, ambiguous or poorly defined synonyms and concepts to the extension.
2. Local extension data had to be represented in a format that could be searched using the same mechanism for core content, and later mapped back to assigned ID's in the pan-Canadian extension and core dataset.
3. A liaison must be appointed to work with standards bodies and working groups, to manage submissions for new content and extension requests.

Challenge 4: Creating algorithms and technological infrastructure for generating fast, meaningful, non-redundant search results

SNOMED CT provides sets of pre-generated indexes to improve the speed of searches. Much like the index in the back of a book, indexes provide shortcuts to the desired SNOMED CT concept. The indexing mechanisms provided with SNOMED CT were implemented, but still yielded unwieldy search results. A keyword-based search for "Pain" returns 3790 results in the January 2009 release. Of the 1280 terms that are current and in a clinician-readable format, 465 are situations, procedures or therapies and are not semantically compatible to be selected as a "symptom". The remaining 815 terms require additional refinement to present an appropriate list of search results. Development of search algorithms with the following capabilities was required:

- Terms relevant to a specialty and more frequently used would appear higher in the search results.
- Unnecessary synonyms would be hidden.
- A search could be limited to terms that fall under a certain classification.
- The above search capabilities would also apply to concepts and relationships from the local extension
- Search capabilities had to be fast and efficient.

Search Algorithms

A technical specialist with experience in numerical methods and algorithm analysis was required to design a search algorithm that could perform well in a multi-user environment.

To search a specific classification the algorithms must traverse SNOMED CT's structures to locate concepts that are linked by 1 or more "is a" relationships. The "is a" relationship defines a concept's ontology relative to its parent concepts. For example, liposuction is a "cosmetic surgery (procedure)", and cosmetic surgery is a "surgical procedure". Therefore, a searching algorithm can start at the concept for "surgical procedure" recursively query all its child concepts and its child concepts' children. Benchmarks showed that this approach was too slow.

To address searching performance all possible inferred relationships were pre-generated. The collection of these relationships is called the *transitive closure*. Figure 1b illustrates the additional relationships that would be stored in addition to the relationships in Figure 1a.

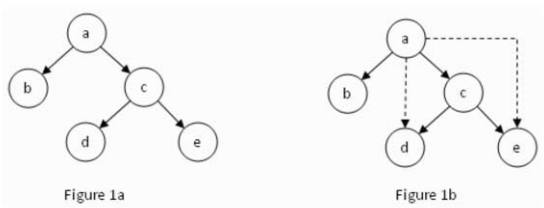

Figure 1 – Transitive Closure Illustration

Several attempts were required to successfully generate the transitive closure. The number of "is a" relationships ballooned to over 5,000,000. Further benchmarking demonstrated that the search response time using transitive closure remained constant no matter the number of child concepts.

IT Infrastructure

Search performance on the terminology server depends on factors such as network traffic and server load. IT specialists were consulted to optimize the performance of the terminology server using load balancing and database optimization.

Considerations

Further analysis and evaluation of the evolution of an ideal process for implementing SNOMED CT is necessary. Additional usability testing and analysis of data completion would assist in identifying the ideal GUI for SNOMED CT integration. Search algorithms can be improved with the help of computer experts. Institutional hardware and budgetary constraints must always be considered. The Electronic Ambulatory Documentation project requires further analysis to determine the effectiveness of the intelligent search algorithms.

Few studies have analyzed the impact that SNOMED CT changes have on clinical applications already in use or those undergoing implementation. [7] Challenges remain when integrating SNOMED CT standards into existing clinical information systems and the continued use of these standards in future EHR systems.[8]

Conclusion

SNOMED CT's comprehensiveness and tree-based data structures created a variety of implementation and resource challenges. Specialists from multiple disciplines had to be consulted for their specific project management, data modeling, technical, or clinical skills. The implementation process evolved and identified the need for several roles and skills. Table 3 identifies the roles and skill sets that were used for SNOMED CT integration across the three projects.

Table 3-Roles and skills required for SNOMED CT Integration

Role	Skills
Clinicians	• Clinical Knowledge for application design • Evaluate effectiveness and clinical value of application
Project Management	• Manage collaboration between disciplines • Facilitate communication between standards organizations • Evaluate clinical requirements, gather specifications and map terms to SNOMED CT codes
SNOMED CT data vocabulary	• Validate SNOMED CT code mapping • SNOMED CT data modeling experience for validating extension data • Train project team in SNOMED CT
Usability	• Usability testing • GUI design
Computer Science	• Improve and evaluate performance of search algorithms and data structures
Information technology	• Load balancing of servers • Database optimization

Figure 2 demonstrates the knowledge transfer required between the various roles involved.

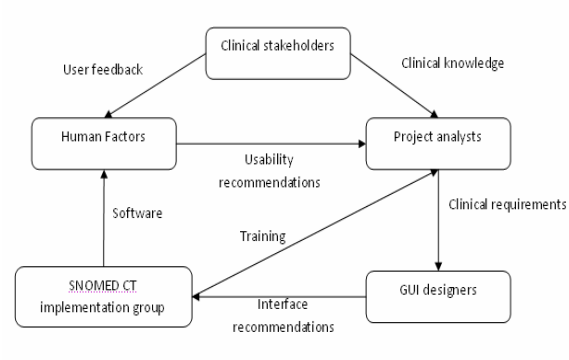

Figure 2 - Knowledge transfer between roles

Through the challenges presented in these various projects, an implementation process was established that helped our teams create working implementations of clinical documentation software that used SNOMED CT to encode data:

1. Project analysts worked with clinicians to obtain requirements for content, synoptic terms, and application workflow.
2. Project analysts and GUI designers collaborated to evaluate clinical requirements and design the appropriate interface.
3. The SNOMED CT implementation group developed the technical implementation and worked with project analysts to map values to SNOMED CT concepts.
4. When available, human factors engineers evaluated application usability at the Centre for Global eHealth Innovation in Toronto. Feedback was evaluated, and incorporated into the application design.

With additional future collaboration, experiences from other SNOMED CT implementations will only improve this process further.

Acknowledgments

Thank you to Lindsay Beckstead, Yuri Belan, Dr. Peter Bray, Raymond Chow, John Christensen, Dr. Michael Jewett, Dr. Alan Okrainec, Chris Rampaul, and Vicky Ramirez for all of your hard work and dedication on the ambulatory documentation project. We would also like to thank Dr. Barry Rosen, CPAC SRTP team, and the Princess Margaret Hospital Foundation for their support in the Ovarian Cancer Synoptic Operative Note. Jeffrey Liu thank you for the insightful algorithm discussions.

Semantic Reasoning with XML-based Biomedical Information Models

Martin J. O'Connor, Amar Das

Stanford Center for Biomedical Informatics Research, Stanford University, Stanford, CA USA

Abstract

The Extensible Markup Language (XML) is increasingly being used for biomedical data exchange. The parallel growth in the use of ontologies in biomedicine presents opportunities for combining the two technologies to leverage the semantic reasoning services provided by ontology-based tools. There are currently no standardized approaches for taking XML-encoded biomedical information models and representing and reasoning with them using ontologies. To address this shortcoming, we have developed a workflow and a suite of tools for transforming XML-based information models into domain ontologies encoded using OWL. In this study, we applied semantics reasoning methods to these ontologies to automatically generate domain-level inferences. We successfully used these methods to develop semantic reasoning methods for information models in the HIV and radiological image domains.

Keywords:

Knowledge bases, Medical informatics applications

Introduction

The Extensible Markup Language (XML) has recently become an important technology in many medical domains, driven primarily by the desire for greater interoperability between biomedical software applications [1]. XML is used extensively to define *information models* that describe the structure and content of biomedical data that can be exchanged between applications. The general approach is to define the structure and content of an information model using XML Schema [2] and to publish this model to enable the production, consumption and validation of XML documents that conform to the model. Some organizations are working to define standard information models for particular domains [3]. For example, the Annotation and Image Markup (AIM) Project of the U.S. National Cancer Institute's cancer Biomedical Informatics Grid has defined an information model to describe annotations on radiological images [4]. Many custom models are produced for particular biomedical systems to support downloading or uploading of application data. Irrespective of their origin, these information models have become invaluable tools for dealing with the high degree of heterogeneity that is typical in biomedical data.

As useful as they have become, data in XML-based information models are not typically in a form that is directly suitable for reasoning. When dealing with these models, system developers must develop custom software to import model content and map it to internal application formats, where it can then be manipulated. This process is labor-intensive and time-consuming and is usually heavily customized to both the source information model and the final reasoning tasks. There is a pressing need for more principled methodologies to automate these processes. Ontologies provide a means of tackling this informatics challenge. The low-level information defined by information models can be significantly enhanced by transforming the data to domain-level content described using ontologies. Automated reasoning tasks can then be applied to the resulting domain-level information. These tasks can include classification, verification, temporal and spatial reasoning, and the generation of high-level domain abstractions that can be used directly by system users. This approach to reasoning with information model data provides an opportunity to leverage the reasoning mechanisms provided by ontology-based tools and to exploit the increasing use of ontologies in biomedicine.

Background

The Web Ontology Language (OWL; [6]) is increasingly being used in biomedical applications. Although OWL and XML share similar content storage goals, OWL provides much more powerful features both for representing semantic information about content and for reasoning with it. In combination with the OWL-based Semantic Web Rule Language (SWRL; [7]), OWL provides facilities for developing very powerful reasoning services. Many XML information models in biomedicine use standardized terms defined using ontologies. For example, the AIM information model supports the use of RadLex terms [5] when describing the anatomic structures in image observations. In general, however, beyond the use of these term references, there is no direct interoperation path between the data in XML-described information models and OWL ontologies. Hence, before reasoning services can be developed, this mapping challenge must be addressed

A variety of XML Schema to OWL mapping tools have been developed [14-15]. These tools typically provide custom mapping languages in combination with graphical user interfaces to allow users to produce OWL equivalents of XML Schema-described documents. The mappings supported by these tools

are generally low level and structural. Most could support the steps required to transform XML-described biomedical information models to their OWL equivalent. However, the more complex transformations needed to generate domain ontologies are beyond the capabilities of these tools. In biomedicine, the temporal components of these mappings can be particularly complex. An array of layered knowledge transformations are often required before the information is directly suitable for reasoning. These transformations usually demand custom solutions. The different approaches currently used to address these tasks can produce a disconnected, fragmented workflow. Integrating the various tools and methods that perform information model mapping, domain model generation, and the final reason tasks could help produce a streamlined end-to-end process that lowers the overall development effort.

A suite of tools to provide this workflow must support: (1) mapping information models to their ontolgical equivalents; (2) mapping these data to domain ontologies; and (3) developing standardized reasoning approaches for processing the resulting information. In this paper, we describe the development of such a set of tools. We outline a workflow that uses these tools to transform XML-based information models into domain ontologies encoded using OWL and then perform a variety of reasoning services on this domain knowledge. We show how we have applied these techniques to perform semantic reasoning with data contained in XML information models in the HIV and radiological image domains.

Methods

Our approach to transforming an XML-based information model to an OWL domain ontology comprises three tasks: (1) produce an OWL equivalent of an XML-based information model, (2) transform its content into instances in an OWL domain ontology, and (3) define and implement domain-level reasoning tasks that use the domain ontology. The goal is to produce an automated process that takes XML-encoded information model documents, transforms them to instances in an OWL domain ontology, and to then perform semantic reasoning with these domain-level instances.

Transforming an XML Information Model to OWL

This step requires development of an OWL ontology to represent the information in the original XML information model. The goal is to transform the XML Schema-described information model into an ontological representation that defines a semantically equivalent information model. This model must represent all the concepts in the original XML model. This transformation is performed by creating classes and properties in the OWL information model that correspond to respective components in the source information model.

We developed a tool called XMLMaster to define these transformations. XMLMaster was written as a plugin to the popular Protégé-OWL ontology development environment [8] and provides a graphical user interface that allows users to interactively define mappings between entities in an XML document and concepts in an OWL ontology. It can be used to define mappings between an XML model and an existing OWL ontology, or it can generate a new OWL ontology as the target of these mappings. We used this latter mode to create an OWL information model that corresponds to a source XML-encoded information model. These mappings were stored by XMLMaster in a mapping ontology. They contain a specification of how entities can be mapped from an XML document to instances in an OWL ontology. We then used an associated tool called XMLMapper to take the mappings and to automatically transform XML documents to OWL ontologies. As part of a workflow, XMLMapper can be used to process streams of XML documents and populate an OWL knowledge base with the resulting transformed content.

Most XML-based information models are designed to be somewhat human readable, so generally the transformations are not structurally complex. In many cases, the structure of the information model in OWL will be similar to the structure of the XML information model. However, specialized transformations are often required to deal with references to external terminologies. Such references to terms in controlled terminologies are common in biomedical information models. The mapping process must maintain these links if possible. XMLMaster supports links to these external terminologies if they are encoded using RDF or OWL. It currently does not support automatic references to terms defined to non OWL or RDF ontologies. In these cases, the original term identifiers are simply mapped unchanged, with additional annotations describing the source terminology.

Transforming an OWL Information Model to a Domain Ontology

An information model does not generally represent data in a form that is directly suitable for use in the complex reasoning typical in biomedicine. The second mapping step is generally required to transform instances in the OWL information model to instances in a specialized domain model. Domain-level reasoning tasks can then be defined using this representation. This second stage is typically far more complex than the primarily structural initial mapping process. It often requires in-depth domain knowledge and its requirements for data transformation are far more demanding. Depending on the complexity of the domain ontology, this process may require several mapping layers that operate at successively higher levels of abstraction. While several OWL-based mapping tools are available, they generally do not offer the flexibility to easily capture the full array of possible transformations required.

Instead of using one of these tools, we used OWL and its associated rule language SWRL [7] to define the mappings. SWRL provides particularly strong support for this type of knowledge transformation. Its tight integration with OWL allows it to be used to define knowledge-level mapping rules that are fully aware of OWL's complex semantics. Moreover, most OWL classifiers support SWRL, so they can be used to semantically validate these mapping rules. Once defined, the rules can be stored in an OWL ontology and later executed to transform information model instances to domain ontology instances as part of a mapping workflow.

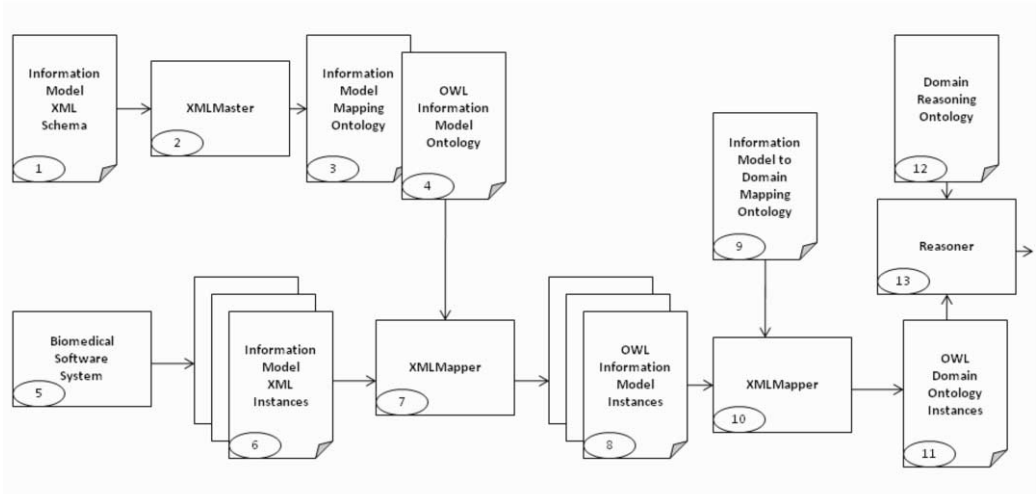

Figure 1-Outline of workflow to take XML-encoded information model instances and transform them to an OWL domain ontology and perform reasoning with them.

Reasoning Ontology and Querying

Once an XML information model is transformed to an OWL domain ontology, users can develop knowledge-level ontology-based reasoning mechanisms to work with their content. A wide array of possible reasoning tasks can then be defined. Common tasks in biomedicine include classification, and spatial and temporal reasoning. Temporal reasoning tasks are particularly central to many biomedical applications. OWL itself provides strong support for classification. It has relatively weak support for temporal and spatial reasoning, however. Fortunately, SWRL provides basic support for spatial reasoning using its core language operators. Crucially, it provides a mechanism to define custom libraries for specific types of reasoning processes. We used this extension mechanism to develop a temporal reasoning library [12].

In some cases, not all reasoning can be carried out using OWL and SWRL, and custom application methods are required. To support the necessary extraction of content from domain ontologies, we used SQWRL, a language that we developed [9]. SQWRL (Semantic Query-Enhanced Web Rule Language) is a SWRL-based query language that can be used to query OWL ontologies. SQWRL supports queries that extract information from ontologies at the knowledge level, and thus minimize the amount of custom application logic required to process this ontology-encoded information.

Defining an Automated Workflow

We defined a workflow to take an XML-based information model and perform domain-level OWL and SWRL-based reasoning with the information in the model. The numbered steps in Figure 1 outline the sequence of steps in this workflow.

We first took an XML Schema-described information model (1), and used the XMLMaster tool (2) to define mappings to an equivalent OWL information model. The XMLMaster tool also produced a mapping ontology (3) that defined how XML documents are transformed into instances of the OWL information model (4). We then produced data (5), which are encoded as document instances of the XML information model (6). These documents were fed through XMLMapper (7), which used the mapping ontology defined by XMLMaster to produce OWL information model instances (8). A separate SWRL-based mapping ontology defined how these instances were mapped to a domain ontology (9) and were used by XMLMapper to transform the instances (10) to domain ontology instances (11). Finally, a domain-level OWL reasoning ontology (12) was applied to these domain instances to reason with them (13).

Once defined, this process can establish a completely automated workflow that takes a stream of XML-encoded information model instances, transforms them to OWL, and reasons with them to generate domain-level inferences.

Results

We used our methodology to generate automated workflows for two applications: (1) reasoning with radiological image annotations for tumor assessment; and (2) discovery of associations between gene mutations, drug regimens, and outcomes in HIV anti-retroviral therapy.

Reasoning with Image Annotations

The AIM Project [4] recently developed an information model that describes the semantic contents of radiological images. AIM defines an XML-encoded information model that describes anatomic structures and visual observations in the images. Information about image annotations is recorded in its information model, with the goal of enabling the consistent representation, storage, and transfer of the semantic meaning of imaging features. A variety of tools are being developed to produce image annotations in AIM format.

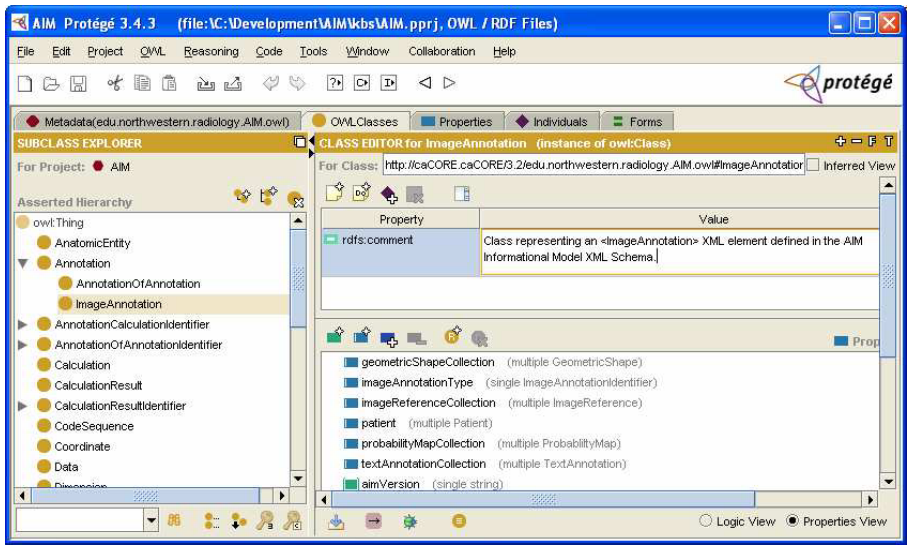

Figure 2-Screen shot of Protégé-OWL tool showing part of AIM information model encoded in OWL.

Our reasoning task employed three types of reasoning subtasks: classification, spatial reasoning, and temporal reasoning. It concentrated on classification of image findings as measurable and non-measurable using a combination of semantic information about the location and type of finding and its calculated length. These reasoning tasks were encoded using OWL and SWRL. Rules for this subtask included: classification of findings as pathologic or non-pathologic based on the imaging observation in the image annotation; temporal classification lesions as baseline or follow-up based on their temporal relationship to the start of therapy; and classification of image findings on baseline images as measurable or non-measurable based on the length of the observed mass or nodule.

We evaluated our system by defining a process to reason about cancer lesions for estimating tumor burden [11]. We used 116 AIM XML annotated images from 10 cancer patients who had serial imaging studies. Lesions in the original images were annotated in AIM format. We successfully defined a process to map image annotations encoded using AIM into OWL (Figure 2) and to reason with the resulting annotations. The image annotations were processed by our system to perform automated reasoning about the image findings.

The inferences from our system were reviewed by an oncologist, who confirmed that they were valid based on his analysis of the image annotation information encoded as instances of the AIM XML information model. In qualitative terms, the oncologist believed that our automated workflow can help streamline the process of evaluating tumor burden.

Outcome Reasoning for HIV Antiretroviral Therapy

Associations between gene mutations, drug regimens, and therapy outcomes is central in HIV therapy. In HIV research, for example, a mutation on the viral genome may be associated retrospectively to past administration of a specific drug or prospectively to the occurrence of poor clinical outcome with one or more drugs. Establishing such temporal associations may help scientists understand how certain mutations in the genome reduce drug efficacy, and can they help healthcare providers design treatment strategies.

To study drug resistance in the context of clinical care, researchers at Stanford University have developed a research system called the Stanford HIV Drug Resistance Database (HIVdb) [10]. This database contains time-stamped data on drug regimens, HIV reverse transcriptase (RT) and protease sequences, and HIV viral load collected at local clinics. Some of this information is downloadable as XML-encoded information model instances from the HIVdb website. An XML Schema for this information model has been published by the developers of HIVdb [13]. This information model describes individual patient therapies—which are termed *treatment change episodes* (TCEs)—and lists the drugs in the therapy, together with each patient's viral load response and mutation information treatment. By using information encoded in TCEs, the website can suggest ranges of suitable drug therapies.

Reasoning with TCEs requires strong temporal reasoning support. As mentioned, we have developed a temporal reasoning library for use with SWRL [12]. We used it to develop domain reasoning tasks defined in terms of these TCEs. These tasks encode several drug resistance interpretation algorithms for predicting the value of genotypic resistance test interpretation algorithms that have been described in the literature [10]. Subtasks of the reasoning task include examining patient treatment histories for particular treatment combinations, viral load patterns, and genotypic test results.

Using the HIVdb XML Schema, we defined an OWL equivalent of the information model it describes. We mapped the

information model to a domain ontology modeling TCEs and then developed a temporal reasoning module to reasoning with the resulting OWL instances. The reasoning mechanisms use OWL and SWRL, and produce high-level abstractions of patient outcomes based on a temporal analysis of their viral loads. This information can then be used for further analysis. The ultimate goal is to replicate a large subset of the therapeutic suggestion functionality of the HIVdb site. We successfully defined an automated workflow that took XML instances of the TCE information model and generated an intermediate analysis of patient outcomes.

Discussion

The increasing use of XML information models in biomedicine provides an opportunity to develop methods to automatically reasoning with the content of these models. However, XML-based information models do not typically represent information in a form that is directly suitable for reasoning—they provide a standardized interchange and storage format only. Elevating the information content from this primarily structural level to the domain level is a prerequisite to performing semantic reasoning. Using a suite of open source Semantic Web tools, we show how we have developed an approach to perform this transformation and to carry out OWL-based reasoning on information encoded in XML-based information models. We show how semantics reasoning methods were applied to these ontologies to generate domain-level inferences. Our approach establishes an automated workflow, taking XML-based information models, transforming them to an OWL domain ontology, and reasoning with the resulting information to generate inferences necessary for the domain task. We applied this workflow to perform semantic reasoning with data contained in information models in the HIV and radiological image domains.

Our approach can be used to take any XML-based information model, generate its OWL equivalent, and then reason over it to produce high-level abstractions. This approach maintains all knowledge of these transformations in OWL mapping ontologies. As a result, these mappings can be maintained at the knowledge level using standard OWL tools. Modifications to the mappings to cater for changes or extensions to the information model or domain ontologies can also be carried out using these tools. We believe that this approach provides a flexible, expandable, and robust mechanism for defining the information transformations necessary to support semantic reasoning on a large variety of biomedical data.

Characterizing Consumer Health Terminology in the Breast Cancer Field

Radja Messai[a,b], Michel Simonet[a], Nathalie Bricon-Souf[b], Mireille Mousseau[c]

Abstract

Despite the large availability of medical information on the Internet, health consumers still encounter problems to find, interpret and understand this information. These problems are mainly due to their lack in medical knowledge and the difference between their language and the language of health professionals. In order to propose information retrieval services more adapted to health consumers language and knowledge, we have developed techniques to collect, identify and analyze the terms and the expressions used by lay persons to talk about breast cancer. The study of health consumers' language is a relatively recent research field. Many studies have been conducted to analyze and characterize the vocabulary used by health consumers to talk about medical subjects in English. We have conducted the same study for the French language in the breast cancer field. We have gathered a corpus of texts to identify terms and expressions used by health consumers who talk about breast cancer in French. The terms have been organized in a concept-based terminology. This terminology has been analyzed on several levels: concept level, term level, term-concept level and finally relation level.

Keywords:

Consumer health terminology, Natural language processing, Breast cancer.

Introduction

A person when she/he is faced with a health problem needs to understand her/his illness, its diagnosis and the different treatment options that she/he is liable to follow. The doctor still remains the more natural way to find such information. However, more and more people are turning to different resources on health information.

A Eurobarometer survey published in 2003 [1] showed that the main source of health information used by European citizens is health professionals (pharmacists, doctors, etc.) 45.3%, followed by television 19.8%, books and medical encyclopaedia 7.7%. Internet is less widely used with 3.5%.

The survey also showed that only a small proportion (23.1%) of people in the EU use the Internet to find health information. Nevertheless, 41.5% of the people within the EU think that the Internet is a good way to get health information.

The Internet has become a popular way to access up-to-date information, and more and more people are turning to it to find information about health. However, technical, cultural and linguistic barriers are numerous when using Internet sites since most health-related information is available in English and uses specialized medical terminology [2-4].

A patient-oriented terminology aims at gathering the different ways lay people express themselves and talk about health topics, and linking them to the medical jargon used by health professionals. Using such a terminology will help bridging the communication gap between the two communities [5].

A terminology reflecting the patients' common language is the first phase of an ambitious project aiming at helping patients to better understand and master their health situation. We have worked on a common terminology in the field of breast cancer. This particular domain has been chosen because of its interest for the citizens and also as a testing ground for a methodology which could be extended both to other health domains and to other languages.

Although it has been long recognized that health consumers talk about and interpret differently medical concepts than health professionals, little efforts have been done to effectively build terminologies to bridge the gap between the two communities. These terminologies gather the terms used by health consumers to talk about their condition, and link them to the underlying medical terms and concepts.

An open source and collaborative development of a consumer health vocabulary has been initiated by the Harvard Medical School (HMS) and the National Library of Medicine in the USA [6]. Their aim is to develop an open source Consumer Health Vocabulary (CHV) by identifying consumer friendly names of medical concepts, correctly map them to UMLS (Unified Medical Language System) the reference terminology in the health domain, and create consumer health-specific concepts and relations. They have gathered 12 millions query log data and then performed automated term mapping and statistical analysis to select candidate terms for manual review. A web-based tool for collaborative review has also been devel-

oped. They have exhibited 90 000 concepts over the whole health domain in their consumer text corpus. The development of the CHV is still in progress.

In France, a team in the Rouen University Hospital has initiated the CISMeF project (acronym for Catalog and Index of French Language Health Resources on the Internet)[1] in February 1995. Its main objective is to catalog and index the most important and quality-controlled sources of institutional health information in French. For this purpose, CISMeF uses: the MeSH thesaurus (the National Library of Medicine's controlled vocabulary thesaurus) and several metadata element sets, including the Dublin Core (a metadata standard). In December 2007, the number of indexed resources totalled over 41 300 with a mean of 80 new resources each week.

CISMeF-patient is the French counterpart to MEDLINEplus [7]. It is a dedicated Website for patients, their families, and the general public. CISMeF-patient has been under development since 1997. CISMeF-patient has been created as a response to a growing need for consumer health information and to extend the awareness of quality health information resources available on the Internet. It uses the MeSH thesaurus end metadata to index web sites. The team has included many health consumer terms into the MeSH in order to facilitate health information seeking for non-professionals.

Materials and Methods

In this section, we describe the materials and the methodology used to develop the breast cancer terminology. This work is based on the experience of Tony Tse with the difference that T. Tse has worked on the whole health domain and for the English language [8].

Building a breast cancer terminology from a corpora of texts

A terminology is the set of words and expressions used to designate the concepts of a domain. A breast cancer terminology for lay people is made of the terms (i.e., words and expressions) that patients use to speak about breast cancer and also the terms they are liable to meet in their medical files or in the breast cancer literature. Therefore, a breast cancer terminology for lay people should contain terms specific to the patients' language, such as *breast pain* for *mastodynia*, but also medical terms such as *pyrexia*, which they are faced with.

Terms which are considered as synonyms are grouped into concepts. The concepts themselves are structured through different relationships. For example: *"Chemotherapy"* Is-A *"Breast cancer treatment"*. We have collected the terms from two types of corpus of texts: a mediator corpus and a health consumer corpus. Tony Tse calls "mediator corpus" a set of texts written by health information mediators (i.e., persons whose intent is to inform or influence the lay public about various medical topics, products, and services) and "health consumer corpus" texts written by participants in Web-based health discussion forums [8].

[1] http://www.cismef.org

The mediator corpus has been built manually by selecting 575 documents issued from the answers of the search engine "Google" to the query "breast cancer". The selection has been done according to several criteria: domain representativeness, targeted public, page author, complexity of the used language. The consumer corpus has been built automatically by the extraction of 9 843 users' messages on two Web-based breast cancer discussion forums: The French League against Cancer and Essentielles.net.

We have used statistical methods to extract n-grams (a n-gram is a sequence of n consecutive words) from our corpora. We have obtained 6 896 candidate terms from the mediator corpus and 11 723 candidate terms form the consumer corpus.

The analysis of the list of candidate terms has been done manually with the help of a concondancer, a tool which helps visualizing each expression in its context [9]. It allows the user to look for terms in the corpus by using regular expressions and it produces concordances, (i.e., lists of occurrences of a term in a source text, surrounded by an appropriate portion of its original context). We have also studied the structure of web pages to identify the important concepts of the domain and to get a first hierarchy of concepts. The building of the terminology has been done progressively by studying every term and creating the appropriate concepts and relations every time it is needed.

The Protégé ontology editing tool has been used to represent the terminology in several standard languages including the W3C languages RDF(s) and OWL. By doing so, the terminology becomes usable by computer applications.

- We have tried to map the concepts of this terminology to those of UMLS and CHV. The connection between these terminologies has been done manually by using the UMLS identifiers, which are attached to the concepts in both terminologies (UMLS and CHV). Only the case of exact matches has been retained. We have obtained 83% of exact matching, 3% of partial correspondence and 14% of no correspondence.

Terminology analysis

The terminology has been analyzed on several levels:

- Term level;
- Concept level;
- Term-concept level;
- Relation level.

The objective of this analysis is to better understand the way lay persons talk about concepts and notions in the breast cancer field and structure them. Recent studies have shown significant differences between the professional and lay languages. However, these studies were conducted on the entire health domain and for the English language [8,10]. The produced terminology will be the core of an Information Retrieval system.

Term analysis

Many studies have used the length of the terms as an indicator of their complexity in order to evaluate the readability of documents [10-12]. We have compared the length of the terms coming from the two types of corpus. The results are shown in Table 1.

Table 1- Length of terms

	Health consumers	Mediators
Mean characters/term	21,5	22,8
Mean words/term	3.1	3

This comparison does not show significant differences between lay terms and mediators terms. The length of terms in this context is not an indicator of their complexity.

Concept analysis

The mapping of the breast cancer terminology to UMLS terms has revealed many interesting situations:

- Five concepts have multiple correspondences in UMLS. For example: *Cancer de l'ovaire* can be mapped to *Ovarian carcinoma* or *Malignant neoplasm of ovary.*
- Two pairs of concepts have a unique correspondence in UMLS. The concepts *Mammography* and *Mammogram* are mapped to the concept *Mammography* in UMLS. The same thing is observed for the concepts *Primipare (primipare)* and *Primiparité (primiparity)* and the concept *Primiparity.*

These cases show problems in the UMLS conceptualization. For example, *mammography* and *mammogram* designate two different concepts: a type of x-ray imaging used to create detailed images of the breast for the first, and an x-ray picture of the breast for the second.

Terms-Concepts analysis

Expressive variability of concepts: For each concept, we have calculated the expressive variability (number of terms which designate the concept) [13]. The objective of this step is to learn about the types of concepts with a high expressive variability. The mean of the expressive variability in the terminology is 2.16 terms. Most concepts are designated by one term (Figure 1).

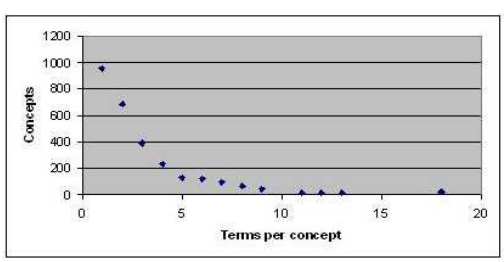

Figure 1- Terms distribution per concept

The study of the concepts with an expressive variability higher than 5 has shown that these concepts concerns medical concepts that we encounter in everyday life and which correspond to complex medical terms. Lay persons tend to describe concepts, which lead to a big production of terms. However, concepts with an expressive variability lower than 5 are of two types: either very well-known concepts like names of common organs (liver, lung, etc.) or highly technical terms like: tamoxifene.

Overlapping between health consumers and mediators terminology: We have compared the sets of terms coming from the two types of corpus (health consumers and mediators) in two steps:

1. Conceptual overlapping: identify the concepts common to both terminologies and the concepts specifics to each of them.
2. Terminological overlapping: for the common concepts, identify the terms common to both terminologies.

The Table 2 shows the results of this comparison.

Table 2- Overlapping between the two terminologies

	Common	Health consumers	mediators
Concepts	1 254	8	25
Terms	2 238	289	182

Relation analysis

Health consumers, in addition to their terminological problem, have often difficulties to understand how medical concepts are related. Among the defined relations in the terminology we have used the relation *Relation_X* to link two concepts without specifying the relation. This type of relation is used to define links between concepts that health consumers link without a medical argument. For example, the concept *contraceptive pill* is linked to the concept *breast cancer* because some health consumers believe that it is the case, although it is not scientifically established. *Relation_X* is also used to link the concepts which are not well understood by health consumers. For example, the concept *Vagina disorders* and the concept *Vaginitis* are linked by both relations *Is-A* and *Relation_X.* Most of health consumers believe that *vagnitis* embraces all the *vagina disorders*; however *vaginitis* represents only the inflammation of the woman's vagina. The use of this type of relation for representing this kind of phenomena preserves the "good" structure of the terminology.

Results

In the resulting breast cancer terminology, we have 1 287 concepts, designated by 2 783 terms in French. We have defined a set of 61 relations in addition to the classical Is-A and Part-Of relations to structure the concepts of the terminology.

Discussion and Conclusion

This work has shown some differences that exist between professional and health consumer terminologies. We have observed that the main differences are not at the concept level but at the term level. However, the current ontology representation languages do not offer the possibility to annotate a term by its "technical" level (lay or professional). An interesting alternative is offered by SKOS[2] which provides metadata to indicate the language of a term (i.e., lay or professional).

The bilingual terminology which has been built for breast cancer is the basis of future extensions to other health fields and other languages. The first considered application will be concept-based information retrieval, which will enable people to ask questions by using their everyday words and retrieve results in any language.

Such work is important for both patients and doctors because through a better understanding of her/his medical situation a patient will be able to better collaborate with the doctor, provide him more pertinent information on her/his situation and become a fully responsible partner in the decisions about her/his treatment. Informed Patients require less time for doctor explanations, and may be more likely to comply with doctors' instructions and to adopt a healthy lifestyle [14].

Exploring Relations among Semantic Groups: A Comparison of Concept Co-occurrence in Biomedical Sources

Sasikiran Kandula, Qing Zeng-Treitler

Department of Biomedical Informatics, University of Utah, Salt Lake City, UT

Abstract

It has been observed and reported that the patient's mental model of the medical domain is different from that of a health professional and this difference is one of the primary obstacle in the effective communication of health information to patients. In this study, to better understand these mental models, we explored the relations among different semantic groups of concepts in consumer- and professional-generated health content by analyzing concept co-occurrence information in three biomedical sources. We found significant differences in the prevalence of the semantic groups and the strength of co-occurrences between semantic groups in the three sources. The co-occurrence defined by consumers differs from that defined by professionals. The two professional sources have noticeable differences with each other as well. We believe that addressing these differences can help us generate more informative and consumer-friendly health content as well as develop better consumer health informatics applications.

Keywords:

Mental models, Concept co-occurrence, UMLS semantic groups

Introduction

The past decade has seen an exponential increase in the development of health content and informatics applications for consumers. From web sites to search engines to decision support tools to personal health records, a common theme of the applications is to provide consumers with useful information and help them utilize the information to improve their health outcome. However, many obstacles remain: for example, it is recognized that most health information that is accessible to patients in the US is too hard to understand [1, 2]. While millions of consumer search for health information online, their queries are not always efficient or effective [3-5].

To improve consumer health content and applications, prior research has suggested that we need to understand the gap between lay consumers' and healthcare professionals' mental models [5-8]. A better understanding of the lay consumer mental models could help us anticipate consumers' information needs, organize the content being presented to consumers, explain concepts to consumers in a question-answer system or through the process of text simplification, and to provide decision support at the point of need. A related study we have been involved with is the development of a consumer health vocabulary that suggests consumer-friendly synonyms for difficult medical terms [9, 10].

In this study, we examine the differences between a layperson's and a professional's mental models through the use of co-occurrence information. We believe that the co-occurrence of two terms or concepts in a textual artifact indicates the belief of the creator of the artifact that these are related though the exact relation may not be known and by analyzing co-occurrence information we can understand the mental models of the content creators. Here we use the term *artifact* quite broadly to include a wide range of health content types such as consumer health education articles, medical records or a series of terms queried on a search engine.

In the following sections, we analyze and compare the co-occurrence information in three (two professional-generated and one consumer-generated) biomedical sources – a repository of clinical reports, a collection of biomedical journal citations and a log of search queries to a health information website.

Since the number of terms/concepts in these sources is quite large, studying co-occurrence data at the concept-level is too complex and may not be useful. Hence, we use a mechanism to group the concepts into broader categories and analyze co-occurrence information at the group level. This is done in two phases. First, we map the concepts to semantic types defined by Unified Medical Language System's (UMLS®) Semantic Network. UMLS' semantic network defines a set of subject categories, or semantic types that can be used to consistently categorize the more than million concepts defined by UMLS Metathesaurus® [11]. This aggregates all concepts in the three sources to a more manageable 135 categories.

Second, we partition the semantic types into 15 semantic groups using a partitioning scheme proposed by Bodenreider and McCray [12]. This scheme adequately adheres to partitioning principles such as semantic validity (the groups must be semantically coherent), completeness (the groups must cover the whole concept domain) and exclusivity (a concept must belong to a single group). Table 1 has a partial list of semantic groups and examples of semantic types in each group[1]. We refer to the semantic group of the semantic type to which a concept maps as the concept's semantic group

[1] A complete listing is available elsewhere [12]

and the exclusivity principle of partitioning ensures that a concept's semantic group is unique.

By analyzing this co-occurrence information at the semantic group level, we try to understand: a) the differences in prevalence of semantic groups in the three sources; b) the difference in mental model of a health consumer from that of a professional; c) the difference in professional-generated co-occurrence with change in the context of communication.

Table 1 - Common semantic groups and associated semantic types

Semantic Group	Semantic Type (TUI[2])
Concepts & Ideas	Quantitative Concept (T081); Functional Concept (T169); Qualitative Concept (T080); Temporal Concept (T079)
Disorder	Disease or Syndrome (T047); Finding (T033); Sign or Symptom (T184); Injury or Poisoning (T037)
Anatomy	Body part, Organ or Organ Component (T023); Body Location or region (T029); Body Space or Junction (T030)
Chemicals/ Drugs	Organic Chemical (T109); Clinical Drug (T200); Pharmacologic Substance (T121); Amino acid, peptide or protein (T116)
Procedures	Therapeutic or Preventive Procedure (T061); Laboratory Procedure (T059)

Materials and Methods

Data Collection

As mentioned in the previous section, we use concept-level co-occurrence information from two sources of professional-generated health content and one source of consumer-generated health content. The sources and definitions of co-occurrence in these sources are described below. Using these concept-level co-occurrence frequencies, we compute co-occurrence frequencies between semantic groups.

Research Patient Data Repository (RPDR)

This is a centralized repository of physician generated electronic medical reports such as discharge summaries and outpatient notes from several clinics and hospitals in the Partners HealthCare system [13]. Though the number of reports available through RPDR is quite large we used a subset of 5500 discharge summaries and mapped the reports' text to UMLS concepts[3]. The co-occurrence frequency of a pair of concepts is defined as the number of reports in which the two concepts occur in the same section of the report.

UMLS Co-occurrence (MRCOC)

The *mrcoc* table is distributed as part of the UMLS Metathesaurus and contains the co-occurrence frequencies of keywords in MEDLINE citations [15]. As MEDLINE is considered to be a comprehensive source of publications in biomedical journals, *mrcoc* is a good resource for studying concept co-occurrence in professional-generated health content.

MedlinePlus Query Log (QLOG):

MedlinePlus is an open-access website with an extensive collection of health information from the National Library of Medicine, National Institute of Health and other US government agencies targeting lay health information seekers [16]. Users can search the site for health topics of interest. We used an anonymized log of user queries to MedlinePlus as an example of consumer-generated co-occurrence. A pair of concepts is considered to have co-occurred if they (or the terms that map to these concepts) are queried in the same user session (from the same IP address within five minutes of each other)

Calculating co-occurrence of Semantic Groups

In the above sources, co-occurrence frequency is defined only at the concept-level and the frequency at the semantic-type and semantic-group level needs to be computed.

In a given source s, if the co-occurrence frequency of concepts c_i and c_j is $f_s(c_i, c_j)$, the co-occurrence frequency at the semantic-*type* level is defined as $f_s(t_p, t_q) = \sum_{i,j} f_s(c_i, c_j)$ where c_i is of semantic type t_p and c_j is of semantic type t_q. Similarly, the co-occurrence frequency at the semantic-*group* level can be defined as $f_s(g_m, g_n) = \sum_{p,q} f_s(t_p, t_q)$ where t_p belongs to semantic group g_m and t_q belongs to semantic group g_n.

Note that,

- $f_s(X, Y) = f_s(Y, X)$ at the concept-level and hence also at the semantic-type and semantic-group level;
- $f_s(c_i, c_j)$ is undefined if $i = j$, but $f_s(t_p, t_q)$ when $p = q$ and $f_s(g_m, g_n)$ when $m = n$ are both valid and well-defined;
- a concept can be mapped to more than one semantic type and in such cases needs to be considered in calculation of $f_s(t_p, t_q)$ for all t_x to which it maps. A semantic type, however, will belong to exactly one semantic group.

Results

Using the methods described above, we found 1.1 million co-occurrences in QLOG and a comparable number of co-occurrences - 0.8 million - in RPDR. MRCOC has larger number of unique concepts and hence a larger number of co-occurrences (11 million).

Figure 1 shows the co-occurrence distribution of the semantic groups in each source. For example, a value of 13% for the DISO semantic group in RPDR indicates that 13% of all co-occurrences defined in RPDR involved at least one concept of the semantic group DISO. As can be seen in the figure, in all the three sources, the semantic groups Anatomy, Chemical & Drugs, Concepts & Ideas, Disorders and Procedures together

[2] UMLS defined unique identifier for semantic type

[3] The text-to-concept mapping is done using the Health Information Text Extraction (HITEx) [14] system - an open source natural language processing tool.

account for about 85% of all co-occurrences. However in RPDR, *Concepts* is the dominating semantic group (33%) while in MRCOC *Chemicals and Drugs* contributes 43% of all co-occurrences. In contrast to these two professional-generated sources, the consumer-created QLOG data shows higher number of co-occurrences in concepts of semantic group *Disorders (32%)*.

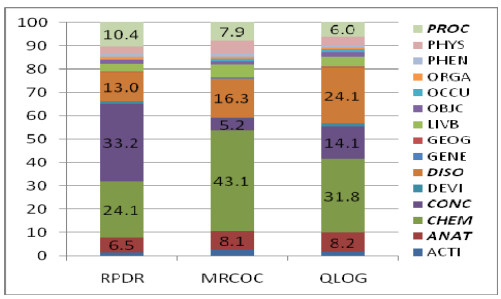

Figure 1- Co-occurrence distribution in each source

It is more interesting to look at co-occurrence between pairs of semantic groups in each of these sources. Figure 2 shows a graph[4] depicting the co-occurrences defined in QLOG. The nodes of the graph represent the semantic groups while the edges show the strength of co-occurrence between the semantic groups. The color and thickness of the edges is proportional to the strength of the co-occurrence between the semantic groups. Additionally, to reduce clutter only the top 20% of the edges have been shown in the graph and loop-edges (source = target) were ignored. Figure 3 and Figure 4 show the graphs for RPDR and MRCOC respectively.

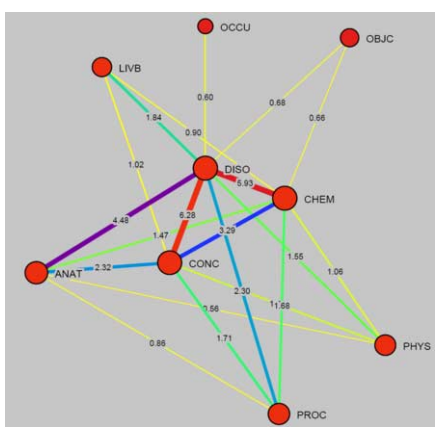

Figure 2 - Co-occurrence in QLOG

In Figure 2 it can be observed that the top three edges are DISO-CONC (6.28%), DISO-CHEM (5.93%) and DISO-ANAT (4.48%) and all three involve concepts of DISO. In RPDR (Figure 3) similar dominance is noted for concepts of CONC with the top three edges being CONC-CHEM (14.4%), CONC-DISO (7.94%) and CONC-PROC (6.12%), while the other professional-generated source MRCOC (Figure 4) has a greater representation from concepts of type Chemicals & Drugs - CHEM-DISO (9.89%), CHEM-ANAT (6.50%) and CHEM-PHYS (4.05%).

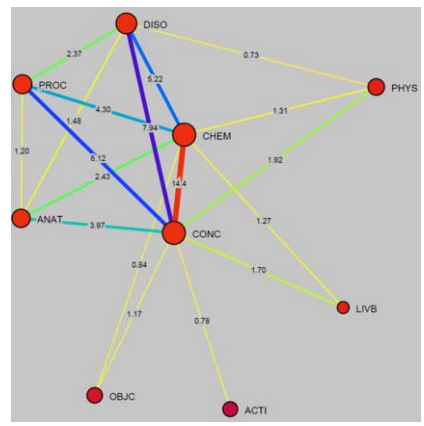

Figure 3 - Co-occurrence in RPDR

We believe that these graphs represent a difference in a consumers' interest in the medical domain and the professionals' interest. The consumers appear to be more inclined to learn about a disease condition and concepts of other semantic groups are explored in their relation to the DISO concept. The other two sources have different focus and the information retrieved from these sources may not be of equal interest to the consumers.

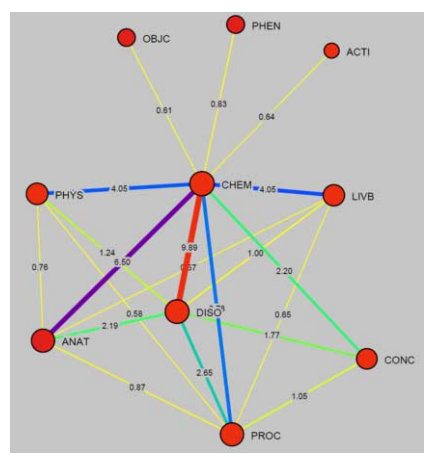

Figure 4 - Co-occurrence in MRCOC

[4] The graphs are generated using visualization software, Himmeli (v3.0.1), provided by the Folkhälsan Research Center at University of Helsinki, Finland.

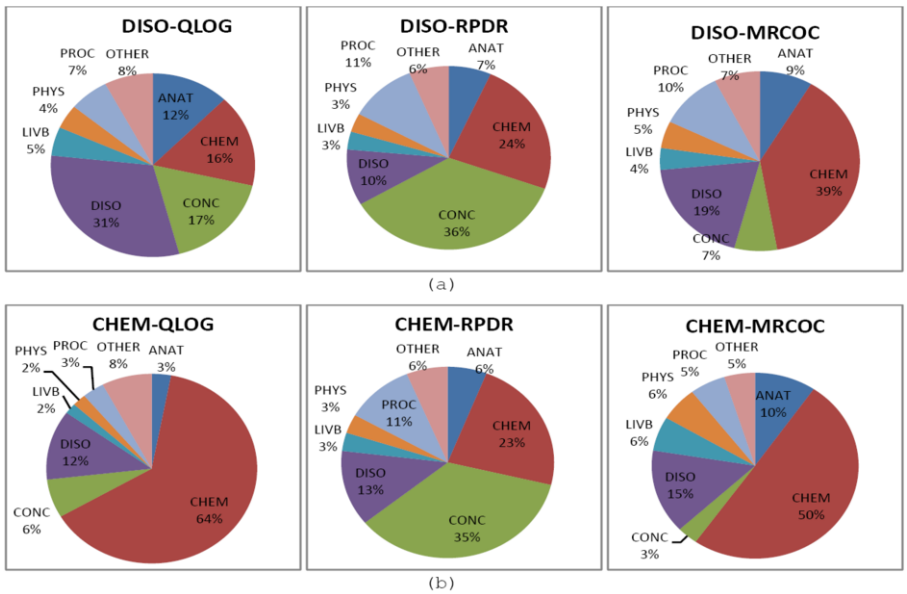

Figure 5 – Charts representing co-occurrence distribution for (a) DISO and (b) CHEM semantic groups in the three sources.

We analyzed the co-occurrence of DISO and CHEM semantic groups from the three sources in greater detail (Figure 5) as we believe they are of higher interest to consumers. The pie charts show the distribution of concepts among the semantic groups when one of the concepts of the co-occurring concept pair belongs to DISO (Figure 5(a)) and CHEM (Figure 5(b)).

Semantic group DISO

Figure 5(a) shows the co-occurrence of concepts of DISO semantic group with each other and concepts of other semantic groups in all three sources. For instance, the 12% ANAT in DISO-QLOG implies that in 12% of all co-occurrences defined in QLOG involving a concept of group DISO, the other concept is of type ANAT. Low frequency groups have been aggregated under OTHER.

DISO in QLOG shows a high intra-group co-occurrence (31%) which probably hints at scenarios where consumers query multiple symptoms they are experiencing or a disease name and follow it up with symptoms that are related to the condition. In neither RPDR nor MRCOC, DISO exhibits similar self co-occurrence. A related observation is the higher co-occurrence of ANAT with DISO concepts in QLOG (patients querying for body parts which are affected or in which the symptoms are manifested).

MRCOC shows a high co-occurrence between DISO and CHEM which may be indicative that in this source the disease terms co-occur with medications that are commonly prescribed to treat the disease or the results of experimental studies (since these are biomedical citations) on the efficacy of a chemical substance in the treatment of a condition. In RPDR, the high co-occurrence between DISO-CONC is consistent with the overall high prevalence of CONC in this source (as seen in Figure 1).

Semantic group CHEM

Figure 5(b) shows the corresponding pie charts for semantic group CHEM. Compared to DISO, CHEM shows a higher degree of intra-group co-occurrence in all three sources.

In QLOG, 64% of the CHEM concepts co-occur with other concepts of the same semantic group. This can mean that when consumers query for a medication or chemical substance they do so in the context of another term of similar type (substitutes or generic alternatives, for instance) or to understand its' chemical composition. The most significant inter-group co-occurrence is with concepts of group DISO (either as prescribed for or as a potential complication of). Similar distribution is observed in MRCOC except for a higher co-occurrence with concepts of ANAT.

CHEM in RPDR, on the other hand exhibits a much higher co-occurrence with concepts of CONC (35%) compared to QLOG (6%) and MRCOC (3%). The self-co-occurrence is also significantly lower.

Discussion

We found significant differences in the prevalence of the semantic groups and the strength of co-occurrences between semantic groups in the three sources. The co-occurrence defined by consumers differs from that defined by professionals. The two professional sources have noticeable differences with each other as well.

We believe these differences are a reflection of the mental models of the content creators in specific communication contexts: QLOG is authored by consumers in the context of information seeking, RPDR is authored by clinicians in the context of documenting patient care, and MRCOC is authored

by researchers (clinical as well as basic science) in the context of describing research studies findings.

In a way, the differences we have found are to be expected. Nevertheless, they have direct implications in consumer health informatics. Professional medical records, for instance, are the content source of many personal health record applications. The differences observed between QLOG and RPDR suggest that the content of medical records in its current form may not sufficiently satisfy patient information needs and has to be re-organized to facilitate information retrieval and understanding by patients.

For example, we have identified that consumers querying signs, symptoms or disorders tend to be very interested in associated signs, symptoms or disorders. While it is fairly easy to find diagnoses in professional or personal medical records, the relations between diagnoses and signs and symptoms are often not explained – this is partially reflected in the relatively low self co-occurrence in the DISO group. For the lay consumers to comprehend the content in their medical records, personal health record applications need to consider ways to help consumers connect the diagnoses with related signs and symptoms.

Similarly, consumers who queried for medications appeared to be very interested in other medications. In this regard, medical records are quite different – the self co-occurrence in the CHEM group in RPDR is 23% while it is 64% in QLOG. On the other hand, CHEM in MRCOC showed fairly high self co-occurrence (50%) compared to RPDR, suggesting that medications are discussed far more frequently in the context of other medications in biomedical literature than in medical records. While we would not expect an average consumer to use medical journals as the primary information source, the information in medical records may not be sufficient either.

We recognize that our analysis just scratched the surface in terms of understanding the layperson's and professional mental models. However, we hope the differences revealed by this study will help draw the consumer health informatics researchers' and developers' attention to the issue.

We also realize that our study can benefit from additional types of consumer generated content and we are looking into using data from online patient fora and from health-oriented social networking sites like PatientsLikeMe [17].

Abstract

SNOMED CT and other biomedical vocabularies provide semantic identifiers for all kinds of linguistic expressions, many of which cannot be considered terms in a strict sense. We analyzed such "non-terms" in SNOMED CT and concluded that many of them cannot be interpreted as directly referring to objects or processes, but rather to information entities. Discussing two approaches to represent information entities, viz. the OBO Information artifact ontology (IAO) and the HL7 v3 Reference Information Model (RIM), we propose an integrative solution for representing information entities in SNOMED CT, in a way that is still compatible with RIM and the IAO and uses moderately enhanced description logics.

Keywords:

SNOMED, Information models, Ontologies

Introduction

SNOMED CT, the emerging global health terminology standard is published by the International Health Terminology Standards Development Organisation (IHTSDO) as a "core general terminology for the electronic health record" [1]. It provides unified meanings for clinical terms from different languages by assigning them to concepts as language-independent identifiers of meaning. Terms are, according to ISO 1087, "*designations of defined concepts in a special language by linguistic expressions*" [2]. Although there are very different, partly contradicting approaches of which criteria should be used to classify a linguistic expression as a term, there is an increasing consensus of terms having both structural (noun phrases) and statistic properties (occurring with a certain frequency and specificity in written and oral communications) [3]. However, any cursory inspection of SNOMED reveals tens of thousands of entries for which it is at least debatable whether they should be regarded as terms along the above criteria, see Table 1:

Here, rather than to terms proper, SNOMED CT concepts correspond to more or less complex linguistic assertions, which include statements of facts, beliefs, and orders. This raises the hypothesis that these "concepts" fulfill tasks that differ from the provision of controlled terms.

Table 1-"Non-Terms" in SNOMED CT

#	SNOMED ID	"Term"
1	59000001	Surgical pathology consultation and report on referred slides prepared elsewhere
2	418577003	Take at regular intervals. Complete the prescribed course unless otherwise directed
3	39399006	Natural death with probable cause suspected
4	168383004	Helicobacter blood test negative
5	281581004	Poor condition at birth without known asphyxia
6	413241009	Suspicion of gastritis

Since SNOMED RT, CT's predecessor, description logics (DLs) [4], formal languages with a well-understood semantics, have been used to formally describe the meaning of SNOMED CT concepts in terms of the common properties of the particular things that instantiate them. We consider these formal descriptions as SNOMED CT's ontology component, considering ontologies as theories that attempt to give precise mathematical formulations of the properties and relations of real-world particulars [5].

Formal representations of electronic health record content have also motivated another line of effort, *viz.* the development of information models for messages and documents in the framework of HL7 Version 3 [6].

In this paper we want to explore the qualitative boundary between "terms" and "non-terms" in SNOMED CT. We postulate that only for the representation of concepts that are instantiated by objects in reality the current logic framework is appropriate, whereas for SNOMED CT concepts that are instantiated by information entities, this framework needs to be extended. We will investigate what kind of things SNOMED CT "non-terms" denote, in which parts of SNOMED CT they occur, and how they relate to clinical information models.

Materials and Methods

Description Logics

SNOMED CT uses a description logics dialect known as **EL**, we will shortly introduce. As a running example, we use the English term "Liver", which belongs to a concept uniquely identified by the number 181268008 and the human-readable

name "Entire liver (body structure)". SNOMED CT concepts are arranged in taxonomic (subsumption) hierarchies. This means that all instances of this concept (i.e. all individual livers) are also instances of its taxonomic parent identified by "272627002|Entire digestive organ (body structure)". We express this as *Liver* ⊑ *Digestive Organ*. Beside the taxonomic arrangement the meaning of SNOMED CT concepts can be further described by the properties all their instances have in common. In the following example, we employ the ⊓ ("and") operator and add a quantified role, using the existential quantifier ∃ ("exists"). For example, the expression *Inflammatory disease* ⊓ ∃ *has-location.Liver* extends to all instances that both instantiate *Inflammatory disease* and are further related through the relation *has-location* to some instance of *Liver*. This example actually gives us both the necessary and the sufficient conditions needed in order to fully define a class, e.g.:

Hepatitis ≡ *Inflammatory disease* ⊓ ∃ *has-location.Liver*, with the equivalence operator ≡ telling that (i) each and every particular *Hepatitis* instance is also an instance of *Inflammatory disease* that is located in some instance of *Liver*, and *vice versa* (ii) that every instance of *Inflammatory disease* that is located at some *Liver* is an instance of *Hepatitis*.

SNOMED CT, in its current version is limited to the constructors summarized in Table 2.

Table 2-SNOMED CT's logical constructors, corresponding to the description logics ***EL***

DL Constructor		Meaning	Example
⊓	$E \sqcap F$	Intersection between E and F	*Acid* ⊓ *Organic Molecule*
∃	$\exists r.G$	Existential restriction of the relation r by the filler G	∃*part-of.Liver*
⊑	$A \sqsubseteq B$	B subsumes A	*Liver* ⊑ *Organ*
≡	$C \equiv D$	C and D are equivalent	*Organic Acid* ≡ *Acid* ⊓ *Organic Molecule*

It is not possible to express value constraints, e.g. that the relation *has-laterality* can only have the values *Right* and *Left*. It is equally impossible to express cardinalities, such as precisely defining a *Coronary bypass with three grafts*. And it is not possible to formulate negations, such as *Injury without infection.*

These restrictions can be tolerated as well as SNOMED restricts itself to the definition of the meaning of simple terms like "Hepatitis" or "Nephrotomy". It is, however, problematic, whenever more complex terms or whole statements as in Table 1 have to be compositionally represented.

Information models

Statements as illustrated in Table 1 typically belong to information models, such as underlying data acquisition templates, questionnaires and the like. Typical standards for clinical information models are open EHR archetypes [7] and HL7 version 3 information models [6]. The Reference Information Model (RIM) is the general structure that guarantees the coherence of the complex set of HL7 version 3 models, which may be used in many contexts to describe particular administrative or clinical health care information. Table 3 contrasts what is typically represented by ontologies with what is typically represented by information models. For example the definition of the class *Act* in the HL7-supported code system is "*a record of something that is being done, has been done, can be done, or is intended or requested to be done*".

Table 3-Ontologies vs. Information Models. In practice the distinction is less crisp. Especially the HL7 RIM contains many classes that can be assumed to represent non-informational entities.

Domain Ontologies	Information Models
Contain classes that have really existing domain entities (particulars) as members	Classes have information entities as members
Represent real-world particulars in terms of their inherent properties	Represent artifacts that are build to collect or annotate information
Can exist independently of information models as long as only the existence of particular things is recorded	Are required to record beliefs or states of knowledge about real things or types of things (as represented by ontologies)
Context independent	Context dependent

Examples are clinical observations, the assessment of health conditions, healthcare goals, treatment services, assisting, monitoring or attending, patient training and education services, editing and maintaining documents, and many others. *Acts* (besides *Entities* and *Roles*) are the pivots of the RIM; all domain information and processes are represented primarily in acts. Any profession or business, including healthcare, is primarily constituted of intentional actions, performed and recorded by responsible actors. An act-instance is a record of such an intentional action. The fundamental difference between such a RIM act instance and an instance of an ontology class (or also most SNOMED CT concepts) is to bring the aspect of recording and thus the person who edits EHR content into the picture. At least in theory, an instance of RIM:*Operation* refers to an information object which is "*about*" some type or concept, which not necessarily is instantiated. Representing discourse about operations that are being planned, postponed, or suspended is quite different from creating and instance of an ontology class *Operation*, as the latter one makes an existence claim which is often too strong.

The Ontology – Epistemology Divide

We may be able, in theory, to draw a crisp line between what is the representation of real objects or processes on the one hand, and what represents information entities on the other hand. In current information models and ontologies this distinction is blurred, and users of both systems tend to be unaware of the very nature of things they represent. The resulting overlaps give rise to conflicting representations, which require sophisticated mitigation strategies (TermInfo). Such a mixed representation of the invariant (and possible definitional) properties of entities as they *are* (ontology) and how they are *seen / known / recorded* (epistemology) is prevalent in most biomedical terminology systems [8, 9].

Ontologies of Information Entities

Whether these epistemic aspects are considered relevant for ontology is a matter of definition. In the Information Artifact Ontology, under the OBO Foundry initiative [10], they are included in an ontology framework as information content entities, and their classes have representations of information as members. Information content entities are immaterial objects (more precisely: generically dependent continuants according to the Basic Formal Ontology, BFO [11]) that can be borne in material objects. So can the latter be a photographic print, and the former an (immaterial) photograph:

PhotographicPrint ≡ *MaterialEntity* ⊓
∃ *bearerOf*. (∃ *isConcretizationOf*. *Photograph*)

Information content entities encompass documents, document parts such as sentences, texts, data, measurement results, serial numbers, datatypes, databases, and ontologies, and the processes in which they are created and consumed, totaling 131 classes. Information content entities are related by the relation *isConcretizationOf* to their material bearers, and by the relation *isAbout* to the things they denote.

There is a rough correspondence between IAO information content entities and the HL7 classes that derive from the class *Act*. In this context, *Act*, in contrast to its implicit meaning is to be understood as an information entity, i.e. *information about* a real act. This becomes obvious by the fact that HL7 acts can be modified by so-called mood or uncertainty codes.

The so-called *moodCode* in the information model distinguishes between acts that occurred and acts that are only planned (ordered, scheduled, rescheduled, etc.). Mood codes encompass intent, appointment, appointment request, promise, proposal, recommendation, resource slot, predicate, criterion, event criterion, expectation, goal, option, permission, permission request, risk.

The *uncertaintyCode* indicates whether the *Act* statement as a whole, with its subordinate components has been asserted to be uncertain in any way e.g., a patient might have had a cholecystectomy procedure in the past (but is not sure). When the uncertainty is associated with an *Observation.value* alone or other individual attributes of the class, such pointed indications of uncertainty should be specified by applying the *Uncertain Value – Probabilistic* (UVP)[1] or the *Parametric Probability Distribution* (PPD)[2] data type extensions to the specific attribute. Particularly if the uncertainty is uncertainty of a quantitative measurement value, this must still be represented by a PPD<PQ> in the value and NOT using the *uncertaintyCode*. Also, when differential diagnoses are enumerated or weighed for probability, the UVP<CD> must be used, not the *uncertaintyCode*. The use of the *uncertaintyCode* is appropriate only if the entirety of the *Act* and its dependent *Acts* is questioned. Finally, the attribute *negationInd* indicates that the *Act* statement is a negation of the *Act* as described by the descriptive attributes.

For example, to test for "systolic blood pressure of 90-100 mm Hg," one would use only the descriptive attributes *Act.code* (for systolic blood pressure) and *Observation.value* (for 90-100 mm Hg). If one would also specify an *effectiveTime*, i.e., for "yesterday," the criterion would be more constrained. If the *negationInd* is true for the above criterion, then the meaning of the test is that a systolic blood pressure of 90-100 mm Hg yesterday does **not exist** (independent of whether any blood pressure was measured).

The IAO does not have so far a fine grained model of moods and probabilities such as the HL7 RIM, but its architecture does not preclude such an extension.

These examples show the crucial difference between a model of information and a model of reality. In the former, "*information related to an act*" can be subsumed by "*information related to a planned act*", whereas in a model of reality, i.e. an ontology in a narrower sense "*act*" and "*planned act*" are not related by taxonomic subsumption.

In the following we are studying several SNOMED CT concepts that clearly belong to the category of information entities. We critique their current representation and propose an alternative representation as information content entities.

Case Study

We center our forthcoming discussion on four SNOMED term cases (C1-C4) which, in our view, represent epistemic states rather than ontological concepts:

C1: ***Absent nose*** (111317000) is stated to imply: *Congenital malformation* ⊓ ∃ *FindingSite. Nasal Structure*

C2: ***Heart operation planned*** (183983001)[3]. This concept is in SNOMED CT's *Situation with explicit context* branch and is fully defined as

∃ *rg.*(
∃ *Associated procedure.Operation on heart* ⊓
∃ *Procedure context.Planned* ⊓
∃ *Temporal context. Current or Specified* ⊓
∃ *Subject relationship context. Subject of record*)

C3: ***Operation on heart, rescheduled***. (64915003|: 272125009|=58334001), This is a postcoordinated concept, refining operation on heart by using the qualifier *Priority* with the value *Rescheduled*, in DL notation: *Operation on heart* ⊓ ∃ *Priority. Rescheduled.*

C4: ***Suspected gallstones*** (390926006). This concept is also in SNOMED CT's *Situation with explicit context* branch and is fully defined as

∃ *rg.*(∃ *Associated finding.Gallstone* ⊓
∃ *Finding context.Suspected* ⊓
∃ *Temporal context. Current or Specified* ⊓
∃ *Subject relationship context. Subject of record*)

Case critique

All four concepts have in common that in their definition they are related to other concepts that are definitely not, or not nec-

1 A generic data type extension used to specify a probability expressing the information producer's belief that the given value holds.
2 A generic data type extension specifying uncertainty of quantitative data using a distribution function and its parameters (mean, standard deviation)

3 *rg* means „role group", cf [12].

essarily, instantiated. SNOMED CT's description logics notation, however, by using existentially quantified roles (∃), asserts the existence of at least one instance of the concepts in question. So does the expression

∃ *FindingSite. Nasal structure* formally assert that some instance of *Nasal structure* exists, whereas the intended meaning is exactly the contrary. Similarly, the expression *Operation on heart* ⊓ ∃ *Priority. Rescheduled* states that there is a heart operation, whilst the intended meaning refers to some heart operation in the future, which still includes the case that there will not be any operation at all (e.g. due to worsening conditions of the patient). The same argument holds for the planned heart operation. Regardless the syntactic difference (the rescheduled operation is a operation, whilst the planned operation isn't), the expression

∃*rg.* (∃ *Associated procedure.Operation on heart*)

is a necessary condition for *Heart operation planned*, i.e. the plan implies its execution, which is certainly not always the case. In exactly the same way, the definition of *Suspected gallstones* leads to the conclusion that there exist real gallstones even in case a doctor registers a suspicion only.

What is wrong with these concept definitions? There is no doubt that there must be a way to refer to "something" which does not exist now, which existed in the past, or which may exist in the future. But statements about non-existence are not terms, although they syntactically include terms. Ideally, they should be represented in an information model, which is distinct from the ontology, or is expressed in an "information Entity" branch in the same ontology. However, there are strong reasons why application builders want to have "real" concepts as well as whole assertion in one and the same representational artifact such as SNOMED CT. So has it been a precondition for the use of this standard with in the UK National Health Service, that the former CTV3 terminology was fused with SNOMED RT. One characteristics of CTV3 (the successor of the former Read Codes) was its abundance of epistemic laden concepts such as in our examples.

Case remodeling

We here propose alternative representations based on the information artifact ontology, using information content entities such as Plan and Suspicion. All the four concepts *Absent nose*, *Heart operation planned*, *Operation on heart, rescheduled*, and *Suspected gallstones* represent information content entities. In order to make this clear (and because the language is often misleading), we slightly rename the concepts to *Patient without nose, Plan of heart operation, Rescheduled plan of heart operation, Suspicion of gallstones.*

To express this adequately, we need to enhance our description language by the constructors given in Table 4.

A further extension of the logics including concrete domains (in this case numeric values) will be necessary if probabilistic values are to be represented such as UVP and PPD in HL7 RIM. This is already possible, e.g. using data properties in Protégé, but it is not yet covered by off-the-shelves terminological reasoners such as Fact++ and Pellet.

Table 4-Additional description logics constructors

DL Constructor		Meaning	Example
¬	¬ *A*	Negation of *A*	*Base* ⊑ ¬ *Acid*
∀	∀*r.G*	Value restriction of the relation *r* by the filler *G*	*Hand* ⊑ ∀*has-Laterality.* (*Left* ⊔ *Right*)
⊔	*A* ⊔ *B*	Union of A with B	

Case remodeling

Coming back to the running examples, we propose the following representations:

C1: ***Person without nose***:

Human ⊓ ¬ *hasPart. Nasal Structure*

C2: ***Plan of heart operation*** (183983001):

Plan ⊓ ∀ *isAbout. Operation on heart*

with *Plan* being an information content entity. The universal quantifier ∀ means that this plan can only be realized by a heart operation. In contradistinction to the existential quantifier ∃ the formula does not assert that there must be an operation for each and every plan.

C3: ***Rescheduled plan of heart operation***:

Plan ⊓ ∀ *isAbout. Operation on heart* ⊓
∃ *hasQuality.Rescheduled*

Alternatively:

Plan ⊓ (∀ *isAbout. Operation on heart*) ⊓
∃ *participantOf.Rescheduling*

with *Rescheduling* being an event.

C4: ***Suspicion of gallstones***.

Suspicion ⊓ ∀ *isAbout. Gallstones*

with *Suspicion* being an information content entity.

Variations

There may be a need to distinguish simple instantiations (e.g. asserting that there is an instance of *Gallstones*) from a record of a finding (i.e. that some physician has diagnosed gallstones).

Note that all version of SNOMED CT until now, have placed *Gallstones* (a material entity), together with processes like *Myocardial infarction*, *Headache* and *Hypercholesterolemia* into an epistemology-infested *Findings* hierarchy.

The subtle difference between instantiations and findings is that there are undiagnosed diseases just as there are false diagnoses (which continue being diagnoses even being false). These special cases should be accounted for in a medical record, and the terminology should provide the means for this. We propose a solution using again the example C4.

We may want to distinguish between:

- C4a: A diagnosis "Gallstones" whatsoever
- C4b: A confirmed diagnosis "Gallstones"
- C4c: A suspected diagnosis "Gallstones"
- C4d: A false diagnosis "Gallstones"
- C4e: Gallstones that have not been diagnosed

In all these cases diagnoses are information content entities. According to the diagnosing person they can be subdivided in terms of medical diagnosis, nursing diagnoses, etc.

C4a: *Diagnosis* ⊓ ∀ *isAbout.Gallstones*

C4b: *Diagnosis* ⊓ ∀ *isAbout.Gallstones* ⊓ ∃ *isAbout. Gallstones*

C4c: *Diagnosis* ⊓ ∀ *isAbout. Gallstones* ⊓ ∃ *hasQuality.Suspected*

C4d: *Diagnosis* ⊓ ∀ *IsAbout.* ⊥

C4e: *Gallstones* ⊓ ¬∃ *inv(IsAbout).Diagnosis*

The examples show the possibilities but also the limitations of using the proposed description logics. If we wanted to represent quantitative statements, e.g. in C4c that there is a probability of 0.1 that the diagnosis is true, then we would need to include numeric values as data properties. As C4d shows, there is no possibility to distinguish between different kinds of false diagnoses. From a HL7 point of view, the establishment of a diagnosis is an observation, a sub-class of the class *Act* defined as "An act that is intended to result in new information about a subject." Being a sub-class of the class *Act*, the class Observation inherits of the attributes of the class Act including *moodCode*, *uncertaintyCode* and *negationInd*. In addition UVP or PPD data type extension may be used to express respectively a probability expressing the information producer's belief that the given qualitative observation value holds or the uncertainty of quantitative data using a distribution function and its parameters.

Conclusion

Numerous SNOMED CT concepts are representations that are more adequately described by complex linguistic statements than by domain terms in a stricter sense. These complex statements address epistemic notions, i.e. information about the user and the context, which clearly extends the realm of ontology. Those SNOMED CT concepts that correspond to "real" terms can generally be defined using the very inexpressive logic **EL**, currently used for SNOMED CT.

In our finding that there are numerous SNOMED "non-term" concepts that cannot be adequately represented giving the current restrictions of SNOMED CT's logic, we are close to the analysis done by Rector & Brandt [13]. Just as we do, they defend the (controlled) use of a more expressive description logic, analyzing a similar scope of concepts as we do. However, the model they propose is different. By understanding findings, procedures, and observables as *situations* they manage to solve the negation problem. Yet their approach reaches short when it comes to uncertainty, such as speculative diagnoses, or plans that have not yet been executed at the time of recording.

Our approach comes closer to what is possible to encode using the HL7 RIM, where medical record entries can be modified in terms of "mood codes" like *Event, Goal, Risk, Expectation, Intent*, or uncertainty codes such as *Possibly done* or *Probably done*. It is also consistent with the Information Artifact Ontology, which, however, lacks detail for representing diagnostic statements. Thus, using one single representation formalism, our proposal brings different worlds together: real-world, heterogeneous terminologies, HL7 information models, as well as philosophically founded ontologies.

Modeling, building and evaluating an ontology for the automatic characterization of adverse drug effects during pharmacovigilance

Abstract

Background: The characterization of spontaneous reported cases is fundamental for pharmacovigilance. This task is time consuming and its reproducibility is low. Objective: To develop a system founded on an ontology that automatically instantiates spontaneous reported cases as "known" adverse drug effects (ADE) only if the reported ADEs are described in drug compendia. Methods: A simple ontology of drugs and their related adverse effects represented in description logics was developed from a drug database. Manual evaluation was carried out on 378 spontaneous reported cases instantiated as "known ADE of a chemical class". The initial manual characterization was reviewed by a pharmacovigilance expert to validate the generated automatic characterization. Results: The ontology is composed by 57,704 concepts and 5 relations. It was successfully validated thanks to Pellet reasoner and it contains neither inconsistencies nor cycles. In this validation, 86% of the instantiated spontaneous reported cases effectively concerned notorious ADEs, whereas only 75% were initially identified manually as related to notorious ADEs. Conclusion: This system can assist characterization by applying a reasoning process similar to that used by experts in the search for ADEs.

Keywords:

Introduction

Pharmacovigilance process has been developed at the local, national and international level to facilitate the collection and analysis of spontaneous reported adverse drug effects (ADE) in treated patients. This process aims to identify rare and dangerous adverse events likely to result in an unfavorable benefit risk ratio.

The nature of the relationship between an adverse event and a drug in a spontaneous reported case is defined by a pharmacovigilance expert on the basis of intrinsic and extrinsic imputability criteria. The intrinsic imputability is founded on chronological (the time interval between the drug intake and the occurrence of the adverse event) and semiological (the symptoms observed are compatible with this type of drug) criteria. Extrinsic imputability (characterization) is based on bibliographic references concerning existing knowledge about the adverse effects associated with the drug (well known effect described in drug compendia, predictable or previously reported side effects and side effects not described or not published).

When considering what is known about the possible adverse effects of the drug, the expert must consult several sources: (a) the drug monograph which reports all the side effects observed during development and post-marketing of drug, (b) a drug compendium reporting the side effects of active substances [1-2], (c) a specific side-effect compendium reporting side effects of active substances and classes of active substances [3], (d) published articles dealing with the reported side effects of the substance.

The automation of these tasks would help the expert considerably in his or her interactions with the available resources. It should also save time and result in more reproducible bibliographic documentation. One possibility for automation would be to develop a dedicated tool which automatically classifies a spontaneous reported case as a "case with known ADE" or as a "case with unknown ADE". To automate this task it is necessary to check the existence of known side effect at different levels : for the substance, for the pharmacological class of the substance and for the chemical class of the substance. For example, a patient takes ibuprofen and a gastric ulceration is reported. This spontaneous report can be characterized as a known ADE because non steroidal anti-inflammatory drugs (NSAID) are known to give gastric ulceration and ibuprofen is a NSAID. As illustrated, this characterization process should use subsumption reasoning.

Ontological reasoning based on formal representation languages such as description logics can be used for this type of classification. The use of description logics has several advantages including the possibility of using advanced inference services (satisfiability, subsumption, classification, consistency checking, instantiation and realization) [4].

An ontology is therefore required. This ontology must describe the drugs prescribed and their known related ADEs, but also the classes to which the drugs belong (chemical and, pharmacological properties, etc...) and the related ADEs of these classes.

The existing ontologies (Galen Drug ontology [5], VA NDF-RT [6], SNOMED CT [7]) do not completely satisfy these requirements: (a) ADEs of drug classes, or of drug are not always given, (b) these ontologies deal essentially with American or English pharmacopoeias but not French ones, (c) they are not necessary kept up to date, may contain information for obsolete drugs and lack information for new drugs.

Information about drugs can also be obtained from commercial drug databases which are regularly updated but have a formalism unsuitable for complex reasoning such as subsomption, classification or consistency checking [4].

In this work, we aimed to develop and use an ontology to describe drugs and their known ADEs, through the following steps: (a) modeling known ADEs, (b) representing the ontology with a formal language, (c) populating it with data from a French drug database, (d) instantiating it with reported cases from a pharmacovigilance center (CRPV), (e) evaluating the results obtained through a classification process.

Materials and Methods

Known ADEs model

The general ways a side effect can occur are explained using pharmaceutical and toxicological knowledge. The main needed concepts and relations are identified.

Modeling the known ADEs is guided by the objectives of the reasoning tasks:

- Classification task should provide (1) a hierarchy of drugs on the basis of their pharmacological and chemical properties (2) a hierarchy of "cases with known ADEs" on the basis of the side effect concerned and the drug involved.
- Instantiation task should provide the list of "cases with known ADEs" for which a "spontaneous reported case" is an instance.

Ontology building

We represent the ontology of drugs and their related ADEs using OWL-DL, a web Description Logics (DL) language [4]. DL structures the domain knowledge on two levels: a terminological level (TBox or ontology) containing the classes of domain objects (concepts) with their properties (roles), and an assertional level (ABox), containing individuals (instances).

The ontology was constructed in a sequential manner. The TOP ontology was first created and stabilized. We then added in the TBox subconcepts of TOP ontology using knowledge from a drug database. Finally, the instances were added in the ABox using a pharmacovigilance database.

TOP ontology

The TOP ontology was stabilized by (a) implementing the general concepts and relations previously identified in Protégé 4.0 ontology development environment[1] and (b) verifying the principles on which our model was based using fictive cases with known ADEs, reported cases and the Pellet reasoning engine [8].

Populating the ontology

We used the French drug database Thesorimed[2] to populate the drug iatrogeny ontology because :

- This drug database is highly structured,
- It includes side effect descriptions at various levels (chemical, pharmacological, active substance),
- It indexes side effects with normalized terms and will soon include a MedDRA (Medical Dictionnary of Regulatory Affairs) indexation of side effects. MedDRA is a terminology commonly used to describe side effects in spontaneous reported cases [9].

The pertinent tables and fields of this drug database were identified. They constitute a subset of the database dealing particularly with the side effects of drugs. Thesorimed side-effect terms were converted into MedDRA terms by computerized string matching and manual matching. A specific script was written to convert the drug database subset into subconcepts of the TOP ontology. The OWL-DL file obtained was concatenated to the TOP ontology OWL-DL file.

Instantiating the ontology

Instances of the ontology are the spontaneous reported cases included in the CRPV pharmacovigilance database. Side effects are expressed using MedDRA terminology, and drugs are expressed as active substances. A script generating the OWL file of these instances was concatenated to existing OWL files. The methodology is presented in Figure 1.

Classification, Instantiation

The ontology OWL file was imported in Protégé 4.0 ontology development environment, and the reasoning engine Pellet was then used for both classification and instantiation.

Classification computes the sub-concept relations between every named concept to create the complete hierarchy. It can be used to answer queries such as getting all or only the direct sub-concepts of a concept.

Instantiation finds the most specific concepts that an instance belongs to (direct types for each instance). It can only be performed after classification since direct types are defined with respect to a concept hierarchy. Using the classification hierarchy, it is then possible to get all the types for that instance.

[1] http://protege.standford.edu
[2] http://www.giesips.org

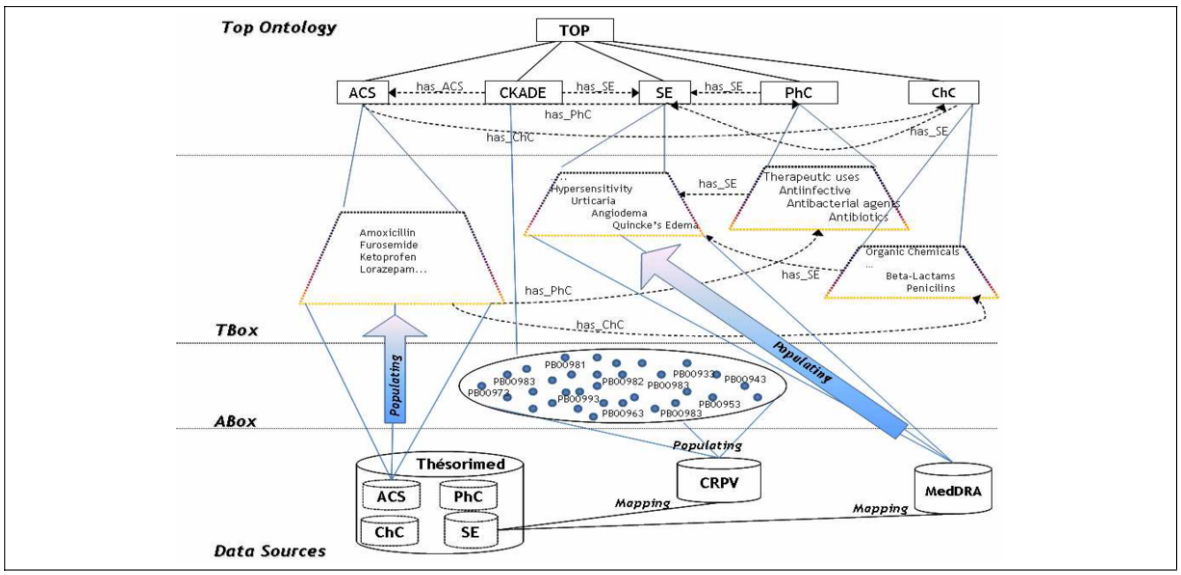

Figure 1 - Methodology of construction of ontology of drugs and their related ADEs. TOP ontology is composed by the concepts: ACS (Active Substance), CKADE (Case with known ADE), SE (Side Effect), PhC(Pharmacological Class) and ChC(Chemical Class).

Ontology evaluation

The logical consistency of the whole ontology (TOP, subconcepts, hierarchies, relations and instances) was analyzed by the reasoning engine. The conceptual validity of the ontology was evaluated by comparing the extrinsic imputability criteria of instantiated reported cases. If cases are instantiated, there is already bibliographic knowledge relating to them. Their extrinsic imputability criteria should therefore be 3 (well known effect described in drug compendium) or 2 (published side effect).

The list of instantiated cases was analysed by a pharmacovigilance expert that was asked to review the characterization of reported cases according to the information given by the "case with known ADE" concepts. The expert was asked whether the case should be considered "notorious" and had to select one of the following options for each reported case: she agrees and the initial criterion should be 3, she does not agree and the initial criterion is true, she partly agrees because she has other information explaining the initial criterion.

This evaluation was first performed on a preliminary set of "case with known ADEs" concepts dealing with chemical classes of drugs associated with side effects (*e.g. oxicam causing diarrhea*).

Results

Known ADEs model

Domain description

An adverse drug effect may be linked to:

- An active substance in the drug (*e.g. amoxicillin may cause tooth discoloration*),
- An auxiliary substance present in the drug with no therapeutic properties (*e.g. the aspartame present in oral formulation of amoxicillin may be dangerous for patients with phenylketonurias*),
- A chemical class of a drugs (*e.g. amidine penicillin may cause nausea*),
- A pharmacological class of a drugs (*e.g. antitussives may cause insomnia*).

An adverse effect may be due to:

- A generic interaction with an organ (non specific action),
- A molecular interaction (enzymatic induction, molecular competition, etc),
- An intrinsic toxicity of the drug (*e.g. ototoxicity of aminosides*).

An adverse effect may occur in various contexts:

- Patient context : physiological, pathological, genetics, allergy,
- Dose context : daily dose, frequency, duration of treatment,
- Administration context: form, route, flow,
- Exposure context: cumulative toxicity,
- Co-administration context (drug interactions).

Model of known ADEs

Modeling focused on the concept of "*case with known ADE*" relating to one or two drugs, one side effect and various con-

texts (patient, exposure, dose or administration contexts). The *case with known ADE* is a kind of *case*.

The drug involved may be a clinical drug (CD) or one of its components (active substance (ACS), auxiliary substance (AS)) or a substance belonging to a particular pharmacological class (PC), chemical class (CC) or interaction class (CI).

Figure 2 shows the model to describe known ADEs.

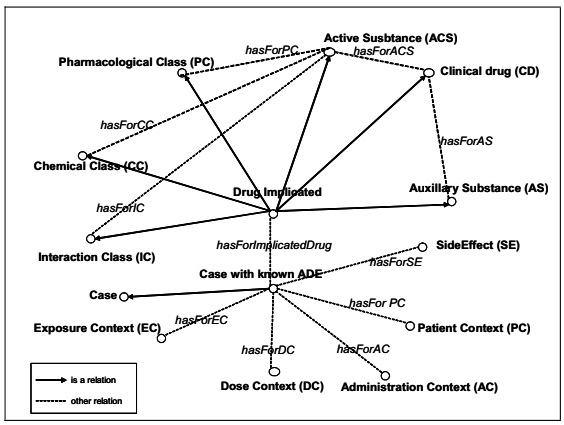

Figure 2- Model of known ADEs

Ontology Description

For the first version of the ontology, we limited the concept "*drug implicated*" to the: "*active substance*", "*pharmacological class*" or "*chemical class*" of the drug concerned. Context concepts had not been included in the ontology at this point.

TBox

Concepts relating to the drug implicated

Active substances are primitive concepts (n=4,481) described by two relations:

- *hasForPC* relating the active substance to its pharmacological class
- *hasForCC* relating the active substance to its chemical class

We created two defined concepts (*owl:Equivalent Class) - ActiveSubstanceHavingPC* (n=844) and *ActiveSubstanceHavingCC* (n=386) - making it possible to link *pharmacological* or *chemical class* to the "*drug implicated*".

Described case concepts

A "*case with known ADE*" is a defined concept based on 2 relations (*owl: ObjectProperty*):

- *hasForImplicatedDrug* relating the case to the drug implicated,
- *hasForSE* relating the case to a side effect

The *cases with known ADE* can be divided in 11,697 concepts of *PC causing side effect*, 5,198 concepts of *CC causing side effect*, and 32,685 concepts of *ACS causing side effect*.

Hierarchically organized concepts

Pharmacological class, chemical class and *side effects* are primitive concepts and are organized hierarchically (*owl:SubClassOf*). There are 844 concepts in the pharmacological hierarchy, 386 in the chemical one and 1,183 in the side effect one.

ABox

We consider all the "*spontaneous reported cases*" to be instances of the concept "*Case*".

Each "*spontaneous reported case*" is described with one or many instances of *drug implicated* and one or many instances of *side effects*. There are 2,555 instances in ABox.

Ontology evaluation

Neither inconsistent classes nor inconsistent instances have been inferred using our modeling principles.

For the preliminary evaluation, we considered only a subset of reported case instances of *"cases with known ADE"* defined as having a side effect related to a particular chemical class (378 of the 1,694 spontaneous reported cases in the CRPV database, corresponding to 565 side effect/substance pairs).

The initial extrinsic criterion was greater than 2 for 75% of the instantiated reported cases. For the others, the initial criterion was less than 2, indicating that the side effect concerned had not previously been described for this drug.

After review by the pharmacovigilance expert,

- 86% of the instantiated reported cases had a criterion greater then two (maintenance of the high initial criterion or increase in the criterion from an initial low value).
- 3% of the instantiated reported cases still had an extrinsic criterion below 2 after review (*e.g.* the reported case "clonazepam causing dyspepsia" is an instantiation of the described case "benzodiazepine causing dyspepsia", but the pharmacovigilance expert did not consider it to be notorious that benzodiazepine gives dyspepsia).
- 11% of the instantiated reported cases could have been given a criterion greater than 2, but the expert maintained the initial criterion because (a) other drugs were involved in the reported case for which the observed side effect had never been described (n= 44), (b) there were other side effects in the reported case that had never previously been described for the drug implicated (n=15), (c) the side effect was merely a sign that the drug was not effective (n=3) (*e.g. pain and ketoprofen*).

One of the benefits of this experiment was that the pharmacovigilance expert obtained new knowledge about drug properties. Indeed, some drugs were found to be classified exclusively on the basis of pharmacological principles and never on the basis of chemical principles (for example amprenavir is a sulfamide but is systematically described as an antiretroviral drug).

Discussion

The ontology we have developed is based on the pharmacovigilance observation and reasoning for the characterization of spontaneous reported cases. Based on these observations, we have repurposed the knowledge contained in a drug database to make it possible automation of the ADEs searching.

This method of ontology building also facilitates the maintenance of the ontology as the drug database is regularly updated and scripts automatically convert some parts of it into OWL-DL.

The automatic instantiation process efficiently identified spontaneous reported case of notorious bibliographically documented effects. Nevertheless, further evaluations with the whole ontology are required to quantify the specificity and accuracy of the instantiation process (true described reported cases, true not described cases, false described reported cases, false not described cases).

The evaluation of the ontology by the pharmacovigilance expert indicated several ways in which the ontology could be improved. New sub-concepts of cases with known ADEs could be created totally or partially matching to the reported cases in term of the number of drug/side effect pairs for the reported case automatically instantiated as cases with known ADEs.

The hierarchies included in the ontology are those provided by the drug database. They suffer from a lack of structure (no polyhierarchy and a very flat hierarchy). We are investigating ways to dissect concepts in these hierarchies to facilitate their reclassification.

In the near future, we will integrate the side effect ontology developed by another team of the VigiTermes project [10] into our system. This should greatly extend reasoning concerning the classification of side effects.

Other drug classification systems are currently integrated into the ontology (*e.g*: MeSH), which can thus be used to generate clusters of reported cases on the basis of common drug clusters. It will be used for the signal detection complementary to the approach developed by Henegar *et al* [11].

As our resource gives the knowledge about a drug and its known side effects, it could also be used to filter results of ADEs detection issued from Electronic Heath Records using NLP tools and data mining methods [12]. Among detected ADEs, known ADEs (True Positives) should be then automatically identified.

Finally, all the documentation services should be implemented in a web service.

Acknowledgments

This research was supported by the VigiTermes project funded by the French National Research Agency (ANR-07-TECSAN-026-04).

Abstract

ICD-coding is a complex and difficult task. Coding results vary a great deal depending on each coder's ability. Although the Japanese Standard Disease-Code Master facilitates the coding tasks, it also engenders post-coordination problems derived from combinations of basic diseases (with ICD code) and modifiers. Post-coordination sometimes alters the original ICD code dramatically. To solve this problem, this paper presents a proposal for using internal structures of disease names to correct the ICD code. First, we built an internal structure analyzer, which achieved high (83.7%) accuracy. Results demonstrated that the analyzed output is helpful for precise ICD-coding tasks.

Keyword:

ICD-10, Disease name, Multi-word expression, Internal structure, Dependency analysis, Post-coordination

Introduction

The international standard diagnostic classification for all general epidemiological purposes and many health management purposes is ICD-10. It is used for analyses of general health circumstances of population groups and monitoring of the incidence and prevalence of diseases [1]. However selecting a suitable disease code for each patient requires a high level of understanding of both patient data and medical knowledge.

We classified the complex language phenomena in ICD coding into three types:

1. Spelling variation
   Myo**c**ardial infarction / Myo**k**ardial infarction [I21.9]
   (value in brackets: ICD code)

The first type, spelling variation, mostly originates from transliteration problems, which occurs in vocabulary importing. Because this phenomenon is a general research topic, and because various methods have been proposed [2,3], this paper does not address this problem.

2. Synonym / Hypernym
   Coats' disease / exudative retinitis [H35.0]

The second type, synonym/hypernym, requires extra knowledge such as ontology. It is also beyond this paper's scope.

3. Order / Existence of Modifier (Post coordination)
   femoral fracture / femoral incomplete fracture [S72.9]
   femoral shaft fracture [S72.3]

The third type—the target of this paper—is *post coordination*, which is the combination of a disease whose correct ICD code is known and modifiers. Post coordination must cope with the expansive variety of disease names. Moreover, it sometimes changes the original ICD code.

The terms "femoral incomplete fracture" and "femoral shaft fracture" are illustrative examples of the post coordination problem. In fact, "femoral incomplete fracture" shares an ICD code [S72.9] with "femoral fracture", however "femoral shaft fracture" [S72.3] does not, even though they appear to have the same structure. The difference between them is the dependency inside of the term: "incomplete" modifies "fracture", whereas "shaft" modifies "femoral". To address the problem, this paper uses an internal structure of disease names (Figure 1).

This paper presents (1) automatic ICD-coding based on internal structure of disease name and (2) a method to build an internal structure analyzer, including internal structure representation for disease names. The experimental results for internal structure analysis achieved high accuracy (83.7%), demonstrating the fundamental feasibility of the proposed ICD coding.

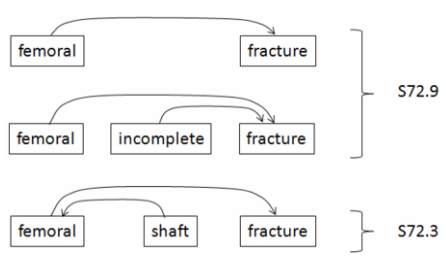

Figure 1 - Internal structures

It must be noted that the automatic ICD-coding task in Japanese is more difficult than that in English because Japanese does not use spacing for word/morpheme separation. That difference complicates Japanese processes.

Although experiments described in this paper are related to Japanese medical terms, the proposed method does not depend on a specific language. The proposed method could be applied with the other languages; especially efficient for Chinese, German and so on, which are also without word/morpheme separation.

Internal Structure Analysis

The core problems examined in this study are: (1) how to represent internal structure, (2) how to train the analyzer.

(1) Representation of Internal Structure

An "internal structure of a disease name" is represented as a collection of dependency relations between the morphemes in a disease name. Figure 2 presents an example of "大腿骨頚部骨折" which means a femur neck fracture. An arrow indicates a dependency relation. Because of the difficulty in defining the adequate unit (morpheme), we regarded a character as a unit. Japanese character "Kanji" are ideographs.

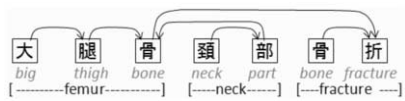

Figure 2 - An example of an internal structure

A basic representation of an internal structure is shown above. However, two exceptions exist: omission and contraction.

Representation for omission

The first exception is OMISSION as shown below:

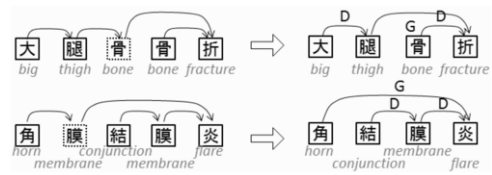
Therein, "臓" is omitted when "心臓" and "疾患" are compounded into "心疾患" (In fact, "心" itself does not mean "heart organ"). To represent the omission, we introduced a new dependency label "G" and assigned label "D" to the normal dependency relation.

In this example, "心" generates a character (actually "臓") and depends on the generated character, the generated character depends on "患".

Representation for contraction

The framework shown above can deal with another phenomenon: CONTRACTION. Contraction resembles omission, but it differs in that morphemes share the omitted character ("骨" for "大腿骨折", "膜" for "角結膜炎").

The internal structures of these two disease names are represented as follows.



A dotted square represents a contracted character.

As in the previous example, the dependency label G represents that "腿"/"角" generates a character ("骨"/"膜") and depends on the character. The character depends on "折"/"炎".

To process the internal structure adequately, it is necessary to reconstruct omitted and contracted characters. Two points must be specified during reconstruction: 1) the position in which the omission/contraction occurred, and 2) the omitted character. As described in this paper, our internal structure analysis has a framework for the first point.

This study does not examine the inference of omitted characters. That point can be solved using other techniques such as predictive transforms.

Dependency relation – which is the head?

Two morphemes in a dependency relation are not symmetrical: one (head) depends on the other (dependent). Here, the question is: Which is which? Regarding the structure of sentences, a head is a constituent that defines the part of speech of a phrase. However, this definition is inapplicable here because a disease name and its constituents are all nouns in Japanese.

We adopted a definition of a head based on an is-a / part-of hierarchy: for a compound noun *C*=<*unit 1, unit 2*>, *unit 1* is the head if unit 1 *is-a C*, else *unit 2* is the head. The next step is to apply a *part-of* relation instead of an *is-a* relation if both do not exist. For example, in the case of "distal femur":

× distal femur *is-a* distal

× distal femur *is-a* femur

No *is-a* relation exists. (We adopted a policy that "distal" is a role concept depending on the context. Here, We use a region of "femur", instead of *is-a* relation between basic concepts.) Next we present a *part-of* relation:

× distal femur *part-of* distal

○ distal femur *part-of* femur

Therein, "femur" is a hypernym of "distal femur" in the *part-of* relation, so "femur" is the head and "distal" is dependent.

Table 1 - Features used by the internal structure analyzer
("Stack[]" and "Input[]" are the data structure used in MaltParser)

Character feature	1	Character	STRING
	2	The type of character (Chinese character, number, etc.)	STRING
	3	Position of the character	INTEGER
Dictionary feature	4	If a substring of the input disease that end with this character is in the dictionary	BOOLEAN
	5	Length of the word in (4)	INTEGER
	6	MeSH category of the word in (4)	STRING
	7	If a substring of the input disease that end with this character is a suffix	BOOLEAN
	8	If a substring of the input disease that contains this character is in the dictionary	BOOLEAN
	9	If a word that is consist of this character and another is in the dictionary	BOOLEAN
	10	Distance between two characters in (9)	INTEGER
Previous label	11	Dependency labels of Stack[0], Stack[1], Input[0], Input[1]	
	12	Dependency labels of the right/leftmost dependent of Stack[0]	
	13	Dependency labels of the leftmost dependent of Input[0]	
	14	Dependency labels of the character left to Stack[0] in the input disease	

The internal structure presented above can be analyzed automatically in the framework of dependency analysis studied in the area of natural language processing.

(2) Training of Internal Structure Analyzer

As a training corpus, we annotated the Japanese Standard Disease-Code Master [14]. We randomly chose 114 disease names from C (Neoplasms), 96 from E (Endocrine, nutritional and metabolic diseases), 101 from G (Diseases of the nervous system), 125 from H (Diseases of the eye and adnexa), 123 from K (Diseases of the digestive system), 137 from L (Diseases of the skin and subcutaneous tissue). As an extraction condition, we apply the condition that the length of a disease name is longer than six characters. Then we defined internal structures manually. Shorter words appearing within the target words are also annotated. For example, "**肝炎**"(two characters) were annotated because it appears within "慢性非活動性**肝炎**"(eight characters).

As an analyzer, we used MaltParser [12], which is an implementation of shift-reduce parsing. Table 1 presents features used by the analyzer.

Experiment

To investigate the performance of the proposed method, we conducted experiments on the performance of internal structure analysis, and discuss its promise for ICD coding. The experimental setting is the following.

Comparable methods

PROPOSED: the proposed method described in the previous section.

BASELINE: method by which each character depends on the subsequent character (majority baseline).

Evaluation Metrics

According to the sentence parse evaluation manner, we adopted two types of evaluation metrics:

Table 2 – Accuracy of Internal Structure Analysis

		C	E	G	H	K	L	C-L	Overall
Average Word Length		7.6	9.0	8.8	7.3	7.3	5.3	7.4	6.1
PROPOSED	C-ACC	91.7±3.3	96.4±2.3	94.4±1.9	95.3±2.4	94.0±2.8	96.3±3.7	94.0±0.9	95.4±0.8
	E_W-ACC	52.8	71.9	60.2	70.4	63.7	81.9	63.3	75.0
	W-ACC	57.5±11.7	77.4±14.0	64.5±14.6	77.0±8.4	71.5±12.3	86.4±11.3	70.1±2.9	83.7±3.8
BASELINE	C-ACC	81.5±2.5	85.5±1.9	84.8±1.5	81.9±1.6	79.7±4.7	83.3±2.6	82.6±0.9	83.3±1.0
	E_W-ACC	21.1	24.4	23.4	23.3	19.1	38.0	24.3	32.8
	W-ACC	8.5±7.0	7.5±11.0	6.8±6.0	12.0±5.6	9.6±6.3	27.6±4.5	12.2±2.8	27.6±1.8

Accuracies with 95 percent confidence intervals. The first line indicates subset of our training corpus:* **C *Neoplasms,* **E** *Endocrine, nutritional and metabolic diseases,* **G** *Diseases of the nervous system,* **H** *Diseases of the eye and adnexa,* **K** *Diseases of the digestive system,* **L** *Diseases of the skin and subcutaneous tissue. "***C-L***" is aggregation of 6 categories, i.e.* **C**, **E**, **G**, **H**, **K**, **L**. *"***Overall***" is the full set of the*

(1) C-ACC: Character level accuracy

(2) W-ACC: Word level accuracy

For the following example (Figure 3), C-ACC is 2/3 and W-ACC is 0/1.

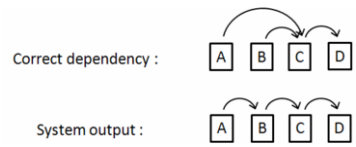


Figure 3 - Example of two accuracies

Materials

Using the annotated corpus, the internal structure analyzer was trained and evaluated using five-fold cross validation.

Results

Table 2 shows the obtained result. An example of the system output is portrayed in Figure 4 (dependency labels were all "D" in the example).

The overall accuracies were 95.4% (C-ACC) and 83.7% (W-ACC). The proposed method is superior to the baseline, especially for W-ACC. The E_W-ACC in this table was calculated as C-ACC to the <average length>-th power. It is the expected word level accuracy with an assumption each character's dependency relations are independent. Actually, W-ACC was superior to E_W-ACC in PROPOSED, although it was not in BASELINE, which shows that the character level-dependency relations are not mutually independent and that the analyzer (proposed method) learned the internal structures well.

The overall accuracy was lower than the reported for an earlier study [11]. As a likely cause, it must be considered that the dependency relation used in our study differs from that in the previous study: the root of the dependency tree was always the end of a word. This difference can influence the result.

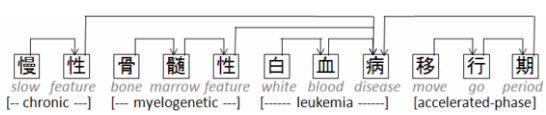

Figure 4 – Example of a correctly analyzed disease

Discussion for ICD coding

The proposed internal structure and its analyzer are helpful for precise ICD coding.

Generally speaking, rule-based ICD coding necessitates two points: coding rules and analyzing input diseases. Coding based on the internal structures proceeds as follows: (step 1) obtain the internal structure of the input disease, (step 2) use coding rules by the internal structure acquired at step 1. At step 1, the analyzer described the work explained above. Next, we discuss the coding rules in step 2.

We defined the representation of the coding rule as "an internal structure => an ICD code". The problem is how to make the rules. The left-hand-side of the rule should be the essence of the concept that the corresponding ICD code (the right-hand-side) denotes.

We propose an example based method: extracting the essential structure from examples sharing the same ICD code.

Figure 5 presents an example of the essential structures of S72.3 and S72.9 based on Figure 1. The structure of S72.3 is the same structure as that of "femoral shaft fracture" in Fig. 1, whereas "incomplete" disappeared in the case of S72.9. That is to say, the essential internal structure for ICD coding is the maximum common subtree of the examples for the ICD code.

The approach described above deals with the order/existence of modifiers (post coordination) that this paper targets. First, the difference of modifiers order is solved by the representation itself because the internal structures of two disease names, which differ from each other merely by the modifier order, are the same. Second, non-essential modifiers disappear when the coding rule is generated.

Once the coding rules have been prepared, the most appropriate rule is sought. An internal structure could fire more than one rule (presuming an input "femoral fracture" and rules presented in Figure 5). Therefore, the question arises: "Which is the correct one?" For this approach, we defined that the rule among candidate rules for which the internal structure (left-hand-side of the rule) size is greatest is the most appropriate.

Coding rules can be adapted even better by changing the comparison strategy: "string match" to "class match". For example, if "femur fracture" is input, neither of the two rules above fire because of the difference of two strings: "femur" and "femoral". The solution is "knowledge", like an ontology, which tells the system that the two strings are of the same class.

As an example, we can presume generation of a rule from two disease names sharing an ICD code, "supracondylar femur fracture" and "distal femoral fracture". The coding rule generated by the strategy "string match" is the same as S72.9. The information that the left-hand-side contains is insufficient. The strategy "class match" is the solution: "supracondylar" and "distal" belong to the same class, at least in the "femur fracture" context.

The rules can be generated automatically by humans or the internal structure analyzer. Which is the better solution—the analyzer or human—presumably depends on the situation.

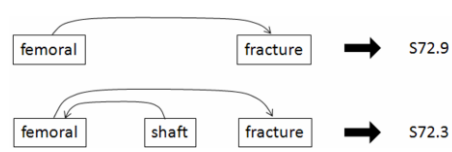

Figure 5 - Examples of coding rules

Previous works

Numerous researchers have examined automatic coding. Such efforts are separable into two groups: (1) term-based [8–10], for which the input is a disease name; and (2) text-based [4–7], for which the input is text such as discharge summaries. The latter have an advantage over the former because they use richer information. Such rich information, however, is not always utilizable. Therefore, it does not motivate our approach.

Another important aspect of coding studies is the coding algorithm such as frequency statistics [10], a Naïve-Bayes classifier [8], and an open registry algorithms [7]. Although various approaches have been proposed, they make use of the input disease name as string, ignoring its internal structure.

Our study differs from these works in the sense that: (1) we use internal structures of disease names, (2) we deal with omission and contraction of characters.

From the perspective of natural language processing, many researchers have examined parsing, i.e., analyzing sentence structures or discourse structures, although they paid less attention to the term structure. Neither is associated with medical informatics. Morphosaurus[13] segments a term into semantically annotated morphemes, however they does not deal with dependency relations.

Conclusion

This paper proposed a new representation for internal structures of disease names. Our character-based representation can deal with peculiar linguistic phenomena—omission and contraction—that previous works have not addressed. For ICD coding, it would be useful to generate coding rules and to analyze the input disease names to be coded.

Abstract

Acquisition and enrichment of lexical resources is an important research area for the computational linguistics. We propose a method for inducing a lexicon of synonyms and for its weighting in order to establish its reliability. The method is based on the analysis of syntactic structure of complex terms. We apply and evaluate the approach on three biomedical terminologies (MeSH, Snomed Int, Snomed CT). Between 7.7 and 33.6% of the induced synonyms are ambiguous and cooccur with other semantic relations. A virtual reference allows to validate 9 to 14% of the induced synonyms.

Keywords:

Natural language processing, Semantics, Vocabulary, Terminology, Medical informatics, UMLS.

Introduction

Within the biomedical area, practitioners and institutions may use different terms, which can convey the same or a close meaning. For example, the terms heart attack, myocardial infarction, and MI present the same meaning to a medical expert, while these expressions remain different to a computer, unless suitable resources and tools are available and used. The purpose of these resources and tools is to compute the semantic similarity between terms and to guarantee semantic interoperability between automatic systems. Such need appears whenever applications like information exchange and retrieval, knowledge extraction, terminology matching are addressed. Lexica of synonyms and of morphological or orthographic variants are typically used for the computing of semantic similarity. Depending on languages and domains, these lexica are not equally well described. The morphological description of languages is the most complete thanks to databases like Celex [1] for English and German, MorTal [2] for French, UMLS Specialized Lexicon [3] for medical English, and similar resources for German[4] and French [5]. At the level of synonyms, little available resources can be found: WordNet [6] proposes synonym relations for English, but the corresponding resources for other languages are not freely available. Otherwise, various existing biomedical terminologies provide complex terms, but their use is less suitable for the biomedical applications [7].

In a previous work, we proposed a method for filling the gap and for acquisition of synonymy resources within biological area: we used an existing structured terminology Gene Ontology [8] in order to induce a lexicon of elementary synonyms. The induced synonyms were then profiled through endogenous information acquired within the same terminology [9]. In the current work, we propose to generalize this method and to apply it to three other biomedical terminological resources: MeSH [10], Snomed Int [11] and Snomed CT [12]. Since synonyms are a contextual phenomena and they may convey more or less close or ambiguous meaning, we propose also a method for transformation of linguistic profiling indicators into numeric values, which are to be used to automatically weight the acquired synonyms. The objective of this part of work addresses the degree of semantic similarity and reliability of synonyms.

Material: semantic relations between terms

Our material is provided by three biomedical terminological resources: MeSH [10], Snomed Int [11] and Snomed CT [12]. These three terminologies are generic to the biomedical area: they propose its general descriptions, although they aim at satisfying different needs. The goal of the MeSH thesaurus is to provide a terminological resource for information retrieval. The goal of the Snomed Int nomenclature is to help the computerization of clinical data. Finally, the goal of the Snomed CT nomenclature is to provide terminological resource for organizing and, more particularly, for exchanging clinical data.

These three terminologies are structured: their terms are related among them with various semantic relationships. We access this information through the UMLS [3], version 2008AB. We extract the semantic relations according to their broad categories as they are defined by the UMLS. These categories are the following: AQ (allowed qualifier), CHD (has child), DEL (deleted concept), PAR (has parent), QB (can be qualifier by), RB (has a broader relationship), RL (has similar

or like relationship), RN (has narrower relationship), RO (has relationship other than synonymous, narrower or broader), RQ (related and possibly synonymous), SIB (has sibling), SY (source-asserted synonymy). These UMLS categories of relationships are assigned on the basis of the source documentation or on the basis of the NLM understanding of the sources. For extraction of our material, we focus on four categories of relationships:

- synonymy relations provide identical or similar meanings. They are extracted within UMLS concepts and correspond to the category SY which links preferred term labels to their synonyms;
- is a relations provide the hierarchical structure for terms. We consider that they are indicated by four broad categories: PAR, RB, CHD or RN;
- sibling relations link terms that have the same hierarchical father. They are indicated by SIB category;
- associative relations may convey various kinds of semantic relations. We consider they are indicated by RO category.

The extracted terms related by these relationships are always restricted to the corresponding terminology. is a, sibling and associative relations take into account preferred and synonymous labels of terms.

Methods

Inducing and profiling synonymy relations

In order to induce and to profile resources of synonymy relations, we applied the method described in previous work [9]. Here, for the sake of clarity, we will mention the general principles of the proposed approach.

Biomedical terms are often coined on the same syntactic scheme and show the compositionality through the substitution of one of their components (underlined):

infection of navel cord; infection of umbilical stump

benign tumour of scrotal skin; benign neoplasm of scrotal skin

We proposed to exploit the compositionality and to induce paradigms of elementary semantic relations (i.e., {*navel cord, umbilical stump*}, {*tumour, neoplasm*} in the examples above). Compositionality of biomedical terms has been exploited previously, especially through Gene Ontology, for consistency checking [13], for adding missing synonym terms [14] or for deriving simple graphs from relations between complex terms [15]. While the cited works are based on the string matching within terms, our approach aims at exploiting the syntactic analysis of terms, according to the compositionality definition [16]: the meaning of a complex expression is fully determined by its syntactic structure, the meaning of its parts and the composition function. We assume that relationship between elementary terms is inherited from the relationship between complex terms having the same syntactic schema and components at the word or semantic level. In this work, we apply the method to several relationships: synonymy, is a, sibling and associative.

Terms are processed through the Ogmios NLP platform[1], and are syntactically analyzed by a dedicated term parser: syntactic dependencies between term components are computed according to assigned POS tags [17] and shallow parsing rules[2]. Thus, each term is considered as a syntactic binary tree (see fig. 1) composed of two elements: head component and expansion component. For instance, *infection* is the head component of *infection of navel cord* and *navel cord* is its expansion component. According to the compositionality principle, the synonymy terms from figure 1 enrich synonym lexicon with {*navel cord, umbilical stump*}. In these two terms, the variation occurs within the expansion components. Besides, the variation can also occur within head components, or even within both components (head and expansion). Each of these cases will be exploited for inducing semantic relations.

Figure 1 - Parsing tree of the synonym complex terms infection of navel cord and infection of umbilical stump

However, semantic relationships as synonymy, are contextual [18]: for a given relation, its profile can vary according to contexts of its instances. In order to help the NLP to exploit such resources, we profile the induced synonymy relations through several types of linguistic indicators generated within the same terminologies:

- Cooccurrence of several elementary semantic relations induced by our approach;
- Lexical inclusion controlled within each induced synonymy pair, because lexical inclusions may convey a hierarchical relation: in the pair {*arterial embolism, embolism*}, *arterial embolism* is a kind of *embolism*;
- Productivity (or number of original pairs from which an elementary relation is inferred) for each induced semantic relation, including lexical inclusion.

Weighting and evaluating induced synonyms

The linguistic indicators (productivity, lexical inclusion, cooccurrence of semantic relation) will be used for automatic computing of weights for each induced synonymy relation. Currently, these indicators are descriptive and symbolic: they are meaningful to human users, but they have no exploitable meaning to a computer. In that respect, we have to: (1) transform the symbolic indicators into numeric values, and (2) propose an approach for combination of these values into a weight associated to each synonymy relation.

According to our general observation, reliability of the induced synonymy relations is closely related to its profile: pro-

[1] http://search.cpan.org/~thhamon/Alvis-NLPPlatform/
[2] http://search.cpan.org/~thhamon/Lingua-YaTeA/

ductivity and cooccurrence with other semantic relations. For computing the numeric weight and reliability of each synonymy relation rel_i, we propose to sum weights of all the cooccurring indicators. The weight of each indicator corresponds to the product of its productivity $prod_j$ and coefficient α_j. The general formula is the following:

$$weight(rel_i) = \sum_{j \in \{syno, is\_a, asso, sib, incl\}} \alpha_j \times prod_j(rel_i)$$

Values of coefficients α_j were determined empirically, they are amplified by their productivity values.

- α_{syno} was set to 1: it is the highest value established, which gives more reliability to a given relation.
- Since is a relation weakens the synonymy reliability, its value α_{is_a} was set to 1.
- Lexical inclusion may convey both hierarchical relation, like is a, and synonymy through the elision phenomena. Its value α_{incl} was thus set to 0.5.
- associative and sibling relations also weaken reliability of synonymy but to a lesser extend than is a: there values α_{asso} and α_{sib} were set to 0.75.

With such set of α values, positive weights signify more reliable synonymy relations. The reliability increases as the positive values increase.

There is no gold standard for the evaluation of a lexicon of synonyms within the biomedical area: the only available WordNet resource appears to be unsatisfying [19, 20]. Here again, we propose to take advantage of the exploited terminologies in order to evaluate our results. We will generate a *virtual truth*: set of synonyms induced by our method, which are already present in the exploited terminologies.

Results and Discussion

Building the material

In Table 1, we give indications on volume of material available in UMLS for the three processed terminological resources: numbers of terms (labels) and of the corresponding CUIs, and numbers of the extracted semantic relations (synonymy, is a, sibling and associative). We can observe that Snomed Int provides low number of semantic relations, but it has also the lesser number of terms. While MeSH and Snomed CT propose a richer network of relations and of the involved terms. Otherwise, sibling relationship is proposed only by MeSH.

Table 1 - Number of terms (labels and CUIs) and number of semantic relations (synonymy, is a, sibling, associative) provided by three exploited terminologies

	MeSH	Snomed Int	Snomed CT
number of terms	684,211	164,180	1,143,186
number of CUIs	291,746	112,709	313,612
Synonymy	469,847	57,111	399,712
is a	1,627,703	237,702	2,496,097
Sibling	7,870,078	—	—
Associative	265,178	213,108	6,166,776

Inducing and profiling the synonymy relations

All the semantic relations among complex terms from the three processed terminologies have been fully analyzed through the Ogmios platform. Compositional rules have been applied and allowed to induce elementary synonymy, is a, sibling and associative relations. Numbers for each type of the induced relations within each terminology are indicated in Table 2. Lexical inclusions have been controlled for each synonymy relation: they are indicated in Table 2, line *l.inclusion*. The last two lines of the table indicate the number of synonymy relations which cooccur with other semantic relations, and their percentage. Productivity of the induced relations within original complex terms have been also computed.

Table 2 - Number of induced semantic relations (synonymy, is a, sibling, associative and lexical inclusion) in three exploited terminologies, and number of ambiguous synonymy relations

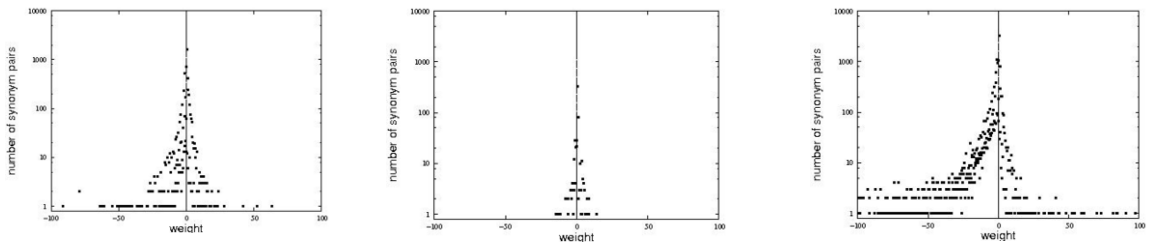
	MeSH	Snomed Int	Snomed CT
Synonymy	29,741	7,950	39,921
is a	53,015	3,906	127,197
Sibling	(142,360)	—	—
Associative	4,623	2,248	96,862
l.inclusion	7,777	999	28,633
common (number)	3,847	611	13,409
common (%)	12.9%	7.7%	33.6%

7.7% of synonymy relations induced within the Snomed Int are cooccurring and ambiguous with other induced semantic relations, while within the MeSH ambiguous synonymy relations are more frequent (12.9%). As MeSH is the only terminology that proposes sibling relationship, these are not taken into account. If they are, number of ambiguous synonymy relations is 6,809 (22.9%). The highest ambiguity is observed within Snomed CT: up to 33.6%.

Weighting and evaluating induced synonyms

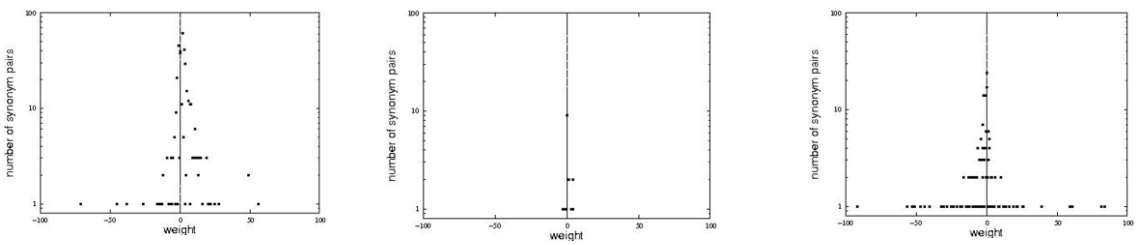
Weights of the synonyms induced within the three processed terminological resources have been computed according to the proposed formula. Figure 2 indicates distribution of these weights (x-axis) for synonyms that cooccur with other semantic relations.

The central vertical line materializes the frontier between positive and negative weights. The y-axis of the figure is



MeSH Snomed Int Snomed CT

Figure 2 - Weights of induced synonymy relations cooccurring with other semantic relations



MeSH Snomed Int Snomed CT

Figure 3 -Weights of induced synonymy relations within the set of the virtual truth (subset of relations from Figure 2)

algorithmically scaled and indicates number of synonym pairs that show a given weight. For instance, within Snomed Int, 2 pairs of synonyms -{*bleeding, haemorrhage*} and {*bleeding, hemorrhage*}- have been assigned the weight of 8.75: they occur 11 times as synonyms and cooccur 3 times with associative relations. The extremities of the weight values can exceed the figure. Thus, the interval of values for MeSH is [-393, 388], [-14.25, 14] for Snomed Int, and [-510.5, 404] for Snomed CT. We can observe that the negative and positive frontiers of these intervals are parallel, except for Snomed CT; and that the amplitude is the highest within Snomed CT and lowest within Snomed Int. But the latter provides also the lowest number of terms and relations. There is a tendency of the point's cloud to be attracted to negative values, except for Snomed Int-induced synonyms.

Table 3 - of induced synonyms which are present in the three terminologies: validation through a virtual truth

	Existing synonyms				
	MeSH	***SNInt***	***SNCT***	***VT***	**%**
MeSH	2,438	198	560	2,692	9%
SN Int	290	438	979	1,102	13.9%
SNCT	1,043	1,322	5,211	5,575	14%

Table 3 indicates number of induced synonyms that are already known in the three processed terminologies. For instance, 2,438 MeSH-induced synonym pairs are already registered in this terminology, and 198 MeSH-induced synonyms are already registered in Snomed Int. We can observe a large number (5,211) of Snomed CT-induced synonyms that are already known in there: this resource provides many elementary, or non defined, terms of the biomedical area, although it doesn't allow to build an extensive set of the synonyms. The total number of the induced synonyms that exist within at least one of the exploited terminologies is 8,023. This set of synonyms is used to build up the virtual truth, on which basis we perform a further evaluation of the results. The last two columns of Table 3 indicate number and percentage of the induced synonyms that are also in the virtual truth (VT) set: 9% of MeSH synonyms, 13,9% of Snomed Int and up to 14% of Snomed CT-induced synonyms are thus validated. Other induced synonyms are new. Figure 3 indicates the distribution of weights for the induced synonyms that are also part of the virtual truth set. We can observe that number of ambiguous synonymy relations is very small among Snomed Int-induced synonyms, and that the point's cloud of MeSH is now attracted to positive values. Within Snomed CT, the ambiguity of synonyms is still the most important.

Quality of results provided by this method depends (1) on precision of POS-tagging and we tried to apply the best currently known tagger [17]; (2) on quality of the source material; and (3) on the verification of a compositional structure of terms: up to now we have found only one pair of French terms where the compositional structure was not respected {*coup de soleil, sensibilité au soleil}* meaning (*Solar sensitiveness*), where *coup de soleil* is not compositional.

Conclusion and Perspectives

We proposed a novel method for inducing a lexicon of synonyms from structured terminologies and for its weighting in order to help the natural language processing-based applica-

tions. This method exploits the compositionality principle and three rules based on syntactic dependency analysis of terms for inducing the synonyms. We exploit also a set of endogenously generated linguistic indicators (is a, sibling, associative, l.inclusion and their productivity) for profiling the induced synonymy relations and for computing their weight. If a synonymy relation is free of other semantic relations, its reliability is not hindered. Otherwise it suffers from these cooccurring relations. Thus, up to 33.6% of synonymy relations induced within Snomed CT are ambiguous with other semantic relations. The ambiguity is lower within MeSH (12.9%) and Snomed Int (7.7%). Weights of these ambiguous synonyms are attracted to negative values, which indicate less reliable synonyms. A virtual truth set of synonyms is built up with those induced synonyms that are also provided by the exploited terminologies. It allows to validate 9 to 14% of the induced synonyms. It also allows to observe that within this set, the ambiguity of the induced synonyms is lesser, particularly within MeSH and Snomed Int. Weights provided by the current work are helpful for the filtering step of synonyms and for preparing their validation. We noticed that the used material can be improved. For instance, it seems that there is an inconsistency in creating the broad categories of relations within UMLS: mapped to relations from source terminologies are currently assigned to RL, RQ, RN and RO relationships, which means that they may appear in both is a and associative categories. If a specific filter is applied, the material may provide less ambiguous set of induced synonyms. Besides, other NLP methods suitable for analysis of corpora may be used in order to enrich or cross-validate lexicon of synonyms acquired in this experience. Once thoroughly validated, this lexicon will be made available to the community. This lexicon can be exploited within various NLP tasks and applications.

Abstract

Recently, electronic medical record (EMR) systems have become popular in Japan, and number of discharge summaries is stored electronically, though they have not been reutilized yet. We performed text mining with Tf-idf method and morphological analysis in the discharge summaries from three Hospitals (Chiba University Hospital, St. Luke's International Hospital and Saga University Hospital). We showed differences in the styles of summaries, between hospitals, while the rate of properly classified DPC (Diagnosis Procedure Combination) codes were almost the same. Beyond different styles of the discharge summaries, text mining method could obtain proper extracts of proper DPC codes. Improvement was observed by using integrated model data between the hospitals. It seemed that huge database which contains the data of many hospitals can improve the precision of text mining.

Keywords:

Text mining, Discharge summary, Electronic medical record.

Introduction

With the spread of recent hospital information systems, the discharge summary begins to be saved electronically at many hospitals in Japan. However, every hospital has its own style of discharge summaries. In addition, an inconsistent form is used in every hospital, so there is no suitable study samples comparisons of discharge summaries among different hospitals.

In Chiba University Hospital, full text computerization of electronic discharge summaries began in 1999. We reported to past MEDINFO congress that useful information was obtained from summaries by text mining [1-3]. However, we were not able to conclude that the results were generally valid, since the styles of summaries are different. Therefore, it is necessary to review whether our conventional method can be applied to other hospitals. We tried a cross-sectional comparison experiment for the discharge summary of the St. Luke's International Hospital and the Saga University hospital. All these hospitals are major hospitals in Japan.

Using text mining we performed an experiment to select DPC (Diagnosis Procedure Combination) from the discharge summary. DPC or so called Japanese version of DRG (Diagnosis Related Group) is a classification that has become the basis of an inclusive evaluation system of hospitalization health care cost.

Figure 1 shows the structure of the DPC code. The first two digits are the Major Diagnostic Category (MDC) and the next four digits stand for the disease name. The remaining eight digits indicate the admission purpose, age, operation, treatment, complication, and severity.

DPC code is given to the discharge summaries of all hospitals. Therefore, we consider that we can compare between different hospitals using a DPC code. We examined the differences in the structure of the discharge summaries of each hospital by examining the type and the frequency of the extracted terms.

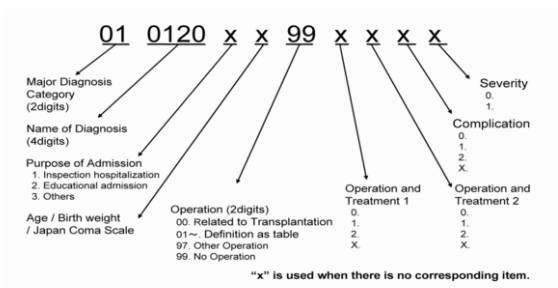

Figure 1 –Sample of DPC code "Idiopathic mono neuropathy; no operation"

Materials

Discharge Summary

We have analyzed discharge summaries of patients, who had been discharged from Chiba University Hospital, St. Luke's International Hospital and Saga University Hospital between April, 2006 and March, 2008. All analyzed discharge summaries had been written and stored electronically and had been

assigned a DPC code. The numbers of discharge summaries extracted from each hospital are as follows.

1. Chiba University Hospital: 24,594
2. St. Luke's International Hospital: 24,002
3. Saga University Hospital: 1,188

Problems with discharge summaries in each hospital

Each of the three hospitals has original discharge summary formats. We describe the general conditions and problems with the discharge summaries of the hospitals in the following.

Chiba University Hospital

A chief physician inputs the discharge summary as free text within two weeks after patient's discharge. The entry item is standardized, but there is no clear standard about the length of a summary, and a significant difference occurs between departments.

St. Luke's International Hospital

Both entry item and length are standardized. Because the length tended to get too long before, they set up one page limit. Their aim was a concise summary which could be read within twenty seconds.

Saga University Hospital

A chief physician can extract necessary information from the electronic patient record semi-automatically to make a discharge summary and convenient for physicians.

Methods

Morphological Analysis and Reconstruction of the Dictionary

Morphological analysis that decomposes a character string into elements such as a noun, adjective, and particle, is necessary for the analysis of Japanese sentences. Chiba University Hospital and St. Luke's Hospital have improved the precision of the Japanese medical dictionary conventionally for the process of morphological analysis. We use the user's medical dictionary of both hospitals together in this study.

The PHYXAM dictionary was used as a Japanese medical technical dictionary for the physical examination field [4]. Terms from the master table of both hospitals were added to the dictionary. The unknown terms from the discharge summaries were also added to the dictionary. Then our dictionaries included about 320,000 terms.

We used Mecab ver0.96 developed at Kyoto University information science graduate course as a morphological analysis system for Japanese sentences [5].

Investigate the characteristics of the summaries

We compared the following points among hospitals. We extracted only the nouns to characterize a sentence, and counted the number of terms and their type that appear in each summary.

Number of terms included in summary

We compare a difference of the summaries by the number of terms which were extracted by morphological analysis. We examined dispersion of the number of terms by values of mean, median, standard deviation, maximum and minimum. Normality was certificated by the Kolmogorov-Smirnov official.

Comparison by MDC

Discharge summary may be different between different medical departments, because the day of hospitalization, surgery and treatment varies according to a disease.

MDC is called major Diagnostic Category, and is expressed with the first two digits of the DPC code. MDC divides all diseases into 16 categories of a macrotaxonomy.

The hospitals we intended for this study were general hospitals with a vast array of medical departments. Therefore we could extract MDC from all discharge summaries (Table 1).

Table 1 - Disease of MDC

MDC	Disease
01	Nervous system disease
02	Ophthalmologic disease
03	Otorhinolaryngological disease
04	Respiratory disease
05	Circulatory disease

07	Musculoskeletal system disease
08	Skin and Subcutanea disease
09	Breast disease
10	Endocrine and Metabolism disease
11	Urogenital system disease
12	Gynopathy and Obstetrical disease
13	Blood and Immunological disease
14	Anomary and Newborn infant disease
15	Pediatric disease
16	Injury, Toxicosis and Other diseases

Comparing the precision of DPC selection

Grouping of data

We arranged the summaries of each hospital according to a discharge date and divided them into two groups in a ratio of 7:3, each of which had at least 10 cases in St. Luke's International Hospital and Chiba University Hospital. The first group was collected to generate document vector space model according to the DPC, the second group was collected as a test group to verify automatic DPC selection. In Saga University Hospital, all the summaries were assigned to a second group. In this way, we selected 20,013 cases for this study. The cases contained 97 different DPC codes. We show the number of the cases in Table 2.

Table 2 - Number of summaries

	Data for model	Data for verify
Saga university hospital	0	218
St. Luke's International Hospital	7,421	3,197
Chiba University Hospital	6,416	2,761
Total	13,837	6,176

Vector Space Model

The vector space model, which converts the characteristics of a document into a multidimensional vector, is a technique widely used in the field of information retrieval [6, 7]. In this study, we calculated the weights of each term to convert the characteristics by term frequency–inverse document frequency (tf-idf) method. The targeted discharge summary set is assumed to be $\boldsymbol{D}$, and the discharge summary sets of each disease are assumed to be $\boldsymbol{d_1, d_2, \cdots, d_j, \cdots, d_n}$. Next, $\boldsymbol{m}$ pieces of index terms extracted from $\boldsymbol{D}$ are assumed to be $\boldsymbol{\omega_1, \omega_2, \cdots \omega_i \cdots \omega_m}$. Thus, the weight in the discharge summary $\boldsymbol{d_j}$ added to index term $\boldsymbol{\omega_i}$ is assumed to be $\boldsymbol{\alpha_{ij}}$. Then, discharge summary $\boldsymbol{d_j}$ can be expressed by a matrix composed of $\boldsymbol{m}$ pieces of element $\boldsymbol{\alpha}$. Consequently, the sets of discharge summary $\boldsymbol{D}$ can be defined as a collection of matrices of $\boldsymbol{d_n}$, as shown in Figure 2.

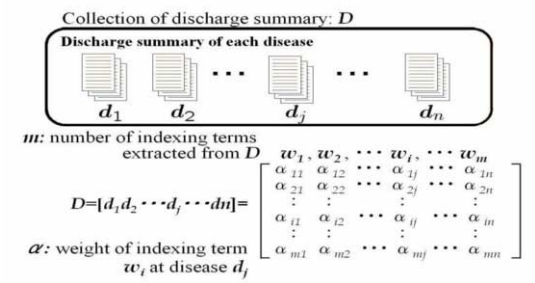

Figure 2 - Vector space model

tf-idf Method

In tf-idf method, weight $\boldsymbol{\alpha_{ij}}$ is shown by $\boldsymbol{\alpha_{ij}=(l_{ij}\times g_i)/n_j}$.

$$\boldsymbol{\alpha_{ij}=(l_{ij}\times g_i)/n_j} \quad (1)$$

$$\boldsymbol{l_{ij}=log(1+f_{ij})} \quad (2)$$

$\boldsymbol{l_{ij}}$ is local weight, and it is calculated based on the frequency data in document D_j of index term $\boldsymbol{\omega_i}$ and a big value is given to the index term that appears frequently in the document. Frequency data $\boldsymbol{f_{ij}}$ in discharge summary $\boldsymbol{d_j}$ of DPC classification $\boldsymbol{j}$ of index term $\boldsymbol{\omega_i}$ was used this time.

$$\boldsymbol{g_i=log(n/n_i)} \quad (3)$$

$\boldsymbol{g_i}$ is global weight, and it is calculated based on the index term $\boldsymbol{\omega_i}$ distribution over the entire document set, and a big value is given to the index term that appears only in a specific document. $\boldsymbol{n}$ is total number of the discharge summary, and $\boldsymbol{n_i}$ is a number of discharge summaries including index term $\boldsymbol{\omega_i}$.

$\boldsymbol{n_j}$ is a document normalization coefficient to which removes the influence by the length of the discharge summary.

DPC Selection

We determined the DPC code from discharge summaries based on the calculated vectors. We calculated the inner products of the vectors to compare the similarity between each summary and the DPC code of a model group. When we select a DPC code of the summary for inspection, we use a DPC code from models that have high similarity. However, as for just using a DPC code of the summary that shows a highest similarity, is influenced by accident. Therefore we judged a DPC code of a test summary by a weighting point calculation of multiple summaries (Figure 3)

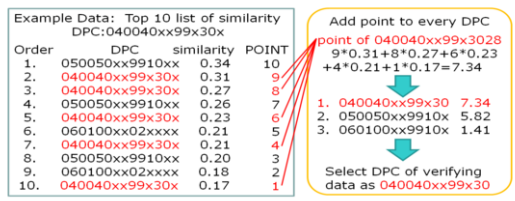

Figure 3 - DPC selection by weighting point

At first we select the top 10 summaries from a model group by similarity, and calculate a weighting point based on order and ratio. We expressed the weighting point (P) by the product of order (Rank) and similarity ratio (S (A, B)).

$$\mathbf{P\ (Rank) = S\ (A, B) \times (11 - Rank)} \quad (4)$$

Then we selected a DPC code of which sum of points was the greatest among DPC code test data. By this technique, precision was improved from 2% to 5% (Data not shown). Next, we counted the cases in two groups. Selected code was exactly the same as the original code of test case in the first groups, and it matched the first 6 digits of the code in the second group.

Cross match selection

We replaced or integrated the data of multiple hospitals and carried out the selection experiment as follows.

- We verified test data with their own model data. (experiment No.1,2)
- We verified test data with other hospital's model data. (experiment No. 3 - 6)
- We verified test data with integrated model data (experiment No. 7-9)

Results

Comparison by morphological analysis

Comparison by number of terms

We have shown the number of terms in the discharge summaries from each hospital in Table 3. The average number of terms is almost the same between St Luke's International hospital and Saga university hospital, however about twice that of Chiba university hospital. St. Luke's International Hospital has a small difference of the median and the mean, and the standard deviation is small, too, Chiba University Hospital has a large standard deviation and the median is smaller than the mean. In Saga University Hospital, the gap is smaller than that of Chiba University Hospital, but standard deviation is the largest among the three hospitals.

The normality of all hospitals was dismissed by the Kolmogorov-Smirnov certification, however St. Luke's International Hospital is the nearest in normal distribution.

Table 3 - number of terms in discharge summary

	Chiba University Hospital	St. Luke's International Hospital	Saga university hospital
mean	136.4	285.0	281.7
median	79	295	247
SD	164.4	123.5	181.5
minimum	1	24	5
maximum	1921	830	1261

As shown in Figure 4, the numbers of cases according to the number of terms in one summary are in inverse proportion at Chiba University Hospital. By contrast, they are distributed in the neighborhood of a mean at St. Luke's International Hospital. Saga University Hospital was in the middle.

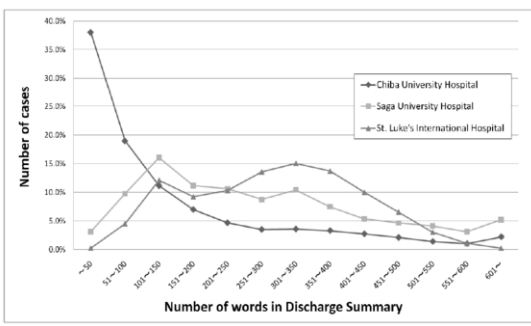

Figure 4 - Number of cases according to the number of terms

Comparison among number of terms by MDC

Figure 5 shows the comparison of the average number of terms according to MDC. Pattern of St. Luke's International

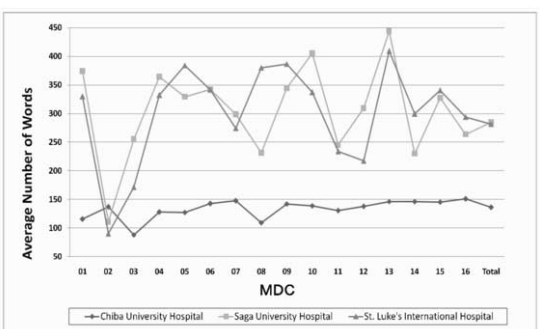

Figure 5 - Comparison among number of terms by MDC

Hospital resembles Saga University Hospital except 06 (Digestive system disease). Chiba University Hospital has a smaller number of terms and smaller difference between diseases than the other hospitals.

Comparison by precision of DPC selection

Selection by the data of same hospital

At first, we show a DPC selection rate where we used the model data of the same hospital for verification (see Table 4). Selection rate at Chiba University Hospital and St. Luke's International Hospital is approximately of equal value. These results show that the application of the method is independent of each institute.

Table 4 - DPC selection by same hospital data

No.	Data for selection		Precision of DPC selection	
	verify	model	Match 14 digit	Match 6 digit
1	Chiba (2761)	Chiba	75.9% (2097)	85.8% (2370)
2	St. Luke's (3197)	St. Luke's	78.9% (2524)	84.7% (2708)

Selection by the data of different hospital

Next, we show a cross match selection where we used the model data of different hospitals (see Table 5). For Chiba University and St. Luke's International Hospital, it seems that the selection rate falls about 10-20% in comparison to experiment 1, 2.

Table 5 - Selection by the data of different hospital

No.	Data for selection		Precision of DPC selection	
	verify	Model	Match 14 digit	Match 6 digit
3	Chiba (2761)	St. Luke's	62.5% (1725)	73.4% (2029)
4	Saga (3197)	Chiba	61.9% (1979)	68.2% (2182)
5	Saga (218)	St. Luke's	56.4% (123)	72.0% (157)
6	Saga (218)	Chiba	50.9% (111)	63.7% (139)

Selection by the integrated data

Finally, we show the DPC selection rate when using the integrated model data of Chiba University and St. Luke's International Hospital and verify data of each hospital (see Table 6).

Precision of St. Luke's International Hospital was the same as the result of experiment 2 where only its own data was used. The results of Chiba University hospital slightly improved in comparison with experiment 1.

The data of Saga University hospital also improved by using integrated data. The ratio extracted from the two hospitals was almost the same (Chiba 54%, St. Luke's 46%).

Table 6 - Selection by the data of integration

No.	Data for selection		Precision of DPC selection	
	verify	model	Match 14 digit	Match 6 digit
7	Chiba (2761)	Chiba + St. Luke's	76.5% (2114)	85.9% (2374)
8	Saga (218)	Chiba + St. Luke's	56.8% (124)	70.6% (154)
9	St. Luke's (3197)	Chiba + St. Luke's	77.1% (2465)	82.7% (2644)

Discussion

In the medical field, text mining applied to clinical contents are still rare [8]. One of the reasons is the lack of accumulated electronic medical documents to be analyzed, although there is a suitable target, Medline, which integrates numerous medical abstracts [9,10].

We described the different and common characteristics among the three hospitals. The length of the summary at Chiba University Hospital is half of that at other hospitals. At St. Luke's international and Saga University Hospital, about 30% of the summary surpasses 400 words. In Saga University hospital about 30% of the summaries have less than 150 words, indicating a big difference of the summaries. The length of the discharge summaries was also different by MDC. For example, 03 (otolaryngology diseases) have fewer words, adversely 13(blood/immune organ diseases) has many words. It was considered that these were common characteristics of the diseases and independent from hospitals.

The DPC selection rate at Saga University hospital is not high, implying that the terms of their summaries were not included in a dictionary. Difference of term structure of the summaries of each hospital decreased the precision of the DPC selection when we use the model data of another hospital. However the difference is not so large that we can consider the vector space model by tf-idf method selects a DPC independent from an institution. Improvement of the precision was observed when we use integrated data of hospitals. It suggests the possibility to improve precision by correct summaries from many hospitals.

When an integrated database of discharge summaries beyond hospitals is available, text mining will provide us with various application, such as acquisition of knowledge [11], similar case search [12], automatic coding of findings [13], extracts cancer staging from pathology reports automatically [14], and making classification automatically [15, 16] as well as comparison of many quality indicators between facilities.

Conclusion

Using a vector space model by the text mining method, we carried out a DPC selection based on the discharge summary from multiple hospitals. We have shown by morphological analysis that there was a difference in term structure among the discharge summaries of each hospital.

We were able to carry out a DPC selection independently of hospitals. Furthermore, improvement was observed by using integrated model data between the hospitals. A giant database which contains the data of many hospitals could improve the precision of text mining.

Abstract

Background: Adverse Drug Events (ADEs) endanger the patients. Their detection and prevention is essential to improve the patients' safety. In the absence of computerized physician order entry (CPOE), discharge summaries are the only source of information about the drugs prescribed during a hospitalization. The French Multi-Terminology Indexer (F-MTI) can help to extract drug-related information from those records. Methods: In first and second validation steps, the performance of the F-MTI tool is evaluated to extract ICD10 and ATC codes from free-text documents. In third step, potential ADE detection rules are used and the confidences of those rules are compared in several hospitals: using a CPOE vs. using semantic mining of free-text documents, diagnoses and lab results being available in both cases. Results: The F-MTI tool is able to extract ATC codes from documents. Moreover, the evaluation shows coherent and comparable results between the hospitals with CPOEs and the hospital with drugs information extracted from the reports for potential ADE detection. Conclusion: semantic mining using F-MTI can help to identify previous cases of potential ADEs in absence of CPOE.

Keywords:

Adverse drug events, Electronic health records, Semantic mining, F-MTI, Medical reports, Discharge summaries, Terminology as topic.

Introduction

Adverse drug events (ADEs) are situations where some drugs, eventually combined with other drugs, lab abnormalities or clinical context lead to adverse events. Those events endanger the patients and induce extra costs. Many of those events can be prevented thanks to appropriate prescriptions or monitoring. ADE study often relies on electronic health records (EHRs). In those EHRs, computerized physician order entries (CPOEs) are the most important components because they provide reliable and available information about drug prescriptions. Unfortunately, many hospitals do not have any CPOE at disposal. But in that case, the free-text documents usually contain the main drug prescriptions: discharge summaries, discharge letters, exam reports, etc. A semantic-mining tool can extract that information from the text. The objective of this work is to check if a semantic mining tool can be used to extract drug codes in order to identify previous ADEs and to compute the confidences of potential ADE detection rules.

A tool has been developed since 2005 by the CISMEF team (Rouen University Hospital) and the Vidal company [1] and is called "F-MTI" French Multi-Terminology Indexer (a generic automatic indexing tool able to index documentation in several health terminologies). F-MTI is the property of the VIDAL Company. The aim of this study is to evaluate the F-MTI's performances for potential ADE detection.

Rationale

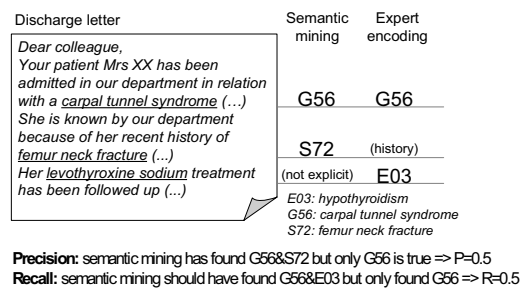

Figure 1 - Example of semantic mining applied on a discharge letter; precision and recall computation

FMTI (the French Multi-Terminology & Multi-Lingual Indexer) indexes any electronic text document with several terminologies. Work on the 2008 European Union funded PSIP project devoted to optimizing patient safety during drug prescription led to the addition of four new terminologies devoted to drugs into F-MTI's knowledge sources: the Anatomical Therapeutic Chemical (ATC) Classification (N=5,514), drug names with international non-proprietary names (INN) and brand names (N=11,353), the Orphanet thesaurus for rare dis-

eases (N=7,424) and the chemical substances and pharmacological action terms of the MeSH Supplementary Concepts translated into French by the CISMeF team (N=6,505 out of over 180,672) [2].

Actually, FMTI includes 16 terminologies and 5 languages (French, English, Spanish, Portuguese and Danish).

- Terminologies : ICD10 (fr/eng/dk), SNOMED3.5 (fr), CCAM (fr), MeSH (fr/eng), TUV (fr/sp/pt/eng), DCI (fr), NC (fr), MeSHSC (fr), ATC (fr/eng/dk), VCM (fr), ICD9 (eng/fr), ICPC (fr), DRC (fr), IUPAC (dk), ACTS (dk)
- Mappings : ICD10-MeSH, ICD10-SNOMED3.5, SNOMED3.5->ICD10, MeSH-SNOMED, ATC->MeSH, MeSHSP->MeSH, ATC->VCM, ICD10->VCM. Some mappings are taken from the UMLS, other mappings were manually created by several experts team from Orphanet, Vidal and CISMeF.

FMTI is called via a Web API, where the terminologies and the languages used for indexing can be selected. The results are returned in HTML, TXT and XML.

For each discharge letters, the document is first broken into sentences. Then each sentence is normalized (accents are removed, all words are switched to lower case and stemmed…) and stop words are removed to form a bag of words containing all the content words. The "bag" thus obtained is matched independently of the order of the words against all the 15 terminologies terms that have been processed in the same way. All terms formed with at least one word of the sentence are retrieved. Longer matches are preferred to shorter ones. All these candidate indexing terms are restricted to the semantically closest ATC and ICD10 terms using inter-concept relationships. FMTI can index a discharge letter in less than 1 second.

Semantic Mining is mainly oriented towards automatic indexing. For the evaluation of automatic indexing, different criteria can be measured, according to the literature [3-4]. The quality of the automatic indexing is evaluated by comparing the results of this automatic indexation (the candidate set) and the results of a gold standard (the gold standard set) on an evaluation dataset. The gold standard is the manual indexing performed by a human expert (Figure 1). For that purpose, different measures are commonly recognized as pertinent:

- **Precision (P)** is the number of indexing terms present in both candidate and gold standard sets divided by the total number of indexing terms in the candidate set. It measures the ratio of signal.
- **Recall (R)** is the number of indexing terms present in both candidate and gold standard sets divided by the total number of indexing terms in the gold standard set. It measures how well gold standard indexing terms are retrieved.
- **F-measure (F)** is the weighted harmonic mean of precision and recall. The traditional F-measure or balanced F-score is: $F = 2 * P * R / (P + R)$ where F is the F-measure, P is the precision and R is the recall.

In this study, three main metrics are calculated to show the performance of F-MTI indexing compared to the gold standard manual indexing: Precision, Recall and F-measure. These metrics are often used to evaluate the performances of automatic indexing tools [5].

Materials and Methods

In order to evaluate the equivalence of Semantic Mining and complete EHRs including CPOEs for ADE detection, three complementary validation methods are applied. The 10th revision of the International Classification of Diseases (ICD10) classification is used for diagnoses. The Anatomical Therapeutic Chemical classification is used for drugs.

Step 1- extraction of ATC codes from free-text documents: agreement between F-MTI and experts

The aim of this first phase is to measure the accuracy of the extraction of the drug names included in the various free-text documents by means of the F-MTI Semantic Mining Analyzer.

Several de-identified discharge letters are obtained:

- 4,000 from the Rouen University Hospital (F), from which 50 are used for the validation task
- 10,000 from the Denain General hospital (F) , from which 32 are used for the validation task

The drug names extracted by automatic semantic mining (F-MTI) are compared with the ones obtained from human medical expertise.

In the discharge letters, the drug names appear as brand or commercial names in 90% of cases, or as international names (INN). The list of brand names and INN names available in France are provided by the Vidal Company [1].

F-MTI indexing tool is used to extract the drug names and index them into ATC Codes: the results are gathered in the candidate set. The gold standard set is the result of the manual indexing performed by a human expert: the gold standard set. Human experts are a pharmacist and a medical archivist in Rouen; and two physicians in Denain.

In each free-text document, the Experts list

- the drug names recorded in the document (this is the "gold standard"),
- the drug names extracted by the F-MTI semantic tool.

Those lists are used to compute the precision and the recall.

Step 2- extraction of ATC & ICD10 codes from free text: agreements between F-MTI and EHR

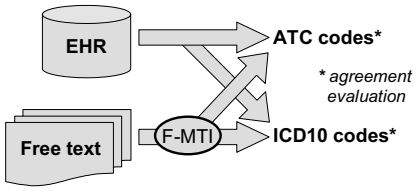

Figure 2 - Second validation step

In the Denain General Hospital, both the CPOE and the free-text documents are available. In this phase, the results of the semantic mining of the free-text documents (for the identification of the drugs prescribed or administered to the patient) are compared with the ones registered in the CPOE (Figure 2). This phase allows for computing the concordance between semantic mining analysis results and CPOE extraction for the identification of the drugs potentially linked with potential ADEs. This phase is only feasible in a hospital equipped both with a Hospital Information System containing the free-text documents and a CPOE System.

37 anonymized patients' complete EHRs from the Denain General Hospital are used. Those records include:

- data from the EHR and the CPOE: ICD10 codes for diagnoses, ATC codes for drugs,
- the free-text documents and the results of the automatic indexing of these letters by Semantic Mining (F-MTI): ICD10 codes and ATC codes too.

The Method consists in the careful comparison of the codes obtained from semantic mining of the free-text documents with the codes contained in the EHR and CPOE. The comparison of drug codes (through ATC Classification) and the comparison of diagnosis codes (through ICD10 classification) are performed separately. The so-obtained codes are compared. The recall R and the precision P are computed in each case.

This third validation phase consists in exploring the results of data-mining-based potential ADE detection rules when drugs are obtained from Semantic Mining of the various free-text documents, in case of absence of CPOE. This is done by studying the frequency of potential ADEs in the Rouen university hospital and comparing this frequency with the ones observed in hospitals where a CPOE is implemented (Copenhagen and Denain) (Figure 3).

The Material is represented by 245 data-mining-based detection rules obtained from various departments [6]. Those rules are a set of conditions that can lead to a traceable potential ADE. For each rule, the confidence is computed in Denain, Copenhagen and in the Rouen University Hospital where Drugs are obtained from Semantic Mining Analysis.

Step 3- validation of the use of the semantic mining results for data-mining-based ADE detection

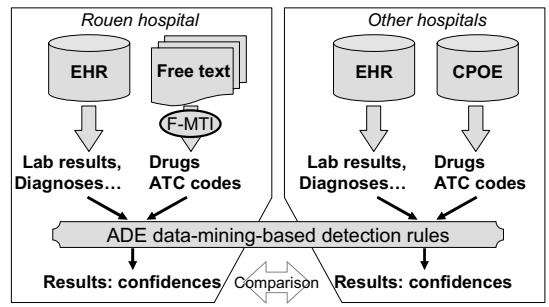

Figure 3 - Third validation step

Each rule is characterized by its confidence (1: proportion of outcome knowing that all the conditions are met) and its support (2: proportion of records matching both conditions and outcome).

$$\text{Confidence} = P(E \mid C_1 \cap \ldots \cap C_k) \quad (1)$$

$$\text{Support} = P(E \cap C_1 \cap \ldots \cap C_k) \quad (2)$$

The Method consists in the comparison of the confidences (positive predictive values) of the rules in the different places:

- the Rouen hospital where ATC codes are extracted from summaries,
- the other hospitals where ATC codes are extracted from CPOEs. The datasets from Denain and Copenhagen are pooled together to have only 2 datasets to compare. Moreover, pooling all the other datasets allows to get a better estimate of the confidence of the rules.

For each rule, all the stays that match the conditions of the rule are considered. The aim is then to test the independency between two binary variables using a Fisher's exact test:

- the occurrence of the effect (0 = "No" / 1 = "Yes"),
- the drug extraction method (CPOE/semantic mining)

For a given rule two results can be obtained:

- if p value < 0.05 then there is a significant difference between the confidence of the rule in Rouen and in other hospitals (the variables are not independent)
- if p value > 0.05 then no significant difference is observed between the confidence of the rule in Rouen and in other hospitals.

None of those results is interesting rule by rule. If significant p value is obtained for one rule, it is not surprising because the PSIP project showed that the confidences of the rules depend on the context in which they are used in (the patients, the practices and the knowledge are different) [7]. But if most of the rules look like having similar confidences in Rouen than in

other places, it is an argument to say that the results of rules evaluation are consistent in Rouen compared with other hospitals.

Results

Step 1- extraction of ATC codes from free-text documents: agreement between F-MTI and experts

The main results in the Rouen university hospital are:

- the overall Precision is **P = 0.84**
- the overall Recall is **R = 0.93**
- the F-measure is **F = 0.88**.

The main results in the Denain General Hospital are:

- the overall Recall is **R = 0.88**
- the overall Precision is **P = 0.88**
- the F-measure is **F = 0.88**

These results are coherent although the hospitals use different Hospital Information Systems, employ different physicians and take in care different populations of patients.

They appear as so successful as compare to the literature [8-10] particularly in the context of the French language where some particular difficulties have to be overcome (particularly negations or some verbal passive forms).

Step 2- extraction of ATC & ICD10 codes from free text: agreements between F-MTI and EHR

ATC codes extraction:

The ATC codes from the semantic mining are considered as "candidates" while the ATC codes from the CPOE are given as "the "gold standard". The results are (Table 2):

- the overall Recall is **R = 0.37**,
- the overall Precision is **P = 0.73**,
- the F-measure is **F = 0.49**

Table 2 - Ability of F-MTI to replace EHR or CPOE codes

	Drugs: SM vs DB	Drugs: SM vs Experts	Diagnoses: SM vs DB
Recall	37.4 % [33-42]	88.4 % [85-92]	26.7 % [21-32]
Precision	72.6 % [67-78]	88.4 % [85-92]	17.3 % [14-21]
F-measure	49.4 % [46-53]	88.4 % [85-92]	21.0 % [18-24]

SM=semantic mining, DB=database

ICD10 codes extraction:

When the F-MTI tool is compared with the spontaneous encoding process, which is essentially based on economic considerations, the results are not as good as when compared with an expert encoding based on the free-text documents:

- the overall Recall is **R = 0.27**,
- the overall Precision is **P = 0.17**,
- the F-measure is **F = 0.21**

Step 3- validation of the use of the Semantic Mining results for data-mining-based potential ADE detection

The comparison between Rouen and other hospitals datasets is performed on each rule separately. Rule n°53 is provided as a detailed example.

Rule N° 11: Vitamin K antagonist (VKA) & Antiepileptic → Appearance of too low an INR (International Normalized Ratio; risk of thrombosis)

In that example, no significant difference is observed between Rouen and other hospitals pooled together.

The same method is applied on the 245 validated rules. A significant difference between the pooled confidence and the Rouen confidence can be observed in 50 rules (20.4% of the rules).

Table 1 - Comparison between Rouen and other hospitals

Object	Rouen	Other hospitals
Stays matching both the conditions and the effect: VKA & antiepileptic & too low INR	2	43
Stays matching the conditions: VKA & antiepileptic & no too low INR	6	206
Confidence	33%	21%

Fisher's exact test: p value=0.61 (independence, α=0.05)

Discussion

The expert review before using the F-MTI is very time consuming, that's what the validation sets (50, 32) are small.

Predicting ICD10 codes is not an easy task when native data from the EHRs are used as the "gold standard" instead of an expert summary-based encoding. The ICD10 codes that are in the EHRs were most often encoded for economic objectives and include other information sources than the text documents. Moreover, the agreement between two experts is not so high [11].The results were coherent with the one obtained in a previous study [12].

Predicting ATC codes looks more successful although that task was performed on unstructured free text. Though mining the summaries poses problems. In discharge summaries, most often, only drugs previously taken by the patient and drugs prescribed at discharge are mentioned. In particular, some treatments only administered during the hospitalization (oxygen, pain killers, rehydration solutions, etc.) are never mentioned, which decreases the recall. Moreover the therapeutic information seems to be very rare when the patient has died during the hospitalization: there is no discharge treatment, and most often only clinical information is provided.

The F-MTI tool has to be improved. It encounters difficulties to recognize brand names in the discharge summaries due to identified problems that are currently being corrected. Some additional problems are linked with incorrect spelling of the names in the discharge summaries. Some brand names are written improperly with dash ("-") or underscore ("_") or with an incorrect space " " (e.g. *di-antalvic*, *diffu k*, *di hydan*, *cacit D*, *calcidose vit D*, *co renitec*). On the contrary, some brand names are written without dash ("-") or underscore ("_") or space (" "), as normally they should have to (e.g. *chibroproscar* instead of *chibro-proscar*; *bipreterax* instead of *bi-preterax*). Some other misspellings or mistyping are quite frequent (e.g. *triapridal* instead of *tiapridal*, *genopevaryl* instead of *gynopevaril*, *dextropropoxifene* instead of *dextropropoxyfene*, *piperacetam* instead of *piracetam*, *ketoderme* instead of *ketoderm*). For this type of mistakes, VIDAL team is now working on a phonemization algorithm to improve the system.

Some mistakes are redundant, e.g. the brand name is *cacit D3*. It is not automatically indexed and *cacit* is indexed instead of it. The same is occurring with *di-antalvic* & *antalvic* and *calcidose Vit D* & *calcidose*.

Some mistakes are more difficult to correct, as they refer to ambiguous terms. For instance in the lab results section of a discharge summary, *Albumin* refers to a lab result, while *Albumin* is also the brand name of a drug. This ambiguity will have to be handled. As FMTI is multilingual (French, English, Spanish, Portuguese and Danish), an extension of this study would be to index the discharge letters with the other 4 languages.

Conclusion

This validation task demonstrates that the F-MTI tool is able to identifying commercial and brand names of drugs in the free-text documents. The study allows identifying courses of action to improve the tool. A semantic mining tool is probably not able to automatically discover ADE prevention rules from previous hospital stays. It is not able to prevent ADEs as the discharge summaries and letters are always written after the end of the stay. Nevertheless, semantic mining of those documents can help to retrieve administered drugs in absence of CPOE in order to compute the confidence of potential ADE detection rules. Doing that, semantic mining of the free-text documents allows for potential ADE detection in former hospital stays.

Acknowledgments

The research leading to these results has received funding from the European Community's Seventh Framework Program (FP7/2007-2013) under Grant Agreement n° 216130 -the PSIP project [13].The authors would like to thank CISMeF & VIDAL Team for their help in implementation, study design and result analysis.

Aligning UniProt and MeSH – A Case Study on Human Protein Terms

Elena Beisswanger[a], Joachim Wermter[a], Udo Hahn[a]

[a]*Jena University Language and Information Engineering (JULIE) Lab, Friedrich-Schiller-Universität Jena, Jena, Germany*

Abstract

Terminologies which lack semantic connectivity hamper the effective search in biomedical fact databases and document retrieval systems. We here focus on the integration of two such isolated resources, the term lists from the protein fact database UNIPROT *and the indexing vocabulary* MESH *from the bibliographic database* MEDLINE*. The generated semantic ties result from string matching and term set inclusion. We investigated the implicit terminological overlap between both resources in the domain of human proteins and evaluated our approach on a sample of 550 randomly selected* UNIPROT *entries that were manually mapped to their corresponding* MESH *headings. We achieved 90% precision and 79% recall (applying taxonomy-sensitive metrics). Fortunately, those proteins we were able to map to the* MESH *are ten times as frequently discussed in the literature as those on which we failed.*

Keywords:

Terminological Alignment, Interoperability of Terminologies

Introduction

Over the past years, MEDLINE – with now over 19M entries – has gained world-wide reputation as the most authoritative and often used bibliographic resource for biomedical literature search via the PUBMED interface.[1] Much of its retrieval power can be attributed to the Medical Subject Headings (MESH),[2] a terminology from which index terms are manually derived as content descriptions for MEDLINE records. The MESH not only covers a controlled vocabulary (of about 25,000 descriptors spanning various domains such as anatomy, diseases, chemicals and drugs) but excels in the provision of a multi-hierarchical taxonomic thesaurus structure (plus synonyms).

For bioinformatics, a comparably authoritative resource for protein and gene fact search has emerged through the UNIPROT KNOWLEDGEBASE (UNIPROTKB) [1]. In particular, UNIPROTKB/SWISSPROT, the curated part of UNIPROTKB, is a comprehensive, high-quality protein database which contains over 400,000 manually annotated proteins from various species. Unlike the MESH, UNIPROTKB does not offer any taxonomic links between terms, but (just as the MESH) contains synonyms of the gene and protein names in a specific protein entry, which are all lined up with their associated unique database identifier. Generally, UNIPROTKB describes proteins on a more specific level than the coarser grained MESH, the latter dealing with proteins in branch D (Chemicals and Drugs).

PUBMED, the retrieval interface to MEDLINE, allows users to search for documents about protein families, groups, or complexes by entering suitable MESH terms. However, literature on a specific protein can only be retrieved by running a free-text search. Yet, this search mode is known to suffer from several shortcomings because protein names are notoriously complex and ambiguous and thus hard to nail down by free-text expressions. A new breed of semantics-based search engines such as SEMEDICO [2] or IHOP [3] aim to cope with these problems by incorporating named entity recognizers (cf., e.g., SEMEDICO's gene name normalizer GENO [4]) which enrich plain documents with semantic metadata, including links to UNIPROTKB identifiers. If a protein name, e.g., **"**Heat shock protein HSP 90-beta", is entered in such a search engine, not only a set of documents matching this term is retrieved, but also a link to the corresponding UNIPROTKB entry (in this case HS90B_HUMAN) is provided which holds additional factual information about the protein under scrutiny.

Even such advanced search engines are incapable of searching for a specific protein and (if requested by the user), at the same time, generalizing to proteins belonging to the same protein group, family or complex. For example, if a document search for **"**Heat shock protein HSP 90-beta" were conducted, one might also be interested in documents about other members of the HSP90 heat shock protein family, or even about heat shock proteins, in general. One way to enable users to retrieve those additional documents would be to establish explicit links from the specific protein name to the appropriate MESH term, in this case "HSP90 Heat Shock Proteins", from where even more generic terms could be reached, such as its parent term "Heat Shock Proteins". To realize such a semantics-rich search strategy we aligned knowledge available from the UNIPROTKB with the taxonomic structure of the MESH, thus enabling new 'taxonomic' search strategies (see Figure 1).

[1] http://www.ncbi.nlm.nih.gov/pubmed
[2] http://www.nlm.nih.gov/mesh

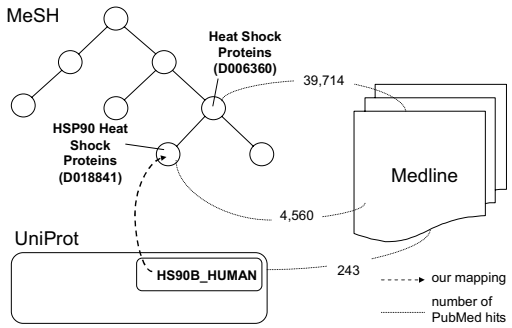

Figure 1- Linking UNIPROT and MESH for taxonomic search. The increasing number of hits (243 → 4,560 → 39,714) directly reflects the increasing conceptual generality of the search terms involved (HS90B_HUMAN → HSP90 Heat Shock Proteins → Heat Shock Proteins, respectively).

Materials and Methods

For our mapping study, we focused on the human subset of UNIPROTKB/SWISSPROT (RDF version from November 2008). Originally 20,328 entries were collected. In a subsequent cleansing step, we excluded those entries where the recommended name contained the phrase *"uncharacterized protein"* so that 19,052 human protein entries remained as input data for our mapping experiments. We also restricted the headings in the MESH thesaurus (MESH version 2008) such that permitted mapping targets were restricted to headings concerned with proteins and genes only, in the broadest sense though. This left us with all headings which belonged to one of the following MESH sub-hierarchies: D05 (Macromolecular Substances), D06 (Hormones, Hormone Substitutes, and Hormone Antagonists), D08 (Enzymes and Coenzymes), D09 (Carbohydrates) restricted to the Glycoproteins and Glycopeptides fraction, D12 (Amino Acids, Peptides, and Proteins), D13 (Nucleic Acids, Nucleotides, and Nucleosides), D23 (Biological Factors), and G14 (Genetic Structures).

We further utilized MESH's Supplementary Concept Records (SCR) as intermediate mapping target. SCR is a separate resource with rather specific, UNIPROT-like headings mainly concerned with chemicals and proteins. Each SCR heading comes with an explicit link to the closest possible MESH heading. Some SCR records are even linked to several MESH headings belonging to different classification axes. We exploited these links by mapping UNIPROT entries to SCR headings and then following the existing links to the associated MESH headings. Table 1 summarizes the sources of our mapping study.

Term Selection

For each UNIPROTKB entry we gathered all recommended and alternative protein names in their long form, as well as all gene names. In addition, for each entry we compiled a set of family and enzyme names based on three additional resources.

Table 1 - Quantitative data of terminological resources used for the mapping experiments

Source	Entries	Distinct Names
MESH protein	5,198	47,210
MESH SCR	182,890	462,673
UNIPROT human (cleansed)	19,052	90,920

We, first, extracted family names from the Similarity Annotation fields of UNIPROTKB entries, using simple regular expressions. A typical example for a Similarity Annotation is

"*Belongs to the protein kinase superfamily. TKL Ser/Thr protein kinase family. Pelle subfamily.*"

from the UNIPROTKB entry "IRAK3_HUMAN" ("Interleukin-1 receptor-associated kinase 3"). We here extracted the names "protein kinase", "TKL Ser/Thr protein kinase", and "Pelle".

Second, additional family names were harvested from INTERPRO,[3] a database of protein families and domains interlinked with UNIPROTKB. For the protein "KT81L_HUMAN" ("Keratin-81-like protein"), e.g., we followed the link to the protein family entry "IPR003054" from which we extracted the family name "Type II keratin".

Third, for entries coming with an Enzyme Commission (EC) number, this number was looked up in the Enzyme Nomenclature database,[4] to gather all attached enzyme names. For instance, UNIPROTKB entry "EYA2_HUMAN" ("Eyes absent homolog 2") is annotated with the EC number "EC 3.1.3.48". From the corresponding entry in the enzyme database we extracted the name "Protein-tyrosine-phosphatase".

While for MESH records, the heading itself and all associated entry terms were extracted, for MESH SCR records we considered the names of substances and all given synonyms.

Preprocessing of Terms

To cope with morphological term variations, we did not use a stemmer (that can be suspected to truncate many of the relevant domain-specific terms) but instead looked up each UNIPROTKB and MESH term in the UMLS Specialist Lexicon inflection file LRAGR.[5] If it is listed as a plural form of a noun, we extracted the corresponding singular form and added it to our term set. Then for all terms, punctuation marks were replaced by spaces, the task-specific stop words "gene", "protein", "family", "member", "domain", and "subunit" were removed from terms, and, finally, terms were lower-cased and tokenized, interpreting spaces as token boundaries.

A special preprocessing step was applied to MESH SCR terms. Many of these terms contain organism names, such as the substance name "IL2 protein, human" from record "C508594". These organism names were removed to make SCR terms compatible with UNIPROTKB terms that usually lack any kind of organism information (in UNIPROTKB, organism informa-

[3] http://www.ebi.ac.uk/interpro
[4] http://www.expasy.ch/enzyme/
[5] http://www.nlm.nih.gov/pubs/factsheets/umlslex.html

tion is kept in a separate field called 'Taxonomic Identifier'). We compiled a list of organism names from the NCBI taxonomy[6] and matched the names against all MESH / MESH SCR terms. If a name was found as substring of a MESH term, the organism-specific substring was removed from that term. However, we kept the NCBI taxonomy ID (TaxID), corresponding to the organism name that we removed, for later comparison with the TaxID associated with the UNIPROTKB entries. In our study on human proteins, this is only TaxID "9606" denoting "Homo sapiens (human)".

Term Mapping

In order to find for all human proteins in UNIPROTKB the closest related MESH heading we pursued a two-step approach. First, for each UNIPROTKB entry we matched all protein and gene names against all extracted MESH and MESH SCR terms. As matching criteria, we required, first, the MESH and the UNIPROTKB term to consist of the same tokens (their order was considered irrelevant) and, second, if a TaxID was associated with the MESH term, it had to match "9606" (human). Then for all these matches the corresponding MESH headings were selected as possible mapping targets for the UNIPROTKB entry. If no suitable MESH heading was found, in the second step, all enzyme and family names compiled for the UNIPROTKB entry were matched against all MESH / MESH SCR terms. Again the MESH headings corresponding to the successfully matched terms were selected as candidate mapping target for the corresponding UNIPROTKB entry. UNIPROTKB entries for which no target MESH heading was found after these steps were marked as *"not mapped"*.

In case several MESH / MESH SCR headings were found as possible mapping targets for a UNIPROTKB entry we determined the most suitable heading amongst the candidates with a LUCENE[7]-based ranking procedure basically relying on a fine-tuned TF-IDF weight (cf. Chapter 3.3 in [5]). In addition, our ranking mechanism took into account the type of terms that had matched. If, for instance, the recommended name of a UNIPROTKB entry matched a MESH term, we considered the associated MESH heading a better mapping candidate than a MESH heading of which a term matched an alternative name of a UNIPROTKB entry. If a UNIPROTKB entry was mapped to a MESH SCR heading, we followed the existing links to the corresponding MESH headings and selected them as mapping targets for the UNIPROTKB entry (only in this case several mapping targets were allowed per UNIPROTKB entry).

Mapping and Evaluation Results

In the first matching step (based on the comparison of protein and gene names from UNIPROTKB with MESH terms) our algorithm mapped 67% of all human protein entries to a MESH heading. In the second step (based on the comparison of family and enzyme names with MESH terms) mappings for additional 11% of the protein entries were found (see Table 2).

Table 2 - Results of the automatic mapping of human UNIPROTKB entries to MESH headings

Matching Step	Number of Matches (%)
Step1	12,691 (67%)
Step2	2,102 (11%)
Step1 + Step2	**14,793 (78%)**
Baseline	13,321 (70%)

As a baseline for comparison, we matched all protein and gene names of a UNIPROTKB entry to all MESH terms (terms were Porter-stemmed,[8] lower-cased, and punctuation marks were removed) and the MESH heading corresponding to the highest ranked match (cf. Section "Term Mapping") was selected as mapping target. Accordingly, mappings for 70% of all UNIPROTKB entries were found (see Table 2).

To assess the quality of automatically generated mapping results we compared them to a manually created gold standard. It consists of a random sample of 550 UNIPROTKB entries (drawn from the set of 19,052 entries) that were mapped by a domain expert to the closest related MESH heading(s). Since MESH is a multi-hierarchy, the expert was allowed to select more than one heading for each entry. A total of 58 entries (10.5%) were mapped to the general heading D011506 (Proteins). These entries were marked as *"not mapped"*.

As evaluation metric, we chose a relaxed precision and recall measure, *overlap proximity*, as introduced by Ehrig and Euzenat [6]. This metric pays tribute to the particularities of taxonomic hierarchies since, besides node-wise exact matches, it also incorporates the grounded intuition that even slightly more general or more specific matches within the taxonomic 'neighborhood' of a term are useful and reasonable matches, rather than treating them as absolute non-matches. Therefore, instead of taking the (strict) intersection of the set of automatically generated mappings (A) and the set of mappings in the manually created gold standard (G) as metrical criterion (as standard precision and recall metrics do), the relaxed variant takes the above considerations into account and measures the overlap proximity of the two sets with respect to a certain proximity function. Let M denote the matching between A and G ([6]) and σ be the proximity function between mappings a in A and g in G. Given the proximity ω

$$\omega(A,G) := \sum_{(a,g)\in M(A,G)} \sigma(a,g) \quad (1)$$

relaxed precision P_ω and recall R_ω are defined as

$$P_\omega(A,G) := \frac{\omega(A,G)}{|A|} \text{ and } R_\omega(A,G) := \frac{\omega(A,G)}{|G|} \quad (2)$$

We chose as proximity criterion for two mappings, $a = (u_a, m_a)$ and $g = (u_g, m_g)$, with u denoting a UNIPROTKB entry and m the MESH heading it was mapped to,

[6] http://www.ncbi.nlm.nih.gov/Taxonomy
[7] http://lucene.apache.org/
[8] http://tartarus.org/~martin/PorterStemmer/

$$\sigma(a,g) := \begin{cases} \dfrac{1}{p(m_a, m_g)} & \text{if } eq(u_a, u_g) \wedge (eq(m_a, m_g) \\ & \quad \vee s(m_a, m_g) \vee s(m_g, m_a)) \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

with p denoting the length of the shortest path between two MESH headings (in terms of the number of nodes in the MESH taxonomy graph) plus one, such that $p(m, m) = 1$, eq denoting the equivalence and s the subclass relationship. As for standard precision and recall, a mapping in A that is also in G is scored '1'. Mappings in A where the predicted and the correct MESH heading are in a subclass relation to each other (hyponym relation, on the term level), are scored with the reciprocal value of the length of the shortest path between the correct and the predicted MESH heading. All remaining mappings are penalized with '0'.

Figure 2 illustrates the scoring logic for three automatically detected mappings. On the left, an exact mapping is shown, scored '1' (predicted and correct MESH heading are equal). In the middle, a too general mapping is shown. Since the predicted MESH heading is a direct parent of the correct heading, it is scored '0.5'. On the right, an incorrect mapping is shown where no subclass relationship holds between the predicted and the correct MESH heading, scored '0'.

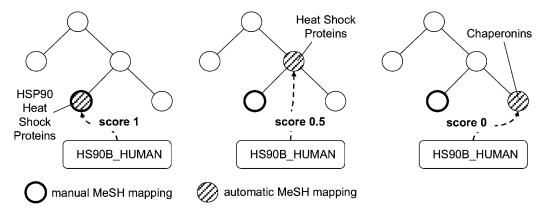

Figure 2 – Scoring of automatically computed mappings

As Table 3 reveals, when we apply the relaxed precision and recall measures we obtain 90% precision and 79% recall, resulting in 88% F-score, setting β to 0.5 in

$$F_\beta := ((1+\beta^2)PR)/(\beta^2 P + R) \quad (4)$$

in order to emphasize precision.

We also measured precision and recall for the constituent matching steps. Obviously, the first step based on matching protein and gene names to MESH terms results in more precise mappings (93% precision) than the second one based on looking up protein family names in MESH (73% precision). Still, adding the second step increases overall recall by 8 percentage points with a stable F-score of 88%. The mapping procedure outperforms the baseline (85% precision and 67% recall on the gold standard), in particular with respect to recall.

Table 3 - *Evaluation results in terms of relaxed precision P_ω, recall R_ω and F-score (values in %).*

Matching Step	P_ω	R_ω	F-score
Step1	93,0	70,7	87,5
Step2	72,7	8,0	27,7
Step1 + Step2	**90,2**	**78,5**	**87,6**
Baseline	85,3	66,6	80,8

This makes evident the value of the additional terms (e.g., from UNIPROTKB annotation fields and external databases like INTERPRO) for the mappings' outcome.

Discussion

For the evaluation of our approach we used a relaxed precision and recall measure and computed the F-score with emphasis on precision. Both decisions reflect requirements from the information retrieval scenario discussed in the beginning. The choice of the evaluation measure reflects our claim that even if the automatic procedure could not detect the fully correct MESH heading for a UNIPROTKB entry, detecting one of its parent or child headings would still enable the user to pass from UNIPROTKB to MESH and to correctly generalize / specialize the original search exploiting the MESH hierarchy. The emphasis on precision reflects our opinion that false mappings that would lead to the retrieval of irrelevant documents are worse than missing mappings due to the negligence of taxonomic relation that particular proteins share.

The terminological heterogeneity of protein and gene names might raise concerns about the size of our gold standard. To assess the plausibility of our evaluation based on this gold standard, let us assume that the random sample of 550 UNIPROTKB entries would have been drawn from an *infinite* set of entries, and the precision and recall estimates, resulting from the comparison of the automatically detected mappings with the gold standard, would be 0.5 (50%). Then the standard deviation of the estimates, ± 2.1, would be 'acceptable'. (In fact, the number is even an upper limit for the real standard deviation, since our sample was drawn from the finite set of 19,052 UNIPROTKB entries, and the determined precision and recall measures are 'far away' from 0.5.)

Still, about 20% of all human proteins in UNIPROTKB / SWISS-PROT could not be mapped properly to MESH headings by our algorithm, although based on the gold standard only 10% of non-matching entries should be expected. We tested two alternatives to increase our recall figures. First, we extended our procedure by a third matching step, again matching all UNIPROTKB terms (protein, gene, and family names) against all MESH terms. This time, we only required a partial token match and allowed for contradicting TaxIDs. Second, we considered additional UNIPROTKB name types for the mapping, *viz* short forms of gene and protein names, allergen names, CD antigen names, and the International non-proprietary names.

Although 1,267 additional UNIPROTKB entries (an increase of 7%) could be mapped, the overall effect (a decrease by 3 percentage points to 85% F-score) was negative due to decreasing precision (86%). The inspection of erroneously missed mappings revealed that many of the UNIPROTKB entries involved come with rather technical names such as "FAM75-like protein FLJ43859" ("YI020 HUMAN") that cannot easily be matched with MESH terms. Thus, we assume that only exploiting further annotations of UNIPROTKB entries (such as textual descriptions) might increase the number of correct mappings.

The good news is that our procedure deals satisfactorily with the most frequently occurring human protein names. We found that those proteins that we were able to map to MESH headings are mentioned, on average, in 10 times as many document as those on which we failed to map (111.3 documents, on the average, compared to 12.6).[9] In terms of precision, our procedure shows decent results. Still, we analyzed the false predictions and found that three-fourth of all incorrect mappings were due to the unresolved ambiguity of gene symbols.

Related Work

Biomedical ontologies and terminological resources are increasingly becoming important for knowledge management tasks in the life sciences [7]. This is witnessed by the rapid growth of single resources such as the GENE ONTOLOGY (GO)[10] which is massively used for the functional annotation of genes and gene products. Also large libraries of controlled vocabularies have emerged such as the UMLS[11] and OBO.[12] Efforts to foster interoperability have already been started, e.g., aligning GO with other OBO ontologies [8]. UNIPROTKB and the MESH have also been the target of deeper integration efforts. In [9], a procedure is described to link diseases mentioned in UNIPROTKB entries to the MESH disease terminology to make disease information in UNIPROTKB more easily accessible to clinical researchers. What has not been studied so far is the connection between protein entries in UNIPROTKB and MESH headings representing protein families, groups, or complexes, the goal of our investigation.

Conclusion

Despite the ever increasing number and size of single biomedical terminologies their usage for searching relevant facts and literature is currently hampered by a lack of semantic integration and interoperability. In this study, we proposed an automatic procedure to align human protein names in UNIPROTKB / SWISSPROT to suitable headings in the MESH.

The mappings we found were evaluated on a manually created gold standard of 550 match pairs resulting in 90% precision and 79% recall (with 88% F-score). Our approach outperformed a simple yet effective baseline by 7 percentage points F-score (5 and 12 percentage points in terms of precision and recall, respectively).

The mapping approach we propose can easily be applied to the whole of UNIPROTKB / SWISSPROT. A preliminary study on protein entries for a set of 29 important model organisms achieved promising results. For 78% of these entries mappings to MESH headings could be found. The research we have described is but a preparatory step for a more thorough evaluation that has to measure the effects of such alignments for the effectiveness of searches in real retrieval settings.

Abstract

A crossmap between successive versions of classification systems is necessary to maintain the continuity of health care documentation. A reference terminology can serve as an intermediary to support this task. Within this study we evaluated the use of SNOMED CT to create a crossmap between two versions of an intensive care classification system. Firstly, the SNOMED CT crossmap was compared with an expert-based and a data-driven crossmap. Next, the influence of these crossmap strategies on the health care outcome was evaluated. For 50% of the analyzed cases, the three mapping strategies resulted in the same crossmaps. In other cases, there was an overlap between the SNOMED CT crossmaps and the crossmaps provided by one of the two other strategies. Differences in the crossmap results had however no significant influence on the health care outcomes. SNOMED CT can be used as an intermediary to solve the problem of crossmapping between versions of classification systems.

Keywords:
SNOMED CT, Classification, Intensive Care, APACHE II, APACHE IV

Introduction

In the healthcare setting, clinical encounters are increasingly documented using classification systems to serve purposes such as mortality and morbidity statistics or financial reimbursement. A classification system is defined as a systematic arrangement of objects or concepts based on their essential characteristics into groups of concepts, called classes [1]. As with all terminological systems, a problem with classification systems is the compatibility between two versions. The 9th revision of the International Classification of Diseases, ICD-9, for instance, was published in 1977 and has been succeeded by the 10th revision, ICD-10, in 1999. The ICD-10 was much more detailed than its predecessor and included alterations in the coding rules, the underlying classification, the number of disease and diagnostic codes, the code structure, and the naming of disease chapters and categories [2]. Health care settings use the ICD classification systems to compile health statistics and to monitor health spending and outcomes. Consequently, the versioning of the ICD has a direct impact on the health care systems in that the changes produce inconsistencies and discontinuities in the heath care statistics [3-5].

Versioning may also be a problem for domain specific classification systems. In the intensive care (IC), for instance, different versions of the APACHE classification system are used to code the reasons for IC admission, which is an important covariate in the APACHE prognostic models. The APACHE prognostic models (e.g. APACHE II and IV) are applied to calculate case mix (i.e. severity of illness, age, and the primary reason for IC admission) adjusted mortality in order to assess the quality of health care [6]. The APACHE IV prognostic model is almost backward compatible with its predecessor, the APACHE II prognostic model, meaning that covariates for APACHE II prognostic model are also used in the APACHE IV prognostic model. The covariate "reasons for IC admission" forms an exception in that it requires another classification system. Therefore, although the detailed registration of the reasons for admission in the latest APACHE IV classification system enables a more accurate prediction of mortality risks, to enable trend analyses, also the older APACHE II classification system is still concurrently applied.

In both the ICD and the APACHE example, a crossmap between the two versions of the classification systems is necessary to preserve the continuity and interoperability of health care documentation and to avoid double registration Yet, accurate 1-to1 crossmaps between (versions of) classification systems may be difficult because these systems have different levels of granularity and the mapping can be influenced by the structure and content of both systems [7, 8]. It has been argued that a reference terminology can serve as an intermediary to support the creation of a mapping between two (versions of a) classification systems [7]. Reference terminologies provide detail and precise meaning to data by formal concept definitions, required for complete and consistent coding of clinical data [9]. An advantage of using a reference terminology to create a crossmap is that once a mapping has been created between the target classification system and the reference ter-

minology, this mapping can be re-used to identify crossmaps between all other (versions of) classification systems which are also mapped to the reference terminology (dashed arrows in Figure 1).

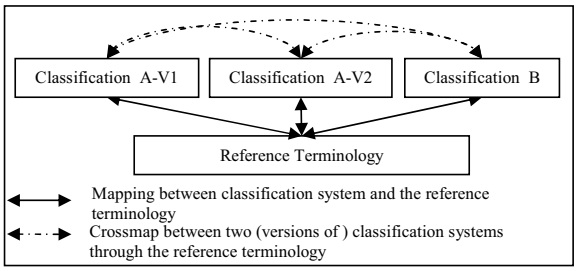

Figure 1- Using a reference terminology to identifying cross-maps between different (versions) of classification systems

SNOMED CT is regarded as the most comprehensive reference terminology for coding clinical data. Our goal within this study was to evaluate the use of SNOMED CT as an intermediary to create an n-to-1 crossmap between the two IC specific classification systems, i.e. from APACHE IV to APACHE II. Firstly, we compared the SNOMED CT crossmap with a manual expert-based and a data-driven crossmap. Secondly, the influence of these cross-map strategies on the calculation of case-mix adjusted mortality risks for quality of care assessment was evaluated.

Materials and Methods

SNOMED CT

The January 2008 release of SNOMED CT, which was used in this study, contains 284,777 active medical concepts associated with 737,695 active terms and interrelated by 860,865 active hierarchical (i.e. IS-A relationships) and non-hierarchical (i.e. Attribute relationships) relationships. SNOMED CT is a compositional terminology, i.e. it supports post-coordination, the use of composite expressions of concepts to define and refine (new) concepts.

APACHE classification systems

The APACHE classification systems are used to code the reasons for IC admission, one of the predictor variables in the APACHE prognostic models [6]. The APACHE II reasons for IC admission classification system is used in the APACHE II prognostic model and contains 54 diagnostic categories, each classified as nonoperative or postoperative, next by body system (e.g. cardiovascular disorder) and then by diagnosis (e.g. sepsis). The APACHE IV reasons for IC admission classification system is used in the APACHE IV prognostic model and contains 445 diagnostic categories, each classified as nonoperative or postoperative, next by body system (e.g. cardiovascular disorder) or a transplant or trauma-related category, and then by diagnosis (e.g. gastrointestinal sepsis). A residual "other" category is used in both classification systems for unlisted diagnoses within the main category (e.g. other listed diagnoses within the main category (e.g. other cardiovascular disorder).

Data

In 1996 the Dutch National Intensive Care Evaluation (NICE) foundation started collecting data on patients admitted to Dutch intensive care units (ICU) in order to monitor and improve the quality of care provided by the participating ICUs. For each ICU admission, the responsible intensivist or IC nurse collects the demographic, physiological and diagnostic variables required among others to calculate mortality predictions according to the APACHE II and IV prognostic models.

Since 2007, the APACHE IV variables can be recorded voluntarily and since 2008 all participants are obliged to record the APACHE IV reasons for ICU admission in addition to the APACHE II reasons for admission, which is recorded since 1996.

This study used a dataset from the NICE registry with data on all patients admitted to the Dutch ICUs between January 1, 2007 and July 1, 2009 for whom the APACHE II and IV variables were collected and who satisfied the inclusion criteria (e.g. excluding burns and re-admissions) of both the APACHE II and the APACHE IV prognostic models.

Data-driven crossmap

In the NICE database, for each IC admission, the reasons for admission have to be collected both according to the APACHE II and APACHE IV reasons for IC admission classification systems. To create the data-driven crossmap, a cross table was created with the APACHE IV categories against the APACHE II categories from the NICE database.

Expert-based crossmap

We used an expert-based crossmap that had been created for the NICE registry. Two intensivists, both experienced in the APACHE II and APACHE IV classification systems, independently mapped each APACHE IV category to exactly one related APACHE II category. The final map was based on consensus between the two intensivists.

SNOMED CT crossmap

As part of a larger study, we first created a manual mapping from the APACHE II and APACHE IV categories to SNOMED CT concepts (Figure 2 I). Each APACHE category was aligned with one or more SNOMED CT concepts. The categories were first matched to pre-coordinated concepts. In case no pre-coordinated match was available, a post-coordinated match was searched for. Concepts that did not exist in SNOMED CT were eventually matched to the appropriate superordinates [10]. To generate the crossmap between the APACHE IV and the APACHE II classification system, for each SNOMED CT concept that did not directly map to a APACHE II or IV category, first the closest superordinate with a pre-coordinated APACHE II mapping and the closest superordinate with a pre-coordinated APACHE IV mapping was identified (Figure 2 II).

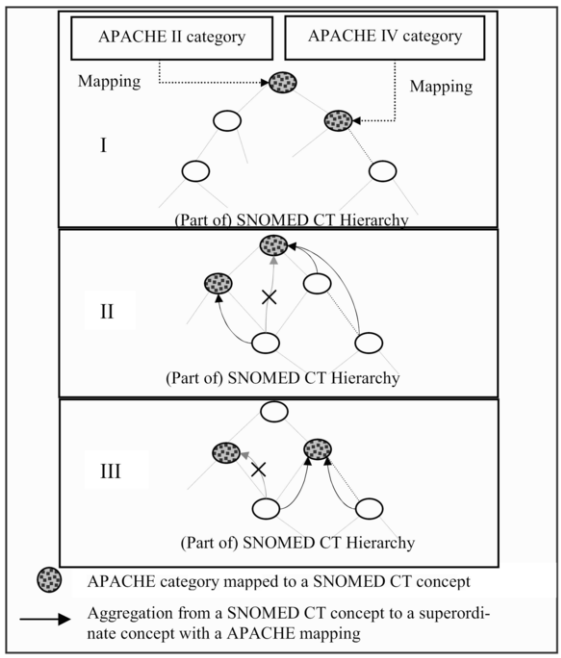

Figure 2- I:Mapping from APACHE categories to SNOMED CT concepts, II: Aggregation from a SNOMED CT concept to the closest superordinate with a pre-coordinated APACHE mapping, III: Aggregation from a SNOMED CT concept to the closest superordinate that results in highest mortality risk.

In case of multiple matches, the superordinate with a pre-coordinated APACHE II or APACHE IV mapping that resulted in the highest predicted mortality were selected in order to achieve a unique match (Figure 2 III). Next, the matched SNOMED CT conceptIDs from the previous step were used to generate a cross table with the APACHE IV categories against the APACHE II categories to identify the crossmap. Table 1 provides an example of such a crossmap through SNOMED CT.

Table 1 – An example of a crossmap between APACHE IV and APACHE II categories through SNOMED CT

SNOMED CT concept	APACHE II category	APACHE IV category
Urosepsis|371093006	Sepsis	Urosepsis

Analysis

Comparison of the mapping strategy

The SNOMED CT crossmap was compared to the expert-based manual crossmap and the data-driven crossmap. To this end, for each APACHE IV category, the matched APACHE II categories were identified according to the three crossmap strategies.

Influence of the crossmap strategy on the outcome

To evaluate the influence of the crossmap strategy on the mortality risk predictions, for all included admissions from the NICE database, an APACHE II predicted mortality was calculated based on the APACHE II categories from the NICE database and the APACHE II categories derived from the expert-based mapping and the SNOMED CT mapping. The predicted mortality risks were then compared for the three crossmap strategies. To this end, mortality risks were expressed as mean ±SD. T-test statistics was used for the comparison and a p-value of 0.05 was defined as statically significant.

Results

Data

From January 1st 2007 to July 1st 2009, 41,211 patients were recorded in the NICE registry who met the general inclusion criteria for the APACHE II and APACHE IV model and for whom an APACHE II and an APACHE IV reason for admission were recorded.

Not all APACHE IV categories occur frequently in the Dutch ICUs. Therefore, although for all APACHE IV categories a crossmap was developed, in here we will analyze and discuss the results for the most frequently occurring pre-coordinated postoperative and non-operative categories in each body system, transplant- or trauma-related class.

Comparison of the crossmap strategies

Table 2 provides the results of the three crossmap strategies For some APACHE IV categories more than 1 match was available in the data-driven crossmap and SNOMED CT crossmap (i.e. expressed in "Number of different APACHE II matches"). For 10 APACHE IV categories, the three crossmap strategies resulted in the same APACHE II categories. In case of disagreement, generally, there was an overlap between the SNOMED CT matches and the matches provided by the two other strategies. An exception was the APACHE IV category "Genitourinary surgery", which was matched to APACHE II category "Renal surgery" in the SNOMED CT crossmap and to "Cardiovascular surgery" in the other crossmap strategies.

Influence of crossmap strategy on predicted mortalities

The mean (±SD) predicted mortality risk was 0.158 (0.18) for the data-driven crossmap, 0.154 (0.18) for the expert-based crossmap, and 0.158 (0.17) for the SNOMED CT crossmap. For categories where more than 1 match was available, the predicted mortalities represent a weighted average score based on the different matches as shown in Table 2. No significant differences were found in the predicted mortalities for the three crossmap strategies.

Discussion

To preserve the continuity of health care documentation and to avoid registration inefficiency, e.g. double registration, a crossmap between successive versions of classification systems is necessary.

*Table 2 – * indicates >= 80%. The APACHE II categories are: CD: Cardiovascular disorder, CS: Cardiovascular surgery, DK: Diabetic ketoacidosis, DO: Drug overdose, GIB: Gastrointestinal bleeding, GID; Gastrointestinal disorder, HD: Hematological disorder, HT: Head trauma, KTRP: Kidney transplantation, MD: Metabolic disorder, MS: Metabolic surgery, MT: Multiple trauma, ND: Neurological disorder, PE: Pulmonary embolus, PVS: Peripheral vascular surgery, RD: Respiratory disorder, REND: Renal disorder, RENS: Renal surgery, RI: Respiratory infection, RIAS: Respiratory insufficiency after surgery, RS: Respiratory surgery, SCCD: Surgery for chronic cardiovascular disease, SEP: Sepsis, SGID: Surgery for GI disorder, SGIN: Surgery for GI neoplasm, SHD: Surgery for hematological disorder, SHS: Surgery for hemorrhagic shock, SND: Surgery for neurological disorder, SMT: Surgery for multiple trauma, TSN: Thoracic surgery for neoplasm: TRP: Transplant.*

Our goal within this study was to evaluate the use of SNOMED CT as an intermediary to create a crossmap between two versions of an IC-specific classification system, i.e. from APACHE IV to APACHE II. For 50% of the most frequently occurring APACHE IV categories, the three mapping strategies resulted in the same APACHE II categories. In other cases, there was an overlap between the SNOMED CT matches and the matches provided by one the two other strategies. Differences in the crossmap results had however no significant influence on the predicted mortalities.

Although there are no differences in the outcome, the crossmap strategies do differ. This might have a large influence on e.g. selection of patient groups based on reason for IC admission. Each of the crossmap strategies has its own drawbacks. Data-driven crossmapping is highly dependent on the amount and the quality of the underlying data, and on the correct classification by clinicians. For rare clinical encounters, for instance, it is not possible to generate a reliable crossmap. Expert-based crossmapping is time consuming and labor intensive, especially for large classification systems. Furthermore, the reliability of the crossmap depends on the skills and knowledge of the experts. Automated tools might be used to assist this task, however, these tools are usually domain and language specific, and, if not available, costly to build. Besides, manual review is required to validate and complement the output of the automated crossmaps [11]. The SNOMED CT crossmap encloses the same problems as the Expert-based crossmapping, as first a (manual or automated) mapping needs to be created from the source classification systems to SNOMED CT. However, the advantage of using SNOMED CT crossmapping is that once the mapping is generated with the target classification system, it can be re-used to identify crossmaps to all other classification systems that are already aligned to SNOMED CT. E.g. for five classification systems, the use of SNOMED CT as intermediary requires the creation of 5 mappings from these target systems to SNOMED CT, possibly by shared effort, to create the 10 crossmaps. Otherwise, each classification system pair (n=10) needs to be crossmapped separately.

When crossmapping two versions of a classification system, an important issue is the relationship between their categories. In general, for the purpose of interoperability, a 1-to-1 crossmap is required. However, a 1-to-1 crossmap between two versions of a complex classification system might not be possible, as the two successor systems not only differ in the level of granularity, but also in the coding rules and structure. In these cases, a n-to-n mapping is generated which requires an additional decision to select the appropriate target links [11].

A key characteristic of classification systems is that they generally serve a specific purpose. DRG-like classification systems for instance are used to generate reimbursement overviews, while classification systems such as the ICD are used for generation of mortality and morbidity statistics [12]. Consequently, the same information is often recorded in multiple systems resulting in multiple registration. Although within this study we focus on the problem of version compatibility of a classification system, our results are also generalizable to settings in which multiple classifications are used for different purposes. Also in these cases, SNOMED CT can serve as an intermediary to support the creation of crossmaps in order to preclude double registration [7]. However, to rule out registration inefficiency completely, clinical information should preferably be captured on a detailed level in daily practice using a reference terminology such as SNOMED CT which holds the promise to (retrospectively) aggregate clinical encounters compatible to different classification systems. Further research is needed to gain insight in the use of SNOMED CT for data collection to serve this purpose.

Abstract

Background: CCAM is a French terminology for coding clinical procedures. CCAM is a multi-hierarchical structured classification for procedures used in France for reimbursement in health care, which is external to UMLS . Objective: The objective of this work is to describe a French lexical approach allowing mapping CCAM procedures to the UMLS Metathesaurus to achieve interoperability to multiple international terminologies. This approach used a preliminary step intended to take only the significant characters used to code CCAM corresponding to anatomical and actions axes. Results: According to the 7,926 CCAM codes used in this study, 5,212 possible matches (exact matching, single to multiple matching, partial matching) are found using the French CCAM to UMLS based mapping, 65% of the corresponding anatomical terms in the CCAM code are mapped to at least one UMLS Concept and 37% of the corresponding action terms in the CCAM code are mapped to at least one UMLS Concept. For all the exact matches found (n=200), 91% were rated by a human expert as narrower than the mapped UMLS Concepts, while only 3% were irrelevant.

Keywords:

Coding system, Mapping, Ontology, Semantic interoperability, Terminology

Introduction

Retrieval and exchange of information from multiple health terminologies and databases becomes increasingly useful. UMLS appears as a powerful candidate for supporting interoperability among all biomedical terminologies. Mapping terminology for coding clinical procedures to UMLS is essential for international case mix comparison between data and practices in different Electronic Health Record systems**.** This mapping will achieve semantic interoperability between CCAM and every international terminology through UMLS, especially SNOMED International ("procedure" axis) and ICD10. All these French health terminologies are integrated into a Health Multi-Terminology server [1]. However, translating information from one terminology to another is not very easy because of their heterogeneity, due to the different scope, points of view, and level of abstraction and detail of each health terminology.

The process of terminology mapping consists of identifying identical (or approximately identical) concepts or relationships between terminologies [2]. A number of algorithms and approaches have been proposed to create an automatic mapping between health terminologies [2-6]. For example, Rocha et al [3] and Cimino et al. [4] both proposed a frame-based approach to perform mappings between health terminologies. Other approaches were proposed using UMLS (Unified Medical Languages Systems) [7] as a knowledge resource to perform mappings between terminologies. For example, Fung and Bodenreider [5] described an algorithm [6] to map between any two terminologies in the UMLS making use of synonymy, explicit mapping relations and hierarchical relationships. However, approaches using the UMLS are limited to the biomedical terminologies already incorporated into UMLS.

The objective of this work is to describe a mapping method to be used by any biomedical terminology in French not yet included in the UMLS, to be subsequently included in this metathesaurus. The mapping approach has been used and evaluated in this work to map the CCAM terminology (Classification Commune des Actes Médicaux) for procedures to UMLS Metathesaurus. This terminology is not yet included in the UMLS.

This work takes place in a more global InterSTIS project, funded by the French National Agency. Semantic interoperability inter and intra terminology is the main objective of InterSTIS. This current work was funded mainly by the InterSTIS project grant.

Materials

CCAM is a multi-hierarchical structured classification mainly for surgical procedures used in France, for reimbursement and policy making in health care. Several terminologies for procedures exist and are used in different countries. For example,

the CPT (Current Procedural Terminology) [8] developed by the American Medical Association and since 2001, selected by the Department of Health and Human Services (HHS) as the standard code set for reporting health care services in electronic transactions. The NOMESCO Classification of Surgical Procedures (NCSP) used by all the 5 Nordic countries [9].

The 10th version of the CCAM covers about 7,926 procedure codes. Each procedure is described by a code using "CCAM Basic Coding System", which consists of coding: (1) body system/anatomical site or function, (2) action and (3) approach/method.

The concatenation of the codes for these axes results in a multiaxial code with 7 alphanumeric characters, which gives a "synthetic" procedure description, based on the code/definition tables of the CCAM Basic Coding System. (See Figure 1).

The construction of the CCAM associated the traditional expertise and ontology-driven terminological tools provided by GALEN (Generalised Architecture for Languages, Encyclopedias and Nomenclatures in Medicine) [10,11] with the constraint of being compatible with the European standards [12]. This process allowed checking the conformity of the label with the significant concepts of medical knowledge. Therefore, CCAM has been the main source of inspireation for the classification procedure in Australia (ICHI) [13] and Germany [14]

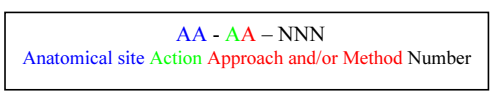

Figure 1- CCAM code structure

UMLS: the "Unified Medical Language System" is a repository of biomedical vocabularies developed by the US National Library of Medicine. Currently, the UMLS integrates over 5 million names of over 1,270,000 concepts from more than 140 biomedical terminologies, classifications, and ontologies, as well as 13 million relations among these concepts. Each concept isolated from terminologies has a concept unique identifier (CUI) in the Metathesaurus. This means that the same concept appearing in various terminologies, perhaps with various names and synonyms, has a unique entry in the Metathesaurus.

Methods

One automated mapping method was used to map CCAM codes to UMLS Concepts. This method is based on the structure of the CCAM code described in the previous section. However, it is impossible to assign one or more specific UMLS concepts using only CCAM label. This is mainly due to the length of CCAM labels. Indeed, there are 85% of CCAM labels equal or with more than 5 words vs. only 5% of the MeSH descriptors equal or with more than 5 words. The approach using the coding structure for mapping to UMLS was also used in [15] to allow the LOINC (Laboratory Observation Identifier Names and Codes) [16] integration to UMLS.

In this approach, only the significant first three characters composing the CCAM code according to the anatomic (two characters) and action (one character) axes are mapped to the UMLS Metathesaurus. For example: The CCAM code "NCCA010" with the label: "*Osteosynthesis of tibial diaphysis fracture by external fixing*", is represented according to the significant three first characters with:

- "*Bones of the leg*" corresponds to "NC" characters (anatomic axis)
- "*Osteosynthesis*" corresponds to the "C" character (action axis)

French natural languages processing tools and mapping algorithms were developed by the CISMeF team to map between French health terminologies. These tools were used in previous works [17, 18] and extended to link terms in multiple French health terminologies.

This approach allows for a given term (obtained by the concatenation of the resulting terms of the preprocess step according to the two axes (anatomic and action) to find a UMLS Concept with French terms that are lexically the most similar to it. Thus, to overcome some problems like account inflections, stop-words, etc., basic natural language processing is necessary beforehand:

1. Remove stop words: frequent short words that do not affect the phrases such as "a", "Nos", "of", etc; are removed form all terms in all terminologies (CCAM and French terminologies of the UMLS).
2. Stemming: we use a French stemmer "Lucene" which proved to be the most efficient for the F-MTI automatic indexing tools using several health terminologies [17], as compared to the stemming tools developed by the CISMeF team and the stemming tools in [18].

The mapping used by this approach provides three types of matches between all terms in source terminologies and the French terms in the UMLS metathesaurus. These levels of matching are inspired in most cases by the "ISO 5964", which is an ISO standard for the establishment and development of multilingual thesauri [19]. Relation types may be also represented in SKOS language [20]. SKOS language is also used to represent French health terminologies into the French Health Multi-terminological Server [1], which intends to integrate the main health terminologies available in French, including those not yet mapped to the UMLS (e.g. CCAM, ATC, Orphanet).

The three types of matching are:

Exact matching

One CCAM term and one French term in UMLS are in "exact matching" if all the words composing the two terms are exactly the same. Thus, according to this matching there is at most one UMLS Concept corresponding to all the significant characters of the CCAM code (see Table 1). Formally, in this type of matching the label obtained by the concatenation of the two terms according to the two axes, is considered as a one and unique term, an

"exact matching" between this term and one French term in UMLS.

Single to multiple matching

One CCAM term and at least two French terms from UMLS are in a "Single to multiple matching" when the CCAM term cannot be matched by one exactly French term in UMLS, but can be expressed by a combination of two or more French terms in UMLS. In this "Single to multiple matching", the CCAM term is mapped to at least two UMLS Concepts.

Partial matching

This type of matching is the less accurate one. In this type of matching only a part of the CCAM term will be mapped to one or more UMLS Concepts. Table 1, list some examples corresponding to the three types of matching described above.

Evaluation

The evaluation was performed on all the types of matching from the "exact" set matching type and for only 100 from the "Single to multiple" set matching type. We chose only 100 matching instances because in most cases the same codes with the same three firsts characters were mapped to the same UMLS concepts (HLHH003, HLHH004...).

The qualitative evaluation was performed by a physician (PM), expert in CCAM and in UMLS. The following terms were used to rate the quality of each matching result: (a) "equivalent" the UMLS concept corresponded exactly to the CCAM code; (b) "BT-NT" when the CCAM code was rated as broader than the UMLS concept according to the label of the CCAM and the preferred terms (PTs) in the UMLS concepts; (c) "NT-BT" the CCAM code was rated as narrower than the PTs in the UMLS concept, (d) "incomplete" when the UMLS concept only reflected some part of the CCAM label and (f) "irrelevant" when the matching was considered by the expert as incorrect.

For example, the matching between the CCAM code "BFGA003" (label: "*manually extraction of lens without intraocular lens implant*") and the UMLS concept C0007389 (preferred term: "*cataract extraction*") was rated as NT-BT because the UMLS concept is narrower and less accurate than the CCAM label. However, for the "Single to multiple" set, the expert performed the evaluation in two steps: 1) each pair (CCAM axe, UMLS concept) was evaluated independently. 2) the matching between the CCAM code and the combination of the UMLS concepts was then evaluated in this second phase. For example, to evaluate the matching between the CCAM code "AAFA003" and the two UMLS concepts: C006104 (preferred term: *"Brain") and C0919588 (*(preferred term: *"Exeresis").* First, the expert evaluated each axis with the corresponding UMLS ((Brain, C006104) =equivalent and (Exeresis, C091958) =equivalent)). Second, the expert evaluated the matching between the label and the combination of the two UMLS concepts: (AAFA003, (C006104, C091958) =NT-BT).

Table 1- Examples of the three types of matchings using the French based UMLS matching

CCAM code	Anatomic axis	Action axis	UMLS concepts	Typeof matching
BDHA001	Cornea	biopsy	C0197417 (Biopsy cornea)	Exact
AAFA003	Brain	exeresis	C0006104 (Brain) and C0919588 (Exeresis)	Single to multiple
DGFA013	Aorta	laparotomie	C0003483 (Aorte)	Partial corres-pondance

Results

Using this approach, there were 5,212 (65%) CCAM codes out of the 7,926 CCAM codes used in this study that provided possible matching between the CCAM and the French terms in the UMLS. The results of each type of matching are displayed in Table 2.

There were 2,210 (27.5%) matches regarding the anatomical and action axes. On the other hand, there were 1,716 (21%) matches regarding only anatomical and 1,286 (16%) matches regarding only the action axis. Overall, 65% of the matching "anatomical terms" in the CCAM codes were matched to at least one UMLS Concept and 37% of the matching "action terms" in the CCAM codes were matched to at least one UMLS Concept.

Table 2- Results of each matching type

Type of matching	Number of matches
Exact	200 (2.5%)
Single to multiple	2,010 (25%)
"Exact**"** Partial matching	3,002(37.8%)

For the set of exact matching (n=200), 182 (91%) of matches between CCAM codes and UMLS concepts were rated as NT-BT and only in nine cases, the matches were rated as equivalent (see Table 3).

Table 3- Evaluation results of the "exact" set matchings type

Equi-valent	BT-NT	NT-BT	Incomplete	Irrelevant	Total
9 (4.5%)	0 (0%)	182 (91%)	3 (1.5%)	6 (3%)	200

For the set of single to multiple matchings (n=100), 61 and 44 of the anatomic and action axes respectively were equivalent to at least one UMLS concept. According to this type of matching, 27 (27%) matches between CCAM code and at

least one UMLS concept were rated as exactly equivalent, when 54 matchings were rated as NT-BT (see Table 4)

Table 4- Evaluation results of the "Single to Multiple" set matching type (n=100)

Single to multiple matching (100)	Equivalent	BT-NT	NT-BT	Incomplete	irrelevant
Anatomic	61	1	29	9	0
Action	44	0	49	1	6
Combinaison	27	0	54	10	9

Discussion

The CCAM is an important French terminology external to UMLS. The objective of this work is to partially map the CCAM to the UMLS. Because the CCAM terms are quite verbose (85% with strictly more than 4 terms), this task is difficult. Our approach using French NLP tools allows mapping 65% of the CCAM. In most of the cases, the qualitative evaluation has shown a NT-BT (narrower than) relation between a CCAM term and an UMLS concept. This result is easily explainable because terms the anatomic and action CCAM axes, which are mapped to the UMLS Metathesaurus, are generally broad terms (e.g. cornea for anatomy and resection for action).

Some fine-tuning of the method is possible. The use of the existing manual mapping between CCAM and MeSH performed by one author of this paper [21] can help find some matches with the UMLS. The impacts of the matching between UMLS and CCAM are: (a) possible matching with other terminologies (e.g. ICD10 used in French DRGs with CCAM); (b) querying PubMed from a CCAM code with a MeSH query (using CCAM-MeSH mapping)

Two main perspectives are identified: (a) the method presented here could be used with the MetaMap tool [22-23] in order to map the CCAM, and then compare our results with those obtained in [24];(b) to map CCAM to the "procedure" axis of the SNOMED International.

Implementing rules to improve the quality of concept post-coordination with SNOMED CT

Abstract

The use of SNOMED CT as a standard reference terminology enables interoperability between clinical systems. This reference tool provides a method for creating post-coordinated terms by users according to local needs. While the creation of these terms is free, there are a number of rules, as defined in the user manual of SNOMED CT that must be followed.The Hospital Italiano of Buenos Aires has a Terminology Server that encodes medical terms, using SNOMED CT as the reference vocabulary. An interoperability analysis performed with the Nebraska Medical Center in 2006 found a high error rate (26%) in post-coordinated terms. Therefore, we implemented an automatic system of rules within the Terminology Server as defined in the user manual.
Following rules implementation, the error rate decreased from 26% to 2%.

Introduction

SNOMED CT has been proposed as a standard terminology in many countries, with an appropriate coverage of medical vocabulary [1]. Development standards are currently maintained by a multinational organization but local implementations often require content extension to address specific requirements. For this reason SNOMED International identifies and promotes mechanisms for post-coordination.

The Electronic Medical Record of the Hospital Italiano in Buenos Aires initially allowed physicians free text entry of problems and procedures. After a period of four years, we analyzed data and migrated this information into a specialized server. Then, a local interface terminology for physicians was developed, where they could choose a more accurate description for a given problem or a procedure [2]. This online terminology interface was created from items originally entered by individual physicians as free text.

The online interface consisted in 21,000 unique concepts, which were related to SNOMED CT as equivalent concepts or as post-coordinated expressions (in those cases where a direct equivalence could not be found). The creation of a post-coordinated expression was necessary for 16,000 of the 21,000 concepts (76.19%). This is a very high proportion of concepts requiring post-coordination, which is related to an implementation decision, by which all concepts recorded for at least 10 times in the problem list repository were included. These included highly specific concepts having a large number of modifiers, such as severity, laterality, clinical course, etc.

There are no specific tools for modeling SNOMED CT logics-dependant vocabularies. Programs such as Apelon or Protégé have been used in the past for modeling ontological standards. However, the specific rules of concept modeling and creation of logical definitions according to SNOMED International and published in SNOMED CT guides had not been tested or reinforced by these programs. The "in house" modeling tool designed and developed in the Hospital Italiano initially did not include rules for controlling modeling logics.

In 2006, an interoperability test was jointly developed and conducted between the Hospital Italiano of Buenos Aires and the Nebraska Medical Center in the United States. It evaluated SNOMED CT features by merging and comparing SNOMED-encoded problem lists from primary care sites in Nebraska and Argentina. Both problem lists showed small differences in semantic content, but differed substantially in the percentage of post-coordinated content. A classification using SNOMED Normal Forms effectively identified semantic equivalence in 65.2% of the reviewed cases. The most common reason for post-coordination failure was non-observance of SNOMED's guidelines (28.8% of remaining 34.8%) [3].

There were also approach differences among users who model post-coordinated expressions [4-6].

After these tests were completed, a new quality assurance tool was added in order to improve the quality of local post-coordinated expressions. This gave users the ability to review, evaluate and correct concept errors online. The system shows a red alert when a rule is broken.

Objective

Our purpose was to test the effectiveness of control modeling rules for concept post-coordination.

Background

The definition of post-coordinated expressions follows the same structure as any concept in SNOMED CT. Concepts included in the current distribution of SNOMED CT and defined by its authority are called pre-coordinated. New concepts defined by local users are called post-coordinated. The User Guide specifies the SNOMED CT post-coordination rules for new concepts. This is the Semantic Model of SNOMED CT [7].

The purpose of post-coordination is to incorporate new concepts into SNOMED CT, building these from existing ones and following their semantic model. The creation of post-coordinated expressions to represent new concepts must follow 2 steps:

- The first one is to define one or more supertypes for the new concept. The supertypes are in this case, more general concepts of SNOMED CT related to the current distribution. The proper assignation of supertypes defines the hierarchy of the concept[1].
- The second step is to incorporate attributes and differentiate the new and more specific concept from its SNOMED CT's supertype included in SNOMED CT. Each attribute is defined as a relationship with other SNOMED concept.

A concept that is fully explained and completely defined by its attributes and by those inherited from its supertypes is called "Fully defined". On the other hand, concepts, which meaning cannot be fully explained or with some different attributes, are "Primitive".

Hospital Italiano's SNOMED CT modeling tool, provides the users utilities for modeling new SNOMED CT concepts created in the local extension. The modeling process includes adding new relationships for describing supertypes and attributes. The creation of a new defining relationship in SNOMED CT consists in the selection of 3 values:

- Source concept: the concept that is being modeled with the relationship
- Relationship type: it can be a "is a" relationship for supertype definition (parent concepts) or any other attribute, like "finding site", "severity", "laterality", etc.
- Target concept: points to the parent concept in "is a" relationships, or to the attribute value, for example in the case of the relationship type "finding site" a usable value can be "lung structure".

According to the semantic model, different types of relationships are valid in different hierarchies, but only a pre-defined proportion of SNOMED CT concepts is a valid target for these relationships. For example, "Severity" attribute is a valid concept of the hierarchy "Clinical Finding", but not for concepts located in the "Procedure" hierarchy. The opposite occurs with the attribute "Direct Device", which is valid for "Procedure" but not for "Clinical Finding".

[1] Relationships: page 10, SNOMED CT User Guide, July 2008

Materials and Methods

Semantic model rules are encoded in a relational database model using tables of valid relationship types. This hierarchical table identifies high-level concepts and a target chart, defined once again by the top level concept of the group of valid target concepts.

The Hospital Italiano vocabulary is also stored in a relational database, including its concepts, descriptions and relationships [8]. A procedure developed using PL / SQL checks if each post-coordinated expression is in accordance with SNOMED's semantic model restrictions.

The following rules were entered to the Terminology server using SNOMED's user guide:

- The concept must belong to only one hierarchy.
- The hierarchy of a given concept cannot be different from the domain hierarchy
- If one relationship depends on the existence of another one, this one must be present.
- The relationship type must be appropriate for that hierarchy.
- Relationship target concepts must be valid.

"In house" Created:

- Only one "IS A (mapping)" relationship can exist
- If the relationship used is "IS A (mapping)" the concept cannot be "Primitive".
- There must be at least one "is a" or "IS A (mapping)".relationship
- There is also a warning if coders use an "entire body structure".

In order to verify the effectiveness of the modeling control system, two samples of post-coordinated terms were selected from the Hospital Italiano vocabulary.

The first one took place in 2006, after Nebraska Medical Center testing and before the implementation of the rules system. The sample included 34,253 post-coordinated terms.

The second sample was assessed in 2008, after the implementation of the rules system (August 2007) and included 9,015 terms.

Post-coordinated concepts included concepts in all domains from the clinical information systems, as well as those included in the list of problems, procedures, drugs or devices.

Each list of concepts was reviewed by an expert that rated the concepts into "right" or "wrong" categories according to the standards of SNOMED post-coordination detailed in the User Guide. A more detailed error description was given for concepts rated as "wrong".

Errors were classified as follows:

- Error in hierarchy definition: The concept is not assigned to the correct hierarchy, e. g. a procedure in the hierarchy of problems (appendectomy as a problem), or a disposable in procedures (as a stent entered as a procedure, etc.).

- Error in the relationship type: a not allowed relationship type used for a given hierarchy, e. g. finding site used in procedure hierarchy.
- Error in relationship target: the target concept is out of the valid range for the relationship type. The relationship is correct, but the target is wrong, e. g. relationship "laterality" with "right knee" as a value, when the proper value should be "right" (otherwise, a "finding site" relationship should have been used).
- Inappropriate use of an anatomical structure as an entire structure: The target concept is a subtype of the concept Entire anatomical structure (body structure), as when the concept "entire leg" is used instead of "leg structure".
- Other errors: those not included in the previously mentioned categories.

The expert also assessed the accuracy of representation; post-coordinated expressions may fulfill the SNOMED CT standards, but not accurately describe the meaning of the concept. Using a 5-point Likert scale, the expert rated meaning representation from the best possible representation to a completely wrong representation.. This measurement will be useful to identify quality control components for the terminology interface, i.e. which parts should be automated and which ones would always require manual review.

Statistical analysis of both samples was performed using a null hypothesis test and power was analyzed. In order to identify a statistically significant difference (0.050), 50 randomly selected terms from each sample had to be analyzed to attain a power of 80.9% in order to obtain a statistically significant result. This estimate assumes that the difference in proportions is 0.20 (specifically, 0.25 versus 0.05).

The sample size also allowed us to report the difference between both samples with an accuracy of approximately 0.13 points (confidence level 95%).

Specifically, a difference of 0.20 would have a confidence interval of 0.07 to 0.33.

Table 1- Examples of post-coordination errors

Physician text	Post-coordination coder error	System Alert	Proper post-coordination
Lobectomy of right lung	is a: Lobectomy of lung Side: Right	The relationship type must be appropriate for that hierarchy	is a: Lobectomy of lung Procedure site - Direct: Right lung structure
Pain in right buttock	is a: Pain in buttock Side: Right	If one relationship depends on the existence of another one, this one must be present	is a: Pain Finding site: Buttock Side: Right
Implantation of cardiac pacemaker	IS A (mapping): Implantation of cardiac pacemaker (Primitive)	If the relationship used is "IS A (mapping)" the concept cannot be "Primitive"	IS A (mapping): Implantation of cardiac pacemaker (Fully defined)
Fracture of tibia and fibula	IS A (mapping): Fracture of tibia IS A (mapping): Fracture of fibula	Only one "IS A (mapping)" relationship can exist	is a: Fracture of tibia is a: Fracture of fibula
Thoracic aorta atheromatosis	is a: Atherosclerosis of aorta Finding site: Entire thoracic aorta (body structure)	Warning of use an "entire body structure"	is a: Atherosclerosis of aorta Finding site: Thoracic aorta structure
Stent (in Precedure Domain)	is a: Stent (in Procedure Domain)	The hierarchy of a given concept cannot be different from the domain hierarchy	is a: Stent (in Device Domain)
Hematoma of left leg	Finding site: Leg Side: Left	There must be at least one "is a" or "IS A (mapping)".relationship	is a: Hematoma of leg Finding site: Leg Side: Left

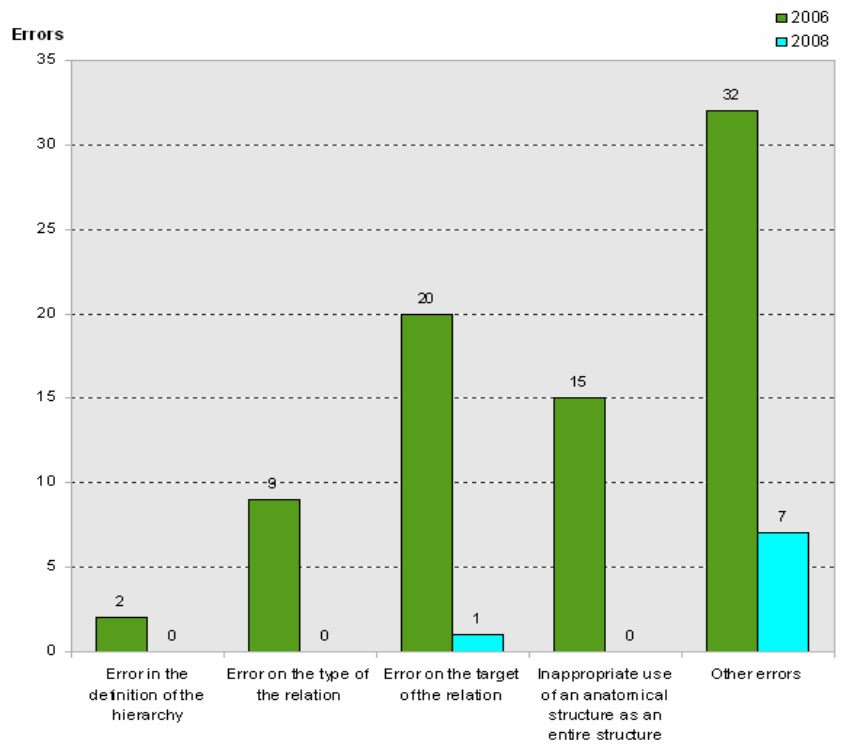

Figure 1- Number of errors grouped by category

Results

In the first sample, we analyzed 300 out of a total of 34,253 concepts; 74% showed no errors. The remaining 26% was distributed as follows: 0.67%, error in hierarchy definition; 3%, error in relationship type; 6.67%, error in relationship target; 5%, improper use of "entire part", and 10.67%, other errors.

In the second sample we analyzed 300 out of a total of 9,015 concepts. No errors were found in 97.3%. The remaining 2.7% consisted in: 0.3% error in relationship type and 2.4%, other errors (Figure 1).

The first sample in the accuracy performance analysis showed that 77% of the terms were adequately represented (points 1 and 2 on the Likert scale), 10.67% were poorly represented (points 4 and 5) and 12.3% could not be determined.

The second sample completed in 2008 showed that 96.33% of terms were properly represented, 2% were poorly represented and 1.67% could not be determined (Figure 2).

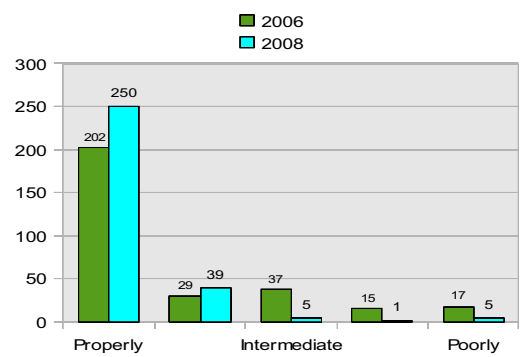

Figure 2- Quality performance

Conclusion

The implementation of an automatic system of rules for concept post-coordination, improves their representation, by enabling the proper use of SNOMED CT relationships, as well as the adequate representation of medical concepts.

Clearly, a system of rules will improve interoperability with other health centers, allowing better results than those achieved in 2006 with the Nebraska Medical Center.

It also has a positive impact in educational settings, by improving the training of users (coders) in charge of concept modeling, who should follow consistent rules to enhance concept representation.

This system of rules may reduce inter-user (coders) variability at the time of interpreting meaning and generating post-coordinated expressions, increasing consensus.

Acknowledgments

A Unified Framework for Biomedical Terminologies and Ontologies

Werner Ceusters, Barry Smith

Center of Excellence in Bioinformatics and Life Sciences, University at Buffalo, Buffalo NY

Abstract

The goal of the OBO (Open Biomedical Ontologies) Foundry initiative is to create and maintain an evolving collection of non-overlapping interoperable ontologies that will offer unambiguous representations of the types of entities in biological and biomedical reality. These ontologies are designed to serve non-redundant annotation of data and scientific text. To achieve these ends, the Foundry imposes strict requirements upon the ontologies eligible for inclusion. While these requirements are not met by most existing biomedical terminologies, the latter may nonetheless support the Foundry's goal of consistent and non-redundant annotation if appropriate mappings of data annotated with their aid can be achieved. To construct such mappings in reliable fashion, however, it is necessary to analyze terminological resources from an ontologically realistic perspective in such a way as to identify the exact import of the 'concepts' and associated terms which they contain. We propose a framework for such analysis that is designed to maximize the degree to which legacy terminologies and the data coded with their aid can be successfully used for information-driven clinical and translational research.

Keywords:

Ontology, Terminology, Mapping.

Introduction

Familiarly, biomedical information is published using multiple different sorts of terminologies, classifications and coding systems. This diversity produces silo effects, which reduce the value of annotations created on the basis of such systems by making data both difficult to access and resistant to integration. Ontologies such as the Gene Ontology, in contrast, seek to overcome these problems by providing corridors of semantic interoperability between distinct information resources [1]. The idea is that, if multiple bodies of relevant information can be annotated using common, non-redundant sets of categories with definitions formulated in some common logical language, then the information they contain will thereby be more easily accessible and more readily capable of being integrated together computationally. This strategy is now increasingly being applied also in the field of human health. [2] Unfortunately, many of the ontologies being employed in specific life science disciplines and in associated clinical specialisms are still built by groups working independently or with no resort to common ontological standards.

Increasingly, one or other version of description logic such as OWL 2.0 is being used in their development. However, the use of a logical representation language alone is clearly not enough to ensure the high quality of an information resource [3], and even ontologies employing the same formal language are often not combinable into a single resource because of incompatibilities between the ways this language is used by different groups. [4]

The goal of the OBO (Open Biomedical Ontologies) Foundry is to counter such tendencies by promoting the creation of a single, expanding family of ontologies designed to be interoperable and logically well-formed and to incorporate accurate representations of biological reality. Ontologies are admitted into the Foundry, and to its on-going process of review, only if their developers commit to an evolving set of common principles [2], of which the most important for our purposes are:

1. that terms and definitions should be built up compositionally out of component representations taken either from the same ontology or from more basic feeder ontologies;
2. that for each domain there should be convergence upon exactly one Foundry ontology; [5]
3. that ontologies should use upper-level categories drawn from Basic Formal Ontology (BFO) [6] together with relations unambiguously defined according to the pattern set forth in the OBO Relation Ontology (RO) [7].

The concept orientation

Concept-based terminologies such as SNOMED CT consist of groups of terms, each such group being linked to a 'concept' that is said to define the meaning of the corresponding terms. We have argued that the inconsistent interpretations of the word 'concept' embraced by the creators and users of such terminologies have given rise to multiple distinct modeling practices, which in turn have given rise to inconsistent representations. [8-9]

Our identification of these problems – which are now acknowledged also by other experts in the field [10-11] – does not, however, imply that we dismiss traditional terminology resources as being without value. On the contrary, it is clear that the majority of these systems will continue to play an im-

portant role in the information-driven clinical and translational science of the future, and this for at least two reasons.

First, huge quantities of clinical and research data have already been annotated (and in some cases compiled *ab initio*) in their terms, and it cannot be expected that these data will be annotated a second time using OBO Foundry ontologies created *de novo*.

Second, where Foundry ontologies seek to represent the entities on the side of reality, traditional terminology systems are designed to reflect the ways language is used by clinicians and others in reporting (for example) patient encounters. This closeness to the needs of clinicians and healthcare institutions suggests that concept-based systems may still be in common use in the future.

The problem must be addressed, however, that the data resulting from such annotation efforts, precisely because they stay so close to the language used in specific disciplinary communities, and because they are affected by the multiple modeling paradigms associated with the orientation around 'concepts', are marked by the detrimental effects of silo formation.

The widespread adoption of SNOMED CT would diminish such effects. But as long as SNOMED CT itself does not use a consistent ontological approach [12], we believe that the data expressed with its aid, too, will involve too high a degree of redundancy and of inconsistent coding [13].

SNOMED's structure does not as yet provide a consistently accessible and reliable representation of the reality on the side of the patient as this reality changes through time. Moreover, SNOMED in its current form will not be able to do justice in consistent fashion to the changes in our knowledge of this reality which will be brought by advances in translational science [14]. To address these problems we need a strategy to map legacy terminologies such as SNOMED CT to OBO Foundry ontologies in such a way as to ensure that both can contribute to the creation of the non-redundant common framework for data integration and exploitation that will be needed in the future.

Objectives

The underlying idea is that both terminology artifacts and ontologies contain representational units (such as single words) and combinations thereof (such as compound word phrases and whole sentences) – together called 'representations' in what follows. The goal is to subject such representations to careful inspection of a sort which can allow terminological representations organized around 'concepts' to be mapped to appropriate ontological counterparts. To this end, we must provide a framework for ontological analysis of terms in legacy terminologies that will support adequate mappings especially for those terms that, because they are declared as 'synonyms', are associated with single 'concepts' under the terminological view. Such terms must be mapped separately wherever they refer – on face value – to entities of different types.

Methods

Our framework rests on three principal distinctions: (1) between *generic* and *specific portions of reality (**POR**s)*, (2) between the various purposes that can be served by *definitions*, and (3) between three distinct levels of reality.

Generic versus specific portions of reality

The first distinction separates *generals* from *particulars*, or in other words it separates *generic* (***GPR***) from *specific portions of reality* (***SPR***). While this distinction, like the remaining proposals outlined in this section, can be applied to both *continuants* (such as cells and organisms) and *occurrents* (such as lives and deaths), we shall concentrate here exclusively on the case of continuants.

Amongst the generic portions of reality are *universals* (***UNV***) and what we shall call *generic configurations* (***GCO***).

Universals are denoted by general terms such as 'human being', 'president', 'nation', 'population'. Universals are *instantiated* by particulars such as President Obama, the USA, the inhabitants of Buffalo. [15]

Generic configurations are configurations formed by *generic portions of reality* (***GPR***) that stand in some relation to each other that can be represented by some statement. An example is the portion of reality represented by the statement '*cell membrane part_of cell*'. Here '*part_of*' represents the generic *part_of* relation as described in the Relation Ontology. [7] Another example is the portion of reality represented by the sentence '*clinicians are human beings*'. Here the word '*are*' denotes what we shall call the *subgroup* relation, which holds between *clinicians* and *human beings*.

Amongst the *specific portions of reality* (***SPR***) are, analogously, *particulars* (***PAR***) and *specific configurations* (***SCO***).

PARs are entities that exist only once and are confined in space and time. Examples are: Mary, Buffalo, and the World Health Organization (WHO). Some ***PAR***s are what linguists would describe as 'named entities', but the majority – a liver cell in Mary, the fracture in her leg, and so forth – are not.

Both specific and generic configurations are represented by statements. Each ***SCO*** involves at least one ***PAR*** that stands in some relation to something else, for example to another ***PAR***, as in the specific configuration represented by the statement '*Mary's left leg part_of Mary*'. If Mary's left leg is amputated, then the two ***PAR***s involved in this ***SCO*** may survive the amputation, but the ***SCO*** itself will cease to exist.

Particulars can be divided into *atomic particulars* (***APA***) and *groups* (***GRP***). An atomic particular is a ***PAR*** that constitutes a unity in the sense that it has a complete, spatially connected external boundary. Examples, again, are: Mary and Mary's left leg. '*Atomic*' is here not to be understood as implying that the entity in question is not further decomposable. If Mary's left leg is amputated, then it may still exist, though not any more as part of Mary. Nor is it to be understood that anatomic particulars cannot themselves contain parts which are atomic (for example Mary herself contains parts which are her cells).

GRPs are entities denoted by generic terms such as 'limb of vertebrate', 'limb of human being', and even 'limb of Mary'. Although the latter example will likely not be found in a terminology or ontology, terms of the same sort do occur, examples being 'citizen of the United States', 'Nobel Prize winner', 'veteran of the Second World War'. Terms denoting ***GRP***s are typically formed via combination of smaller terms which themselves denote universals, particulars, or other ***GRP***s.

If Mary is a healthy human being, the entity denoted by the noun phrase 'Mary's limbs' is an example of a group (***GRP***). Each of healthy Mary's limbs is at the same time a *part* of Mary and a *member* of the corresponding ***GRP***. All members of a ***GRP*** at any given time are such as to exist at that time.

Among ***GRP***s, we distinguish further between, *bona fide groups* (***BGR***), *fiat groups* (***FGR***) and extensions (***EXT***) [16]. While these distinctions are by no means trivial, their correct understanding is important if we are to find coherent ways to manage the large families of terms (for example in SNOMED CT the family consisting of terms such as 'absent leg', 'amputated leg', 'withered limb', 'absent bone in leg', 'limb amputee', 'amputation of lower limb', 'amputation of limb'), whose meanings are otherwise difficult to capture in a coherent way.

A bona fide group (***BGR***) is a group whose members are homogeneous, are causally linked together, and which is maximal in the sense that all causally linked entities of the relevant sort are members of the group. Examples are: Mary's limbs, Mary's cells, Mary's molecules.

A fiat group (***FGR***) is a group that is demarcated by fiat, such as: left lungs of people currently in Buffalo, the left lungs of all the people now participating in clinical trial #77639.

At any time at which the ***BGR*** constituted by healthy Mary's 4 limbs exists, a cognitive being may explicitly recognize the simultaneous existence of any combination of two or more of her limbs. Some of these combinations, for instance any group of 3 of her limbs, are distinct ***FGR***s, since they fall short of being maximal. The groups formed by her two arms and by her two legs, in contrast, are ***BGR***s. The relation between fiat subgroups of the bona fide group that is formed by Mary's limbs is analogous to the relation between some proper part of Mary that is demarcated by fiat and Mary as a whole. There is a fiat boundary between healthy Mary's left arm and the rest of Mary's body in the region of her left shoulder.

To each continuant universal corresponds a group, called its *extension* (***EXT***), formed by all and only those particulars that are instances of that universal at any given time.

The purposes of definitions

Our second distinction recognizes three purposes which a *definition* of a representational unit may serve:

P1: to specify the conditions that must be satisfied for a term to be an acceptable designator for a given entity in some given community. An example would be:

chronic pain =def. *a pain that has been present for more than 3 months*

P2: to specify what is characteristic of particulars that instantiate a certain universal, for instance:

disorder =def. *a part of an organism which serves as the bearer of a disposition to pathological processes* [17]

P3: to demarcate groups and classes by specifying characteristics that their members or elements must exhibit.

P1 definitions are essentially a matter of terminological decisions. The definition given as example excludes the use of the term 'chronic pain' for pains lasting less than 3 months. This does not mean, however, that a pain in a specific patient that has already lasted for 90 days *becomes* a chronic pain one day later. It was, in fact, a chronic pain already from the very beginning, even though this fact was unknown to any observer.

P2 and P3 definitions help in determining whether a given particular is to be classified in a given way. P2 does this at the level of universals, while P3 does it for ***GRP***s and as further explained, classes.

First-order entities versus representations

The third distinction concerns the *level of reality* at which the referent of some representation exists. Of importance here is the distinction between

1. *first-order entities* such as patients, disorders, families,
2. *beliefs* in people's minds (including beliefs putatively about objects such as unicorns which do not in fact exist), and
3. *representations* in some publicly accessible medium, for instance a term in an ontology.

Applying the framework

When a terminology has been selected as one that needs to be mapped to OBO Foundry ontologies, each of its representational units should be inspected to identify, in terms of corresponding representations in Foundry ontologies, what sorts of ***POR***s it is able to denote. A problem is that terms from concept-based terminologies often denote multiple distinct sorts of ***POR***s, for example because of asserted subtype relationships, as in SNOMED CT, whose concept 'Finger structure' subsumes the concepts 'entire finger' (a ***UNV*** under a realist framework) and 'all fingers' (a ***GRP***) (though SNOMED does not specify whether the latter means: 'all fingers in the world', 'all fingers of a given patient', 'all fingers on a given hand').

To address this problem, we introduce an intermediary layer made up of *classes* (***CLA***), understood as arbitrary totalities of elements which are either (i) defined through some descriptor referring to ***POR***s of any of the sorts described thus far (for example: 'the disorders in all the patients treated by Dr. McX'), or (ii) totalities whose elements are themselves so defined, or (iii) combinations of (i) and (ii).

Classes under (i) thus carve out ***POR***s in ways which go far beyond ***GRP***s as defined in the foregoing. Classes under (ii) and (iii) allow simultaneous reference to entities associated together in ways which have no counterpart ***POR***, for example

when we wish to assert heritability relations between Mary and certain of her ancestors who died many years before she was born.

Defined classes

Where groups have *members*, classes have *elements.* A *Defined Class* (***DCL***) is a class all of whose elements are specified by some class description. In the simplest case, this will be of the form '*ξ which stands in R to λ*', where '*ξ*' names some universal, for example 'person born in Belgium', which defines what we shall call a *Specifically Defined Class* (***SDC***), or 'patient who has tuberculosis', which defines a *Generically Defined Class* (***GDC***), each of whose elements enjoys the same relation (*exemplifies*) with instances of the single universal: tuberculosis. In more complex cases the definition will be of a logically more complex form, such as '*ξ* **has duration** *which stands in R to λ*', for example in the ***GDC*** *chronic pain*, where *ξ* is the universal: pain, *R* is the relation *longer_than* and *λ* is the temporal interval: 90 days. Many of the terminological definitions distinguished under P1 above will define terms which refer to ***GDC***s in the outlined sense.

For each ***GDC*** and for each ***SDC*** there is some universal from whose extension all its elements are drawn. An *Ad Hoc Class* (***AHC***), in contrast, is a ***CLA*** formed through combinations of ***GDC***s and ***SDC***s which is such that there is no such overarching universal. An example is, again, the SNOMED CT concept '*finger structure*', since among the entities that can be denoted by this term are both ***GRP***s and ***APA***s

Among ***AHC***s, too, we can distinguish both *Generic* (***GAC***) and *Specific Ad Hoc Classes* (***SAC***). An example of a ***SAC*** is the class whose elements are the clinical signs exhibited by some specific patient with tuberculosis [17]. An equivalent ***GAC*** would be the class whose elements are the clinical signs exhibited by all tuberculosis patients assigned to the control group of a given clinical trial.

Solving the semantic proximity problem

In its January 2009 version SNOMED CT associates the concept '*Fractured nasal bones (disorder)*' with the following synonyms: 'Fractured nasal bones' (S1), 'Broken nose' (S2), 'Fractured nose' (S3), 'Fracture of nose' (S4), 'Fracture of nasal complex' (S5), and 'Fracture of nasal bones' (S6). One consequence of the multiple interpretations that are given to the term 'concept' both inside [12] and outside [8] of SNOMED CT is that it is difficult to understand precisely how this 'association' is to be understood. In practice, what it means is that SNOMED is here acknowledging the different ways language users capture nasal bone fracture-related information when entering patient data into a record, and providing an aid to translating the corresponding bodies of data into SNOMED form. As realist ontology (and common sense) would suggest, however, it can be assumed that when a study nurse enters the term 'fractured nasal bones' into a patient record, then what he means thereby is not a *nose of a certain (fractured) sort* but rather a certain *group of bones.* If, accordingly, we are to devise a strategy for translating the resultant SNOMED data into the OBO Foundry framework, then our mapping will need to take account of the mentioned 'associations' in a more careful way than is possible when all the mentioned synonyms are treated *en bloc*. It is for this reason that we introduce the machinery of ***CLA***s and ***GRP***s in the above. This machinery is designed to make apparent the unarticulated complexity of SNOMED's synonymy relation by allowing each synonym to be treated separately in a way which at the same time allows formulation of the needed mappings to the corresponding OBO Foundry terms.

Human bones and noses are represented in the FMA Anatomy Ontology [18] by means of representational units denoting the universals *bone* and *nose* respectively. Fractures, in contrast, would be included in an ontology of disorders [17]. To realize our proposed strategy, now, scholars developing a mapping from SNOMED CT to OBO Foundry ontologies would have to decide, in collaboration with the SNOMED authors, what precisely the synonymous terms (S1–6) mentioned in our list above should properly be understood as denoting. In the framework here proposed, for example, S2 and S3 would both denote a ***GDC*** that is a subgroup of the extension of the universal *nose*. S1 would denote, according to further context, either a ***GRP*** which has *nasal bones* as members or a ***GDC*** denoted by the plural term 'bones of the nose'.

Another advantage of our strategy is that it helps us to understand the structure of the *is a* hierarchy in SNOMED CT. 44 concepts in SNOMED CT are described as being *is a* parents of *Fractured nasal bones (disorder)*. Where all of the synonyms referred to above denote first-order entities on the side of the patient, this is not the case for all 44 of the parent concepts listed. '*Disorder by body site (disorder)*', for example, reveals itself upon inspection to denote not a disorder at all but rather the way the representational units about disorders are further organized.

Another problematic case is '*Finding by site (finding*)': fractured nasal bones cannot, in our terms, be a (type) of finding, since something can only be found – and hence give rise to a finding – if it pre-exists, and is thus independent of, the corresponding act of observing. On our strategy, in fact, finding data would be mapped, not to bones directly, but rather to the corresponding datable observations.

Conclusion

It has been stated that '*Terminologies should not be developed by reference to a system of preferred terms, rather they should be developed in such a way that their individual nodes and* [the] *relations amongst these nodes are modeled on an underlying formal ontology, where the linguistic content of these nodes will be filled in based on a system of terms and synonyms (from many different languages) that is associated with each node based on the intended ontological interpretation of that node'*. [19] Few, if any, existing biomedical terminologies exhibit these characteristics. The framework we propose is designed to promote progress in this respect, with the goal, not of developing an underlying formal ontology for these terminologies themselves, but rather of achieving appropriate mappings to OBO Foundry ontologies. The approach provides a tool for terminologists to detect ambiguities and conflations in

the conceptual structures they have designed and to determine the correct handling of terms proposed as synonyms; it also forces developers of realism-based ontologies to be more precise about what exactly the representational units in their artifacts denote. Certainly there is a long way to go. We acknowledge that the proposed approach is not easy to apply because of the subtle distinctions it requires, distinctions which are perhaps not easy to understand especially for adepts of the concept-based approach. We believe, however, that the approach promises significant benefits, both practical and theoretical, in the long run.

Abstract

The U.S. Agency for Healthcare Research and Quality has created a public website to disseminate critical information regarding its health information technology initiative. The website is maintained by AHRQ's National Resource Center (NRC) for Health Information Technology. In the latest continuous quality improvement project, the NRC used the site's search logs to extract user-generated search phrases. The phrases were then compared to the site's controlled vocabulary with respect to language, grammar, and search precision. Results of the comparison demonstrate that search log data can be a cost-effective way to improve controlled vocabularies as well as information retrieval. User-entered search phrases were found to also share many similarities with folksonomy tags.

Keywords:

Classification, Information retrieval, Internet, Health informatics

Introduction

Since September 2004, the U.S. Agency for Healthcare Research and Quality (AHRQ) has invested over $266 million in its health information technology (health IT) initiative. The goal of AHRQ's investment is to develop and disseminate health IT evidence and evidence-based tools to support AHRQ's overall mission of improving the quality, safety, efficiency, and effectiveness of health care for all Americans. A major component of AHRQ's health IT initiative is the National Resource Center (NRC) for Health IT, initially created by AHRQ to assist its grantees and contractors. Today the NRC is a public resource for those interested in implementing and using health IT. The main point of interaction with the AHRQ NRC is through its website[1].

Since its launch in 2006, the NRC has strived to continuously improve the website. To accomplish its goal, the NRC routinely captures usage metrics and user feedback, considered a best practice in the industry [1]. The metrics and feedback are used to identify website performance and usability issues. In addition, the data are used to identify content gaps. The NRC website supports a large, heterogeneous group of informatics practitioners and researchers, including novice providers just starting down the path towards implementation, adoption, and usage of health IT applications.

During the past two years, the NRC has focused on supporting these novice users in their quest to find knowledge resources to support local implementation and adoption of health IT. Part of this support involved the creation of a controlled vocabulary to describe the diverse content available on the site. The taxonomy of health IT terminology was used to organize web pages and index items made available through a search function. However, initial usability testing revealed that the taxonomy was confusing to novice users who did not use the same language and grammar as that used by the experts who created the taxonomy [2]. Based on the results of the usability testing, the NRC team removed the taxonomy from the site's outward facing information architecture but continued to use it for categorizing knowledge resources on the back-end.

The initial emphasis on users' ability to effectively browse the website, or click through the various pages to find information and knowledge resources, resulted in a lower priority for improvements to the search function. This changed in 2008 when usability testing revealed that many users, both novice and experienced, were frustrated with the website's search function. Furthermore, usability testing results showed that experienced site users tend to use search first, rather than browse through a site's information architecture.

To improve the site's search function, the NRC focused on enhancing its taxonomy. Best practice in information retrieval calls for the use of domain specific, controlled vocabularies to index the content made available through the search function [3]. Since the NRC already employed a controlled vocabulary to index its content, efforts focused on enhancing the taxonomy to improve search queries.

Recent information science literature has described the use of a folksonomy, in addition to or in place of, a controlled vocabulary to improve the user experience for searching. A folksonomy involves the use of open-ended, collaboratively generated metadata (or tags) for categorizing a site's content [4]. Folksonomies are further referred to as social bookmarking, social tagging, and social classification based on the fact that users typically create metadata tags for themselves and then

[1] http://healthit.ahrq.gov

share the content and tags with others. Common folksonomy websites include Digg, Delicious, and CiteULike.

Whereas taxonomies are top-down, controlled vocabularies, created and maintained primarily by librarians or domain experts, folksonomies are bottom-up, uncontrolled vocabularies that utilize familiar, accessible, and shared concepts created and maintained by a community of users [3,4]. In addition, folksonomies may have several advantages over taxonomies. First, folksonomies have been described as dynamic and forward looking with the capacity to categorize unforeseen subject matter, including emerging technologies [5]. Second, folksonomies may be a less expensive alternative to the development, maintenance, and enforcement of a tightly controlled vocabulary [5,6]. Finally, folksonomies may have a gentler learning curve for novice users [6]. These advantages may be attractive to a publicly funded program with limited resources for long term site development and maintenance.

Creating the ability for users to develop and share folksonomy tags on the NRC site would be difficult. U.S. Government policies restrict agencies from collecting users' names and other identifying information without strong oversight [7]. Before the NRC could ask for permission to enable users to login to a personal profile, create folksonomy tags, and view other users' tags, the Web team desired to explore the use of user-generated language and grammar to enhance the search function. In this paper, we outline our methods for approximating a folksonomy with user-generated search queries and present the results of an exploratory study in which user-centered language and grammar is compared with the expert-created taxonomy. We further suggest how folksonomies and other forms of user-entered concepts can be used to improve taxonomies as well as search functionality.

Materials and Methods

The AHRQ National Resource Center website utilizes the social networking plug-in AddThis (www.addthis.com). This application enables users to share web pages and content items with others via third-party Web 2.0 applications, including Twitter, Delicious, and Digg. Although these third-party applications make sharing easy for users by leveraging existing infrastructure, they do not allow AHRQ to easily review the content tags assigned to the items shared by users. Attempts to retrieve public folksonomy tags via Delicious and Digg for AHRQ pages and content did not yield substantive results. Nearly all of the users utilizing these services are storing the links and tags as private, perhaps sharing them with a limited number of peers or using them as personal bookmarks. This prevented a direct evaluation of folksonomy tags associated with NRC information and knowledge resources.

Therefore we approximated user-generated concept tags by utilizing an available data source, the maintenance logs of the NRC website. These logs contain many data on anonymous users' interactions with the site, including search phrases and keywords automatically captured each time users perform a query. The logs are comprehensive, and they are routinely used for other performance and usability monitoring.

Our hypothesis was that user-entered search phrases and keywords, extracted from queries, would exhibit the same characteristics as folksonomy tags. When testing the NRC site's taxonomy, we observed that users typically searched for information using concepts and phrases from their language and grammar. These concepts did not always overlap with the highly controlled vocabulary used in the first version of the site's taxonomy [2]. So in our search to identify an alternative, practical source for pilot data to evaluate the potential use of a folksonomy, we hypothesized that user-entered search terms may reflect users' language and grammar in a similar way to that of folksonomy tags.

We examined twelve months worth of search logs ranging from July 1, 2008 through June 30, 2009. The logs from December 2008 were corrupt, so they were excluded from the final analysis. A total of 34,816 user-entered search phrases were extracted from the logs and analyzed.

Three analytical methods were employed to review the search phrases and determine their appropriateness as a source of quality improvement data. First, the occurrence of each search phrases was counted, and the top 100 phrases were analyzed for patterns and trends. Our belief was that the search phrase patterns and trends would be similar to those observed of folksonomies by previous information science researchers.

Second, the top 100 phrases were mapped to the National Resource Center's taxonomy [1] to qualitatively evaluate its robustness and identify gaps. The mapping was also performed to examine the search phrases. We believed that the phrases would represent health IT concepts in the natural language and grammar of the end users.

Third, a non-random sample of five search phrases from the top 100 was selected for additional qualitative review. Each original search phrase and its mapped taxonomy concept were used to execute independent searches of the website. The search results were then examined for relevance. The search results were evaluated using 10-*Precision* method as described by Pera [8] and defined in Equation (1). This 10-*Precision* equation produces a precision value for the top 10 search results for a given query (*Q*).

$$10\text{-}Precision = \frac{\#_{of_{Retrieved_{Relevant_{Records}}}}}{10} \quad (1)$$

Precision values for the five user-generated search phrases and repeated, independent searches using the mapped taxonomy concepts were calculated. The values were then compared and contrasted. We hypothesized that the mapped concept precision values would be higher for each of the 5 paired queries. We further hypothesized that precision values for the mapped concept queries would be 1.0 since the taxonomy was engineered to facilitate precise information retrieval.

Results

Top 100 User-Entered Search Phrases

The 34,816 log records contained 8,574 unique search phrases. The number of occurrences for each unique phrase was counted for analysis. When sorted in descending order, the search phrases reveal an inverse logarithmic relationship as

shown in Figure 1. The curve begins to level off after the fifth most popular phrase, and just 30 phrases were entered more than 100 times in the eleven month period. These top 30 phrases were entered 12,707 times, which represents 36.5% of the total phrases observed over the 11 month period. The top search phrase, "health information technology," was entered 2,650 times and accounted for 7.6% of the total queries.

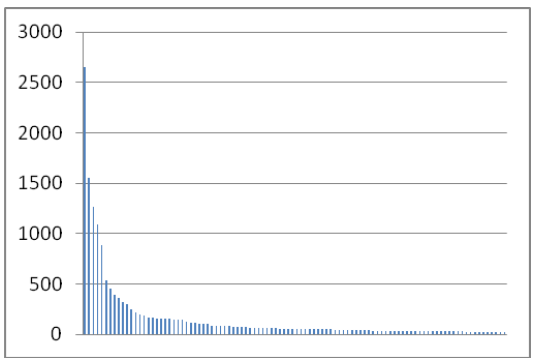

Figure 1- Distribution of the Top 100 User-Entered Search Phrases for http://healthit.ahrq.gov

Mapping User-Entered Search Phrases

Ninety-three of the top 100 search phrases were successfully mapped to existing taxonomy concepts. Thirty-three percent of the mapped terms pertained to just four political/administrative concepts: the Office of the National Coordinator for Health Information Technology, the Health IT Policy Committee, the Health IT Standards Committee, and the American Health Information Community.

The seven phrases that could not be mapped to existing taxonomy concepts are presented below in Table 1. The "knowledge library" concept refers to the area of the site where searches are executed, but the concept itself is not represented in the taxonomy. The concept "betaa" appears to be a misspelling. Two concepts (medical home, medical home model) are related, and they represent a health care delivery concept frequently discussed in the American medical community. The remaining three concepts appear to be terms invoked by robots scanning the site for downloadable content.

User-Entered Search Phrases versus Taxonomy Concepts

Five unique search phrases from the top 100 were non-randomly chosen for additional analysis by the primary author. The author selected phrases that did not pertain to overly general concepts, such "health information technology," and phrases were further selected to represent a range of concepts.

For each phrase, two searches were performed. First, the original, user-entered phrase was used. Second, the mapped taxonomy concept was used. A total of 10 queries were independently performed. For each query, the authors examined the search results and calculated a 10-*Precision* value using Equation 1.

The selected search phrases and their 10-*Precision* values are summarized in Table 2. The original, user-entered phrases are listed first, followed by their 10-*Precision* values. Next the mapped taxonomy concepts are listed, followed by their 10-*Precision* values. The results show a general trend in which the taxonomy concepts performed as well or slightly better than the user-entered phrases.

Table 2 – Selected Search Phrases and Their Precision Scores

User-Entered Phrase	10-*Precision*	Mapped Taxonomy Concept	10-*Precision*
system implementation	0.9	Implementation	0.9
emr readiness assessment	0.2	Readiness Assessment	1.0
snomed	0.9	Coding Standards -> SNOMED	0.9
cpoe systems	0.6	Systems -> Computerized Provider Order Entry	0.9
time and motion study pdf healthcare	0	Workflow Impact -> Efficiency of Care	0.4

Discussion

Proponents of folksonomies suggest that they should replace traditional controlled vocabularies given the latter's limitations and expense [9]. Others in the information retrieval community view folksonomies as potential supplements to taxonomies, enhancing knowledge management practices with input from users [3,6]. Based on our review of the literature and exploratory study, we believe that folksonomies may be able to play a supporting role. We further assert that there are other sources of user input that can enhance information retrieval and knowledge management, namely search logs.

When we originally sought to enhance the NRC taxonomy, we looked towards a folksonomy. Because U.S. Government website policies do not favor private user accounts that collect

identifiable information [7], we turned to an alternative source of user input we believed would exhibit the same characteristics as folksonomy tags. Our exploration of this data source confirmed our hypothesis, revealing that user-generated search phrases indeed share characteristics with folksonomy tags.

Similarities between Folksonomy Tags and Search Phrases

User-generated search phrases are like folksonomy tags in the sense that they are uncontrolled. Folksonomies have been described as lacking rigor in their use of spelling, parts of speech, and use of plurals [4,6,10]. For example, the concepts "cat" and "cats" are typically unique concepts in a folksonomy, even though more structured vocabularies would relate the concepts to one another.

We found similar patterns within the search logs. For example, users varied in their use of "cost" versus "costs" when searching for information on the "typical cost" of a computerized provider order entry (CPOE) system. Thus one can imagine that if users were asked to tag a study on the "costs and benefits" of health IT [11], some users would use a "cost" tag while others would use a "costs" tag.

Also, like folksonomy tags, user-generated search phrases tended to be broad and less specific than the NRC taxonomy. Previous studies have shown that when users tag content when contributing to a folksonomy, they often choose the cognitive path of least effort [12]. The example described by Munk and Mørk involved an article by Milton Friedman in the *New York Times*. Folksonomy users tended to label the article with very broad tags, such as "business," "economics," and "politics," whereas the article dealt primarily with the concept of corporate social responsibility.

We found that many of the top 100 search phrases exhibited similarly broad concepts. The top search phrase, accounting for 2,650 (7.6%) of the 34,816 total phrases, was "health information technology." Other broad phrases in the top 100 included: "hit standards," "it tools," and "data reporting." These labels would likely apply to many of the articles, white-papers, and other information resources found on the AHRQ Health IT website, making them generally unhelpful to users seeking more narrow concepts such as EHR adoption, standard clinical vocabularies, and project management tools.

Search phrases are like folksonomy tags in the sense they both follow inverse logarithmic or power law distributions. Folksonomy tag distributions are the subject of several detailed analyses [10,12]. Each analysis revealed a general trend whereby a handful of so-called "power tags" are very popular followed by the long tail of tags used sparsely.

We observed a similarly long tail of unique search phrases, accounting for nearly two-thirds of all search phrases. However, the caveat is that we did not apply any intelligence to the raw search phrases, matching them to similar concepts or attempting to relate them to each other in any fashion. It could be that many of the phrases overlap in semantic meaning and, as a result, there may be a shorter tail than these data would otherwise indicate.

Synonymy is another similarity between folksonomies and search phrases. Folksonomies are described as possessing large semantic overlap between tags [5,6,12]. Often this is a function of the folksonomy platform. Delicious, for example, does not permit spaces in tags. Therefore "New_York_City" and "NewYorkCity" are distinct tags with no relationship. In a controlled vocabulary, the synonymy of these two concepts would be managed by content experts.

When reviewing the top 100 search phrases, we observed quite a bit of semantic overlap. Twelve of the top 100 phrases conveyed the broad subject of "health information technology." If these variants were used as distinct, unrelated tags in a folksonomy, they would likely not improve the precision of the search function. Users would instead need to execute 12 queries, one for each variant of "health IT," to retrieve all items tagged with the various synonyms of "health IT."

Enhancing Taxonomies and Information Retrieval

Folksonomies have been described as forward thinking, meaning that they keep pace with changing language, grammar, and trends in society (e.g., emerging technologies and concepts) [6,9,10]. This benefit is one of many reasons that many web managers and information system designers are looking towards folksonomies to enhance or complement controlled vocabularies. Our exploratory study of user-entered search phrases revealed not only that search log data are similar to folksonomy tags but that search phrases can be used in a similar manner to enhance controlled vocabularies and improve information retrieval within a web site or application.

Proactive monitoring of search log data to enhance controlled vocabularies yielded three main benefits. First, the review of search phrases identified users' evolving language, grammar, and search behavior. Consider the 12 variants of "health IT." Using the search logs, additional variants of this concept were identified and mapped as synonyms of the general term "health information technology." This process expands and enhances the controlled vocabulary and will likely to lead to search function improvements, since users could enter any of the 12 variants and, once the synonyms are linked within the taxonomy, and receive a very similar list of precise search results.

We further identified a concept that was not yet in the taxonomy: medical home. Although medical home is not a core informatics concept, much of the discussion in the U.S. surrounding medical home development and maintenance has involved the use of health IT systems to enable efficient and effective coordination of care among a diverse set of providers. Therefore this concept is an important, related concept that should be represented in a controlled vocabulary designed to encompass the field of health IT.

We also noted unanticipated patterns of users' search behavior. Consider the search phrases for four government entities, the Office of the National Coordinator for Health Information Technology (ONC), the Health IT Policy Committee, the Health IT Standards Committee, and the American Health Information Community (AHIC), which accounted for a significant number of searches. Three of these four concepts are non-permanent government committees, which raises the issue of whether currently popular labels should be included within the controlled vocabulary or incorporated in other ways (e.g., folksonomy tags, related terms).

Second, enhancing the taxonomy using user-entered search phrases improved the precision of the site's search function.

The 10-*Precision* values associated with mapped taxonomy concepts were greater than or equal to the values associated with the original search phrases. If the controlled vocabulary was routinely enhanced to reflect users' behavior and language, then the search function should significantly improve over time. Furthermore, we learned that the fifth term, "Workflow Impact -> Efficiency of Care," yielded a low precision value and should therefore be modified. User data might therefore benefit taxonomies beyond just the identification of synonyms and new terms.

Finally, the use of search phrases can be cost-effective. The search logs used to collect the data were already a foundational component of the website. They worked in the background, logging queries. The process of extracting the search phrases from the logs was quick and simple. Loading the phrases into an application for review and analysis also took less than a half a day. In total, less than one business day per quarter could be devoted to active review of search logs for new phrases and patterns of usage.

Other sites and applications that host controlled vocabularies could benefit from this study. For example, the Medical Subject Headings (MeSH) vocabulary maintained by the U.S. National Library of Medicine (NLM) currently does not contain concepts for health information exchange (HIE) and personal health records (PHRs). Reviewing search logs would probably reveal a number of queries for these concepts, which could prompt NLM to add them more rapidly to the MeSH tree than through the usual process of search term development. EHR and PHR applications might also benefit from collecting and analyzing user search data, which could aid in the retrieval of patients' health information or relevant evidence-based medicine knowledge.

Limitations of the Study

There are several limitations of this study. First, the study was exploratory in nature. The data were gathered from just one website, and they were not cross-checked with similar data from other websites. Second, only one expert was involved in reviewing the data and mapping search phrases to taxonomy concepts. Third, the sample used for analyzing precision was small. Finally, the study did not take advantage of natural language processing (NLP) techniques which could be utilized to perform automated scanning of the data to find new patterns and trends. NLP methods might also help us understand the structure of search phrases, which in turn may help to develop new methods for enhancing the search function interface and the way queries are formed by novice and intermediate users.

Conclusion

Website and application search logs contain user-generated phrases and keywords that exhibit similar characteristics to folksonomy tags. Using user-entered search phrases and keywords to enhance controlled vocabularies can be a cost-effective strategy for improving information retrieval. It may also be an effective complement to approaches, including folksonomies. Health informatics websites and applications should consider this technique to improve information retrieval and the overall usability of end-user products.

Abstract

Antibiotics resistance development poses a significant problem in today's hospital care. Massive amounts of clinical data are being collected and stored in proprietary and unconnected systems in heterogeneous format. The DebugIT EU project promises to make this data geographically and semantically interoperable for case-based knowledge analysis approaches aiming at the discovery of patterns that help to align antibiotics treatment schemes. The semantic glue for this endeavor is DCO, an application ontology that enables data miners to query distributed clinical information systems in a semantically rich and content driven manner. DCO will hence serve as the core component of the interoperability platform for the DebugIT project. Here we present DCO and an approach thet uses the semantic web query language SPARQL to bind and ontologically query hospital database content using DCO and information model mediators. We provide a query example that indicates that ontological querying over heterogeneous information models is feasible via SPARQL construct- and resource mapping queries.

Keywords:

Ontology, Knowledge sharing, Antibiotics, Semantic heterogeneity, Systems integration, Information storage and retrieval

Introduction

After fifty years of unreflected and abundant use of antibiotics, the emergence of resistant and potentially untreatable pathogens has led to increased healthcare costs and patient risks. Comparison of antimicrobial resistance data across Europe led to the discovery of a wide diversity in practices. For instance, in Urinary Tract Infection (UTI) by uropathogenic E.coli, Trimethoprim is used as first line medication, while Fluoroquinolones are preserved as backup for patients with contraindications, allergies and where first line drugs fail. Although increasingly widespread use of Fuoroquinolones will promote bacterial resistance, an uncontrolled prescription can be observed in some areas. While resistance to Fluoroquinolones averages 5% in Europe, it can be as high as 24% in Spain [1].

The **DebugIT** project (**D**etecting and **E**liminating **B**acteria **U**sin**G** **I**nformation **T**echnology, http://www.debugit.eu/), a large scale data integration project funded within the 7th EU Framework Program, intends to analyze these practices and their outcomes across Europe and to exploit this knowledge to detect patient safety related patterns in hospital data, i.e. to discover indicators for better treatments and antibiotics resistance prevention.

In this project, a semantic infrastructure allowing bidirectional communication between locally distributed Clinical Data Repositories (CDR) and the DebugIT knowledge mining services is being built[1]. Most of the required semantics are provided by the DebugIT Core Ontology (DCO), which represents the formal and explicit computer-interpretable meaning throughout the project using semantic web technologies. DCO focuses on patients, diseases, pathogens, their analyses and medications.

We present DCO's current state of development and demonstrate how DCO is used within DebugIT to bridge the semantic gap between two heterogeneous clinical information systems. In order to do so, we briefly introduce some core aspects of the DebugIT interoperability platform which enables the semantic query integration over different hospital CDRs via DCO. The overall DebugIT knowledge mining architecture is described in [2].

Materials and Methods

Querying within the DebugIT interoperability platform

In order to understand how DCO is used for building cross-hospital queries, we here describe the query building process and the involved modules:

1. A data miner receives a clinical question and determines the needed datasets in the list of different hospital CDRs by iterating through steps 2 to 4 for each of the targeted CDRs. Soon the system will eventu-

[1] D. Teodoro, R. Choquet, E. Pasche, J. Gobeill, C. Daniel, P. Ruch, C. Lovis, Biomedical Data Management: a Proposal Framework. MIE 2009

ally possess a large battery of solved questions and their queries, which in turn give rise to the needed datasets for certain type of questions, therefore simplifying any subsequent query making process.

2. Previously stored SPARQL[2] dataset queries for the selected CDR are searched in order to be reused. Also partially matching queries may be used.
3. If no adequate query is found, a new SPARQL query is created (or an existing one adapted) by the data miner. We bridge the gap between the different CDRs by linking the specific CDR concepts via the DDO to DCO classes in a SPARQL query.
   a. First the **CONSTRUCT** clause is created using DCO according to a graph pattern template that specifies how results of the query should be returned. This CONSTRUCT clause can be reused for further CDR SPARQL queries the data miner is building and can be the same for all of the CDRs.
   b. Then the **WHERE** clause is created using an RDF file mediator called 'DataDefinitionOntology', DDO, expressing the information model and the mapping between its local concepts and DCO. The data miner needs to build a SPARQL query for each targeted CDR, because they are independent storage systems and normally have different DDOs. If a DDO concept is missing, the local CDR maintainer is notified who should fill this gap by defining the missing concepts.
4. The SPARQL query is sent to the targeted CDR and the returned RDF result is analysed to determine if it provides the needed data to solve the clinical query. If this is not the case, steps 2 to 4 are repeated to refine the SPARQL query. If the result is adequate the steps are repeated for the next selected CDR.
5. Finally, the SPARQL queries are sent to all distributed hospital SPARQL endpoints[3] to access their CDRs. The results are then aggregated into one RDF data result set, which can be exported to different formats, depending on the needs of the used data mining approach.
6. The constructed dataset SPARQL queries can be stored together with the RDF result and additional metadata in a knowledge repository for later reuse.

The gap between the different CDRs is bridged by linking the specific CDRs to DCO concepts in a mapping SPARQL query. In the query process described, we apply two kinds of ontologies to communicate between different modules of the interoperability platform. DCO classes and relations are used for formulating a hospital independent clinical query using SPARQL. It is mapped to the local IM via an RDF converted database schema[4], the DDO, acting as a query mediator to the proprietary hospital CDR. The physical IM was converted into RDF syntax by a syntax conversion tool to render it accessible to the SPARQL WHERE clause.

DCO design principles

We subscribe to a realist perspective towards biomedical ontologies as detailed in [3], however this is not in conflict with integrating information entities (see footnote 6).

Whereas according to [4] domain ontologies describe the vocabulary for a generic domain (medicine) and task ontologies describe a generic task or activity (e.g. diagnosing), DCO has to be classified as an application ontology according to this system, because DCO describes terms depending both on a particular domain (infectious disease) and task (data mining). From an engineering standpoint, we apply the normalization approach of [5] and use single asserted parenthood throughout the taxonomy. This will facilitate the orientation in the taxonomy and its maintenance. A reasoner infers multiple parenthood from the formal restrictions.

Ontology builders and users root their modeling decisions and interpretations into upper-level assumptions, whether they make it explicit in an upper-level ontology or not. We build DCO as an extension of the already existing upper level ontology BioTop [6], which renders the meaning of classes and relations explicit and less ambiguous. It helps to ensure a rigid modeling view and eases modeling decisions by providing basic constraints on a high level that can readily be exploited. To allow non-ontologist biomedical experts to view and check parts of the ontology we apply user-friendly ontology visualizations as generated by the OwlPropViz Protégé plugin[5] (see Figure 1).

Scope delineation

In order to maintain the ontology manageable and not to fall into "analysis paralysis", a restriction of the representation to an area of more immediate interest is mandatory. The top requirement for DCO is the coverage of the conceptual space for the detection of harm patterns and the exchange of clinical information, focused on infectious diseases. We decided to model the full circle for a concrete application and querying scenario first, rather than going for broad coverage. This will result in a better idea of how time series of events and branching within processes can be handled and it will contribute to test where the DCO upper level model needs to be updated in order to capture all information in the different CDRs.

Use Case and Competency questions (CQs)

A simple and common scenario, the antibiotic therapy of UTI with the most commonly used drugs Fluoroquinolones and Trimethoprim/Sulfametoxazol (TMP/SMX), has been chosen as the core of our first modeling iterations. We first look at a prototypical 'treatment course' of patient urine sample collection, culturing and antibiogram testing with and without intro-

[2] Simple Protocol and RDF Query Language, http://www.w3.org/TR/rdf-sparql-query/
[3] E.g. http://debugit1.spim.jussieu.fr/ for the Paris hospital
[4] E.g. a DDO with a PREFIX inserm: http://debugit1.spim.jussieu.fr/resource/vocab/ as in example query
[5] http://protegewiki.stanford.edu/index.php/OWLPropViz

ducing empirical therapy with TMP/SMX. The result of the antibiogram can then influence the empirical therapy (adaption) or directly result in a targeted antibiotic therapy.
To be able to verify whether DCO is sufficiently complete to represent our use case, we have collected a set of ten competency questions [7] from clinicians. The ontology needs to contain a necessary and sufficient set of axioms to represent these questions. As such, they will later serve as benchmarks for the DCO evaluation.

From the full set, we choose CQ #5 that we want DCO to be able to answer in the DebugIT prototype. We will use this in all examples in the remainder of this article: "select all Patients that have UTI caused by E. Coli and that are Trimethoprim resistant" The abstract formulation of this CQ is: "Select patients with treatment courses, where disease x caused by agent y, and agent y has a certain quality z (i.e. has susceptibility test result: resistant)". The formalization of this CQ in DCO is illustrated in the DCO query example below.

Term harvesting to populate DCO

We have chosen a data-driven approach in order to acquire a first set of terms for the ontology. Whereas the project seeks to reuse existing ontologies, major parts had to be built from scratch. To gain input for DCO development we harvest terms via the following channels:

- harvesting the set of CQs and abstractions thereof
- harvesting the partners hospitals' CDR schemata
- harvesting concepts of terminologies already in use in the clinical domain (e.g. SNOMED CT)

Concepts from the 'information artefact' realm were integrated via a so called information model ontology (IMO) that was build by 'ontologization' of a semiautogenerated RDF model of an HL7 v3 based information model[6]. IMO mainly amends DCO with 'information entity' concepts found in HL7.
These sources permitted a first representational scaffold to represent the domain, which since then has been incrementally refined.

Ontology modularization and imports

Besides BioTop, for which bridges to all major top level ontologies exist, the following external domain ontologies are aligned with DCO:

An Image mining Ontology IRON.owl has been created[7], which also describes an approach to handle numeric values in owl-DL.

We use an ontology of medical evidence to allow application users to choose between different sources of evidence (e.g. patient records, clinical trials, data mining results). This ontology also describes data exchange concepts like 'request' and 'response' to facilitate interoperability in message exchange systems, e.g. for querying. These operational feature descriptors will soon be factored out into a separate task ontology.

[6] A paper describing this approach has been accepted for MEDINFO 2010 by D. Ouagne et al.
[7] http://www.cs.ucy.ac.cy/itab2009/ (paper accepted)

Mapping to external vocabularies

Whereas DCO follows strict architectural guidelines it is devised to co-exist with less expressive ontologies by some of our collaborators. Specifically, we agreed to re-use the following external vocabularies within the DebugIT project:

- For **diseases** we will re-use and adapt the SNOMED CT finding hierarchy. Currently about 2/3 of the present DCO classes are mapped to matching SNOMED CT terms.
- For **anatomical entities** needed to describe disease and specimen locations we are re-using and adapting portions of the Foundational Model of Anatomy.
- For **bacteria** we are reusing the NEWT taxonomy.
- For **drugs**, we are using the WHO ATC codes.

DCO administration and access

DCO is maintained using a shared Subversion (SVN) repository[8] that allows easy detection of work progress using the log files and allows for file revision history tracking, revert to previous file states and a diff function to detect atomic changes made in single files. All more immediate exchange of ideas and progress monitoring is realized via weekly teleconferences along the SCRUM[9] project management methodology.

Administrative and editorial metadata schemes

We have developed a metadata schema optimized to the project's needs via a self-standing owl file that contains all necessary annotation properties[10]. This allows us to use the RDF:comment field for its intended purpose of capturing comments as well as action items for all entities.

To keep track of abundantly used core entities, we use the bookmark plugin[11] in Protégé 4. This helps in the selection process of ontology modules, especially for repeated evaluations and visualizations of certain views.

To ease DCO development and to foster a common view on use case relevant subsets of classes we have created a DebugIT specific Protégé Tab that shows

- the Bookmark view on selected DCO classes
- the OWLPropViz view to see a graph of DCO nodes linked via edges representing relations
- a cloud view on DCO classes, that displays them according to their subclass count or other criteria.

Results

The DCO ontology and the DebugIT Protégé 4 Tab are available in the project SVN. To access the ontology conveniently in a web browser, we have set up an owlDoc generated HTML serialisation[12].

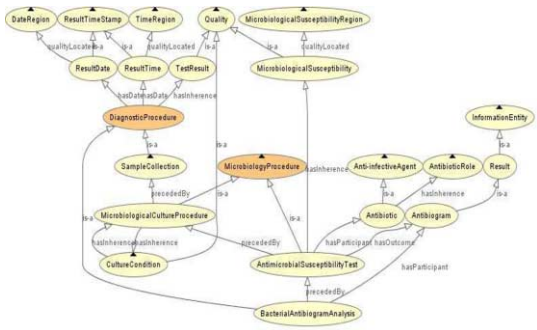

Figure 1- Graph based view on a DCO module

Figure 1 displays a use case relevant view on DCO as a graph created by the OwlPropertyViz plugin. A simple timeline of Processes, starting with the 'Bacterial Antibiogram Analysis' is shown along the *preceded_by* relation allowing for a simple model of relative time flow.

DCO Metrics

The current description logic expressivity is SRIQ(D). We are using the Hermit DL reasoner[13], which takes ~4 seconds to classify DCO including BioTop on an average PC. Table 1 illustrates the metrics of DCO and BioTop.

Table 1- Ontology metrics at submission time

Ontology Idiom	Count (all)	DCO	BioTop
Classes	1029	686	343
Object Properties (relations)	82	21	61

Object property Range Axioms	28	0	28

DCO in a SPARQL mapping query - an example

SPARQL endpoints (see footnote 3) have been implemented in three hospitals. Mappings between the information models of local data repositories and DCO have been performed in order to run SPARQL queries. To illustrate how a mapping SPARQL query links DCO concepts to IM schema elements, we look at competence question CQ #5, which has been exemplarily modelled using DCO and BioTop concepts in the CONSTRUCT clause and entities of a particular hospitals IM schema in the WHERE clause:

}
```

Challenges

The pursued SPARQL mapping approach requiring a mediation layer is still experimental. It depends on novel formats and tools, which challenges the stability of such a complex project. Considering the large data volumes performance might become a problem[14], and it is still an open question whether the whole setup will be scalable and well-performing. The on-the-fly IM schema to RDF conversion and SPARQL querying over DDO-DCO mappings is slow on certain constructs[15].

The mapping between an ontology and a clinical data repository is not trivial as the recording of clinical data blends ontological with epistemological, pragmatic and contextual aspects. The difficulty will be to find a metamodel that can consistently deal with the rather different implicit top level assumptions in the heterogeneous information models (see footnote 6). Time modeling will be another complex problem in the near future. DCO currently includes a relation 'preceded

[13] http://hermit-reasoner.com/

[14] The clinical data from George Pompidou hospital in Paris (of a year period of time) was migrated into the clinical data repository corresponding to 59000 patients, 89000 stays, 170000 episodes of care, 28000 culture results and 9800 antibiograms.

[15] http://www.w3.org/2007/03/RdfRDB/papers/d2rq-positionpaper/

by' to link processes and allows to model relative time flows (see Figure 1). To allow for absolute time modelling we have to include date-time stamps, e.g. using xsd:dateTime.

Conclusion

Whereas earlier attempts tried to integrate CDRs via purely syntactical integration, e.g. via XML schemata as in [8], recent approaches acknowledge the benefit of a computer interpretable formally defined semantics [9,10]. Not only are the requirements for medical data integration ontologies well investigated [11], recent projects have shown their usefulness in healthcare data integration settings [12]. As in the Advancing Clinico-Genomic Trials on Cancer (ACGT) project [13], which aims at improving Post-genomic clinical trials by providing seamless access to integrated clinical, genetic, and image databases, we use IM model-derived mediator artefacts and SPARQL to resolve syntactic and semantic heterogeneities when accessing wrapped databases. Along these lines DebugIT adopts a federated data warehouse model approach for clinical data integration as described by [14].

Although it seems too early to evaluate the full potential of DCO as core communication channel for the DebugIT interoperability platform, few preliminary properties can already be evaluated. Of the four properties of an ontology that may be quality-assured [15] philosophical validity, compliance with meta-ontological commitments, fitness for purpose and content correctness, we will primarily concentrate on the latter two, because an ontology compliant with all current philosophical theories, following all necessary ontological commitments, and with entirely 'correct' content, may be too complex to be directly usable. The next steps will be identifying and fixing coverage gaps for additional competence questions. We will continue to add logical definitions for at least all bookmarked classes in order to make these accessible to automatic reasoning. We believe the application of CQs and the example given illustrates DCOs 'fitness for purpose' and its 'content correctness' has been ensured via the application of consistency checks and automated reasoning. DCO has reached a level of completeness and formality to start to interoperate data queries across clinical sites as a proof of concept. We have provided a working example for a successful query execution of a query expressed using DCO answering one given competence question.

Acknowledgements

Daniel Schober is funded by the DebugIT project of the EU 7th Framework Program grant agreement ICT-2007.5.2-217139, which is gratefully acknowledged. We acknowledge Hans Cools who has significantly contributed to the DebugIT ontology development and Djamila Raufie who helped curating DCO.

Mapping BFO and DOLCE

Lynda Temal, Arnaud Rosier, Olivier Dameron, Anita Burgun

U936 INSERM University of Rennes 1, IFR140, Rennes, France.

Abstract

Upper level ontologies are key technology for integrating heterogeneous information coming from different sources. DOLCE and BFO, are the favorite candidates which propose rigorous foundational principles to model any domain. The objective of the AKENATON project is to improve alert management and to support patient-centered medical decision in telecardiology. This requires to integrate information transmitted by implantable cardiac devices with clinical data extracted from patient health records. To achieve this goal, we have designed an ontology of telecardiology based on DOLCE. In order to integrate ontologies based on BFO such as FMA, we have developed a framework for mapping BFO and DOLCE categories in terms of equivalence and subsumption between categories.

***Keywords*:**

Upper level ontologies, BFO, DOLCE, Ontology, Mapping, Telecardiology

Introduction

Upper level ontologies (ULO), also called top ontologies or foundational ontologies describe very general concepts (e.g. *substance*, *physical object, event, quality*) and relations (e.g. *parthood, participation*) that are common to all domains. They are key technology for integrating heterogeneous knowledge coming from different sources [1]. DOLCE (Descriptive Ontology for Linguistic and Cognitive Engineering) [2] and BFO (Basic Formal Ontology) [3], are the favorite candidates which propose rigorous foundational principles to model any domain. These ontologies were elaborated in the context of the WonderWeb project [2], whose ultimate aim was to build a library of foundational ontologies, and to establish the foundations enabling the "negotiation of meaning" between agents. In the biomedical domain, several projects rely on BFO as a foundational ontology, e.g. [4, 5] while others use DOLCE, e.g. [6,7, 8].

In the AKENATON[1] project, we have designed an ontology of telecardiology in order to enrich and classify automatically alerts coming from Implantable Cardiac Device (ICD). The goal is to integrate clinical information from the patient health record (e.g. *diseases, prescriptions, procedures*) together with information provided by the ICD. The objective is to help physicians to assess their relevance and emergency level and to support patient-centered medical decision in telecardiology. The AKENATON ontology is based on DOLCE as it appears that DOLCE offers a better support for representing temporal qualities (e.g. *heart rate, atrial fibrillation duration*) and cognitive entities (e.g. *prescriptions, diagnosis, therapy plan*). However, our choice of DOLCE as framework should not hinder the future reuse of ontologies aligned to BFO (e.g. FMA, Foundational model of anatomy [9]). Conversely, it should not be an obstacle to ensure interoperability between the AKENATON ontology and ontologies based on BFO. Therefore, we investigated the compatibility between BFO and DOLCE. In this paper, we propose a mapping between BFO and DOLCE categories, in terms of equivalence and subsumption relationships between their respective categories.

[1] http://resmed.univ-rennes1.fr/akenaton/

Material and method

Several authors have proposed methods for mapping or merging ontologies, including lexical methods, structural methods, logical and semantic approaches based on models such as propositional satisfiability (SAT) and modal SAT techniques or description logic based techniques [1]. Contrary to domain ontologies and application ontologies, top ontologies would not benefit from these mapping techniques. ULOs adopt different philosophical perspectives that guide their defining of formal categories. Consequently, we generated the mappings between BFO and DOLCE categories, by analyzing and comparing their respective formal, textual definitions, with a focus on constraints and characteristics as well as examples of each category provided by authors. We focused on *equivalence* and *subsumption* relations. For each category of BFO (respectively DOLCE) we determined relations of equivalence or of subsumption considering the constraints of their DOLCE (respectively BFO) counterpart, and their philosophical approach.

BFO

BFO adopts a *realistic* approach. According to the modes of existence in time of the entities populating the world, BFO subdivides the reality into two orthogonal ontologies: SNAP and SPAN.

SNAP: SNAP ontology (Figure 1) is an ontology of *Continuants* (also called *Endurants*), which are entities that have continuous existence and fully exist in any instant of

time at which they exist. SNAP entities are separated into three main categories:

1. `bfo:Substantial entities` subsumes the categories of substances, their fiat parts, their aggregates, their boundaries and sites.
   - `bfo:Substances` are maximal connected substantials which they have the following main features: *i)* not depend entities, *ii)* bearers of qualities, *iii)* preserves their identity *iv)* located in space *v)* they are self-connected wholes with bona fide boundaries. Examples are organism and organ such as *human* and *heart*.
   - `bfo:Fiat parts` are part of `bfo:Substances`, on which they depend. `bfo:Fiat parts` cannot have their own complete bona fide exterior boundary, e.g. some body part such as *leg* and *nose*.
   - `bfo:Aggregates of substances` are mereological sums comprehending separate substances as parts. They may be scattered and thus have non-connected boundaries. Examples include *groups of human beings*.
   - `bfo:Boundaries` are lower-dimensional parts of spatial entities. Examples are *surface of skin* and *external surface of heart*.
   - `bfo:Sites` are holes, cavities and similar entities. They are generally filled by a medium such as air or water. Examples are *atrial cavity*.
2. `bfo:SNAP dependent entities` are continuant entities that depend for their existence on the `bfo:Substances` which are their bearers. However, if endurance and dependence are necessary conditions for `bfo:SNAP dependent entities`, they are not sufficient conditions. The distinguishing feature of these entities is that they *inhere in* `bfo:Substances`. They include particularized `bfo:Qualities` (e.g. *blood pressure, blood glucose level*), `bfo:Functions` (e.g. *function of heart to pump blood*), `bfo:Roles` (as *patient*, as *physician*).

`bfo:Spatial regions` are continuants, such that other SNAP entities can be located at or in them.

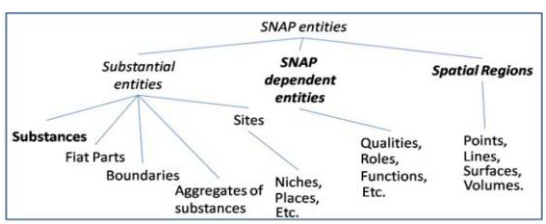

Figure 1-Top SNAP entities from BFO

SPAN: SPAN ontology (Figure 2) is an ontology of *Occurrents* (also called *Perdurants*), which are entities that occur in time and they unfold themselves through a period of time. The SPAN entities are divided into three separate categories:

1. `bfo:Processual entities` are entities that happen in time**,** they involve participants of a kind of `bfo:Substantial entities`. They are dependent on their participants, and occupy spatiotemporal regions. Conversely to `bfo:Substantial entities`, `bfo:Processual entities` do not have qualities [10]. Five main categories are subsumed by `bfo:Processual entities`:
   - `bfo:Processes` are those extended `bfo:Processual entities` which are self-connected wholes, they have beginnings and endings corresponding to real discontinuities, which are their bona fide boundaries. Examples are *blood circulation*, *course of disease*, *life*.
   - `bfo:Fiat parts of process`. All the proper parts of a process share the same level of granularity (e.g. *first phase of blood circulation*, and *metastasis phase of cancer*).
   - `bfo:Events` are instantaneous boundaries of processes and instantaneous transitions within processes. Examples are *birth, death, stroke, cardiac arrest*.
   - `bfo:Aggregates of Processes`. Examples include the aggregate of *all episodes of atrial fibrillation* in a given year; and the aggregate of *all surgical procedure* in a given period.
2. `bfo:Temporal region`, *Time*, the maximal temporal region, is an occurrent, and thus a SPAN entity. A `bfo:temporal region` is a part of *Time*.
3. `bfo:Spatiotemporal region` the totality of spatiotemporal regions reflects the totality of possible fiat demarcations of that maximal region, called *spacetime*.

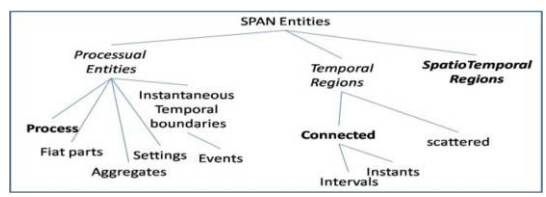

Figure 2-Top SPAN entities from BFO

DOLCE is a foundational ontology of *Particulars* which adopts a *Descriptive/Multiplicative*[2] approach and has a clear *cognitive bias*. Entities are classified into four separate categories, depending on their modes of existence (Figure 3):

1. `dol:Endurants` are entities that "are wholly present in time". Among `dol:Endurants`, and according to whether the entity has direct spatial qualities, `dol: Physical Endurants` (e.g. *heart, lung*) are distinguished from `dol:Non-Physical Endurants` (e.g. *prescriptions*, *diagnosis*), which cover social and cognitive entities. Furthermore, based on the unity criterion discussed in [11], `dol:Physical endurants` are divided into:
   - `dol:Amount of Matter` are `dol:Endurants` with no unity (according to [11], none of them is an essential whole). Examples are *some blood, some gas, and some water*.
   - `dol:Physical Objects` are `dol:Endurants` with unity. `dol:Physical Objects` change some of their

[2] A multiplicative ontology allows for different entities to be *co-localized* in the same space-time. This case is often presented through the problem of the vase and the clay it is made of [2].

parts while keeping their identity. Examples are *humans*, and *pacemakers*.

- `dol:Features` whose typical examples are "parasitic entities" such as *holes*, *boundaries*, *surfaces*, or *stains*, which are generically constantly dependent on `dol:Physical objects` (their hosts). Examples are *lesions*, *interior surface of coronary artery*, and *edema*.

2. `dol:Perdurants` are entities that "occur in time" in which `dol:Endurants` *participate* (e.g. *disease cours*). Among `dol:Perdurants`, `dol:Statives` are distinguished from `dol:Events` according to whether the `dol:Perdurants` are *cumulative*[3] or not. `dol:Events` are divided into `dol:Achievements` (e.g. *death*, *cardiac arrest*) and `dol:Accomplishments` (e.g. *scan session*, *clinical studing*) according to whether they are *atomic* or not. `dol:Statives` are divided into `dol:States` (e.g. *setting*) and `dol:Processes` (e.g. *pumping blood*, *coagulation*) according to whether they are *homeomerous*[4] or not.

3. `dol:Qualities` are neither `dol:Endurants`, nor `dol:Perdurants`. They are dependent entities which are *inherent in* either `dol:Endurants`, `dol:Perdurants` or `dol:Qualities`. `dol:Qualities` are entities that we perceive and/or measure. Examples are *blood pressure*, *blood glucose level*, and *duration of atrial fibrillation*.

4. `dol:Qualities` take "values", called `dol:Quales` (e.g. *120/80 mmhg*, *1.12 g/l*, *10 min*) within associated `dol:Region`.

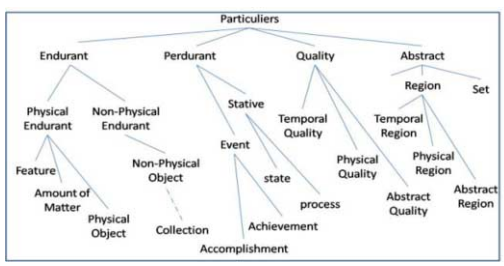

Figure 3-An excerpt from DOLCE's top-level taxonomy.

Mapping result

The result obtained when mapping an ontology O_1 to O_2 is a set of triples $C_1 R C_2$ where `C1`(resp. `C2`) is a concept of O_1 (resp. O_2) and `R` is a relation which is either *equivalence* or *subsumption*.

100% of BFO categories were successfully mapped to DOLCE resulting in 6 equivalence relations and 13 subsumption relations (Figure 4). However, 81% of DOLCE categories were successfully mapped to BFO, and we obtained 6 equivalence relations and 13 subsumption relations. 3 categories in DOLCE did not have any correspondence in BFO, such as the `dol:Temporal qualities`, and `dol:Abstract qualities`, because of BFO *realistic* approach.

Mapping snap entities (see Figure 4):

- `bfo:Substantials entities` is a general category. We map its five sub categories:
  - `bfo:Sites` are defined by examples such as *holes*, *cavities* or *places* depend on physical hosts. These same examples are given by DOLCE for the `dol:Feature` category, whose entities also depend on physical hosts. The `dol:Feature` category also subsumes other categories which are not `bfo:Sites`. Therefore `dol:Feature` *subsumes* `bfo:Sites`.
  - `bfo:Boundaries` are defined as lower-dimensional part of spatial entities, depend on entities they bound, as part depend on wholes. DOLCE gives boundaries as typical examples of `dol:Feature` entities (e.g. *surface of skin*) which also depend and are part of their hosts. Then, as `bfo:Sites`, `bfo:Boundaries` is also *subsumed by* `dol:Feature`.
  - `bfo:Fiat parts` are defined as parts of `bfo:Substances`, on which they depend. BFO distinguishes them according to their boundaries, and considers that each entity with no complete boundaries is a kind of `bfo:Fiat parts` (e.g. *noses*, *hands*). DOLCE is based on identity and unity criteria to determine the kind of entities which are parts of physical entities. Thus, for DOLCE, the body parts such as *legs* and *hands* are kind of `dol:Physical objects` because they keep their identity, even if they are detached from the body. Then, if this position is considered to hold in DOLCE, `bfo:Fiat parts` *are subsumed by* `dol:Physical objects`. If it is rejected, `bfo:Fiat parts` *are subsumed by* `dol:Features`. In our case, we chose the second proposition.
  - `bfo:Aggregates of substances` are defined as mereological sums comprehending separate substances as parts. In DOLCE, a new category called `dol:Collection` was introduced to represent the notion of aggregation [12]. `dol:Collection` is a category defined to manage entities such as *groups*, in which `dol:Endurants` are members. Thus, the *aggregate of humans* of BFO is a *group of humans* in DOLCE where the *humans* are the members. Then `bfo:Aggregates of substances` *are subsumed by* `dol:Collections`.
  - `bfo:Substances` category corresponds to the union of `dol:Physical objects and dol:Amount of matter`, which are based on unity and identity criteria. Unlike BFO, DOLCE distinguishes entities such as *some blood*, *some water* (entities with no unity (**~U**), which change their identity when they change their parts) from objects (entities with unity (±U) which can change some of their parts while keeping their identity). Thus, according to

[3] An occurrence is cumulative if its corresponds to the mereological sum of two of its instances

[4] An occurrences is homeomerous if each part of the instance stay belong the same occurrence. eg: each part of an instance of *setting* is a *setting*

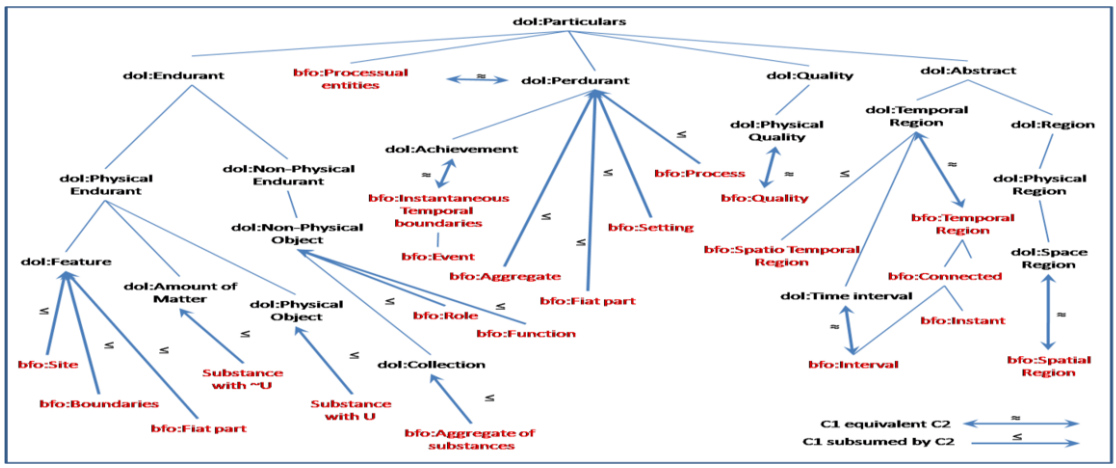

Figure 4- Mapping BFO to DOLCE

DOLCE distinctions, we subdivided `bfo: Substances` into two categories: `Substances with ±U` *subsumed by* `dol:Physical objects` and `Substances with ~U` *subsumed by* `dol:Amount of matter`.

- Except `bfo:Qualities` all categories subsumed by `bfo:Dependent entities` such as `bfo:Functions`, `bfo:Plans` and `bfo:Roles` are in DOLCE *subsumed by* `dol:Non-physical objects`, which are defined also as dependent entities with no spatial location. Concerning `bfo:Qualities`, because BFO considers only qualities for substantial entities, `bfo:Qualities` *are equivalent to* `dol:Physical qualities`.
- `bfo:Spatial Region` *is equivalent to* `dol:Space region`.

Mapping span entities (see Figure 4):

`bfo:Processual entities` are equivalent to `dol:Perdurants` in DOLCE. Moreover, DOLCE distinguishes `dol:Perdurants` according to three criteria: *cummulativity*, *homeomerousity,* and *atomicity.* However, often designers find these criteria elusive and not very intuitive. Therefore, we suggest that categories subsumed by `bfo:Processual entities` are directly *subsumed by* `dol:Perdurants`.

Actually, we cannot map directly in DOLCE the category `bfo:Processes` which are defined as `bfo:Processual entities` with unity criterion and with a beginning and an ending. Indeed, an entity, which is a kind of `bfo:Processes` may be either a kind of `dol:Process` (e.g. *cardiac rhythm*), or `dol:State` (e.g. *waiting*) or `dol:Accomplishment` (e.g. *scan session*). All of these examples have an unity criterion and have a beginning and an ending, but according to DOLCE *cardiac rhythm* is a `dol:Process` because it is *cumulative* and non *homeomerous*; *waiting* is a `dol:State` because it is *cumulative* and *homeomerous;* and *scan session* is an `dol:Accomplishment` because it is non *cumulative* and non *atomic*. Furthermore, at the same level of granularity, `bfo:Fiat part` of a `dol:Process` is a `dol:Process`, and `bfo:Fiat part` of a `dol:State` is a `dol:State`. However, `bfo:Events` defined in BFO as instantaneous temporal boundaries *are equivalent to* `dol:Achievements`. Because they are instantaneous, they satisfy the atomicity criterion. Otherwise, if designers want to adopt the DOLCE distinctions criteria of `dol:Perdurants`, they must examine the DOLCE criteria for each new subcategories of `dol:Perdurants` which may require to split one category into several categories. `bfo:Temporal region` as a part of *time is equivalent to* `dol:Temporal region` of DOLCE. However, the notion of `bfo:Spatiotemporal region` is not represented in DOLCE but can be easily added as a new specialization of `dol:Region`.

Mapping DOLCE categories to BFO (see Figure 5).

As we did with BFO categories, we now map the DOLCE categories to BFO with respect of BFO philosophical approach. Some categories are mapped without difficulties: such as: *i)* `dol:Feature` (union of `bfo:Sites`, `bfo:Boundaries`, and `bfo:Fiat parts`) *is subsumed by* `bfo:Substantial entities`, *ii)* `dol:Physical objects` and `dol:Amount of matter` *are subsumed by* `bfo:Substances`. *iii)* `dol:Physical qualities` *are equivalent to* `bfo:Qualities`. Although BFO does not accept the notion of `dol:Non-physical objects`, we find that categories such as `bfo:plans`, `bfo:functions`, `bfo:roles` subsumed by `bfo:Snap dependent entities`, *are subsumed by* `dol:Non-physical objects` in DOLCE. Hence, `dol:Non-physical objects` *are subsumed by* `bfo:Snap dependent entities`.

Furthermore, we have to be careful that all subcategories satisfy the constraints. For example, `dol:Collections` can be either collection of `dol:Physical objects` or `dol:Non Physical objects` in DOLCE. Since in BFO, `bfo:`

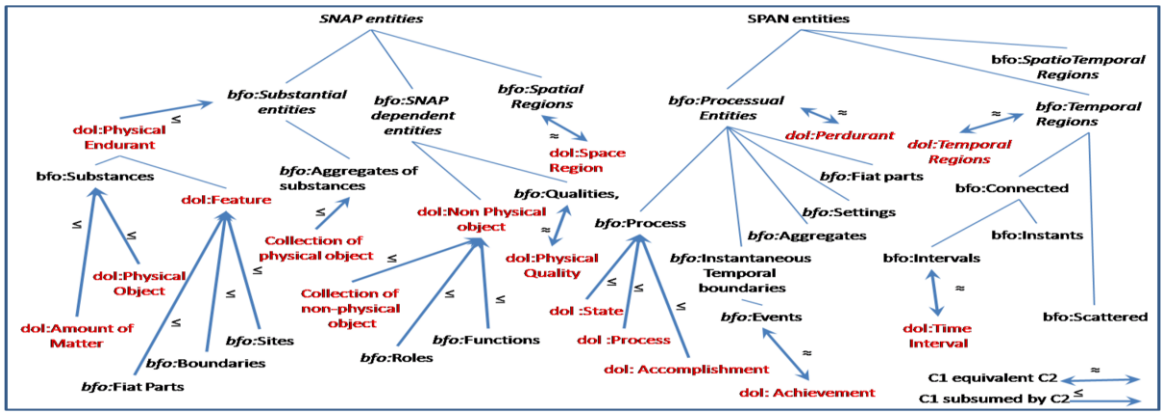

Figure 5-Mapping DOLCE to BFO

`Aggregates of substances` are kind of substantial, we divide collections into `Collections of physical objects` *subsumed by* `bfo:Aggregates of substances`, and `Collection of non physical objects` *subsumed by* `bfo:Snap dependent entities`.

Discussion

Grenon compared informally the main DOLCE and BFO categories. He presented similarities and differences between them, and gave some indications to do the mapping [10]. To our knowledge, no effective mapping between these foundational ontologies has been made available. However, this mapping is a crucial preliminary step to address interoperability issues. In this work, the goal is not to approve a particular model or to discuss philosophical choices, but rather, to give an opportunity to those who chose to use DOLCE (respectively BFO) as a framework, to reuse ontologies designed under BFO (respectively DOLCE). We have developed this mapping with respect to the philosophical approach inherent of foundational ontologies. There are aspects in DOLCE, e.g. qualities for perdurants, that are no recognized in BFO, because of the *realistic* approach of BFO. In fact, it is not yet clear how one can represent notions such as, *duration*, and *heart rate* in BFO. It is then difficult to give a satisfactory mapping for this kind of entities. This work proposed a mapping between the DOLCE and BFO upper-level ontologies, where their respective *realistic* and *cognitive* could be reconciled. We have developed and evaluated the mappings in the AKENATON project. The expected outcome is to support future mappings between a domain ontology based on DOLCE and another one based on BFO in other biomedical projects.

Using the Abstraction Network in Complement to Description Logics for Quality Assurance in Biomedical Terminologies - A Case Study in SNOMED CT

Duo Wei[a], Olivier Bodenreider[b]

[a] *Structural Analysis of Biomedical Ontologies Center, New Jersey Institute of Technology, Newark, USA*
[b] *US National Library of Medicine, NIH, Bethesda, USA*

Abstract

Objectives: To investigate errors identified in SNOMED CT by human reviewers with help from the Abstraction Network methodology and examine why they had escaped detection by the Description Logic (DL) classifier. Case study; Two examples of errors are presented in detail (one missing IS-A relation and one duplicate concept). After correction, SNOMED CT is reclassified to ensure that no new inconsistency was introduced. Conclusions: DL-based auditing techniques built in terminology development environments ensure the logical consistency of the terminology. However, complementary approaches are needed for identifying and addressing other types of errors.

Keywords:

Systematized nomenclature of medicine, Comparative study, Quality assurance, Description logics, Abstraction network.

Introduction

SNOMED CT is one of the largest clinical terminologies in the world. The most recent release (July 31, 2009) comprises more than 289,000 active concepts and 1.5 million relations (hierarchical and associative). SNOMED CT concepts are organized into 19 hierarchies, such as **"**Procedure"**, "**Clinical finding" and **"**Body structure."

Modern terminologies including SNOMED CT and the NCI Thesaurus are created with the support of Description Logics (DL), which ensures the logical consistency of the terminological assertions. However, due to its sheer size and complexity, it is almost unavoidable that SNOMED CT should contain errors, such as inaccurate or incomplete logical definitions (e.g., errors in the nature or in the target of asserted relationships, as well as missing relations).

A number of techniques have been developed for auditing SNOMED CT, based on lexical, structural, and ontological principles. Lexical approaches have been used by [1-2] to suggest missing and erroneous relations based on the compositionality of biomedical terms. Additionally, [2] exploited formal ontological principles. Formal Concept Analysis was employed by [3] to analyze semantic completeness. Based on various structural approaches, [4] detected improper assignment of relationships, redundant concepts, and omission of relationships. Finally, [5] identified redundant and underspecified concepts by detecting equivalent concept definitions. In summary, these approaches applied computational method to the identification of potential errors. This automated process is designed to facilitate the work of human editors (subject matter experts) and it contributes to the quality assurance of biomedical terminologies.

The objective of this paper is to investigate errors identified in SNOMED CT by human reviewers, with help from the Abstraction Network methodology. More specifically, we examine why such errors could not be identified by a Description Logics classifier and propose a strategy for using the Abstraction Network in complement to DL-based techniques for the quality assurance purposes. The contribution of this paper is not to propose novel approaches to identifying errors in SNOMED CT, but rather to tease out differences between existing approaches based on several cases of errors thoroughly investigated.

Background

Description Logic

Description logics (DL) are a family of knowledge representation formalisms often used as ontology languages [6]. Not only does DL provide support for defining concepts, but it also provides methods for reasoning about concepts and their instances. DL reasoning services are carried out by DL classifiers.

The basic inference on concept expression is subsumption, i.e., comparing two classes and checking whether one class is more general than the other. For example, "brain disorder" is more specific than (i.e., subsumes) "disorder," because "brain disorder" is defined as a "disorder" located to the brain. Another important inference is concept satisfiability. A class is deemed unsatisfiable (i.e., inconsistent) if it cannot possibly have any instances. For example, nothing can be at the same time a procedure and an anatomical structure. If a class "C" were defined as a subclass of both "Procedure" and "Body structure," while "Procedure" and "Body structure" are defined to be disjoint, a DL classifier would identify "C" as unsatisfiable. The interested reader is referred to [6] for additional details about DL.

There are, however, many different dialects of DL in terms of the set of constructors they offer, resulting in different levels

of expressiveness for what can be defined. The expressiveness of the DL also determines the kinds of inference a DL classifier is enabled to perform and the kinds of logical inconsistency it is able to identify. The dialect of DL natively used by SNOMED CT is "EL", whose expressiveness is relatively limited. For example, EL does not allow disjunction to be stated between classes and the example of unsatisfiability presented earlier could therefore not be identified by the DL classifier used for the creation of SNOMED CT.

From the perspective of error identification in ontologies, two major types of errors can be distinguished. Type I errors are the logical inconsistencies in concept expression that can be detected by DL classifiers (assuming the DL dialect used is expressive enough to state the circumstances under which concepts would be inconsistent, e.g. disjointness). In contrast, Type II errors are those content errors (e.g., wrong relations, missing relations) that would not generate logical conflicts in the DL system. Quality assurance processes in SNOMED CT ensure that all Type I errors have been identified and corrected before the terminology is released to users. All the errors under investigation in this study are therefore Type II errors. (Here, Type I and Type II errors are defined in reference to the level of expressiveness of the EL dialect of DL).

In practice, several views of SNOMED CT are provided to users. The main view is the inferred view, in which all inferences are precomputed and redundant relations removed. The inferred view is automatically derived from the asserted view by a DL classifier. In this work, we analyze the inferred view, but, unlike most users, we also modify the asserted view and use a DL classifier in order to check any suggested changes for consistency.

Abstraction Network

The Abstraction Network (AN) is a structural methodology developed for reducing the complexity of large biomedical terminologies [7]. The AN methodology is based on the associative relationships and their inheritance patterns in the hierarchies of the terminology. It has been applied to auditing SNOMED CT. Here, we give a brief description of its underlying principles and review its application to SNOMED CT. Our examples focus on the "Specimen" hierarchy of SNOMED CT.

AN provides an abstraction of the hierarchical and associative relations of concepts in a SNOMED CT hierarchy. The idea is to partition such concepts into structural uniformity groups (strUGs), and then to refine the partition into semantic uniformity groups (smtUGs). A detailed description can be found in [7-9][1].

A "structural uniformity group (strUG)" is the group of all concepts with exactly the same set of associative relationships. In a graph structure, we use a node to represent a strUG. The label for the strUG node is the set of associative relationships in which its concepts participate.

Five different associative relationships are introduced to the concepts of the "Specimen" hierarchy; they are ***substance***, ***morphology***, ***procedure***, ***topography***, and ***identity***[2]. For example, the concept "Surgical excision sample" has one relationship ***procedure*** pointing to a concept "Excision" (from the "Procedure" hierarchy). Therefore, the concept "Surgical excision sample" is in the strUG{***procedure***}. Similarly, the concept "Abscess swab" has two relationships ***procedure*** and ***morphology*** pointing to "Taking of swab" and "Abscess morphology" (from the "Procedure" and "Body structure" hierarchy, respectively). Thus, "Abscess swab" is in the strUG{***procedure***, ***morphology***}. Note that strUGs do not overlap, because, by construction, one given concept belongs to one and only one strUG corresponding to its relationship pattern. Therefore, the entire set of strUGs forms a partition of the concepts in a given hierarchy of SNOMED CT.

StrUGs can be organized into a graph structure. Hierarchical relations between strUGs are determined by the inclusion of the sets of relationships they represent. For example, the strUG{***procedure***} subsumes the strUG{***procedure***, ***morphology***}. Figure 1(a) shows a portion of the graph of strUGs for the "Specimen" hierarchy. Each colored box represents a strUG. The boxes are color-coded to differentiate the levels. Each level corresponds to the number of relations in the strUG. The concepts in the strUG Ø have no associative relationships.

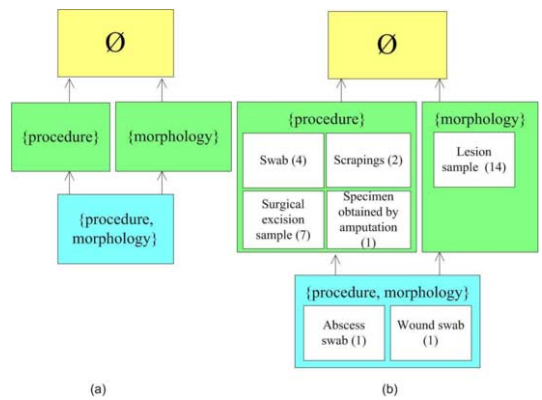

Figure 1- (a) Portion of the graph of StrUGs for the "Specimen" hierarchy (b) Corresponding portion of the graph of smtUGs

A "semantic uniformity group (smtUG)" is a group of concepts within a structural uniformity group sharing the same lowest common ancestor (LCA). In other words, the smtUG groups concepts with the same associative relationships by hierarchical relations. The label for the smtUG is the LCA from which all other concepts in the smtUG are descendants. A strUG may have more than one LCA, and thus more than one smtUGs. The smtUGs form a semantic subdivision of the strUG, but not necessarily a subpartition of it, since a concept may have more than one LCA.

[1] In our previous work, *structural uniformity group* is referred to as *area*, while *semantic uniformity group* is referred to as *partial-area.*

[2] The full name of these relationships is ***specimen substance***, ***specimen source morphology***, ***specimen procedure***, ***specimen source topography***, and ***specimen source identity***, respectively.

The graph of strUGs in Figure 1(a) can be refined with the smtUGs contained within each strUG, as shown in Figure 1(b). For example, the strUG{*procedure*} contains the four smtUGs: smtUG("Swab"), smtUG("Scrapings"), smtUG("Surgical excision sample") and smtUG("Specimen obtained by amputation"). The number in the parentheses indicates the number of concepts within a smtUG. For example, in the smtUG("Surgical excision sample"), there is a total of seven concepts. The six hidden concepts are all subsumed by "Surgical excision sample."

The strUGs and smtUGs form a graph structure called abstraction network (AN), which hides some of the complexity of the terminology. This abstracted view has proved a useful auditing tool for manual review of biomedical terminologies by subject matter experts.

Auditing Method based on Abstraction Network

Several strategies have been devised to help subject matter experts review parts of SNOMED CT based on the Abstraction Network methodology.

Group-based auditing takes advantage of the grouping of concepts in semantic uniformity groups [7]. All concepts from a given group are reviewed at the same time, making it easier for experts to identify discrepancies among concepts expected to be both structurally and semantically similar. Errors exposed via "group-based auditing" include redundant concepts, erroneous relationships, incorrect ***IS-A*** assignments, and other content errors.

Auditing "complex" concepts focuses on those concepts within a structural uniformity group, which belong to several semantic uniformity groups because they have ancestors in several smtUGs [9]. Errors found in such complex concepts include missing child and incorrect parent.

Error concentration based auditing is predicated on the fact that small semantic uniformity groups are more likely to contain errors, because small sets of similar concepts might have received less modeling attention, compared to larger sets (e.g., based on a concept model). The correlation between small smtUG size and error concentration was assessed in [8].

Case study

We selected two of the errors detected in SNOMED CT by subject matter experts with help from the Abstraction Network methodology and reported to the International Health Terminology Standards Development (IHTSDO)[3], the organization in charge of SNOMED CT. Our objective in this paper is to investigate these cases and examine how they escaped detection by the DL classifier used to check the logical consistency of SNOMED CT.

DL reasoners are stand-alone tools that point out logical inconsistencies in an ontology. In contrast, the Abstraction Network methodology helps organize the workflow of subject matter experts, in order to focus their attention to parts of the ontology where errors are likely and by grouping the concepts to be audited according to the principles described earlier.

[3] http://www.ihtsdo.org/

The two errors under investigation were identified in the "Specimen" hierarchy of SNOMED CT. In the first one, "amputation", it was argued that two sibling concepts actually stand in a subsumption relation. The issue is thus a missing ***IS-A*** relation between these two concepts. The second case, "leukocyte", highlights two concepts that are arguably equivalent, but stand in a ***IS-A*** relation.

In addition to discussing the errors, we also want to test the remediation suggested to the IHTSDO. Toward this end, we loaded the asserted version of SNOMED CT in OWL DL into the ontology editor Protégé[4] and tested the suggested changes with the DL classifier Fact++[5]. Our goal is to verify that the proposed changes did not introduce any inconsistencies to SNOMED CT. Classification was performed on a standard desktop machine with the 64-bit Microsoft Windows operating system and 4 GB of RAM. The classification of the OWL version of the SNOMED CT takes about 17 minutes.

Case 1: Amputation

This error was identified by the subject matter expert while examining a group of concepts from the "Specimen" hierarchy corresponding to one particular structural uniformity group, namely the strUG{*procedure*}. By construction, the concepts naming the smtUGs within a strUG are not expected to stand in any kind of hierarchical relation. The assumption for the subject matter expert reviewing the concepts from a strUG is that they are all expected to be siblings. Therefore, reviewing these concepts as a group makes it easy to identify errors including missing or incorrect parent/child relations, for example.

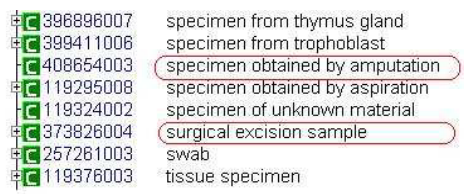

Figure 2- "Specimen obtained by amputation" and "Surgical excision sample" displayed in the CliniClue browser

Figure 2 shows a portion of the inferred view of the SNOMED CT displayed in the CliniClue browser[6]. The two concepts circled in red, "Specimen obtained by amputation" and "Surgical excision sample", are siblings. Both of them are in the "Specimen" hierarchy under the root concept "Specimen." The corresponding target concepts with the relationship *procedure* are "Amputation" and "Excision," respectively, in the "Procedure" hierarchy, under the parent concept "Surgical removal" (not shown in the figure). The four concepts "Specimen obtained by amputation", "Surgical excision sample," "Amputation" and "Excision" are fully defined.

The subject matter expert determined that "Specimen obtained by amputation" is, in fact, a kind of "Surgical excision sample." The fact that the two concepts were grouped in the

[4] http://protege.stanford.edu/
[5] http://owl.man.ac.uk/factplusplus/
[6] http://www.cliniclue.com/

strUG{*procedure*} made it easier for the expert to identify this error. Of note, there was no logical inconsistency in the concept expression and the DL reasoner failed to detect the missing subsumption relation because its absence did not create any kind of conflict in the terminology. One particular reason why no conflict could be identified is because there was a parallel error on the target side. The target concepts "Amputation" and "Excision" are siblings (descendants of "Surgical removal"), while amputation is actually a kind of excision. Because of a missing ***IS-A*** relation in parallel on both sides of the *procedure* relationship, there was no logical error that could be identified by the DL classifier.

From the perspective of the Abstraction Network, both smtUG("Surgical excision sample") and smtUG("Specimen obtained by amputation"**)** are in the strUG{*procedure*} (see Figure 1(b)). But the existence – indicated by the expert – of an ***IS-A*** relation between these two concepts within the same strUG{*procedure*} violates the principles under which the strUG was constructed.

Figure 3 shows the comparison before and after addition of the missing ***IS-A*** relations. As a result of this modification, "Specimen obtained by amputation" is now subsumed by "Surgical excision sample", and the smtUG("Surgical excision sample"**)** has gained a new member.

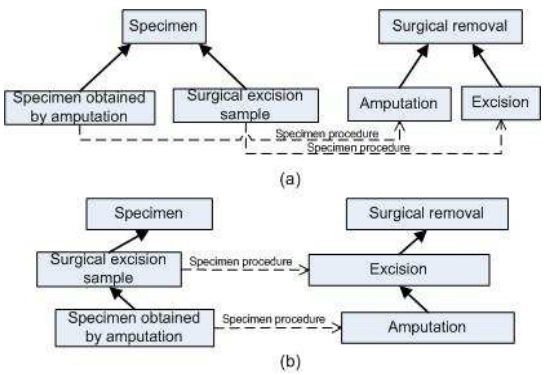

Figure 3- Parent-child error with "Surgical excision sample" and "Specimen obtained by amputation" (a) Before correction (b) After correction

We modified the target hierarchy ("Procedure") by making "Surgical Excision" the super class of "Amputation" in our copy of SNOMED CT in Protégé, while leaving the source hierarchy ("Specimen") unchanged. After reclassification, we saw that the classifier had used the changes we made to the target hierarchy ("Procedure") to automatically make parallel changes to the source hierarchy ("Specimen"), where "Surgical excision sample" has become the super class of "Specimen obtained by amputation" (Figure 3(b)).

Case 2: Leukocyte

This error was identified by the subject matter expert while examining a group of concepts from the "Specimen" hierarchy corresponding to one particular semantic uniformity group, namely the smtUG("White blood cell sample"). By construction, concepts within a smtUG are expected to stand in an ***IS-A*** relation with the lowest common ancestor after which the smtUG is named. The assumption for the subject matter expert reviewing the concepts from a strUG is that they are all expected to be distinct and descendants of "White blood cell sample". Therefore, reviewing these concepts as a group makes it easy to identify duplicate concepts, for example.

As shown in Figure 4, "Leukocyte specimen" is one of the children of "White blood cell sample." The subject matter expert determined that "Leukocyte specimen" and "White blood cell sample" are, in fact, duplicate concepts. The fact that the two concepts were grouped in the smtUG("White blood cell sample") made it easier for the expert to identify this error.

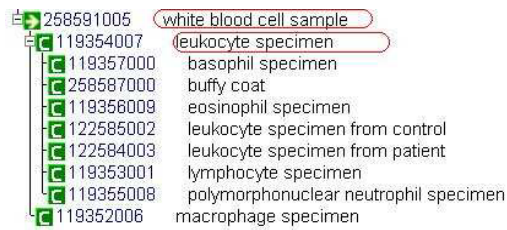

Figure 4 – "Leukocyte specimen" and "White blood cell sample" displayed in the CliniClue browser

In DL, concepts exhibiting the same logical definitions are treated as equivalent concepts by the classifier. In this case, the DL classifier did not identify these two concepts as equivalent, because the logical definitions were actually slightly different. "Leukocyte specimen' is a primitive concept, whereas "White blood cell sample" is fully defined. Because the definition of "Leukocyte specimen" is underspecified (primitive), the DL classifier cannot recognize it as equivalent to the fully defined "White blood cell sample."

From the perspective of the Abstraction Network, there is no difference between primitive and defined concepts. Only the set of relationships is taken into account during the creation of the groups.

We modified the definition of "Leukocyte specimen" in our copy of SNOMED CT in Protégé, so as to make it fully defined instead of primitive. After reclassification, "White blood cell sample" and "Leukocyte specimen" were indicated as being equivalent concepts.

Discussion

Strengths and limitations of each approach

The main advantage of DL is that it identifies errors completely automatically, while the Abstraction Network (AN) methodology only constrains the workflow of subject matter experts in such a way that it facilitates their work and improves their chances of identifying errors by reducing the complexity of the terminology and by organizing the concepts to be reviewed in small groups, with assumed relations among concepts within and across groups.

Unlike the DL classifier, AN does not rely on defined concepts, but simply takes advantage of the structural properties of concepts, i.e., their sets of relationships. Unlike AN, the DL classifier processes the terminology as a whole and can address remote inconsistencies, whereas experts tend to focus on a small portion of the terminology and may not foresee the consequences of local changes to distant parts of the terminology.

Finally, DL classifiers are limited to the identification of logical inconsistencies. Moreover, they are limited in the type of logical inconsistencies they can identify by the level of expressiveness of the dialect of DL used for creating the ontology [10]. In contrast, subject matter experts guided by the Abstraction Network methodology can address a wider range of issues (i.e., beyond logical inconsistencies) and identify content errors, such as inaccurate and missing relations.

Auditing strategy

The DL classifier is used for detecting logical inconsistencies at the time the terminology is built. The performance of the classifiers has improved tremendously in the past few years and the editors of large terminologies will soon enjoy real-time classification. We recommend the use of the Abstraction Network methodology for targeted auditing, as a possible alternative to dual editing. However, multiple auditing strategies combining lexical, structural and ontological methods are required for quality assurance of large, complex terminologies such as SNOMED CT.

Current developments and future work

One of the limitations of the Abstraction Network methodology is that it relies heavily on the structure of relationships of the concepts and is therefore not applicable to concepts with few or no relationships. In order to address this limitation, we have developed the converse abstraction network [11].

Conclusions

In this study, we examine the differences between two approaches to identifying errors in large biomedical terminologies such as SNOMED CT. On the one hand, Description Logics classifiers can automatically identify logical inconsistencies in the terminology. On the other, the Abstraction Network methodology helps experts perform targeted manual reviews of the terminology by reducing its complexity and grouping the concepts by their structural and semantic properties. We illustrate the differences between the two approaches through two cases of errors identified in SNOMED CT.

Information-Content-based Measures for the Structure of Terminological Systems and for Data recorded using these Systems

Ronald Cornet

Department of Medical Informatics, Academic Medical Center – University of Amsterdam, Amsterdam, The Netherlands

Abstract

Terminological systems such as SNOMED CT play an increasingly important role in contemporary record keeping. This drives the need of assessing the content of these systems, as well as the content of medical records captured using these systems. In this paper, the use of information content as a measure for the structure of terminological systems and the content in medical records is explored. Two complementary information-content-based measures for terminological systems are proposed: the proportion of concepts with zero information content, and the average information content. The measures are applied to the latest releases of SNOMED CT. The measures are useful as an indicator of the overall structure of terminological systems or parts thereof. Furthermore, two measures are described which can provide an estimate for the content of medical records that is captured using a terminological system. Information content is shown to provide a useful basis for assessing the structure of terminological systems and the content of medical records.

Introduction

Medical terminological systems provide a systemized representation of medical knowledge. A large number of terminological systems have been developed over the last decades. Whereas these systems originally were small lists or hierarchical systems, contemporary systems are large and complex.

The increasing size and complexity of terminological systems raises a number of challenges. First, the need arises for automated ways to assess their quality, as the effort of doing this manually becomes too high, and because maintenance of terminological systems increasingly becomes a team effort, which further increases the need for structural and reproducible methods[1]. Recently, a special issue of the Journal of Biomedical Informatics was fully dedicated to the auditing of terminological systems in medicine [2].

Second, the adequate use of terminological systems becomes increasingly intricate. Traditionally, terminological systems focused on the task of classification, i.e., determining the most appropriate category or "label" for a patient. Classification brings the challenge of adequately applying the classification rules to determine which category is the most appropriate. In contemporary compositional terminological systems, where the emphasis shifts from mere classification to structured and detailed coding of information, the user needs guidance not only on determining the most appropriate concept, but also on providing necessary and relevant detail. For example, the 2007 release of the 10th edition of the International Classification of Diseases (ICD-10) distinguished 12 categories of viral meningitis, and 4 residual categories (i.e., "other" or "unspecified"). The July 2009 release of the Systematized Nomenclature of Medicine – Clinical Terms (SNOMED CT) [1] contains 29 types of viral meningitis and 4 residual categories (which are likely to be removed from SNOMED CT shortly). As another example, ICD-10 contains 4 categories of acute myocardial infarction, and 2 residual categories; SNOMED CT distinguishes 49 types and 3 residual categories.

Using SNOMED CT for capturing patient information enables multiple uses of the data. For this purpose it is required that data is captured with maximal detail. Consequently, rather than resorting to a generic concept such as acute myocardial infarction, the user must be supported to provide any available detail, while having the possibility of being less specific when information is not (yet) available. In order to assess the amount of detail provided, metrics are needed.

In this paper, the use of information content is explored to measure both the structure of terminological systems as well as the content of records captured using these systems. As an example, these measures are applied to SNOMED CT.

Background

Terminological systems have a variety of structural aspects that influence their quality. Generally, metrics such as number of concepts and number of relationships are presented, but these do not necessarily correlate with quality. Other metrics which related more closely to quality are for example: number of superordinate concepts, subordinate concept, and roots, and number and nature of differentiae [3].

[1] http://www.ihtsdo.org/

Information content is applied to biomedical terminological systems, for example to investigate semantic similarity of concepts in the Gene Ontology [4, 5].

A benefit of these measures is that they can be calculated automatically. However, in the case of number of super- or subordinate concepts, averages or frequencies need to be analyzed to summarize the quality of a terminological system. In the case of the semantic similarity measures, a GO-specific measure was developed, which provides concept-based measures and can not be applied to other terminological systems.

Materials and Methods

SNOMED CT

Today, SNOMED CT is among the largest clinical healthcare terminological systems. The most recent release, of July 2009, contains about 290,000 active concepts. SNOMED CT provides formal definitions for these concepts using about 430,000 IS_A relationships and some 700,000 attribute relationships such as finding site, method, and associated morphology. These relationships serve three purposes: making semantics explicit; automated classification; and allowing post-coordination. SNOMED CT content is organized in a number of categories, such as clinical finding, body structure, and procedure.

Information content

The information content of a concept is a numerical measure of the information that is represented by the concept [6]. The information content of a concept c can be quantified as negative the log likelihood, -log p(c). Generally any base of the logarithm can be used (e.g., 2, e, or 10). In this paper, the $\log_2$ will be used.

For example, when tossing a fair coin, the probability of coming up heads is 0.5, and the information content thereof is 1. Likewise, when throwing a fair die, the probability of throwing 2 is 1/6, and the information content thereof is 2.58. So, a lower probability corresponds to higher information content.

As the above examples show, information content is determined based on actual probabilities. Suppose one has a manipulated die that always results in throwing 6, the information content of a throw is 0, as the probability of throwing 6 is 1.

The fact that information content depends on actual probabilities is a drawback when attempting to determine the information value of concepts in a terminological system. As terminological systems can be used in a broad range of situations, the actual information content may differ. For example, the probability of a person to be of female gender may be about 0.5 in the general population, 0.1 in the army, and 1 in a gynecology department, in which cases the respective information content is 1, 3.3, and 0. To get round this, the probability of coordinate concepts will be regarded as equal, i.e., when a concept has 4 subordinate concepts, each is regarded as having a probability of 0.25, and an information content of 2.

The information content of concepts is used in various ways to provide measures for a terminological system. First, two de-

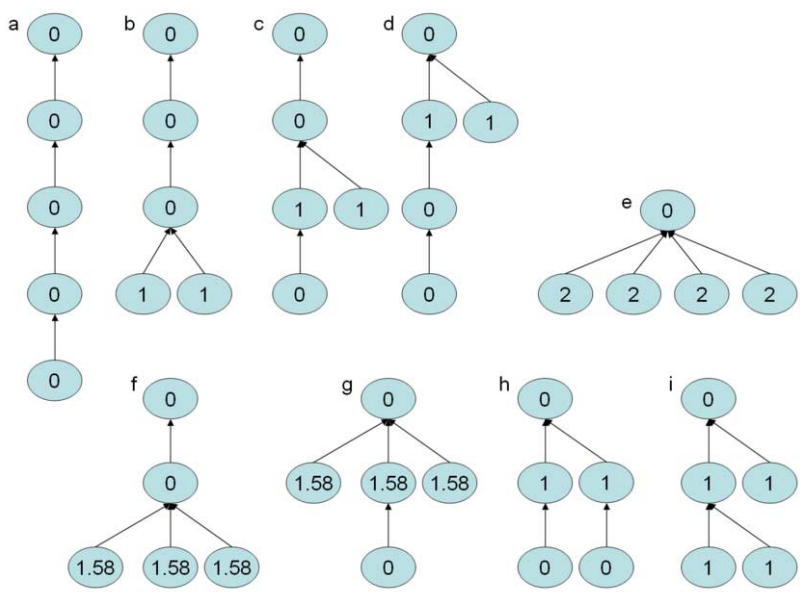

Figure 1- Possible configurations of a rooted mono-hierarchical terminological system with 5 concepts. Arrows denote Is_A relations, ovals denote concepts, and the numbers indicate the information content of the individual concepts.

rived measures for terminological systems are defined which are illustrated by a small example, consisting of 5 concepts, as shown in Figure 1. Then, the use of information content for data in a medical record will be addressed. Finally, the measures will be applied to SNOMED CT. Calculation of these measures was done by importing the text files of the latest releases of SNOMED CT into a database. The basic relational structure that is reflected in the SNOMED CT text files were extended, so that for every content its number of superordinate, subordinate and coordinate concepts could be recorded, as well as the resulting information content.

Measures

Information content as a measure of the structure of terminological systems

Figure 1 shows the possible configurations of a terminological system consisting of 5 concepts. In this figure, all concepts are subordinate to exactly one superordinate concept, apart from the root concept, which has no superordinate concept.

From these straightforward examples, a number of measures can be determined. First, the total and average information content of the terminological system can be calculated. In this example, the total differs between 0 for configuration (a) and 8 for configuration (e). The average (excluding the root concept, which is 0 by default) differs likewise between 0 and 2. As shown in Figure 1, both of the configurations (a) and (e) have hardly any structure, from which it can be concluded that neither a large nor a small value for the total or average information content is preferred. In the examples, concepts with zero information content contribute significantly to the small total values. These concepts are subordinate concepts without co-ordinate concepts (i.e., they are the single child of their parent concept). As stated in [3] "the presence of such cases is reason to suspect the presence of error." In configuration (e), all concepts are co-ordinate. According to [3], when there are a large number of co-ordinate concepts, these concepts "may point to issues such as a lack of organization or incomplete descriptions."

These examples show that information content can provide a measure for the organization of the terminological system. A terminological system which is organized as a full binary tree (in which every node other than the leaves has two children) has an average information content of exactly 1, and can be regarded as a maximally organized system.

The configurations from Figure 1 are all mono-hierarchies, whereas terminological systems such as SNOMED CT are poly-hierarchies, in which concepts can be subordinate to more than one superordinate concept.

Examples thereof are shown in Figure 2. In these cases the information content is calculated from a likelihood which is the division of the total number of superordinate concepts by the total count of co-ordinate concepts, in which any concept that is a co-ordinate concept for multiple superordinate concept count multiple times.

In configuration (a) of Figure 2, one concept has 2 superordinate concepts, which have 1 and 2 subordinates respectively. So the information content is $-\log(2/3) = 0.58$. In configuration (b), the two "leaf" concepts both have two superordinate concepts, each of which has 2 subordinates. So for the leaf concepts the information content is $-\log(2/4) = 1$.

Using these measures, a terminological system can be characterized by the proportion of concepts with zero information content, and the average information content of the other concepts. These measures can also be calculated for parts of a terminological system, thereby providing insight in the structure of sub-hierarchies of the system.

Information content as a measure of the content of medical records

Information content can not only play a role in evaluating the structure of a terminological system, but also in estimating the information content of terminological-system-based data entered into a medical record. As terminological systems such as SNOMED CT should enable multiple use of patient information, data is preferably captured with maximal detail.

To determine the amount of detail a concept provides, rather than the individual information content of a concept, cumulative information content is used. A distinction is made between total and relative information content.

Total information content is the sum of the information content of superordinate concepts up to the root. In configuration (a) from Figure 2, the leaf nodes will have a total information content of 2 and 1.58 respectively.

Relative information content is the sum of information content of superordinate concepts up to a non-root superordinate concept. For example, if one records gender, the information content relative to gender (e.g., "Finding related to biological sex" in SNOMED CT) can be calculated.

Application to SNOMED CT

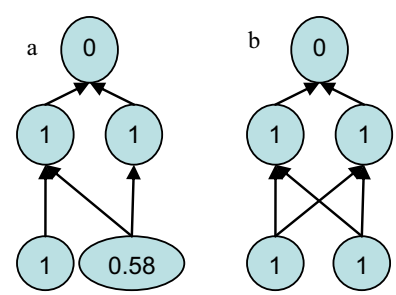

Figure 2- Example configuration of two rooted poly-hierarchical terminological systems with 5 concepts.

The above measures were calculated for the last three releases of SNOMED CT (July 2008, January 2009, and July 2009). To this end, all active non-limited concepts (i.e., those where concept status is 0) were taken into account, and all Is_A relationships between them. Table 1 shows the total number of concepts in each release, the proportion of concepts with zero information content, and the average information content of the concepts that have non-zero information content. Table 2 shows the measures for the 15 largest categories in the July 2009 release of SNOMED CT (based on the category mentioned in the fully specified name). The highest and lowest values for the proportion of concepts without information content and the average information content of the remaining concepts are shown in bold. These figures indicate that the subhierarchy of body structures overall contains relatively small numbers of subordinates per concept. This is indicated by the high proportion of concepts without information content (i.e., which are to only subsumer of a concept) on the one hand, and by the low average information content on the other hand. Conversely, the category "pharmaceutical/biological product" shows have relatively little organization, having many subordinates per concept. It turns out that the 4500 concepts with the highest information content in SNOMED CT are all products, with "Saliva stimulating tablet" having the highest information content of 11.33 (as it has 2580 co-ordinate concepts and 1 superordinate concept).

The "event" hierarchy combines a low proportion of concepts without information content with an adequate structure.

Application to data collected using SNOMED CT

At the department of Intensive Care of the AMC, SNOMED CT is used in a pilot to record reasons for admission to intensive care. This pilot started mid-December 2008. Figure 3 shows for the reasons for admission that were recorded at the Intensive Care of the AMC in the period January-June 2009 their average total information content and their total number of recorded concepts. This figure does not take into account a small number of concepts that were post-coordinated. Figure 3 suggests that the level of detail in which users are recording was stable for the first four months, and dropped thereafter. More data will be needed to see if this reduction is permanent, and further analysis of the data is needed to explain any loss of information content.

Table 1 – Measures for the latest releases of SNOMED CT

Release	# concepts	no content	avg content
July 2008	289028	5.14%	3.79
January 2009	292104	5.05%	3.94
July 2009	289897	5.11%	3.89

Discussion

Information content as a measure of the structure of terminological systems

Two measures were introduced regarding the structure of terminological systems: the proportion of concepts with zero information content, and the average information content of concepts with non-zero information content. These measures provide insight into two complementing structural aspects of terminological systems: concepts without co-ordinate concepts and concepts with large numbers of co-ordinate concepts. These types of concepts are identified as possibly erroneous or ill-defined.

The benefit of these measures is that they can be applied to either a complete terminological system or any part thereof. A drawback of the measure of average information content may be that it is strongly influenced by concepts with large numbers of co-ordinate concepts. As all of the co-ordinate concepts have a large number of co-ordinate concepts, the higher information content is multiplied by the large number of concepts, and outweighs the concepts which have a small number of co-ordinate concepts and hence a lower information content. Further research is needed to determine whether this is actually a drawback, or whether this helps in pointing out areas that need review.

Information content as a measure of the content of medical records

Measuring total or relative information content is especially useful for record items that can be captured with a varying level of detail. This is the case for example when recording findings or procedures, which can be recorded with more or less detail. For example, with increasing level of detail, one can use SNOMED CT to record infective meningitis, bacterial meningitis, Gram-negative bacterial meningitis, Haemophilus meningitis, and thromboembolic meningoencephalitis. As not all detail will be available in any situation, the possibility of recording information with less detail must exist. However, it is useful to analyze whether users generally resort to generic concepts, or try to provide maximal detail. The information content can provide insight in this recording behavior, for example over time, or depending on the way in which information is recorded by users. In a previous study, an analysis was performed on the level of detail in which information was recorded and a comparison was made between free-text recording and terminology-based recording [7]. In that research it turned out that it was generally hard to determine whether one or the other provided more detail due to lack of an adequate measure for that. Figure 3 provides an example of how information content can be used for such purposes.

Further work

This paper applies the measures only to SNOMED CT, which shows that the three most recent releases are relatively constant regarding these measures. Applying the measures to other terminological systems will provide more insight into the results, enabling comparison between terminological systems rather than between versions or specific parts thereof.

Ideally, measures like these are not only calculated for evaluation purposes, but also for providing guidance or prioritization for future maintenance and improvement of these systems. It needs to be determined whether this is practically feasible.

Contemporary terminological systems such as SNOMED CT include other than Is_A relationships. Currently these relationships are not explicitly addressed in the measures presented, but only implicitly, as they are essential for the way in which the hierarchical structure in SNOMED CT is realized, namely by automated classification. However, as these attribute relationships are also important for supporting post-coordination, it would be important to address them. As post-coordination can play an important role when capturing information in a medical record, further research on the measure of information content of recorded data is necessary.

Conclusion

In this paper 2 measures are presented that are based on information content: the proportion of concepts with zero information content, and the average information content of a terminological system. Two other measures are described for the content of medical records that is captured using a terminological system: total and relative information content. Benefits of these measures are that they can be relatively easily calculated, and are grounded in information theory.

The measures are useful as an indicator of the overall structure of terminological systems or parts thereof. Information content is shown to provide a useful basis for assessing the structure of terminological systems and the content of medical records.

Quantifying the level of detail in which information is captured in a medical record is a first step towards assessing the quality of recorded data.

Abstract

This paper presents: (1) a framework of formal representation of ICD10, which functions as a bridge between ontological information and natural language expressions; and (2) a methodology to use formally described ICD10 for computer-assisted ICD coding. First, we analyzed and structurized the meanings of categories in 15 chapters of ICD10. Then we expanded the structured ICD10 (S-ICD10) by adding subordinate concepts and labels derived from Japanese Standard Disease Names. The information model to describe formal representation was refined repeatedly. The resultant model includes 74 types of semantic links. We also developed an ICD coding module based on S-ICD10 and a 'Coding Principle,' which achieved high accuracy (>70%) for four chapters. These results not only demonstrate the basic feasibility of our coding framework but might also inform the development of the information model for formal description framework in the ICD11 revision.

Keywords

ICD10, Ontology, Knowledge bases, Natural language processing, Computer-assisted coding

Introduction

The World Health Organization (WHO) officially launched the 11th revision of the International Classification of Disease (ICD) in April 2007 [1]. One important planned feature of ICD11 is structurizaton of the clinical meaning of each disease category to provide formal representations of ICD categories to describe the characteristics of each disease in various dimensions such as Etiology, Anatomic site, Manifestation attributes, and Pathophysiology. Figure 1 shows a possible formal representation of 'Venezuelan equine encephalitis (A92.2).' The meaning of the disease concept is represented as a tree-structure using two component concepts (*CC*) (e.g "Encephalitis") and semantic links of two types (e.g. "<hasCause>").

The structurization process might have several levels of granularity, but such a formal representation of ICD will be useful for advanced information retrieval systems. It is anticipated as a useful knowledge base for computer-assisted ICD coding.

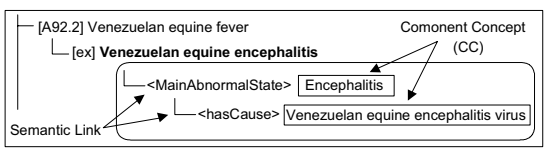

Figure 1 – Simple example of 'formal representation'.

Computer-assisted ICD coding (or Automated ICD coding) has attracted attention continuously since the 1990s. Although several studies have sought to represent ICD categories formally and to use it for ICD coding [2–8], their framework and information models for formal representations were insufficient to cover all ICD categories because they investigated only a few domains. For example, Héja et al. [6,7] developed an information model to describe ICD categories using six concept categories and semantic links of five types. However, they analyzed only two chapters. Moreover, it is not clear that such a small information model is applicable to all chapters. No comprehensive information model has included the complete list of semantic links to describe all ICD categories.

In addition, the ICD coding frameworks in those studies did not consider distinctions among concepts and their string expressions (labels). Fundamentally, the first step to perform ICD coding is to map input strings to *CCs*. However, that is not always possible because of an omission or an abbreviation. As might be apparent, no substring of the input disease name "*Venezuelan equine encephalitis*" can be mapped directly to the CC in Fig. 1 – "*Venezuelan equine encephalitis virus.*" A new methodology to address mapping between concepts and string expressions is needed to improve coding results.

This study has two major goals. The first is to develop a structured ICD10 ('*S-ICD10*'), which functions as a bridge between ontological information and natural language expressions, based on a robust and comprehensive information model that can cover all ICD categories. The second is to develop a methodology to use S-ICD10 for computer-assisted ICD coding.

Materials and Methods

Development of S-ICD10

Step 1): Structurizing the ICD10 Tabular List

First, 20 Japanese ICD coders manually analyzed the ICD-10 book (Volume 1: Tabular List, 2003 Japanese edition) and described formal representations for all ICD categories and example entries in 15 chapters (excluding Chps. 5, 15, 16, 18, 20, 21, and 22). It is noteworthy that Chps. 20, 21 and 22 are additional information, so the number of main chapters in ICD10 is 19. As Fig. 2 shows, each ICD category and an example entry has at least one formal concept representation (hereinafter '*FCR'*) represented as a tree structure, and each semantic link has cardinality information. The main tasks in this step were: (1) to identify CCs from the title of each category; and (2) to assign semantic links to CCs to form tree representations. Two Japanese medical and ontology experts reviewed all results. If at least one disagreed with the result, then the information model and the list of all semantic links were reconsidered; all descriptions were revised based on the new information model. We started this project in 2005. These iterative revisions were repeated three times.

Step 2): Expanding S-ICD10 and adding labels

Step 1 includes no distinction between CCs and their labels. Therefore, in this step, we separated those labels from CCs and assigned additional labels derived from Japanese Standard Disease Names (*JSDN*) [9] to S-ICD10. The 25,280 disease names in JSDN were manually parsed (every disease entry in JSDN has a proper ICD10 code); the 20 annotators (same as step 1) assigned each token—a morpheme or substring of each disease name—to the corresponding FCR as one of the following types: (1) *a direct label of CC(s)*; (2) *a label of subordinate concept of CC(s)*; and (3) *a label of an additional CC of the FCR.* For example, in Fig. 1, we assigned the label '*Venezuelan equine*', as a direct label of CC *[Venezuelan equine encephalitis Virus]*. It means that the string '*Venezuelan equine*' can indicate the CC under a certain context, even though the string itself is not a virus name. Regarding M254 in Fig. 4, a new concept *'[Knee Joint]'* together with its label '*Knee Joint*' was added to the CC *[Joint]*, as its subordinate concept; a new concept '*[Swelling]*' together with its label was also added to the FCR as an additional CC with cardinality '0..1'. These new concepts were derived from disease entries in JSDN that have the 'M254' ICD code.

This step was very important to perform ICD coding. ICD10 is a classification system and each ICD category is an aggregation of diseases. Therefore, component concepts of an input disease are sometimes more granular than CCs of ICD entries. Two experts (same as step1) reviewed the results obtained in this step. Furthermore, in cases where they did not agree, the annotation result was excluded. Results show that approximately 85% of all tokens in JSDN were included in the expanded layer of S-ICD10.

Automated ICD coding framework based on S-ICD10

Overview of our coding framework

Figure 2 depicts an overview of our coding framework. The coding module leverages a Japanese general tagger called YOMOGI, which we developed in 2007, for tokenizing an input disease name based on the label set in S-ICD10.

First, YOMOGI outputs *N*-best tokenization of an input disease name. Each token has corresponding CC(s) in S-ICD10. However, some tokens might correspond to various CCs in different ICD categories. For example, as shown in Fig. 2, an input disease name was tokenized into four tokens, and the token '*universal*' corresponds to a label of the CC in B007, D65, K650, L631, and so on. The system then considers all possible combinations of corresponding CCs and selects one which best covers a certain ICD code. As Fig. 2 shows, the system regarded "*universal*" as a label of CC in D65:ex3/ D65 and "*blood*" as a label of CC in D50–D89, because both D65 and D50–D89 are upper categories of D65:ex3.

Finally, the input disease is mapped to the ICD entry 'D65:ex3'; the system then outputs its ICD code (D65).

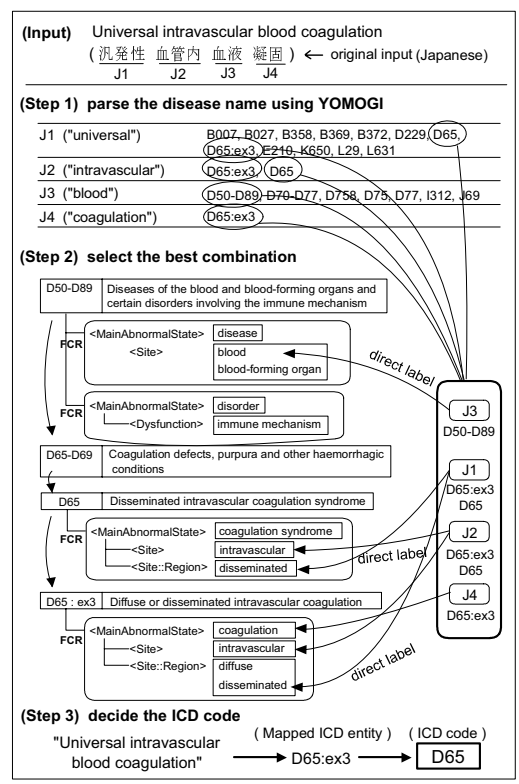

Figure 2 – Overview of our coding framework.

'Coding principle'

In the coding process, the system uses a '*Coding principle*' to decide ICD codes. From the ontological perspective, 'Concept B' is a child concept of 'Concept A' if: (1) every CC in 'Concept B' is the same as or the specialization of the corresponding CC in 'Concept A'; or (2) some additional CCs exist aside from the condition explained above, as shown in Figure 3.

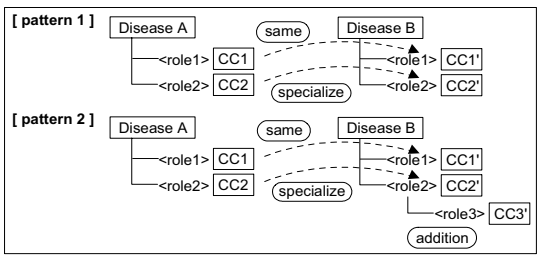

Figure 3 – Is-a relations between two concepts.

However, those rules are too strict for ICD coding purposes. In Fig. 4, the "*swelling*" label in the input string was mapped to the CC in M254; the "*knee joint*" label was mapped to the subordinate concept of the CC in M254. However, not all CCs in M254 were covered by the input string, although the input disease concept is fundamentally a child concept of M254. Therefore, we cannot apply the [pattern1] rule in Fig. 3 to this case. We used a *'Coding principle'* to solve this problem—"An input disease has the ICD code 'X' if every token in the input disease can be mapped to: (1) CC in X; (2) subordinate concept of CC in X; or (3) CC that can be inherited from ancestor categories of X". This '*Coding principle'* does not require that all CCs in X whose cardinality is one or more be covered by the input disease name. In that sense, it is a weakened condition of two patterns in Figure. 3 for coding purposes.

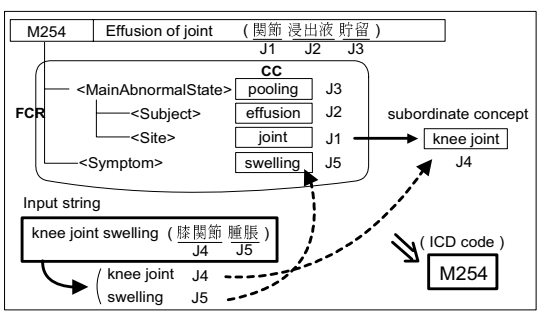

Figure 4 – Label mapped to a subordinate concept of CC. (where J1-J5 denote Japanese tokens)

If an input disease name cannot satisfy the Coding Principle, then the system outputs ICD code candidates according to the coverage ratio (# of tokens satisfying the Coding Principle / # of total tokens). The system outputs nothing in cases where the coverage ratio is low (< 50%).

Evaluation on the ability for ICD coding

To investigate the performance of the proposed coding framework, we evaluated the capability for ICD coding based on S-ICD10 and the '*Coding principle*'. We randomly chose 1,255 disease names collected from various hospitals in Japan and coded them manually. Entries present in Japanese Standard Disease Names (JSDN) were excluded beforehand because S-ICD10 had already included knowledge derived from JSDN.

Results

S-ICD10 and the information model to describe FCRs

Table 1 – Categorization of all semantic links

Category	Type of semantic link	# of ST	Freq.
Pathophysiology	Main Abnormal State	-	13,111
Site	Has Site	2	8,411
	Related Site	-	54
Cause	Cause	1	4,146
	Modifier of Cause Entity	2	4
	Cause-related	5	91
Function	Dysfunction	-	247
Temporal Relation	Features of Occurrence	-	298
	Progress/ Timing/ Age	-	1,110
Symptoms/ Findings	Symptoms/ Findings	1	1,428
	Modifier of Symptoms/ Findings	6	71
Specification of other items	State	11	545
	Treatment-related	2	2
	Type	3	152
	Route/ Mode of intake	2	10
	Certainty	3	3
	Others	7	35
Subject of others	Subject	2	565
Examination/ Diagnosis	Mode of confirmation	-	81
	Diagnostic method	-	1
Relation to other disorders	-	11	1,899
Other	-	9	66

15,221 ICD entries (categories and examples) in 15 chapters were structured. S-ICD10 has 15,463 FCRs, 55,453 CCs (20,320 unique CCs), and 81,478 labels (39,164 unique labels) in total. The information model to describe FCR includes 74 types of semantic links. Table 1 shows a categorization of all semantic links.

Each type of semantic link might have sub-types (the third column shows the number of sub-types). For example, the type 'State' includes 11 sub-types of semantic links, such as 'Shape', 'Benign/Malignant', 'Atypia', 'Severity', 'Quantity', and 'Grade of Progress'. The category 'Relations to other disorders' includes 11 sub-types, such as 'Complication', 'Underlying disease', 'Follow', and 'Sequela'. The fourth column shows the frequency of the semantic link. For example, the semantic link 'Diagnostic method' was used only once in the formal representation of 'I252:ex2' – "*Past myocardial infarction diagnosed by ECG or other special investigation, but currently presenting no symptoms.*"

Automated ICD Coding

Table 2 shows results of automated ICD coding. Overall, 61.7% (747/1211) disease names were coded correctly. The best result (76.4%) was Chapter 7 (Diseases of the eye and adnexa); the worst (46.2%) was Chapter 4 (Endocrine, nutritional and metabolic diseases). We excluded diseases of four chapters (5, 15, 16, and 18) because S-ICD10 does not cover them. However, diseases from those excluded chapters were only 44 (total = 1,255). Therefore, if those categories are included later, they will little affect the overall result.

Table 2 – Automated coding results

Ch	#C	#N	*R*(%)	Ch	#C	#N	*R*(%)
01	72	28	72.0	10	32	13	71.1
02	61	56	52.1	11	35	30	53.9
03	19	20	48.7	12	109	47	69.9
04	42	49	**46.2**	13	37	30	55.2
06	32	12	72.7	14	46	24	65.7
07	29	9	**76.3**	17	26	17	60.5
08	15	8	65.2	19	144	82	63.7
09	48	39	55.2	**Total**			**61.7**

Note: Ch, Chapter No.; **#C**, # of correctly coded diseases; **#N**, # of non-coded diseases; ***R*(%)**, the ratio of #C).

Discussion

Disease description framework

The S-ICD10 result description process showed that all ICD entries, at least in 15 chapters (of 19 main ones), can be represented formally using our information model to describe FCR. The information model based on the categorized list of the semantic link types shown in Table 1 is much more granular than in any previous study. Many newly found semantic link types were indispensable for formal representation of ICD categories, showing the importance of comprehensive analysis.

Some semantic links must be refined for further development toward more sophisticated ontological representation of ICD10. Also, a '*Subordinate'* relation should be separated into '*Is-a*' and '*Part-of*' relations from an ontological perspective. Consequently, we call it '*Structured*' ICD-10, not '*Ontology*'.

Nevertheless, the information model is useful for development toward ontological representation. It might inform the ICD11 revision project as a pilot study to create a comprehensive information model to describe ICD categories formally.

Computer-assisted ICD coding

As for the ability for ICD coding, although it is difficult to compare results among coding systems which use different test sets, the overall accuracy (61.7%) is similar to the best result among previous studies [13] and much better than other previous results. The system achieved high accuracy (>70%) for four chapters, but the accuracies of Chapter 3 and 4 diseases were low. The main reason is the lack of subordinate concepts, especially in anatomical entities. We added many subordinate concepts and labels derived from JSDN. However, JSDN had insufficient information to cover all disease names collected from various hospitals in Japan. A possible solution is the use of semantic relations between anatomical entities defined in other ontologies such as FMA and SNOMED-CT.

The system outputs other ICD codes along with the correct one in cases where candidates have equal scores (coverage ratios). We counted those cases as 'correctly coded' in the evaluation study because it is apparently easy for human coders to select the correct code from those candidates in later screening. The system can also output the reason for the coded result, showing the mapping result between tokens in the input disease names and CCs, which will be helpful for later screening.

The overall accuracy decreases to 34.8% if we do not use the 'Coding Principle' and perform ICD coding based on simple matching between an input and FCR. The 'Coding Principle' is important in terms of: (1) using information (CCs) inherited from the upper categories: and (2) allowing the case in which not all CCs of a certain FCR are covered. This important feature of our coding framework enables us to address the case in Fig. 4, which the previous knowledge representation-based approaches could not cover.

Related works

Substantial efforts have been made for automated or computer-assisted ICD coding to date. They are classifiable into two types: (A) using disease names or clinical notes, which already have correct ICD codes, to calculate similarities by statistic measure (***'example-based'***) [10–13]; and (B) using formal representation of ICD categories to describe coding rules (***'knowledge representation-based'***) [2–8].

Type-A methods can be implemented easily, but they have not shown high accuracy. The coding systems require numerous examples to achieve better results. However, it is difficult to collect them evenly. Some ICD codes have no coded example.

Moreover, it cannot provide explanation capability, which is useful for later screening by human coders.

On the other hand, Type-B methods present advantages to provide explanation capabilities. However, developers must describe vast amounts of knowledge. Therefore, previous studies only proposed designed framework or implemented the system in a small limited domain. Our framework is also 'knowledge representation-based'. However, it differs from other Type-B studies in the following respects: (1) our project achieved high coverage (15 of 19 main chapters), and our information model representing ICD10 categories is considered highly robust; (2) 'concepts' and their 'labels' are distinguished explicitly so that S-ICD10 can work as a bridge between ontological information and natural language expressions; (3) our coding framework uses the 'coding principle', which allows property inheritance and weakened conditions of concept subsumption.

Limitations and future directions

The S-ICD10 covers most chapters, but some, such as 'Mental and behavioral disorders (Chap. 5)' have not been addressed. The information model to represent disease concepts might not be sufficient to cover all disease concepts in ICD10. We plan to apply our methodology to the remaining four chapters and to produce a more comprehensive formal representation of ICD10. We also plan to map all concepts (CCs) and labels to the current existing terminologies and ontologies such as SNOMED-CT, GALAN, FMA, and Japanese Medical Ontology, and to create an English version of S-ICD10.

Conclusion

This paper presents: (1) a framework of formal representation of ICD-10, which functions as a bridge between ontological information and natural language expressions; and (2) a methodology to use S-ICD10 and the '*Coding Principle*' for computer-assisted coding. The results demonstrate the effectiveness of our framework. In fact, S-ICD10 has unprecedentedly high coverage of all ICD10 categories. The resultant information model to describe formal representation of ICD categories might inform ICD11 revision as a pilot study.

Abstract

The overall objective of the EU-ADR project is the design, development, and validation of a computerised system that exploits data from electronic health records and biomedical databases for the early detection of adverse drug reactions. Eight different databases, containing health records of more than 30 million European citizens, are involved in the project. Unique queries cannot be performed across different databases because of their heterogeneity: Medical record and Claims databases, four different terminologies for coding diagnoses, and two languages for the information described in free text. The aim of our study was to provide database owners with a common basis for the construction of their queries. Using the UMLS, we provided a list of medical concepts, with their corresponding terms and codes in the four terminologies, which should be considered to retrieve the relevant information for the events of interest from the databases.

Drug toxicity, Semantics, Medical records, Indexing, Information storage and retrieval, UMLS.

Introduction

The medical information gathered during clinical follow-up can be reused for a wide variety of related purposes from medico-economic and epidemiological applications to clinical alerts [1, 2]. This information, collected at every stage of the healthcare process, is often registered as free text and is increasingly coded by using one or several specific medical terminologies. Though time-consuming, choosing an appropriate code to describe medical information has the advantage of clarifying unambiguously the significance of the information. Information coding allows automated processing of the information and facilitates semantic interoperability between different information systems. Medical information with appropriate coding can be transmitted, interpreted and processed more easily by different systems and thus enables sharing and reuse of the data among information systems [2, 3].

In the area of drug safety, information sharing could enhance the current spontaneously reported information on adverse drug reactions (ADRs), as reporting rate is far from optimal. Underreporting is high, and it is estimated that only 4% of ADRs are reported through this channel [4]. Therefore, safety signals may be detected too late, as was recently highly debated after the rofecoxib (Vioxx®) withdrawal due to concerns regarding cardiovascular safety. It has been recognized that additional complementary systems are necessary [5, 6], which could profit from the wide availability of health care databases throughout Europe. The use of several medical databases for signal detection could overcome the underreporting problems existing with the current system and may detect signals faster and/or earlier.

From this rationale, the European EU-ADR project has been launched. The aim of this project is to design, develop and validate a computerised system to process data from eight electronic healthcare databases and biomedical knowledge databases for the early detection of safety signals [7]. Each of the eight healthcare databases contains information which is coded according to different terminologies, in different languages, and has its own specific characteristics, depending on its initial objective and local function (administrative, healthcare, medical records, etc.) [2]. Given the structural and semantic heterogeneity of the databases involved in the project, it is impossible to construct a single, completely reusable query system on the different databases, to undertake the same search for each event and drug.

Objective: The aim of this research was to provide a method for extracting relevant information contained in the various databases regarding the event under study and the drugs taken in the population. Our task also entailed a search for greater coherence to enhance our method of extracting information from the different databases. The method described was evaluated through a process using analogy as a logical tool.

Materials and Methods

Concept selection

Different terminologies are used to code the clinical events in the eight databases. Thus, a common basis was required in order to set up queries (adapted to target databases) built-on a shared semantic request. The aim was to provide researchers with a list of medical concepts and associated terms that they must use to identify the events being investigated in their respective databases. A unique query cannot be performed to extract information from the databases used since, intrinsically, different terminologies are used. We built a shared semantic foundation for the eight databases[8]. The constituents of this shared foundation are UMLS[9] concepts (grouping together terms from different terminologies with the same medical meaning) and not terms.

Medical terminologies are structured in the form of lists of concepts[1], generally set out in a hierarchical way. A concept can be defined in many ways since the terms[2] defining it come from different languages and, furthermore, because each language can use distinct synonymous terms to describe the same concept.

The eight databases involved in the EU-ADR project contained information stemming from the medical files of more than 30 million European citizens (Table 1). Four terminologies are used to describe the events: the «international statistical classification of diseases and related health problems» (ICD9-CM and ICD10), the «international classification of primary care» (ICPC) [10] and the READ CODE (RCD) classification[11]. Seven databases use the Anatomical Therapeutic Chemical (ATC) system[12] to code drugs. In the QRESEARCH database, drugs are initially coded using the British National Formulary (BNF) [13], but a mapping between the BNF codes and the ATC classification has been established by the QRESEARCH team. The Unified Medical Language System® (UMLS®) [14] is a biomedical terminology integration system handling more than 150 terminologies. The four terminologies used in the EU-ADR project are integrated in the UMLS. The Metathesaurus® consists of a central vocabulary comprising roughly 1.8 million concepts connected by more than 3.75 million relations. A UMLS concept is identified by a Concept Unique Identifier (CUI) and describes a single medical concept that can be expressed using different synonyms (terms).

To develop our method, we initially studied the event «upper gastrointestinal bleeding» (UGIB) which has a complex medical definition and thus raises difficulties when searching for it in a standardised way in databases. A similar approach is used for the other twenty-three events that have been identified to be of primary importance in the EU-ADR project [7].

Our method is based on the projection of UMLS concepts in the targeted terminologies. The whole method consists of the following: 1) literal definition of event, 2) identifying the UMLS concepts for the event; 3) discussion about concepts with database's administrators; 4) term identification for each concept in each terminology.

Regarding step 1, a «broad» definition approach was initially adopted. The definitions were drawn from clinical reference manuals and were validated by gastroenterology specialists.

Regarding step 2: for each literal expression matching the inclusion criteria listed in the definition of the event, we performed an automated search using Knowledge Source Server (UMLSKS, version 2008AA), in order to identify the UMLS concept and all the terms used to designate the concept in the four terminologies of the project. When this automated search failed to identify terms corresponding to a given concept in one of the terminologies studied, we undertook a manual search in the concerned terminology to identify the potential terms of interest.

In step 3, database's administrators were asked to follow their 'usual approach' to query their databases and compare the criterions they have used with the concepts and terms provided at the step 2 issue. The relevance of each concept, term and corresponding code were discussed via the EU-ADR consortium Internet forum, conference calls and plenary meetings. Thus a consensual list of items (codes, terms and free text expressions) was set up.

[1] A concept is a unit of thought [ISO 5963]

[2] A term is the designation of a given concept in a language in its linguistic formulation [ISO 1087]

Table 1- Description of the eight databases

Database	Terminology		Free text	Type of data*	Patients†
	Event	Drug			
Pedianet – Italia (ITA)	ICD9-CM	ATC	yes (ITA)	EHR	C
Health Search (ITA)	ICD9-CM	ATC	yes (ITA)	EHR	A/C
Lombardy Regional DB (ITA)	ICD9-CM	ATC	no	SDC, D	A/C
Tuscany Regional - ARS (ITA)	ICD9-CM	ATC	no	SDC, D, L, M	A/C
IPCI – Netherlands (NL)	ICPC	ATC	yes (NL)	EHR	A/C
PHARMO (NL)	ICD9-CM	ATC	no	SDC, P,L, M	A/C
QRESEARCH United Kingdom (UK)	RCD	BNF/ATC	no	EHR	A/C
Aarhus University Hospital DB (DK)	ICD10	ATC	no	SDC, D, L, M	A/C

*EHR (Electronic Health Record), SDC (Standardized Discharge Codes), D: Dispensation, L: Laboratory, M: Mortality, P : Prescription. † C: Child, A : Adult

In step 4, the list of items from different terminologies and languages were provided to the databases administrators. Every listed item had necessarily to be present in their query. The list of items that we provided was non-restrictive. Database administrators were free to add all additional criterions/terms that they would consider relevant in order to recover the UGIB event from their database, providing that these criterions offered a new way of describing the selected concepts. Hence, when a given code had "children" (i.e. a more accurate description), the query also had to include the "descendants" of this code that were considered relevant for the retrieval of the information.

Evaluation process

To evaluate this semantic-based method, we needed a knowledge source that could confirm that the events retrieved by the databases administrators correspond really to UGIB. Unfortunately, manual evaluation on a sample of events is a lenghty and expensive process that is not scheduled in the EU-ADR project. On the other hand, we found that sensitivity of the semantic-based method could be estimated in a fast, albeit indirect, way. By exploring the MEDLINE National Library of Medicine's (NLM) database. As in the patient medical records, the full-text versions of the articles indexed in MEDLINE include medical concepts. The MEDLINE notices created by the NLM indexers can thus be considered by analogy as discharge summaries where an effort of selecting an appropriate MeSH code to resume the full content is done. A subset of the MEDLINE database, identified through a classical Pubmed search, can then constitute a validation set. The sensitivity of the search methodology for the UGIB events could be evaluated by performing the search through the MEDLINE notice. The manual examination of the full-text versions of the articles included in the identified subset constitute the "gold standard" for the assessment of the presence of UGIB events in the indexed papers. In order to constitute the validation set using the Pubmed website, we entered the query "upper gastrointestinal bleeding" with the limits: "links to free full text" AND "Humans" AND ("English" or "French"). Using the "Humans" descriptor restricted the selection to notices with MeSH descriptors and then avoids the notices not yet indexed in MEDLINE. Restriction to English and French languages was due to the language expertise of the workgroup performing the manual examination. A random selection of 20% of the notices was done. We then examined the full-text versions of the selected papers to confirm that the notion of UGIB was present.

We compared three methods for retrieving the event UGIB within the notices validation set. The two first ones were initial methods written by the database owners of Lombardy (in ICD9-CM) and Aarhus (in ICD10) and the last one was our proposal.

Because the MEDLINE database is coded in MeSH terms, we first had to translate the ICD9-CM and ICD10 codes used by database owners into MeSH terms. Several steps were conducted: 1) we used the UMLS Metathesaurus to recover the UMLS CUIs associated with the ICD9-CM and the ICD10 codes; 2) we used the tool developed by Bodenreider[3] [15] to obtain only MeSH codes from the resulting CUIs. 3) we extracted the English preferred term for each MeSH code in the Metathesaurus (because there is no MeSH codes in MEDLINE, only the preferred terms); 4) Finally, we checked, for each of the three methods, the ratio of the notices retrieved (within the validation set, our gold standard) when using MeSH terms previously obtained. We then computed the retrieval sensitivity in our subset test of MEDLINE notices.

Results

Concept selection

For the event UGIB, a broad clinical definition was created including the following conditions: Upper gastrointestinal

[3] http://mor.nlm.nih.gov/download/rtm

haemorrage, Oesophagal haemorrage, Gastrointestinal haemorrhage, Bleeding from peptic ulcer, Haematemesis/blood vomiting and Melaena. We then devised a table listing all the UMLS concepts matching the inclusion criteria. Upon evaluation of the usual behaviour of the databases and the provided concepts, the concepts and terms were adapted. These included: *Upper gastrointestinal hemorrhage, Gastrointestinal Hemorrhage, Hematemesis, Melena, Esophageal bleeding, Acute {gastric|duodenal|peptic} ulcer with hemorrhage (and/or) perforation, Acute gastrojejunal ulcer with haemorrhage, without mention of obstruction, Acute gastrojejunal ulcer with hemorrhage and perforation, Acute gastrojejunal ulcer with hemorrhage, Atrophic gastritis, with haemorrhage, Other specified gastritis, with hemorrhage, Unspecified gastritis and gastroduodenitis, with hemorrhage, Acute gastric mucosal erosion.*

Subsequently all codes and terms were provided. As an example, the concept *"Haematemesis"* is coded "578.0" in ICD9-CM, "K92.0" in ICD10, "D14" in ICPC and "J680" in RCD. Some of the corresponding terms (useful for search in the clinical notes that are registered as free text) are as follows: "Ematemesi/vomito sanguinolento" in Italian, "Bloed; braken" in Dutch, "Haematemesis/vomiting blood" in English, etc.

Evaluation process

We performed a broad search on Pubmed, looking for possible citations of a wide set of gastroenterological disorders. From the resulting 1,044 MEDLINE citations, we extracted a random selection of 20% of them (n=208), only 199 of which were working with Pubmed LinkOut (the internet link to retrieve full-text articles). After full-text revision, we classified 151 articles as containing the UGIB notion. So 48 articles did not contain the UGIB notion but other medical notions (lower GIB for example). These 151 notices constitute the test set for our evaluation of the three extraction methods. The number of notices retrieved by each method is described in Table 2. Our proposal of a common semantic base method retrieved 107 notices out of a total of 151 notices with the event UGIB present in the full-text. The sensitivity is the percentage of retrieval in our subset test of MEDLINE (not in all MEDLINE).

Table 2 - Number of notices retrieved for each method

	Gold Standard: presence of UGIB in Full text article	**Sensitivity (%)**
Lombardy's initial method	100	*66.2*
AARHUS's initial method	108	*71.5*
Common Semantic based method	107	*70.9*
Total	**151**	

As a result, we can observe that the common semantic-based method is nearly as sensible as the better between the other two, that is, Aarhus accepting to delete some of its customary concepts on the ground of homogeneity with other databases did not lead to a dramatic fall in sensitivity, whereas Lombardy's sensitivity improved.

Discussion

The process we implemented allowed the homogeneous identification of events in various European databases. It is based on UMLS concepts. This foundation enabled us to propose a list of terms along with their codes and strings in order to standardise queries and, thus, extractions from the eight databases participating in the EU-ADR project. The discussion and harmonisation process led to additional concepts to be included in the list, the definite version included a total of 21 potentially usable concepts for the coding of the UGIB event in the databases. The databases were heterogeneous regarding the terminology used, the presence, or not, of free text data (used in two languages: Italian and Dutch), and the type of data they contain (medical record and claims databases). The UMLS may be helpful to map between these heterogeneous databases and to promote semantic interoperability among these databases. The sensitivity of the retrieval in our validation set is estimated by an analogy method to be around 70%, similar to those of initial queries from the participating databases.

Our process creates an homogeneous set of relevant terms/expressions useful for requesting heterogeneous databases, but does not exhaustively describe the event extraction. First, databases with free-text must perform a local algorithm, based on local information, that avoids ambiguities in the use of free-text. Second, databases with hospital discharge records must agree on whether looking for the UMLS concepts only in primary or also in secondary diagnosis fields. Third, all databases must specify in which health sources they are looking (e.g. only hospitalizations *or* both hospitalizations and deaths). Finally, some health sources contain information that is not corresponding to UMLS concepts: for example, the use of laboratory test results involves identifying a concept by its biological results and not by its name or its place in a nosologic description, and this identification might be crucial for some events (e.g. acute kidney failure). A more detailed terminology mapping instrument must be developed that further describes event extraction.

When common concepts are translated into database-specific codes, it is important to consider when analysing results that each database is confined to the granularity of its terminology. SNOMED CT for instance, can be coded by the user with a high level of granularity whereas ICD is much less granular. Hence, the level of information acquired is not always identical.

Concerning the evaluation process, the analogy between a medical doctor summarizing apathology in a clinical or claim database and a NLM indexer which selects the appropriate code to resume the full content of an article is new and needs confirmation. Secondly, the projection from ICD9-CM or ICD10 codes to MeSH terms could result in some classification bias, according to the numerous steps of the process. In order to compare the three methods, we used the same projec-

tion process. The different biases should then have affected equally the different methods. The EU-ADR workgroup selected 21 concepts for the search of UGIB. To create the selection of citations for the gold standard, we had to work on a small subset of MEDLINE focusing on gastroenterological disorders and to examine the full-text versions of the articles from this subset for the presence of UGIB. We decided to use only the concept "upper gastrointestinal bleeding" and to select only a sample of the relevant papers for the evaluation of the identification of the event UGIB. This does not constitute a major issue as our objective was not to determine the prevalence of the event UGIB in MEDLINE, but to constitute a validation set for our method. .Remark that the same technique cannot be used to estimate the specificity of the common semantic-based method because one can not have the confirmation of absence of the concept UGIB in the full text version of the articles indexed in MEDLINE and not identified by a classical Pubmed search for UGIB.

Conclusion

The projection of UMLS concepts in the terminologies and the additional manual adjustments have been exploited for the four terminologies used in our study. This enabled us to provide a shared semantic basis for the creation of queries adapted to the heterogeneous electronic health record databases we exploited. The list of concepts, accompanied by the list of associated codes, and strings in free text text (where applicable) have been used by the database administrators as a base to build queries designed to retrieve information from their database using the appropriate terminology. We provided evidence that the homogenization of concept selection does not worsen the sensitivity of each database. This method will be used for the other events selected for the EU-ADR project. The extraction of the same medical concepts from the eight databases will enable biostatisticians working on the project to use comparable data from different databases, with respect to the definition of the events sought despite of the high level of heterogeneity between the databases.

Acknowledgments

This research received funding from the European Union Community in the framework of the FP7/2007-2013 convention governing subsidy nº 215847 - the EU-ADR project. The authors also wish to thank the NLM for making UMLS available free of charge and Mr George Morgan for his translation.

Abstract

Clinical Trial Management Systems promise to help researchers in managing the large amounts of data occurring in clinical trials. In such systems Case Report Forms for capturing all patient data can usually be defined freely for a given trial. But if database definitions are automatically derived from such trial-specific definitions then the collected data cannot be easily compared to or integrated into other trials. We address this interoperability issue with an approach based on ontology and semantic data mediation. This resulted in the development of the ObTiMA system which is composed of a component for setting-up clinical trials and another for handling patient data during trials. Both components offer data reusability by relying on shared concepts defined in an ontology covering the whole cancer care and research spectrum.

Keywords:

Clinical trial management system, Application ontology, Semantic data mediation.

Introduction

Clinical Trial Management Systems (CTMS) promise to help researchers in hospitals and biotechnology/pharmaceutical companies to better manage the tremendous amounts of data involved when conducting clinical trials [1]. Their goal is to simplify and streamline the various aspects of clinical trials, such as planning, preparation, performance, and reporting, by providing functionalities, like automatic deadline tracking for legal or regulatory approval, progress report issuing, keeping participant information up-to-date, or import/export data from/into other clinical information systems. For example, it is still a common yet tedious and error-prone practice to collect data at each trial site on paper-based Case Report Forms (CRF) and then to enter them manually into the trial database at the trial center. CTMSs are supposed to avoid this by providing user interfaces that blend into clinical work settings and shield users from underlying data and system complexity.

But as standardized, commercial CTMSs are not yet widely deployed, trial databases and their entry interfaces are often developed in-house specifically for a given trial and therefore not readily reusable in other trials. This issue causes an additional reimplementation burden and makes it difficult to compare or integrate data between different trials. But even if CTMSs are used, the following issue remains unresolved: Those systems allow a user to freely define the CRF items and structures without the need of any informatics skills. But although this is very desirable, it can create the same interoperability problems. If a database is derived from the trial-specific CRF definitions, the database in turn is again also trial-specific and data reuse in further research stays problematic. Thus, our work focuses on solving this interoperability issue through an approach based on ontology and semantic (data) mediation.

This work has resulted in the development of the Ontology-based Trial Management Application, or *ObTiMA* for short. Its development started as part of the European Union project *ACGT* (Advancing Clinico-Genomic Trials on Cancer) aiming at creating an open, semantic and grid-based technology infrastructure to support clinicians and scientists in post-genomic clinical trials in cancer research [2]. Its development continues now in the European Union project ContraCancrum intended to develop a platform for simulating tumor development and response to therapeutic modalities to optimize the disease treatment procedure in a patient's individualized context [3].

An early ObTiMA prototype was presented in [4]. Here we describe the current state of its development. To this end, we first cover the ontology and semantic mediation as the basis of the data management in ObTiMA. Then we describe the two main components of the system: the Trial Builder for designing clinical trials and the Patient Data Management System for handling patient data within a trial. We conclude by referring to related research and how ObTiMA is now being evaluated.

Relevant ACGT Components

The advent of innovate technologies, like high-throughput screening or pharmacogenomics, has lead to the creation of new data on a previously unknown scale. However, tools to automatically analyze these data are still missing or not yet in an applicable stage. This is the core issue ACGT wants to

solve by developing a unified technology infrastructure to facilitate seamless, secure access to clinical and genomic data: High-performance knowledge discovery techniques are being created to support multi-centric, post-genomic clinical trials.

Among the various ACGT components, the two most relevant ones for ObTiMA are the *Master Ontology*, providing a unified set of (logically defined) domain concepts necessary to describe all aspects of clinical trials, and the *Semantic Mediator* providing ontology-based mediation between data sources.

Master Ontology

The task of this ontology is to comprehensively represent the domain of research on cancer and its clinical management and care, with special emphasis on mammary carcinoma (breast cancer), nephroblastoma (Wilms' tumor) and rhabdoid tumor. Due to the multiplicity of entities and processes present in this domain, the ontology contains elements ranging from genetics, the medical and administrative field, up to the legal domain. Therefore it forms a cross-section between all of these subdomains with each one being a vital part of the overall domain.

Basically, domain ontologies represent a given domain by formally and univocally defining the types and their connecting relations, as used within that domain. Hence, the Master Ontology could effectively be seen not as "proper" domain but rather as application ontology since it is tailored towards the functionality requirements of the application services of ACGT. For example, "proper" domain ontologies exhibit a clear-cut, distinguishable domain that can be found in basic scientific disciplines, like anatomy or cytology. But since our ontology incorporates many different aspects, it is not possible to clearly delineate such a single, specific domain. However, in using ontologies the differentiation between domain ontologies and application ontologies blur considerably, anyway.

An ontology is thus a representation of the referents, in the linguistic sense of the word, in some domain or for some specific application providing references for the terms used in describing the domain. All naming and labelling in the Master Ontology was checked against actual term usage in the domain to ensure end-user usability [5] (which also contains examples from the ontology missing here due to space restrictions).

For the ontology development, the principles for state-of-the-art ontology engineering, as proclaimed by the OBO Foundry [6] have been followed closely. Those "best praxis" criteria for ontology design support in producing an artifact which is both sensible from the point-of-view of content as well as coherent regarding its logical, internal structure. As an example, all concepts are defined by formal subsumption ("is-a" relation) and logical constraints based on the relations between concepts. Hence concepts are clearly delineated from each other and ambiguity of pure natural language definitions is avoided.

Semantic Mediator

The process of semantic (data) mediation involves the matching, combination, and retrieval of data stored at disparate data sources to offer a unified view over them. It is semantic since the relationships between all parts of the data are made explicit by using ontological concepts and relations. The Semantic Mediator has initially been designed to fulfil this task as a part of the ACGT platform. It accepts queries to and retrieves results from disparate data sources, like databases or flat files, based on Master Ontology concepts and relations. Hence, users who want to retrieve data via the mediator do not have to know any technical details of the underlying data sources but employ ontological concepts and relations and combine them into queries to access all data sources in a unified way [2].

A new data source is integrated into the semantic mediator by creating a set of rules for mapping this data source onto the Master Ontology. For databases, this task is simplified by a graphical tool that assists in mapping from database tables and columns onto appropriate ontological concepts and relations. Still this process remains a complex task that needs to be performed by users who are experts both in the domain, the database, and the ontology. They must be able to realize the subtle differences between similar ontological concepts and how this is mirrored in the data sources (and vice-versa) [7]. On the upside, this mapping needs to be created only once when a data source is first added but can be reused for other tasks, so a genomic data source can be directly reused in other trials.

ObTiMA System Components

Trial Builder

The Trial Builder represents one of ObTiMA's two main components (cf. Fig. 1) and enables the user to specify the various aspects of a clinical trial. The trial outline and metadata can be defined in a master protocol based on templates for describing the trial goals and its administrative data, like start or end date. Treatment plans can be graphically designed to guide clinicians through the treatment of individual patients and particular treatment events, such as chemotherapy or surgery, can be defined with all necessary information. The particular order of treatments for individual patients can be defined by placing them on a timeline. Also, treatment stratifications and randomizations to be applied for a patient can be described. For each stage on the treatment plan a CRF can be assigned to collect the data documenting the treatment.

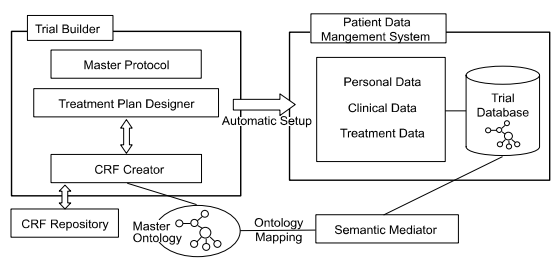

Figure 1 – ObTiMA System Components

Ontology-based CRF Creation

The creation of CRFs marks the core functionality of the Trial Builder. In a graphical user interface, the user can define the content, layout, and navigation of the CRFs which are used to

capture all patient data during a clinical trial, like the patient's history, medical findings, diagnostic data, or genomics data.

It is important that all information can be defined here which are necessary for the data integration, i.e., each CRF item is described based on ontology concepts together with metadata, like data type and measurement unit, to set-up the trial database. However, the internal CRF (data) representation is not the focus of clinicians but their "user interface" (layout) and their adaption and integration into the specific workflow of the planned trial: clinicians are not to be bothered with the underlying aspects of the trial database or the ontological metadata. Thus all these aspects are made transparent to the user through a graphical user interface which hides the actual complexity yet gathers all required information for automatically creating the trial database. This interface is derived also automatically from the content and structure of the Master Ontology but presents a simplified ontology view, adapted to the task of creating items (Figure 2). It comprises the following sections:

In the *Ontology View* (1), the user selects concepts from the ontology to create a CRF item. Here, the interface tries to overcome the gap between clinical practice and the actual logical representation of ontology concepts: Although the ontology provides natural language descriptions for its concepts/relationships (in addition to the logical definitions), those often do not fully mirror the needs of practical or clinical perception of reality. In order to meet this need, we do not present the full Master Ontology here but rather a simplified clinical view which contains a trial-independent basic classification of CRF contents from a clinician's point of view.

It is by intention that the clinical view is far less detailed as the actual Master Ontology and since this allows the possibility to provide a much easier entry point for the user. The interface of the clinical view is implemented as a tree always that starts at node of the concept "Patient" as focus of any clinical study (and hence CRF) and only presents those concepts that are directly reachable from this concept, like "Weight" or "Tumor" (indicating a patient's tumor). Only when a concept is selected then also the concepts directly reachable from this one are shown, such as "Laterality" in the case "Tumor" was initially chosen (indicating the laterality of the patient's tumor).

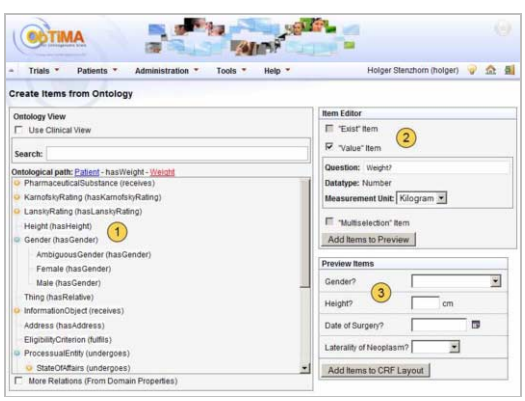

Figure 2 – Ontology Viewer while Creating CRF Items

When a concept is chosen in (1) then a corresponding item is automatically created and shown in the *Item Editor* (2) together with its attributes determined automatically based on the chosen concept, such as label, data type, or answer possibilities, and which can be manually adopted. For example, the concept "Weight" has a numerical data type and a list of suitable measurement units attached. So, when the CRF with this item is used in a clinical trial then the measurement units are offered as selection possibilities (in a drop down menu). The specified value (entered into a text field) is automatically tested to be of numerical type and also to be non-negative (since a weight cannot be negative). Finally, *Preview Items* (3) presents all created items in the order in which they are intended to appear on the CRF. Single items can be reordered by simple drag and drop and subsequently transferred to the interface where the overall layout of the CRF is then defined in turn.

CRF Repository

Revisiting the reuse and interoperability issue discussed in the introduction, in many trials similar or equal data are collected, yet stored differently because of different data(base) definitions. Applying the Master Ontology already improves this situation through using standardized concepts when creating CRFs. Going a step further, the situation would be further improved by partial or complete reuse of existing CRF in case similar data is collected. This idea realized by creating a unified CRF Repository as crucial part of ObTiMA. This repository allows the storage and retrieval of entire ontology-based CRFs and single CRF items or components for reuse and adaption in subsequent trials: When setting-up a clinical trial, fitting CRFs can either be directly reused or new ones quickly created by "plugging together" existing CRF items and components. This in turn fosters the standardization of CRFs even more, since CRFs can now be compared not only on the level of single items (through their basis on ontological concepts) but also on the level of larger components or in their entirety.

Patient Data Management System (PDMS)

The PDMS supports clinicians when conducting a clinical trial and is automatically set-up based on the master protocol and CRFs defined in the Trial Builder. The PDMS guides the clinicians through the actual treatment of patients according to their individual treatment plans and provides a graphical user interface to fill in the CRFs relevant to the patient's current treatment situation. The interface is adjusted to everyday clinical needs: As with the Trial Builder, the complexity of the underlying ontology is hidden from the user, yet its logic-based concept definitions are used to provide direct validity checking when CRF are filled in. The basic look of the data entry interface corresponds to section (3) on Fig 1 with each input element providing on-the-fly feedback about its current state based on the just mentioned checking, i.e., in case a negative value is specified for a weight then this error is immediately highlighted along with an explanation of the error.

Data Export

To integrate ObTiMA into real-world clinical settings, the system must be capable to interface with other existing CTMS

and be able to exchange data in a format they understand. To meet this requirement, ObTiMA allows to import and export trial metadata, CRF descriptions and patient data through an extended version of the CDISC Operational Data Model (ODM) format [8]. This platform-independent, quasi-standard for exchanging and archiving clinical trial data is supported by many current CTMSs. Observing CDISC's extension guidelines, we enriched this format by allowing the additional inclusion of (metadata) descriptions based on Master Ontology concepts. In the case other CTMSs want to import data generated by ObTiMA, they can chose to interpret the supplemental descriptions but if this is not feasible the resulting data is still "ODM complete" and can sensibly be used by those systems.

Administration, Security and Pseudonymization

To administer multicentric clinical trials, ObTiMA contains several advanced facilities for managing the multitude of institutions, researchers, and patients usually participating in such trials. An elaborated, fine-grained security architecture has been implemented to handle the rights and roles that can be attached to the system's users in order to guarantee that they can only perform the tasks which they are fully authorized for. It is also straightforward to dynamically react to changes within a running clinical trial, since new institutions and users can always be added or extra security roles and rights be defined.

It is also indispensable that ObTiMA, as a system holding real patient data, securely stores all of the data which could possibly identify some patient to non-authorized persons in pseudonymized and encrypted form. To foster security even more, such personal data is physically separated from the actual clinical research data through the use of two distinct database servers: One server holds the database for storing the personal data of the patients, such as their names and addresses (which must never be shared, e.g., via the Semantic Mediator). The protection of this database strictly follows all current legal regulations for data protection in clinical environments. The other server hosts the database that contains the actual research data collected in a clinical trial (through the use of the CRFs). It is possible within the Trial Builder to mark certain CRF items as personal which results in this data being stored in the database for personal data and not in the one for research data.

Advantages of Using Ontology and Semantic Mediator

Built-in Semantic Trial Interoperability

As pointed out before, when clinical trials are designed with the Trial Builder (and thus linked to the Master Ontology) then this means that all items defined on the CRFs are also attached to the corresponding ontological concepts. Therefore, when data is entered for some CRF item then this data is also directly linked to the ontology based on the item's attached concept. No manual and error-prone data annotation happening subsequently and using biomedical terminologies is necessary. The advantage can be easily seen when looking at recent studies highlighting that the accuracy of SNOMED annotations exceeds 50% only slightly for three different scenarios [9] and hence annotated data cannot be reliably compared at all.

The automatic link of the collected data to the ontology makes it further simple to "publish" collected data or "blend in" external data into a current clinical trial via the Semantic Mediator: As ObTiMA automatically generates the mapping rules needed by the mediator from the concept-based item definitions, its (research) database can be readily added as data source to the mediator. Other trials running on ObTiMA (and therefore also based on the Master Ontology) or other applications based on that ontology, can perform concept-based queries on the trial data using the Semantic Mediator. The opposite direction to integrate other, external data sources into the current clinical trial is also made possible: for biomedical or biomolecular data sources containing, e.g., genomic data or data collected in related clinical trials (but not using ObTiMA) a mapping based on the Master Ontology can be created for the mediator (see above). Then by using the same concepts (combined with using the same interface) to query external data and data collected in the current clinical trial, it becomes straightforward to perform cross-trial meta-analyses.

Increased Data Quality

Continuing the above, by basing the data collection on the shared Master Ontology which has been developed by clinical domain experts in cooperation with ontology experts, the data becomes consistent to the knowledge of the underlying domain and hence its quality increases. The Trial Builder in ObTiMA ensures, mostly transparently to the user, that during the creation of CRF items only concepts from the ontology are chosen and logical restrictions attached to the concepts, like domain and range restrictions, are satisfied. However, currently not all of the restrictions encoded in the ontology, such as number restrictions, can be guaranteed automatically. Therefore we are currently investigating novel algorithms to support the user in further improving the data quality and consistency [10]. As with the ontology integration, those algorithms will be applied "below the surface", in order to support the user and improve quality but without exposing their intrinsic complexity.

Conclusion

In this paper we have described ObTiMA, the Ontology-based Trial Management Application and presented the details of its two main components to design clinical trials and to manage the patient data within them, as well as the Master Ontology and Semantic Mediator as the foundation of the system.

Related Work

We are aware of other research initiatives aiming to achieve data integration by utilizing ontologies in the clinical trials. Ontology based data integration frameworks, such as the Epoch project [11], are a very active research field. The difference between the latter and ObTiMA lies in the fact that these frameworks focus on only integrating existing data sources (instead of creating CRFs to gather new shareable data). Other initiatives focus on applications for creating standardized CRFs by using ontologies, like TermTrial [12], which also allows automatic database creation based on those CRFs. ObTiMA combines the advantages of the two research strains enabling both a user-friendly ontology integration during the trial design and the automatic set-up of the PDMS as well as the seamless integration of external data and the "publication"

of its own database. It is also attractive that all ontology and semantic mediation integration is transparent to the user and so any additional complexity that might be introduced by those technologies/methodologies is hidden, but still their application provides a strong support and added value to the user.

Evaluation

ObTiMA is currently being evaluated within the SIOP 2001/GPOH study [13] at the Saarland University Hospital as that study's trial center. The evaluation is performed by two trial administration experts who, until now, have been using a Microsoft Access database created in-house along with self-defined templates to enter the data collected on paper-based CRFs. Both ObTiMA's trial design and execution facilities are evaluated, accompanied by a user study where users are asked to report their experiences and propose improvements. In the first step, the CRFs have been designed together with the Master Ontology developers. For this, the existing paper-based study CRFs were taken and "translated" into their electronic, ontology-based pendant. The Trial Builder's user interface was found to be mostly straightforward and quick to understand after a short tutorial. Yet some possible improvements, e.g. regarding performance and user guidance, were identified and are now being worked on. Also some minor concepts were initially missing from the ontology necessary to fully model all details of the original CRFs but which have been added since. In a second step, ObTiMA's PDMS is evaluated by entering a large collection of CRFs. Feedback is also very encouraging here since it was expressed that the given functionality and its interface suit the clinical audience and are easy and quick to use. Still, a scientifically valid evaluation on a larger user basis is needed and therefore an evaluation including several clinical centers (based on a Rhabdoid tumor study) is now on its way. (The feasibility of ontology-based data integration via the Semantic Mediator has been successfully proven in ACGT [7].)

Acknowledgements

Our work is carried out jointly within the ContraCancrum and ACGT projects funded by the European Commission (FP7-ICT-2007-2-223979 and FP6-2005-IST-026996). We are very grateful to all our project collaborators but especially to Alberto Anguita and Luis Martín for their Semantic Mediator work.

Querying the National Drug File Reference Terminology (NDFRT) to Assign Drugs to Decision Support Categories

[a] *Regenstrief Institute, Inc., Indianapolis, IN,*
[b] *Indiana University, Indianapolis, IN*

Abstract

Introduction: The accurate categorization of drugs is a prerequisite for decision support rules. The manual process of creating drug classes can be laborious and error-prone. Methods: All 142 drug classes currently used at Regenstrief Institute for drug interaction alerts were extracted. These drug classes were replicated as fully-defined concepts in our local instance of the NDFRT knowledge base. The performance of these two strategies (manual classification vs. NDFRT-based queries) was compared, and the sensitivity and specificity of each was calculated. Results: Compared to existing manual classifications, NDFRT-based queries made a greater number of correct class-drug assignments: 1528 vs. 1266. NDFRT queries have greater sensitivity (74.9% vs. 62.1%) to classify drugs. However, they have less specificity (85.6% vs. 99.8%). Conclusion: The NDFRT knowledge base shows promise for use in an automated strategy to improve the creation and update of drug classes. The chief disadvantage of our NDFRT-based approach was a greater number of false positive assignments due to the inclusion of non-systemic doseforms.

National Drug File Reference Terminology, Drug classification, Knowledge bases, Computer-assisted drug therapy

Introduction

Clinical decision support for computerized provider order entry (CPOE) depends on the assignment of drugs to classes used to express generalized medical knowledge. For example, a CPOE system could detect a risk of interaction between Macrolides and Statins (for a patient who is given both). As a prerequisite, the computer must know which of the drugs on the patient's profile belong to these classes.

The Gopher CPOE system was developed by Regenstrief Institute over the past two decades, and has provided decision support to thousands of physicians caring for patients in central Indiana. Regenstrief informaticians have created drug classes (e.g., "HMG-CoA reductase inhibitors"), and have manually populated these with individual drugs (e.g., "Lovastatin" and "Simvastatin"). Such drug classes facilitate writing decision support rules to detect drug-drug interactions or to suggest laboratory monitoring.

As the years pass, old medications are retired, and new ones enter the market. We have found that the manually-created Gopher drug classes accumulate older medications, but lack newer ones. Therefore, we are searching for a solution – an automated strategy – to improve and update the Gopher drug classes.

The Food and Drug Administration (FDA) is driving the Structured Product Labeling (SPL) initiative. SPL is an HL7 version 3 standard for drug knowledge representation based on the HL7 Reference Information Model (RIM). The FDA has already published over 5000 drug labels in this format. As of June 2009, all drug manufacturers must use the SPL format to register all of their new products with the FDA. An "indexing initiative" is underway, which will annotate these products using the Veteran Administration's National Drug File Reference Terminology (NDFRT). [1]

Already today, the NDFRT contains knowledge annotations for a large number of drugs, and NDFRT drug concepts are linked to NDC, RxNorm and other terminologies in the Unified Medical Language System (UMLS). Can NDFRT knowledge improve the way that drugs are categorized for clinical decision support? Carter and Brown have delivered an initial analysis to answer whether the drug classes used in real systems might be encoded using the available NDFRT categories. [2] We have previously reported on the use of this knowledge to organize basic drug terminology, [3] improve detection of drug intolerances, [4] and to create links between drugs and a patient's problem list. [5] In this paper, we investigate if another area of decision support – the detection of drug interactions – can be supported by NDFRT knowledge content.

Principles

NDFRT is an ontology of medication-related concepts that uses a highly restricted description logic formalism to define drugs in the form:

$$D \sqsubseteq B_1 \sqcap \ldots \sqcap B_n \sqcap \exists\ R_1.\ C_1 \sqcap \ldots \sqcap \exists\ R_m.\ C_m,$$

i.e. a drug concept D is described as the conjunction of base classes (a D is a B_1 and a D is a B_n) and existentially quantified role restrictions.

Some of the important roles in the NDFRT include the following: (a) has ingredient, (b) has mechanism of action, (c) has physiologic effect, (d) may treat, (e) may prevent, or (f) is contraindicated with a disease. Using such roles, we can define Statins as "drugs that have some mechanism of action which is a hydroxylmethylglutaryl-CoA reductase inhibitor"; or Tricyclic antidepressants as "drugs that have some ingredient which is a tricyclic ring structure derivative, and which may treat depression".

The NDFRT does not include fully-defined concepts to represent drug classes. (A fully-defined concept is one defined so that the constraints of the definition are sufficient criteria to declare a concept subsumed.) Instead, the NDFRT distribution file marks all concepts as primitive, where the criteria are descriptive (and necessarily true) for all subsumed concepts, but are not sufficient. In this paper, we attempt to show how we can describe conventional drug classes as fully-defined concepts in the NDFRT ontology.

Methods

NDFRT Knowledge Adapted to a Relational Database

The NDFRT knowledge base is made available for public use in a proprietary description logic XML format. [6] We downloaded the 2008.11.11 version of this file, and applied an XSLT transform to load it into our relational database.

As a matter of routine, we reason with such proprietary file formats in a relational database schema, which we have repeatedly described elsewhere. [3,4,7] In this schema, all NDFRT concept relationships are represented in one table with a relationship type, source concept id, and target concept id (see Figure 1). If the relationship type is transitive and reflexive (like the "is_a" relationship), then we compute the materialized transitive and reflexive closure and distance metric:

- reflexive: distance = 0
- direct: distance = 1
- transitive distance = 2,3,4…

We have found that this approach is fast even for large terminologies and instance databases.

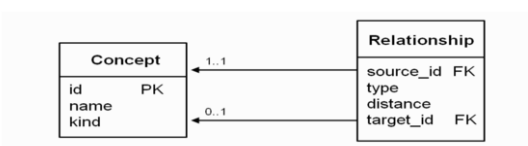

Figure 1 – NDFRT simple relational schema

Our relational database contained 136,054 NDFRT concepts. Of these, there were 120,877 drug concepts: NDC-level packages; drug products (with strength); and abstract "drug preparations" (without strength). There were also 8433 chemicals (derived from the MeSH chemical classification), 1815 physiologic effects (PE), 438 mechanisms of action (MoA), and 4258 diseases. Our relational database contained NDFRT-derived relationships as well: 158,717 is_a relationships, 4720 has_ingredient, 3167 has_PE, 2150 has_MoA, 5670 may_treat, and 793 may_prevent relationships.

Regenstrief Gopher Drug Classes

The Regenstrief Terminology Dictionary stores drug classes relevant to clinicians. Each drug class has a numerical identifier, a name, and a brief description. Physicians can create prescriptions for some of these drugs – in this paper, we will call these "Leaf-Level Drug Classes" (LLDC). Lisinopril is an example. There are also other drug classes, not at the leaf level, and not orderable by physicians. ACE Inhibitor is an example.

The Regenstrief Gopher CPOE system uses 808 non-leaf-level drug classes for various decision support purposes. Each such drug class has been assigned – manually – a set of LLDC identifiers representing orderable drugs. In order to focus our analysis on patient safety, we extracted only those 142 drug classes used by Gopher decision support to identify drug interactions. These drug interactions have been compiled over many years by Regenstrief pharmacists. Although there are several drug knowledge bases in the United States which list drug interactions, there is no single source recognized as a standard.

Defining Drug Classes as NDFRT Queries

The 142 Regenstrief drug classes were encoded using a few description logic templates (see Figure 2) and implemented as relational database queries (written in SQL). The authors, both physician-informaticians, captured the definition of each of the 142 drug classes taking into consideration: (a) the name of the class, (b) the LLDC members of the class, and if in doubt (c) the purpose of the class as it is used in the interaction rules. For example, "Macrolides" and "HMG-CoA reductase inhibitors" are understood from the name. For "Antipsychotics", the name was not sufficient, and the LLDC members of the class had to be examined to see that "Neuroleptics" are meant – excluding Antidepressants. For "Non-sedating antihistamines", the use of the interaction rule had to be examined to see that only those Antihistamines with the risk of QT interval prolongation (e.g., Terfenadine) were intended.

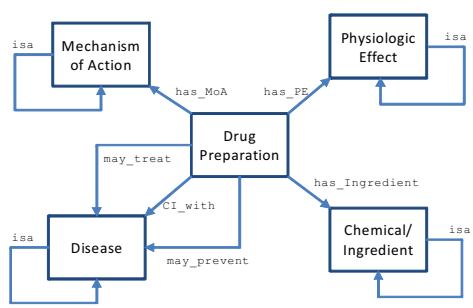

Figure 2 – Some of the Concepts and Relations in the NDFRT. The ones shown were used in this study to define drug classes.

Most (137 of 142) class definitions could be written as one of the following two schemata:

1. For 133 cases: $D \sqsubseteq \exists\ R.\ C$

Role R indicated these relationships: has_ingredient (94 times), has_MoA (21 times), has_PE (7 times), may_treat (7 times), may_prevent (3 times), and contraindicated with (1 time). Oxidizing meds were defined as those contraindicated with glucose-6-phosphate dehydrogenase insufficiency.

2. For 4 cases: $D \sqsubseteq \exists R_1.\, C_1 \sqcap \exists R_2.\, C_2$

In two of these cases, the roles R_1 and R_2 indicated the "has_ingredient" relationship (Cotrimoxazole and Advicor had been defined as sets, and each represents two ingredients). In the two other cases, one of the roles indicated "has_ingredient" and the other role indicated "may_treat" (e.g., Azole antifungals and Tricyclic antidepressants)

These NDFRT-based class definitions can be implemented as SQL queries. For the definition $D \sqsubseteq \exists R.\, C$, the role R is implemented as a database table linked to two other tables: the source concept of the role, and the target concept of the role. We join the source concept via a transitive and reflexive "is_a" relationship to the drug concept D. We join the target concept via another transitive and reflexive "is_a" relationship to the concept C. For the definition $D \sqsubseteq \exists R_1.\, C_1 \sqcap \exists R_2.\, C_2$, the conjunction is implemented as an SQL intersection.

Finally, 5 of the 142 drug classes could not be defined based on the knowledge in the NDFRT ("CYP3A4 inhibitors", "Class Ia antiarrhythmics", "Class III antiarrhythmics", "Non-sedating antihistamines", and "Kayexelates"). The minor effect (e.g., increased repolarization time for "class III antiarrhythmics") was not annotated in the NDFRT knowledge base. In order not to introduce a bias into the comparison of the manual approach with the NDFRT-based approach, these classes were not excluded from analysis, but were left to count against the NDFRT method.

Mapping NDFRT Drug Preparations to Regenstrief LLDC

In order to compare the NDFRT-based drug classes with the manually-created Regenstrief drug classes, we needed an element common to both. NDFRT-based drug classes consist of NDFRT Drug Preparations. Regenstrief drug classes consist of Regenstrief LLDC. We needed to link the two terminologies together. (See Figure 3 for a summary of the links required.)

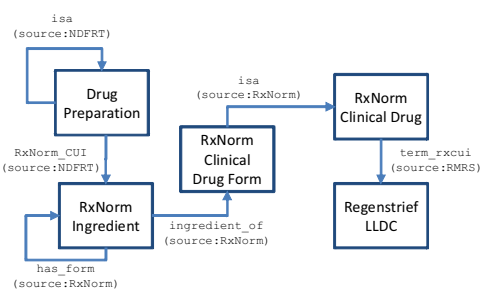

Figure 3 – Relations linking NDFRT Drug Preparations to Regenstrief LLDC

Comparing NDFRT Classes with Regenstrief Drug Classes

The analysis of the comparison is based on a full outer join table that connects NDFRT class members with Regenstrief class members, if either exists. The unit for comparison was the Regenstrief LLDC. In other words, the definition of Regenstrief classes as sets of Regenstrief LLDCs was not disturbed. However, the definition of NDFRT classes was expressed as a set of Regenstrief LLDCs, relying on the mapping linkages described above.

For each of the 142 drug classes: we examined the Regenstrief LLDCs assigned to that class during the manual creation of the class; and we examined the Regenstrief LLDCs assigned to that class by the automated NDFRT-based queries. If a LLDC was assigned to the class by both strategies (manual and NDFRT-based), it was declared to be correctly assigned. If a LLDC was assigned by only one strategy, and not the other, then it required review. A reason for the discrepancy was determined. This review established a consensus set against which both methods were measured.

Results

Over the years, Regenstrief knowledge engineers had manually populated the 142 classes with a combined total of 1271 LLDCs. Our NDFRT-based definitions subsume a combined total of 1905 LLDCs. The two strategies overlap for 754 LLDCs. (See Figure 4.)

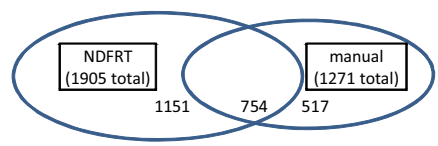

Figure 4 – Overlap of LLDCs collected by the two strategies

The combined totals are disproportionately affected by classes with many LLDCs; therefore, we broke down the counts by class. NDFRT definitions subsume more drug LLDCs in 64 cases; Regenstrief classes subsume more in 54 cases; and the two strategies collect equal numbers in 24 cases.

In order to study performance metrics, we needed to assign some "gold standard" of true class membership. We declared that the 754 LLDCs returned by both the NDFRT-based queries and the Regenstrief classes were true members of their classes. We reviewed the 517 LLDCs in the Regenstrief classes (which had not been included in NDFRT queries), and could only find 5 cases of inappropriate class membership. For example, Digoxin Fab antibody fragments do not share the proarrhythmic effects of the other cardiac glycosides, and thus were considered inappropriately placed in that class. Finally, we reviewed the 1151 in the NDFRT queries (which had not been manually included in the Regenstrief classes). We designated 774 as truly members of the class – in accordance with the original Gopher definition of the drug class. As discussed below, making this designation was a matter of judgment. In sum, we found 2040 class-member assignments (754 + 512 + 774 = 2040) which we considered true.

Having made this designation of true class membership, we calculated sensitivity and specificity. (See Figure 5.) Note that the 2616 LLDCs lacking true class membership are calculated as the sum of the 5 LLDCs inappropriately placed in Gopher classes, the 377 LLDCs inappropriately placed in the NDFRT-based classes, and the 2234 remaining Regenstrief Dictionary Drug LLDCs which do not participate in either strategy.

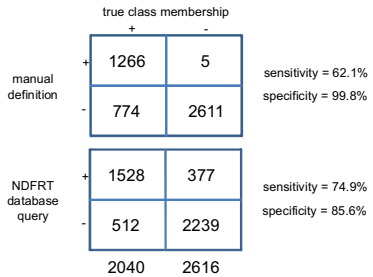

Figure 5 – Performance metrics of the two strategies for defining classes: manual (top) and NDFRT-based (bottom)

The low specificity calculated for the NDFRT strategy derives from 377 false positives. We discovered that 44 of these were due to a medication of incorrect formulation for a drug class where the formulation was explicitly stated. For example, topical Erythromycin gel had been assigned to the class of "Macrolides Systemic". An additional 192 were due to incorrect formulation, where the formulation was implied. For example, Atropine ophthalmic drops had been assigned to the class of "Antiarrhythmics". The systemic route is implied, though not explicitly stated.

The sensitivity calculated for the NDFRT strategy depends on the number of NDFRT Preparations successfully mapped to a Regenstrief LLDC. But 387 of the LLDCs in the manually defined classes are not mapped to RxNorm clinical drugs, and thus cannot be linked to NDFRT Preparations. The greater part of these unmapped LLDCs are outdated medications which are no longer marketed (e.g., Oxytriphylline). These unmapped LLDCs contribute to the count for the manual strategy, but cannot contribute to the count for the NDFRT strategy. Simply excluding the unmapped LLDCs would improve sensitivity of the NDF-RT approach to (1528/1653 =) 92.4%.

The sensitivity of the manually-defined classes is greatly affected by the failure to include combination products. For example, among the medications detected by NDFRT queries, but not included in manually-defined classes, were 229 combinations of ingredients. For example, Fiorinal had been correctly included in the Gopher Barbiturates class; but it had not been included in the Gopher Aspirins class.

Discussion

In this study, knowledge derived from the NDFRT was used to categorize medications and enable a specific type of decision support: checking for drug interactions. However, the accurate categorization of drugs has broader applicability, and can enhance other types of decision support, such as treatment guidelines (e.g., Beta blockers for myocardial infarct).

We demonstrated that classes defined in the NDFRT ontology subsume a greater number of medications than the manually defined classes currently used by our institution. The manual classes are incomplete, and lack many medications which could rightly be assigned to them. This fact is not surprising. We know how difficult it is for a limited number of knowledge engineers to monitor the unrelenting arrival of new drugs on the market, and to manually update drug classes and other features of a complex decision support system. This is especially problematic for combinations of ingredients (e.g., Amlodipine/atorvastatin should be assigned to two classes: Statins and Calcium channel blockers). If we could harness an automatic process of class assignment based on NDFRT definitions, we could improve the completeness of our Gopher classes.

We measured a modest improvement (from 62% to 75%) in sensitivity with the use of NDFRT. But these numbers understate the potential benefit of the NDFRT strategy. Our analyses used Regenstrief LLDCs as the unit of measure. This had no negative impact on the Gopher classes. However, this put the NDFRT queries at a disadvantage. Not all of the NDFRT Preparations in the queries were successfully mapped to Regenstrief LLDCs. Despite the handicap of incomplete mapping, the NDFRT strategy outperformed the manual strategy.

Nevertheless, it would be premature to use NDFRT definitions "as is". This strategy could introduce a lack of specificity. This problem is especially important in the domain of drug interaction decision support. Physician users consider most drug interaction reminders unhelpful; in one study, they overrode 89.4% of such alerts. [8]

We determined that the majority of false positives were due to the wrong formulation of the right ingredient. Thus medications intended for non-systemic (e.g., topical or ophthalmic) use were placed with medications intended for systemic use. As noted by Carter et al, a reference hierarchy of formulated routes would greatly improve the NDFRT. [2] Another promising approach is the definition of drug classes based on the SPL model, which includes dose forms and routes, and will include NDFRT annotations. Such an approach would routinely take form and route into consideration. [3]

An important lesson learned is that to correctly assign drugs to a class, one must understand the purpose of the drug class. A drug class assembled for the purpose of allergy detection may include more members (be more sensitive at a cost of specificity). For example, Penicillamine might be included in a set of warnings for Penicillin allergy. A drug class assembled for treatment guidelines should have less members (be more specific at a cost of sensitivity). For example, not all Quinolones should be suggested for treatment of pneumonia. A drug class to monitor interactions might include only those formulations known to produce sufficient systemic concentrations. Unfortunately, at our institution, a drug class, once it is defined, is often reused for several different purposes – and may not suit them all.

The expressiveness of NDFRT has already been investigated: Rosenbloom et al determined that the Physiological Effect hierarchy is adequate for representing the effects of commonly prescribed medications. [9] Nevertheless, not all of the possible physiological effects of a medication have been instantiated as relationships. We found that the primary treatment effects were well represented; but not all the possible side effects were. For example, the class of anticholinergic medications collected by the NDFRT query did not include some medications (e.g., Diphenhydramine) which geriatricians at our institution have flagged for anticholinergic side effects.

One limitation of our study is the use of Regenstrief LLDCs as the unit of measure: other institutions do not use Regenstrief terminology. However, it must be noted that Regenstrief LLDCs have survived real-world testing over several decades. Furthermore, many Regenstrief LLDCs have a direct correspondence to RxNorm identifiers. Finally, we needed to use Regenstrief LLDCs to put the NDFRT strategy to a real-world challenge. The fact that the NDFRT strategy still outperformed in sensitivity adds credibility to our belief that this strategy should replace the manual maintenance of drug classes.

Another limitation is that these performance metrics depend on our own designation of which drug LLDCs are correctly assigned to a class. In many cases, the authors reached consensus promptly. However, in some cases, careful judgment was required. For example, an NDFRT relation states that Warfarin "may treat" Atrial Fibrillation. But Atrial Fibrillation is an Arrhythmia. Thus the "may treat" relation places Warfarin in the class of Antiarrhythmics. In our judgment, this was a false positive.

Categorization of medications is an important feature of commercial drug knowledge bases. Our experience with some of these products has been favorable. The advantage of the NDFRT is that it has been made freely available in the public domain and that it is part of the SPL system of drug product descriptions published by the pharmaceutical industry through the FDA. We believe there is future potential for decision support that uses a knowledge base maintained by these authoritative sources. An additional advantage of using our method to manipulate a medication terminology is the high degree of expressiveness allowing us to adjust the definition (especially the granularity) of a drug class provided the drugs are annotated with the NDFRT concepts at sufficient detail.

Conclusion

The manual process of creating and updating drug classifications could be automated by a strategy based on the NDFRT, with some human oversight. The level of detail and consistency of assignment of the NDFRT relationships should be improved to allow even more precise definition of classes. Knowledge engineers who write decision support rules could then be more specific about the drug classes they require for the purpose at hand.

An important improvement that our automated method still requires is the recognition of form and route. We believe that the most promising strategy to implement this may derive from the SPL indexing initiative, which will link detailed product descriptions with NDFRT role relationships.

Abstract

Methods for presentation of disease and health problem distribution in a health care environment rely among other things on the inherent structure of the controlled terminology used for coding. In the present study, this aspect is explored with a focus on ICD-10 and SNOMED CT. The distribution of 2,5 million diagnostic codes from primary health care in the Stockholm region is presented and analyzed through the "lenses" of ICD-10 and SNOMED CT. The patient encounters, originally coded with a reduced set of ICD-10 codes used in primary health care in Sweden, were mapped to SNOMED CT concepts through a mapping table. The method used for utilizing the richer structure of SNOMED CT as compared to ICD-10 is presented, together with examples of produced disease distributions. Implications of the proposed method for enriching a traditional classification such as ICD-10 through mappings to SNOMED CT are discussed.

Keywords:

Visualization, Disease distribution, Health problems, ICD-10, SNOMED CT, Terminology models

Introduction

Methods for visualization of disease distribution in a health care environment rely on the structure of the controlled terminology used for coding. In this study this is explored with a focus on the use of ICD-10 and SNOMED CT.

ICD-10 [1] is primarily intended for statistical reporting and administrative tasks such as disease monitoring and quality assurance. Although neither based on nor intended as a model of health problems, the ICD classifications are by far the most used terminology systems in electronic health records [2]. The grouping of diseases in the ICD classifications, and still reflected in ICD-10, is done based on categorization of health problems into epidemic diseases, constitutional or general diseases, local diseases arranged by site, developmental diseases and injuries [3].

While ICD-10 is mono-hierarchical, SNOMED CT is poly-hierarchical, allowing one concept to have multiple parents [4]. SNOMED CT is also more fine-granular as compared to ICD-10. The SNOMED CT hierarchy *Clinical findings* contain approximately 110,000 concepts as compared to 12,000 disease categories in ICD-10. SNOMED CT is a clinical terminology intended for clinical documentation and reporting [4], and could be used as the basis for coding and aggregation in Electronic Health Records (EHRs). However, there is still a need to explore the potential of SNOMED CT in EHRs and other clinical information systems.

Use of Electronic Health Records (EHRs) by general practitioners is almost universal in Sweden [5]. EHRs also support diagnostic coding, which is mandatory, and has made it possible to systematically collect information on health problems [6]. In Swedish primary health care practice there is a widespread tradition of using a primary care version of ICD-10 [7] with the Swedish abbreviation KSH97-P. Sweden, being a member of the IHTSDO-organization [8], is in the process of introducing SNOMED CT as a terminological resource in the health care sector.

The primary objective of this study was to explore the use of SNOMED CT as a mean to enrich visualization of disease distribution through mapping from KSH97-P to SNOMED CT. A second objective was to analyze the distribution of health problems from a large primary health care database and to describe and compare the results from using the KSH97-P/ICD-10 versus the SNOMED CT structure.

Materials and Methods

Diagnostic data

The diagnostic data used in this study were coded by primary care physicians and collected from Electronic Health Records (EHRs) in Stockholm County during 2006, in all approximately 2,5 million encounters. Diagnostic codes were reported in an average of 78% of the encounters. Up to 15 diagnostic codes were allowed for each care contact. 82% of all care contacts had one (1) code, 13% of all care contacts had two (2) codes, and 2% of the contacts had three or more diagnostic codes.

Coding systems

The Swedish National Board of Health and Welfare has worked out a primary health care version of ICD-10 with the Swedish abbreviation KSH97-P [7]. KSH97-P contains 972 categories which relate to diseases and health related problems

that are common in primary health care. KSH97-P has the same chapter division as ICD-10. The exceptions are that chapter XX, External causes of morbidity and mortality is left out from KSH97-P and chapter XXII, Codes for special purposes, is left out in both the Swedish version of ICD-10 and KSH97-P.

SNOMED CT is intended both for clinical documentation and reporting [4]. SNOMED CT consists of concepts, descriptions and relationships. Relationships link concepts to each other and relationships are of different relationship types. The generic relationship type "Is a" relates from subtypes to supertypes and is always defining relationships. All concepts, except for the root concept, have at least one "Is a" relation to a supertype concept. The other relationship types that are defining relationships are the defining attribute relationships. The defining relationships logically represent a concept by establishing relationships between the concepts.

Mapping between KSH97-P and SNOMED CT

We used a category mapping from KSH97-P to SNOMED CT that was based on a previous mapping reliability study [9]. Of the 972 categories in KSH97-P, 14 (1%) did not have a matched concept in SNOMED CT and 67 (7%) were mapped to more than one concept. We applied an additional mapping on an ICD-10 chapter level, described in another study [10]. Two ICD-10 chapters (Symptoms, signs, abnormal clinical and laboratory findings, not elsewhere classified (XVIII) and Factors influencing health status and contact with health services (XXI)) had no direct mapping match to SNOMED CT concepts.

Computational methods

We used the mapping results of categories and chapters to aggregate the diagnostic data through SNOMED CT "Is a" relationships to describe the data and make comparisons between ICD-10 and SNOMED CT on the chapter level. For each chapter we extracted the mapped chapter concept(s) together with the mapped concepts' "Is a" descendants. All diagnoses belonging to a category that were mapped to any of the extracted concepts were assumed to belong to the specific chapter. This implies that a specific category could belong to zero, one or more chapters.

To explore complementary ways of aggregating diagnoses, we used the category mapping. We carried out aggregations through the defining "Is a" relationships and defining attribute relationships. For each category the mapped concepts were extracted together with their ancestors (all supertypes) to a mapped set. All defining attribute relationships from concepts in the mapped set were then followed, and the target concepts were included in a specific attribute value set for each relationship type. In each attribute value set the concepts that were ancestors of another concept in the same attribute value set were removed. The remaining concepts in each attribute value set were assumed to be attribute values of the respective attribute types in the category.

The computational methods are performed in a relational database management system (PostgreSQL).

Results

A chapter level comparison of the diagnostic data between KSH97-P/ICD-10 and SNOMED CT is presented in Figure 1. The frequency distribution differs somewhat between ICD-10 and SNOMED CT due to the poly-hierarchical structure of SNOMED CT, allowing one ICD-10 category to be mapped to more than one SNOMED CT concept. This means that each category may belong to zero, one or more new chapter(s), which is shown in Table 1.

The use of "Is a" relationships in SNOMED CT aggregated the diagnostic data to 2861 concepts, showing a new, multidimensional view of different medical aspects, where every view can be further explored. A subset of such concept views is shown in Table 2, with a diagnosis percentage share cut-off at 10 %. Examples of new concept views below the 10 % cut-off are "Neurological finding" (8.0%), "Acute disease" (9.5%), "Pain/sensation finding" (6.6%), and Acute inflammatory disease (5.8 %). Aggregations into high-level concepts such as Clinical finding or Disorder by body site are not presented.

The attribute relationships in SNOMED CT can also be used for creating new views of the diagnostic data. Unlike the "Is a" relationship showing disorders concepts in Table 2, Table 3 could be used for further analysis of specific perspectives of e.g. causative agents, finding sites or associated morphologies for disorders and clinical findings.

Discussion

The results of this article show hidden information about health problems and diagnoses, coded with KSH97-P/ICD-10. The multiple views that are explored in this study illustrate the advantage of a poly-hierarchy. The multiple views of diagnostic data offer new possibilities for follow-up of specific aspects of the disease panorama. Clinically relevant views could also be used for navigation in order to support classification, thereby possibly improving coding validity and reliability.

The results presented rely on the soundness of the chapter and category mapping between KSH97-P and SNOMED CT which have been developed by the research group [9, 10]. Although rigorously developed, these mapping tables need to be further validated in an international research context. Another limitation is that the impact of possible quality errors in the diagnostic coding process that have been shown in previous studies is unknown [5, 6, 11, 12].

The results are also dependent on the soundness of the SNOMED CT concept model. Analysis and further refinement of the SNOMED CT model are beyond the scope of this study, but is obviously a topic for further research.

Ontology Based Modeling and Execution of Nursing Care Plans and Practice Guidelines

Muzammil Abdulrehman Din, Syed Sibte Raza Abidi, Borna Jafarpour

NICHE group, Faculty of Computer Science, Dalhousie University, Halifax, NS, Canada

Abstract

Nursing Care Plans (NCP) and Nursing Clinical Practice Guidelines (NCPG) promote evidence-based patient care, but in their paper form they are difficult to be applied at the point-of-care. We present our approach to generate patient-specific nursing care plans by modeling and computerizing these nursing knowledge resources. We present a Nursing CarePlan Ontology (NCO) that models the NCP and NCPG to realize an integrated knowledge base for designing and executing patient-specific nursing CarePlans. We adapted the METHONTOLOGY methodology for ontology engineering to develop our OWL-based NCO, and instantiated a set of NCP and NCPG. We have developed an execution engine that provides recommendations to nurses based on the patient's data. NCO was successfully evaluated for representational accuracy and completeness using a set of test NCP and NCPG.

Keywords:

Nursing care plan, Nursing clinical guidelines, Ontology, Care planning, Clinical decision support systems.

Introduction

Nurses represent the largest group of health care professionals that are directly involved in patient care in hospitals. The quality of care to hospital patients is strongly linked to the performance of nursing staff [1]. Hence, nurses need to be informed about evidence-based methods as well as being skillful in applying these methods, in a timely manner, to achieve the desired patient care outcomes [2].

Nurses organize the care process in terms of a Nursing Care Plan (NCP) that are concise, structured written 'plans of action' targeted at providing patient-specific care. A patient-specific NCP is designed guided by the disease diagnosis (performed by a physician) and a critical assessment of the patient care needs in terms of his/her condition—the resulting NCP comprises a summarized plan of action and tools to monitor the care activities undertaken by nurses and to record the patient's progress [3]. To execute the care activities stipulated in the NCP, nurses need to have knowledge of numerous medical procedures and how to interpret patient's physiological parameters. Nursing Clinical Practice Guidelines (NCPG) provide evidence-based instructions/recommendations about how to handle specific patient care issues related to nursing.

For quality patient care, we argue that a patient specific CarePlan [4] needs to be both customized to the patient's care needs and standardized in terms of best evidence. This means that to design a patient-specific CarePlan the following activities are needed: (a) the available NCP need to be customized as per the patient care requirements; and (b) the care activities within the customized CarePlan need to be supplemented with corresponding NCPG to ensure quality and standardization. Given the work pressures on nurses, the reality is that (i) the manual design, modification and maintenance of the patient's NCP is quite difficult, especially in response to the changing dynamics of the patient; (ii) the manual referencing of NCPG, which are not readily available, is not practical; and (iii) the execution of a paper-based care plan, in a timely and coordinated manner, is challenging. In this regard, we argue that to improve the quality and standardization of patient care there is a need to provide nurses with computerized nursing care planning and management systems to support their care roles.

In this paper, we present our research covering the computerization of NCP and NCPG in order to design and execute patient-specific nursing CarePlans. We take a semantic web approach, whereby we model the NCP and NCPG in terms of an OWL-based ontology. We modeled both the form and function of NCP and NCPG in terms of domain and workflow concepts, establishing semantic interrelationships between the concepts, and instantiating select NCP and NCPG using our Nursing CarePlan Ontology (NCO).

Nursing Care Planning: Concept & Solution

Individualized care has been described as ".. the management of care of the patient on the basis of his unique needs, the objective being maximum independence from the necessity of such care" [5]. This demands that the nursing care plan is customized to the specific needs of a patient and is able to dynamically adapt as the patient needs change. Although, nursing care is guided by the medical diagnoses, nurses work on the basis of a subsequent nursing diagnosis that deals with the nursing interventions required to treat the patient. At a conceptual level, the nursing care plans are categorized on the basis of the medical diagnosis and illustrate a set of care activities pertinent to the patient care for that specific disease (as shown in Figure 1). At the operational level, the patient-specific CarePlan is based on nursing diagnosis that determines a selection of care processes relevant to the patient—a single medical diagnosis can lead to multiple nursing diagnoses. Therefore, a patient' CarePlan transcends across multiple nursing care plans and is a composite of individual patient-specific tasks originating from multiple disease-specific nursing care plans.

Here, two patients with the same medical diagnosis can have different nursing care plans (shown in Figure 2).

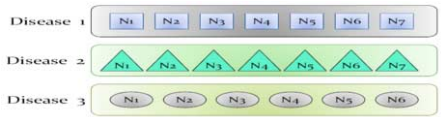

Figure 1–Nursing care plans for different medical diagnosis

Figure 2–Patient-specific CarePlan comprising tasks, in a particular order, selected from the disease-specific NCP based on the nursing diagnosis to handle co-morbidities.

To model NCP for the generation of CarePlans, we argue that it is important to work with modeling formalisms that allow the decomposition of larger concepts into constituent components, and then inter-relate the relevant components to realize a customized solution. Semantic web ontologies provide such a knowledge modeling formalism, whereas Task Network Models (TNM) organize knowledge components to realize a composite executable process workflow [6]. A number of existing formalisms to model clinical practice guidelines, such Asbru, EON, GLIF, PRO*forma,* and SAGE use ontologies and some form of TNM. Therefore, since NCP and NCPG outline complex actions, we plan to model them as ontological TNM as it will allow us semantic descriptions of concepts and reusability of the components to generate a range of CarePlans.

Modeling Nursing Care Process

In line with our modeling decisions of using ontologies and TNM, as the first step we developed a hierarchal representation scheme that takes into account the hierarchical knowledge and workflow classifications observed in NCP and NCPG. We examined NCP and NCPG to determine the different levels of care process classifications. We observed that the terms 'Procedure' and 'Activity' consistently appeared in NCP and NCPG. We used UMLS to disambiguate their meaning and functional purpose in the care process, and determined a three-level care process classification as follows: *Procedures* → *Activities* → *Tasks*. Each process can have *n* number of procedures (P_n), while a procedure itself can have *n* number of activities (A_n) and finally an activity can have *n* number of tasks (T_n) as shown in Figure 3. It may be noted that processes in the NCP/NCPG are typically recommendation/intervention. Thus, in our nursing care model, NCPG based Recommendations and NCP based Interventions are represented as procedures, activities, and tasks. A CarePlan is a composite of recommendations/interventions employing individually modeled procedures, activities and tasks in a patient-specific workflow.

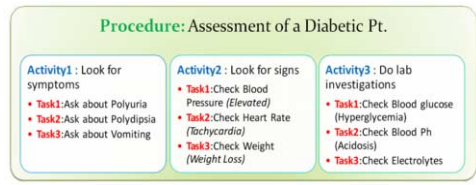

Figure 3 – Hierarchical decomposition of NCP and NCPG

Nursing CarePlan Ontology Engineering

To develop NCO we designed a three-stage methodology, an adaptation of METHONTOLOGY [7], as discussed below:

Stage 1 - Ontology Specification and Knowledge Identification: The first stage involved the specification of ontology parameters such as domain, purpose, scope, and identification of knowledge sources. A large set of NCP and NCPG were collected and used to design the NCO.

Stage 2 - Ontology Modeling: The second stage involved ontology conceptualization in which we abstracted concepts from a sample of NCP and NCPG, described concept hierarchies, defined relationships, and finally axioms. We then constructed our primitive Ontological model using Protégé-OWL. We used a cyclic inductive approach for concept abstraction, where in each cycle we refined our model based on concepts from the sample NCP and NCPG. Model refinement was concluded when we achieved a concept saturation point whereby no further modifications were required to the NCO to model additional concepts abstracted from new NCP/NCPG.

Stage 3 - Ontology Evaluation: The final stage involved evaluating our ontology in three steps. First, we evaluated our model for representational accuracy by encoding five randomly selected NCP and NCPG. Secondly, we evaluated our model with the guideline modeling dimensions described by Peleg [8]. Finally, we evaluated our ontology against the standard ontological design principles [9, 10]. The resultant NCO was found to be consistent and complete.

Ontological Representation of NCP and NCPG

To describe our NCO, class names are given small caps e.g. DISEASE, properties using italics e.g. *isFollowedBy*, while Individuals are written within quotes e.g. "Tuberculosis".

NCO depicts NCP (NURSINGCAREPLAN) and NCPGs (NURSINGCLINICALPRACTICEGUIDELINE) as a set of Interventions (NURSINGINTERVENTION) and Recommendations (NURSINGGUIDELINERECOMMENDATION) respectively, and in order to activate them, a predefined INCLUSIONCRITERIA has to be satisfied. The inclusion criteria can be a particular AGEGROUP, GENDER, SYMPTOM, SIGN, or a particular DIAGNOSIS. An EXCLUSIONCRITERIA can also be defined which excludes a NCP or NCPG from activation. The top-level recommendation/intervention is modeled as NURSINGGUIDELINERECOMMENDATION, and it has sub-classes PROCEDURE, ACTIVITY and TASK, where each has PRECONDITIONS and EXPECTEDOUTCOMES. This is modeled as NURSINGGUIDELINERECOMMENDATION *hasPrecondition*

PRECONDITION and *hasExpectedOutcome* EXPECTEDOUTCOME. To model sequences among procedures, activities and tasks we defined properties *isFollowedBy* and *isPreceededBy*. To describe the status of tasks we modeled four discrete Task States by defining a class STATE with individuals "Inactive", "Active", "Completed", and "Failure" (also shown in Figure 4). Next, we describe how we use NCO to model the workflow of NCPG.

Modeling Workflow of a NCPG

Outcomes play an important role in our model, as they not only define the result of a task but also link different tasks together. We modeled the interconnection between tasks by relating the EXPECTEDOUTCOMES of one or more tasks as PRECONDTIONS for other tasks (see Figure 4). In this regard, our model operates as a workflow, where states have binary outcomes such as 'Yes' or 'No' depending on their a priori desired outcomes. Depending upon the outcome of a task the workflow takes a specific path. The advantage of this approach is that it is intuitive to model using an ontology as this does not demand complex rules. Furthermore, the interlinking of tasks in this manner allows us to control the workflow for tasks that entail multiple choices and need the satisfaction of multiple constraints before proceeding to the next task.

Modeling NCPG Execution Criterion

The first step in executing the CarePlan is the satisfaction of the INCLUSIONCRITERIA of the NCP/NCPG—the said NCP/NCPG is considered active and our execution engine searches for the satisfied PRECONDITIONS of their component tasks. The component tasks are by default in an "Inactive" State even after the activation of the NCP or NCPG. Once the PRECONDITIONS for any task are satisfied the STATE of that task changes to "Active". In Figure 4, the lower left task is "Active" since its PRECONDITION has been satisfied (depicted by the yellow color). Activation of any task causes the execution engine to display that task to the user who then acts upon it. After executing the task, the user is presented with a list of EXPECTEDOUTCOMES for that particular task and can choose the one that reflects what actually happened. This user feedback is modeled as the ACTUALOUTCOME of that task. When the ACTUALOUTCOME entered by the user is one of the predefined EXPECTEDOUTCOMES, the state of the task changes to "Completed" (depicted by a blue color, First task in Figure 4). In Figure 4, for the first task there are only two EXPECTEDOUTCOMES defined, the number "1" or "2", the ACTUALOUTCOME in this case turned out to be the number "1" and this outcome had already been defined as a PRECONDITION of the next task and thus the following task is activated. The newly activated task then goes through the same steps as described for the preceding one to reach completion. In cases where the ACTUALOUTCOME is not any one of the predefined EXPECTEDOUTCOMES, the state of the task changes to "Failure" (depicted by a red color). Here we imply that the task did undergo completion but was deemed a "Failure" since the ACTUALOUTCOME was simply not what was intended and such an outcome is modeled as an UNEXPECTEDOUTCOME. An unexpected outcome could be because of an adverse event or reaction. We intend to use unexpected outcomes to gain insight into that particular clinical scenario. They are saved for variance analysis and provide feedback to the authors of the original NCP and NCPG.

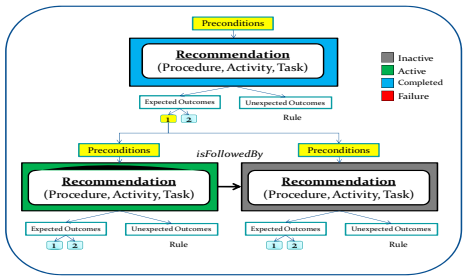

Figure 4 - The interrelationships between tasks and their states are shown using the color code

Modeling NCPG Execution Control Rules

To model the execution of a NCP we designed a set of ontology-based rules that work in tandem with the NCO. The rules are written using the Semantic Web Rule Language (SWRL). Below we give some rules in natural language.

Rules governing Preconditions

- A Recommendation/Intervention may or may not have PRECONDITIONS but their 'Expected Outcomes' should be defined whenever possible.
- IF two or more PRECONDITIONS are defined, THEN a 'Satisfaction Criteria' (All, Any One, Any Two, Major, Minor) has to be declared for activation.

Rules governing State Change

- Interventions are all initially in an 'Inactive' STATE.
- After activation, all TASKS will terminate with an outcome. This will be provided by the user by selecting from a list of predefined EXPECTEDOUTCOMES or manual input and will be declared as that Task's ACTUALOUTCOME.
- The "Inactive" state changes to "Active" only if Preconditions & satisfaction criteria are satisfied i.e. PRECONDITION (Expected Outcome of a Task) = ACTUALOUTCOME of any 'Completed' TASK and/or PRECONDITION = 'User Input'.
- IF the ACTUALOUTCOME of a TASK is equal to any of its EXPECTEDOUTCOMES THEN set STATE to "Completed".
- IF the ACTUALOUTCOME of a TASK is not equal to any of the predefined EXPECTEDOUTCOMES THEN set STATE of that TASK to "Failure". "Failure" implies that the task has completed but failed to achieve the expected outcome.
- IF EXPECTEDOUTCOMES have not been defined for a task THEN set the STATE to be "Completed".

Rules for competing Recommendations/Interventions

In situations where multiple interventions are available and only one intervention has to be selected but the selection criteria is not clearly defined, then interventions will be prioritized based on the number or type of satisfied preconditions—i.e.

by employing major and minor criteria. For example if three interventions are competing then the one with the most pre-conditions satisfied will be activated.

Rules governing 'Task Reuse'

- IF two different ACTIVITIES want to reuse the same task THEN the PRECONDITIONS and Sequence cannot be directly related to one TASK. The TASK should then have a PRECONDITION defined that belongs to the class SCENARIO.
- Individuals belonging to the subclasses of SCENARIO will serve to define uniquely the PRECONDITIONS and Sequence for that TASK for a particular scenario.

From NCO to Patient-Specific CarePlans

The modeling of NCP as a set of atomic procedures, activities and tasks, allows these constituent elements to be systematically selected and organized, as a task network, to design a patient-specific CarePlan. A CarePlan comprises a linked graph of procedures/activities/tasks from different NCP (as shown in Figure 5), where the individual properties of its components and its execution workflow (i.e. pre-conditions and outcomes) is determined based on the patient parameters.

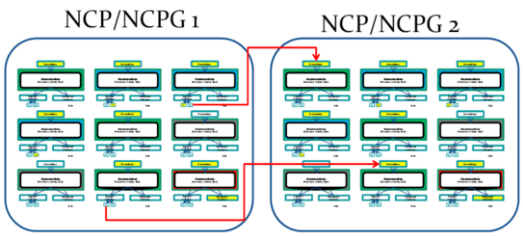

Figure 5 – A CarePlan comprising connected atomic components spanning multiple NCP/NCPG

NCO-Driven Execution Engine

The execution engine assists nurses in coordinating the care process as follows: (a) Recommending the sequence of care steps that need to be performed as per the NCPG; (b) Showing all the currently active steps; (c) allowing nurses to record the patient's parameters—note that a patient's condition determines the next steps; (d) allowing nurses to record the completion of a step by specifying its outcome or by specifying their decision; (e) the completion of previous steps and/or the availability of the observed outcomes triggers the recommendation of the next appropriate step. In this manner, the execution engine enacts the NCPG to guide nurses through the care process. At any stage, the execution engine can inform nurses the completed steps, past outcomes, the current active steps and their expected outcomes and the prospective next care steps.

Our execution engine executes NCP/NCPG, modeled using NCO, based on patient data and nurse input. The domain and execution concepts modeled in the NCO (described earlier) were extended as per the execution logic to achieve the desired outcomes, for instance the NCO describes four possible states of a task, however to control the execution as per the intended semantics of the NCP/NCPG we added three additional states. We use JENA reasoning API to access and manipulate RDF statements defined in the instantiated NCO.

Our execution strategy is to consider each NCPG step (Procedure, Activity or Task) as a Deterministic Finite State Machine (DFSM). The entire NCPG is therefore a directed graph of DFSMs. A DFSM is a quintuple (Σ,S,s_0,δ,F). Σ is the input (finite and non-empty), S is set of possible states, s_0 is the start state, δ is the state transition function: $\delta:S\times\Sigma\rightarrow S$ and F is the set of final states. Below is a brief description of the transitions needed for executing NCPG (shown in Figure 6a).

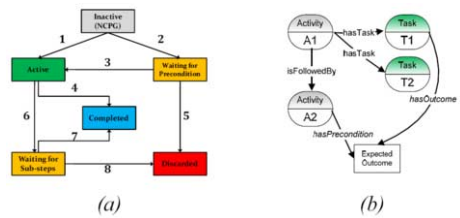

Figure 6 – (a) The DFSM assigned to each step, its states and possible state transitions (b) A small instantiated ontology

- **1** and **2:** An active step can activate its sub-steps and a completed step can activate the steps following it**.** For example when a *procedure* is executed, its first *activity* (or *task*) is added to the active list. If the step that is going to be added to active list is waiting for a precondition to be satisfied, it will go the "Waiting_for_Preconditions" state instead of "Active" state.
- **3:** If the precondition of a step is satisfied (either because of the outcome of other steps or user input) the task's state changes to "Active" state.
- **4:** If the step is a leaf in the hierarchy (it has no further sub-steps) and it is selected for execution, then subsequently it will be moved to "Completed" state.
- **5:** If all the steps that produce outcomes necessary for satisfaction of the preconditions of a task undergo completion and the precondition remains unsatisfied, the waiting step moves to "Discarded" state.
- **6:** If a non-task step (a procedure/activity) gets selected for execution, it will move to "Waiting_for_Sub-steps" state.
- **7** and **8:** If a step is waiting for completion of its sub-steps, then as they are completed it will be regarded a completed task. If any of its sub-steps were discarded instead of being completed, it will move to "Discarded" state as well.

To execute a NCPG we first build its RDF graph, where nodes are instances of classes and edges are the properties of the NCPG. This RDF graph captures the information flow between DFSMs as per the NCPG workflow. During execution, the Σ for each DFSM (step) is the state and the expected outcome of other incoming steps. For instance, in Fig 6b the Σ for A2 is the state of A1 and expected outcome of T1 and Σ for

A1 is the states of T1 and T2. In figure 6b, we show a segment of a NCPG with multiple steps and explain an execution scenario through DFSM. Suppose that the states of the steps are A1 (Waiting_for_sub-steps), A2 (Inactive), T1 (Completed) and T2 (Active). Now, when the engine executes T2, its DFSM will move to "Completed" state. This state transition will cause A1 to change its state from "Waiting_for_sub-steps" to "Complete". State change of A1 will trigger DFSM of A2 to change its state from "Inactive" to "Active". In this manner, execution proceeds till all DFSMs reach their stable state and no further state transition is possible. Our execution engine is able to handle multiple active steps, whereby we have implemented a timesharing breadth first search strategy that allows all active tasks to progress in parallel.

Evaluation Results

We evaluated our ontological model in three phases. We first tested our model for representational accuracy by encoding a sample of test guidelines and care plans and documenting any instantiation problems. Secondly, we tested our model against the guideline modeling dimensions described by Peleg et al [8]. Finally, we tested our ontology against the standard ontological design principles [9, 10].In terms of representational accuracy, NCO was found to miss knowledge about various drug doses and titrations. We plan to link NCO with a drug ontology to address this issue. Otherwise, NCO successfully represented the concepts found within the test NCP and NCPG. We evaluated NCO using the 8 CPG representational dimensions, proposed by Peleg et al [8], that cover structural and linkage aspects of a CPG model. We instantiated the original test guidelines used by Peleg et al using our NCO, and observed that NCO was able to aptly represent these guidelines. Finally to assess compliance with the design principles mentioned by Gomez-Perez [9] we manually went through the class hierarchy, properties and individuals in NCO. Additionally, we checked NCO to be compliant with the ontological principles described by Bodenreider for the medical domain [10]. Hence, NCO was deemed to be fully compliant with these principles.

Conclusion

We have encoded 6 NCPG using the NCO and they are now available for execution through our execution engine.

The computerization of NCP and NCPG is the first step towards their incorporation in the care process and their availability at the point of care. We presented an ontology-based modeling and execution framework for the computerization of NCP and NCPG, leading to the generation of patient-specific CarePlans. The key feature of our approach is that we were able to decompose large monolithic NCPG and NCP into small-scale, independent atomic components that can subsequently be used (and re-used) to design patient-specific CarePlans that cover clinical workflow, nursing knowledge and care coordination. The linkages between the care processes given within NCP with corresponding evidence within NCPG provides an integrated care environment where knowledge is impacting the care process—such linkages are desired by nurses but are neither practical in a paper-based setting nor implemented in current nursing systems. At the execution level, we have demonstrated the execution of complex NCP/NCPG through a rather simple graph traversal approach that is supported by lightweight SWRL rule based reasoning. At the next stage, we will be building data transfer interfaces to both collect and store data from the patient's EMR. Here we are planning a semantic web services based architecture built using HL-7 standards—the use of a OWL-S service ontology will allow for improved data interoperability between different care services. Although, our execution engine is capable of handling concurrently active care processes (i.e. execute processes in parallel), we lack the ability to reason with time and duration. Our future plan is to incorporate the OWL-Time ontology, developed by W3C, to handle the temporal aspects of NCP/NCPG execution.

Abstract

The purpose of this study is to evaluate the ability of SNOMED CT to represent concepts of the ICNP Version 1 – the 7-Axis model. We selected the 1568 concepts of the ICNP 7-Axis model. From January 2007 through June 2007, the first author mapped the ICNP Version 1 concepts to the SNOMED CT using CLUE browser 5.0. The second author from the SNOMED Terminology Solutions and the third author from the ICN validated mapping result. In total, SNOMED CT covered 1381 concepts of 1658 (83%) ICNP 7-Axis model concepts ranging from 65% coverage rate of the Actions Axis concepts to 94% coverage rate of the Judgment Axis concepts. SNOMED CT can represent most (83%) of the ICNP Version 1 concepts. Improvements in ICNP Version 1 in terms of concept naming and definition, and adding missing concepts to the SNOMED CT would lead to greater coverage of the ICNP Version 1 concepts.

Keywords:

Clinical terminology, ICNP, SNOMED, Coverage

Introduction

Standardization in the field of health information becomes important as computer-based information system and electronic health record are being introduced rapidly in health care facilities around the world. A variety of standard development activities are happening in the International Standard Development Organizations such as ISO, HL 7 and CEN. Standardized health care terminologies and classifications are the most important standard for data quality, data sharing and exchanging and decision support [1].

Unfortunately, most of application packages and institution-based systems have its own terminologies, resulting in overlooked synonymy and semantic collisions among concepts, which in turn producing non-interoperable data. Furthermore, most of countries have designated more than one health care terminology and classification standards for institution-based and interoperable medical records instead of recommending one single terminology and classification. For example, the United States, United Kingdom, Canada and Australia recognize more than one health care terminology and classification [2]. Thus, critical challenges are to link terminologies and classification used in the existing clinical information systems to standardized terminologies and classifications for data sharing and exchange. One solution for this problem is to map different terminologies to a broader health care terminology such as SNOMED CT (Systematized Nomenclature of Medicine – Clinical Terms) before storing data in database.

SNOMED CT is the most widely used health care terminology in EHR because it is richer, more granular expression, more familiar to clinicians, hierarchical, and group-able and susceptible to concatenation, which are ideal qualities for decision support analysis and population-based clinical and public health intervention [3]. ICNP (International Classification for Nursing Practice) is the most widely used nursing terminology in electronic nursing record because it allows communicating and comparing nursing data across settings, countries and languages [4].

The SNOMED CT is a systematically organized computer processable collection of health care terminology covering diseases, clinical findings, and procedures. It is designed to capture granular detail and provides common language for clinical data to be indexed, stored, retrieved, and aggregated across specialties and sites of care. Clinical expressiveness of SNOMED CT supports clinical care and drives decision support technology. It is designed for use in electronic medical records, reducing the variability in the way data is captured, encoded and used for clinical care of patients and research.

The SNOMED-CT is a reference terminology that provides a means of integrating healthcare classification and terminologies from different healthcare disciplines. Many healthcare classifications have been mapped into SNOMED-CT such as ICD -9-CM Epidemiological/Statistical Mapping, ICD-O3, ICD-10 (UK edition), OPCS-4 (UK edition), NIC, NOC, NANDA, PNDS, Clinical Care Classification, and The Omaha System.

The ICNP® is a unified nursing language system. It is a compositional terminology for nursing practice that facilitates the development of and the cross-mapping among local terms and existing terminologies. The ICNP Version 1 is comprised of 7 different axes, Focus, Judgment, Means, Action, Time, Location and Client [5].

The ICNP Version 1 is used to represent nursing diagnoses (client status, problems, needs, and strengths), nursing interventions (or nursing actions), and nursing outcomes. The 7-Axis model is intended to facilitate the composition of nursing diagnoses, interventions and outcomes statements. These statements can be organized into meaningful sets for nursing practice, which is called ICNP catalogues [6].

In order to support interoperability of nursing concept with other health care concepts, it is important to have a collaborative effort to come up with principles, processes and strategies to integrate, map and/or model nursing concepts within wider healthcare related concepts. As a part of this described collaborative effort, we would like to propose draft principles, processes and strategies that would be necessary to integrate, map and/or model ICNP Version 1 concepts within SNOMED CT, a copyrighted work of the International Health Terminology Standards Development Organization (IHTSDO). For the purpose of this project, concepts from the ICNP 7-Axis model, will be examined in the context of their potential for addition to a broad healthcare based terminology, SNOMED CT. This process hopes to contribute valuable feedback to the ICN (International Council of Nurses) regarding refining the definitions and hierarchies of ICNP Version 1 concepts. The study also hopes to inform the IHTSDO about the benefits of providing ICNP content to the participating member organizations.

Materials and Methods

We selected the 1658 concepts from the ICNP 7-Axis Model. The first author mapped the ICNP Version 1 concepts with the concepts of the SNOMED CT using Apelon's TermWorks and CLUE browser 5.0.

The first phase of matching is the linguistic matching of concepts based on concept label. Label matching involves putting the label into a canonical form by stemming and tokenization; comparing equality of labels; and matching sub-strings [7]. Concept names with suffix such as verb variation (ex, assessing vs assessment vs assesses) and singular versus plural (medication vs medications), use of preposition (ex, monitoring vs monitoring for,), American English versus British English (ex, diarrhea vs diarrhoea), compound word with or without space (well being vs wellbeing), and compound word with or without hyphen (ex, self toileting vs self-toileting) were treated as linguistically identical. Apelon's TermWorks was used for this phase.

If a concept in ICNP Version 1 matches linguistically with a concept in SNOMED, The next phase is the structural matching of concepts based on the similarities of their context or vicinities in the hierarchy of concepts. In structural matching, parents, sibling and children concepts were examined. If a concept in ICNP Version 1 matches with a concept in SNOMED linguistically and structurally, then it is classified as mapped. CLUE browser 5.0 with SNOMED CT 2007 July release was used for this phase.

If a concept in ICNP Version 1 does not match linguistically or structurally with a concept in SNOMED, next phase is the semantic matching of concepts. Semantic matching is an approach where semantic relations are examined between concepts (not between labels) based on textual definition or usage in nursing practice and hierarchical relationship of the concept with other concepts [8, 9]. For semantic matching, we traced back to the original source of the ICNP Version 1 concepts, examined the display name of the concept in the source language and then tried to map the display name to SNOMED CT concept. Possible semantic relations are equivalence, more general, less general, mismatch, and overlapping. Again CLUE browser with SNOMED CT 2007 July release was used for this phase.

For our study, mapping results were classified as following. If an ICNP Version 1 concept is matched linguistically and structurally to a SNOMED CT concept, it is classified as lexically mapped. If an ICNP Version 1 concept matched semantically to a SNOMED CT concept, it is classified as semantically mapped. If an ICNP Version 1 concept matched to a more general SNOMED CT concept, it is classified as mapped to broader concept. If an ICNP Version 1 concept matched to a less general SNOMED CT concept, it is classified as mapped to narrower concept. If a concept is a compound concept or has text definition describing more than one concept we mapped to more than one concept of SNOMED CT (ex, 'Craving' mapped to 'Craving for food or drink' and 'Craving for drugs'). In this case, we classified as one-to-many mapped. However, we tried not to map to either a broader or a narrower concept as much as possible. Otherwise, it is classified as not mapped.

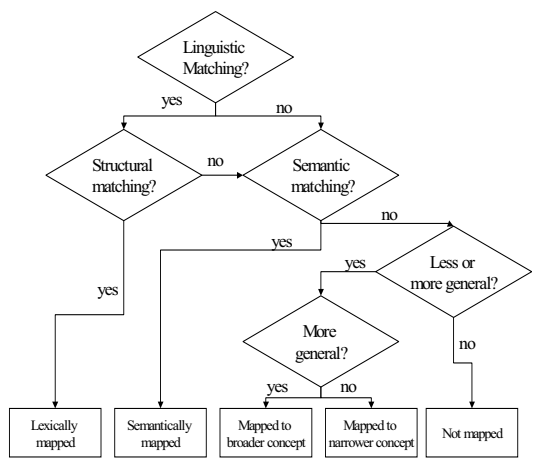

Figure 1- Mapping process of ICNP Version 1 concepts to SNOMED CT concepts

The mapping was validated by a team of SNOMED and ICNP experts including the second and third authors by more than fifteen 1-2 hour web conferencing such as GoToMeetings and four two day face-to-face meetings. If there was any disagreement during validation process, we convened another meeting to reach a consensus.

During mapping, we used the text definition of ICNP concept as our first mapping criteria. If an ICNP concept does not have a working definition, we tried to find where the term came from and how it is being used in nursing practice. If we could not find how it is being used in nursing practice, we did not attempt to map the concept. If possible, we tried not to map to either a broader or a narrower concept.

Results

Concepts in the Focus, Mean, Time, and Location Axis were mapped to more than one SNOMED CT hierarchies. Concepts in the Focus Axis were mapped to Clinical findings, Observable entity, Body structure, Environment, Event, substance, Organism, Physical force, Specimen, and Qualifier value hierarchies. Concepts in the Mean Axis were mapped to Physical object, Procedures including Regime/Therapy, Social context - occupation, Substance, Product, Staging and scales including Assessment Scales, and Qualifier value hierarchies. Concepts in the Time Axis were mapped to concepts in the Qualifier value and Event hierarchies of the SNOMED CT. Concepts in the Location Axis were mapped to concepts in the Body structure including Morphological abnormality, Environment, Qualifier value, Findings, and Physical object hierarchies of the SNOMED CT. Concepts in the Judgment, Action and Client Axis were mapped to one hierarchy of the SNOMED CT, the Judgment Axis to Qualifier Value hierarchy, the Action Axis to the Procedure hierarchy, and Client Axis to the Social context hierarchy of the SNOMED CT.

Table 1 shows the mapping result. In total, 1381 out of 1658 concepts were mapped. (83%). Mapping rates range from Axis to Axis. While most of concepts in the Judgment and Location Axis were mapped to concepts of the SNOMED CT (94%), the Action Axis has the lowest mapping rate (66%).

Table 1-Mapping results of ICNP concepts to SNOMED CT concepts

Mapping Result		Focus	Action	Means	Time	Judg-ment	Loca-tion	Client
Mapped	LM	345	20	122	22	15	153	18
	SM	304	111	115	21	17	68	1
	BT	20	2	5				
	NT	10	7					
	1:n Map	2	1				3	
Not Mapped	add new con-cept	122	3	18	18	1	8	8
	No usage	13	70	9		1	6	
Total		816	214	269	60	34	238	27

In detail, Focus concepts describing disease, disorders, signs and symptoms were mapped concepts in the Finding hierarchy of SNOMED CT. 'Community leadership', 'management', 'participation', 'law', 'committee, and policy' were mapped to Community Resource findings of the Finding hierarchy.

Focus concepts with neutral connotation such as Process, Function, Status and Pattern related concepts were mapped to concepts in the Observable entity hierarchy of SNOMED CT. 'Process' concepts of the ICNP Version 1 were mapped to Function concepts of the Observable entity hierarchy of SNOMED CT, because they are describing body function (ex, cardiac process). 'Status' concepts of the ICNP Version 1 were mapped to concepts in the Observable entity of SNOMED CT (ex, respiratory status). 'Pattern' concepts of the ICNP Version 1 were mapped to concepts in the Observable entity hierarchy (ex, eating pattern).

System concepts of the Focus Axis were mapped to concepts in the Body structure hierarchy of SNOMED CT (ex, cardiovascular system). Morphological abnormalities without any judgment or body sites were mapped to concepts in the Morphologic abnormality of SNOMED CT, which is part of Body structure (ex, ulcer).

Focus concepts describing pressure, radiation, light, and weather were mapped to concepts in the Physical force hierarchy of SNOMED CT. Focus concepts describing abuse, suicide, and environmental events such as flood, earthquake, and wind were mapped to concepts in the Event hierarchy of SNOMED CT. Focus concepts describing agricultural development, industrial development, residential development, recreational development, infrastructure, food supply, and foul odor were mapped to concept in the Environment hierarchy of SNOMED CT.

Focus concepts describing Body secretion, gastric contents, body fluid, and body material were mapped to concepts in the Substance hierarchy of SNOMED CT. Concepts describing animal, microorganism, and plant were mapped to concepts of the Organism hierarchy of SNOMED CT. Specimen concept was mapped to hierarchy of the Specimen of SNOMED CT. Social status concepts of the Focus Axis were mapped to Social context hierarchy of SNOMED CT. Focus concepts describing Services (ex, funeral service), rate and ratio were mapped to concepts in the Qualifier value hierarchy of SNOMED CT.

All of concepts in the Judgment Axis except 'Positive or negative judgment' and 'Potential for enhancement' were mapped to concepts in the Qualifier value hierarchy of the SNOMED CT. 'Positive or negative judgment' is a compound concept used as a grouper in the Judgment Axis. We did not map this concept to SNOMED CT. 'Potential for enhancement' can be modeled as a child concept of 'Finding context value' of the Qualifier value hierarchy of SNOMED CT.

Means Axis of the ICNP consisted of artifact, care provider, health service, material, technique and therapy. Artifact concepts were mapped to Physical object and Qualifier value hierarchies, care provider concepts to Social context hierarchy, health service concepts to Qualifier value hierarchy, material concepts to Substance and Product hierarchies, and technique and therapy concepts to Procedure hierarchy of the SNOMED

CT. We did not map compound concept in the Mean Axis used as a grouper to organize concepts. Examples of compound concepts are 'Absorbing or Collecting Device.' 'Meal' concept was not mapped to SNOMED CT because it has IS-A relationship problem with its parent concept, 'Nutrient.' There are synonymous concepts in the Means Axis. For example, 'Hemostasis technique' and 'Hemostasis technique for patient' are synonymous.

The Action Axis has the lowest mapping rate because concepts in the Action Axis are mainly gerund form of verbs used to as a building block to populate nursing intervention catalogue concepts rather than actual nursing intervention or nursing activity (ex, facilitating, promoting, and collaborating). These verb concepts are very ambiguous and can be used only when they are combined with concepts from other axis. There are over 200 verbs in the Action Axis. Some of these verbs are very difficult to distinguish from one another. One example is 'Teaching', 'Educating', and 'Instructing'. Another example is 'Describing', 'Documenting', and 'Recording'. On the contrary, there are very specific concepts in the Action Axis which has more detailed granularity than the other verbs. Examples are 'Alcohol life style prevention', 'Contamination prevention', 'Fall prevention', 'Safety measure', and 'Anticipatory guidance.' These concepts can be moved to the ICNP nursing intervention catalogues. There are compound verb concepts with unnecessary word 'act' attached (ex, 'Setting up act', and 'Giving act'). For these concepts removing the word 'act' would not change the meaning of the concepts.

Concepts in the Time Axis were mapped to concepts of the Qualifier value and Event hierarchies of SNOMED CT. 'Birth', 'Death', 'Fall', and 'Rite of passage' were mapped to concepts of the Event hierarchy of SNOMED CT. Most of the Time Axis concepts were mapped to the Qualifier value hierarchy. However, for the Time concepts not mapped to SNOMED CT such as 'Always', 'Never', 'Future', 'Today', 'Tomorrow', 'Yesterday', 'Toddler period', 'Pre school childhood', 'School childhood', 'Duration of operation', 'Examination', 'Delivery' and 'Menarche' can be added to the Qualifier value hierarchy of the SNOMED CT. There are synonymous concepts in the Time Axis. For example, 'Neonatal period' and 'New born period' of ICNP are synonymous and mapped to 'Neonatal (qualifier)' of SNOMED CT.

Concepts in the Location Axis were consisted of construction, position and structure related concepts. Construction related concepts were mapped to the Environment hierarchy of SNOMED CT. Position related concepts were mapped to the Qualifier Value and the Findings hierarchies of SNOMED CT. Structure related concepts were mapped to the Body structure including Morphological abnormality, the Qualifier value and the Physical object hierarchy of SNOMED CT. Concepts not mapped to SNOMED CT includes grouper such as 'Body opening', 'Structure', 'Social structure', and 'Diagnostic department'. Also, there is a problem of hierarchical relationship among 'Parenteral route', 'Intravenous, Intramuscular', and 'Subcutaneous route' of ICNP Version 1. These four concepts were treated as siblings even though 'Parenteral route' and three other routes should have a IS-A relationship.

Concepts in the Client Axis consisted of fetus, group and individual. All the concepts except 'Fetus', 'Couple', 'Nuclear family', 'Extended family', 'Single parent family', 'Female headed single parent family', 'Adolescent community', 'Family caregiver' were mapped to concepts of the Social context hierarchy of SNOMED CT.

Discussion

Mapping ICNP Version 1 concept to SNOMED CT was a very challenging task because two terminologies covers different domains and areas of focus, and have different structures. SNOMED CT is a very broader healthcare terminology covering nursing as well, however ICNP is a nursing terminology. ICNP is consisted of 7-Axis (Focus, Judgment, Means, Action, Location, Time and Client) to represent nursing diagnoses, nursing interventions and nursing outcomes and SNOMED CT is consisted of 19 hierarchies to represent diagnosis, procedures, anatomy, chief complaints, vital signs, physical findings, plans, problem list, history, allergies, immunization and medication management.

Also, the two terminologies have different areas of focus. ICNP covers not only critical care nursing but also community health nursing; however SNOMED CT focuses more on critical care. Also, a concept with same label has different meaning in the two different terminologies. For example, 'depression' in medical domain means 'depressive disorder', however 'depression' in nursing means 'sadness'.

Mapping was also very challenging because it was hard to understand different hierarchies of SNOMED CT. Same concept label was found in different hierarchies. Especially it was hard to distinguish the Finding hierarchy from the Observable entity hierarchy when mapping concepts of ICNP Focus Axis and the Procedure hierarchy from the Qualifier value hierarchy when mapping Service related concepts.

The ICNP concepts were mapped to SNOMED CT concepts based on the definition and/or location of the concept in the hierarchy. Descriptive definitions of ICNP concept was very helpful when mapping to SNOMED CT, however, there are quite a few concepts without text definition (ex, environmental process), with ambiguous definition (ex, obstruction) or more than one definitions (ex, informal settlement). The definitions need to be clarified or new definitions needs to be added.

There was hierarchy problem between parent and child concepts. For example, Integrity was a concept describing a trait of person; however a child concept of Integrity, Skin integrity is a concept describing physical aspect of skin. There are concepts misplaced in wrong Axis. For example, pregnancy prevention, and pregnancy promotion are in the Focus Axis. These concepts should be in the nursing intervention catalogue. Also, there are catalogue concepts in the 7-Axis model. Examples are Alcohol life style prevention, Contamination prevention, and Fall prevention in the Action Axis. They should be in the nursing intervention catalogues.

During the mapping process, we found that SNOMED CT lacks concept describing community health such as health ser-

vices, health policy, community resources, population statistics (e.g., mortality rate, incidence rate, immunization rate, infant death rate, unemployment rate); industrial health, value belief and psychological finding. This can be explained by the history and scope of the two terminologies. ICNP was developed to describe not only acute care setting, but also the community health; however focus of the SNOMED CT has been the acute care setting.

We also found that ICNP concept can be mapped to more than one SNOMED CT concept from different hierarchies. For example, 'specimen' can be mapped to concept in the Substance hierarchy and the Specimen hierarchy. 'Social Status' concept with home ownership, income and social isolation as children concepts can be mapped to concepts of the Observable entity hierarchy and the Social context hierarchy. Concepts describing Services can be mapped to the Regime/Therapy hierarchy and the Qualifier value hierarchy of the SNOMED CT. This is due to the fact that ICNP Version 1 – the 7-Axis model is a building block that can be used to generate nursing diagnosis, nursing interventions and nursing outcomes statements. Thus, a concept can be very ambiguous and not be used before it combines with concepts from other axis.

There are many synonyms in the ICNP Version 1 concepts (ex, 'rash' and 'exanthema'; 'autonomic dysreflexia' and 'dysreflexia'; 'care plan' and 'critical pathway', 'guideline' and 'protocol'). There are concepts hard to distinguish even though their concepts labels are different (ex, 'Tissue perfusion' vs 'Tissue perfusion status', 'teaching' vs 'educating' vs 'instructing'; 'dressing' vs 'getting dressed or undressed' vs 'putting on clothes vs taking off clothes)

There are compound concept which used as a grouper, these concept need to be renamed or divide into two different concepts. Examples are Positive or Negative Judgment from the Judgment Axis, Self dressing or undressing from the Focus Axis, Absorbing or collecting device from the Means Axis, and Heating cooling device from the Means Axis.

When mapping ICNP to SNOMED CT, sometimes parent and child concepts were mapped to different hierarchies of SNOMED CT. For example, 'weight' of the Focus Axis was mapped to Weight in the Observable entity hierarchy; however 'overweight' which is a child concept of 'weight' was mapped to 'overweight' in the Finding hierarchy.

When a concept is not mapped to SNOMED CT concepts and is being used in nursing practice, we either can model the concept in the SNOMED CT or post-coordinated the concept by combining existing SNOMED CT concepts. Examples are pain related concepts such as arthritis pain, cancer pain, and ischemic pain. They can be added under 'Pain (finding)' or they can be post-coordinated by combining 'Pain' in the Finding hierarchy and other concept from other hierarchy. SNOMED CT has atomic concept as well as pre-coordinated concept. Thus, it is hard to decide to add a new concept or post-coordinated a concept by combining two concepts. However, for the concepts from ICNP Version 1 concepts, we have decided to model the concept in the SNOMED CT rather than post-coordinate the concept. We recommended unambiguous fully specified name of the concept and location within the hierarchy to model the concept.

Facilitating Secondary Use of Medical Data by Using *open*EHR Archetypes

Abstract

Clinical trials are of high importance for medical progress. But even though more and more clinical data is available in electronic patient records (EPRs) and more and more electronic data capture (EDC) systems are used in trials, there is still a gap which makes EPR / EDC interoperability difficult and hampers secondary use of medical routine data. The openEHR architecture for Electronic Health Records is based on a two level modeling approach which makes use of 'archetypes'. We want to analyze whether archetypes can help to bridge this gap by building an integrated EPR / EDC system based on openEHR archetypes. We used the 'openEHR Reference Framework and Application' (Opereffa) and existing archetypes for medical data. Furthermore, we developed dedicated archetypes to document study meta data. We developed a first prototype implementation of an archetype based integrated EPR / EDC system. Next steps will be the evaluation of an extended prototype in a real clinical trial scenario. Opereffa was a good starting point for our work. OpenEHR archetypes proved useful for secondary use of health data.

Keywords:

Computerized medical record systems, Clinical trials, Interoperability, Multiple use of data, Single source, *open*EHR archetypes.

Introduction

Clinical trials are the major element in clinical research and of high importance for medical progress. By now, more and more clinical data is available in electronic patient records (EPRs). Similarly, there is a trend to collect data in clinical trials by using electronic data capture (EDC) systems. Numerous efforts in research and industry have led to improvements of EPR and EDC systems in the past years. However, there is still a gap which hampers a straightforward data exchange between EPR and EDC systems and which makes it difficult to use routinely collected medical data in clinical research [1-3] – especially in multicenter studies [4].

The lacking interoperability between EPR and EDC systems not only hampers translational biomedical research but also results in the necessity to manually enter data for a clinical trial in an EDC system which is already available electronically in an EPR: A time-consuming task which beyond that may also cause transcription errors [5].

Another obstacle for EPR / EDC interoperability is that standards for electronic data exchange in clinical care (for instance Health Level 7 version 2) and in clinical research (for example standards of the Clinical Data Interchange Standards Consortium – CDISC) are still quite different [2-4].

Facilitating EPR / EDC system interoperability would not only help clinical research by saving time and money and avoiding transcription errors but also support translational research by reusing clinical care data for medical research and vice versa. Therefore, different efforts have been made in the last years to bridge this gap and there are some examples of successful approaches (for instance [5]). These approaches often integrate a particular EPR system with a particular EDC system (for example [6]). Even though this is a good starting point, many times multicenter trials involve trial centers which have different EPR systems in place.

Bridging the gap with *open*EHR

The *open*EHR architecture for Electronic Health Records (EHRs) is based on a two level modeling approach which makes use of 'archetypes' [7, 8]. Archetypes "... are reusable, structured models of clinical information concepts that appear in EHR, such as 'test result', 'physical examination' and 'medication order'..." [9]. We think that archetypes could not only facilitate the documentation of medical data and interoperability between different EPR and EDC systems but also support data recording in clinical trials and help to integrate study data management systems [10].

The overall aim of our study is to explore how a system for recording data in clinical trials can be built based on the *open*EHR approach so that it is able to reuse the data of an EPR system. We further want to investigate whether such an archetype-based approach enables smooth integration of existing medical data at different sites.

Therefore, we built the **open S**tudy **D**ata **M**anagement **S**ystem (openSDMS). OpenSDMS is a prototypical system based on

*open*EHR concepts which allows not only recording of medical routine data but also electronic data capture for clinical trials. OpenSDMS facilitates both entering medical data for clinical trials manually and also (in a 'single source approach') reusing medical routine data which were previously stored in the EPR module. Furthermore, the system shall be able to integrate data of different (also non-*open*EHR) EPR systems for one trial. This paper describes our concept and first experiences with implementing the openSDMS.

Materials and Methods

Opereffa

As a basis for openSDMS we use the '***open*EHR REF**erence **F**ramework and **A**pplication' (Opereffa – http://opereffa.chime.ucl.ac.uk) which is developed at the University College London. Opereffa is a web based application which uses Java Server Faces as web layer technology. In addition, the Dojo Toolkit is used to provide Asynchronous JavaScript and XML (AJaX) and extended user interface capabilities. To physically store data Opereffa uses Hibernate with an underlying PostgreSQL database as persistence layer. In an entity-attribute-value (EAV) model approach all archetype nodes are saved as attribute/value pairs in a single generic table [11]. That means the system uses only one table to store all medical data. Every row of this table contains one data element recorded for a certain patient at a certain time. Expressed in simplified terms, one dataset respectively one row consists of the following elements: Patient id (identifying a certain patient), session id (identifying a certain documentation context), archetype name, archetype path (together with archetype name unambiguously identifying one data element) and the actual value of the data element.

Opereffa itself makes use of the *open*EHR Java Reference Implementation [12].

Archetypes for clinical trials

As we wanted to document not only medical data which has been recorded for a clinical trial but also the structure and a description of the trial itself, we started to assemble meta data which describe typical concepts of clinical trials. We identified these data elements in a systematic review of the feature categories which are recorded in the German Clinical Trials Register (German CTR – http://www.germanctr.de) respectively in the International Clinical Trials Registry Platform of the WHO (ICTRP – http://www.who.int/ictrp/en/). Additionally we evaluated feature categories which are used in the Coordination Center for Clinical Trials Heidelberg (http://www.kks-hd.de) to register information about the trials conducted or supported by the coordination center. This list of feature categories was developed in an iterative process involving its end users.

In a next step, we defined archetypes for the study meta data in addition to existing archetypes for medical data. For this, we designed a model of concepts based on the previously assembled meta data which are necessary to describe the structure and nature of a clinical trial. The model is described in detail in the results section (Figure 1).

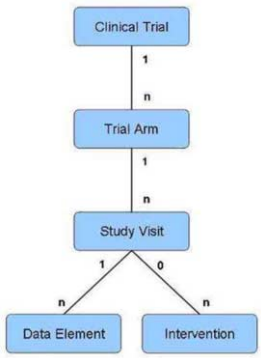

Figure 1 - Generic trial structure

Even though, these concepts are not directly related to clinical data but to clinical trials at a meta level, we used the *open*EHR Clinical Knowledge Manager (http://www.openehr.org/knowledge/) to check whether corresponding archetypes were already available or not. We used 'clinical trial', 'clinical study', 'trial', and 'study' as search terms. As suitable archetypes were not available, we started to define new archetypes using the 'Ocean Archetype Editor'. We created one archetype per concept of our model. Each of these archetypes defines the data elements which are necessary to describe an instance of the underlying concept.

openSDMS

In a next step, we built the openSDMS by extending Opereffa according to our requirements. For this, we added a 'trial view' to the user interface of Opereffa and implemented the underlying program logic. There, we took advantage of existing Opereffa code and used our newly defined archetypes.

Results

Archetypes for clinical trials

Based on our model of concepts for describing the structure and nature of clinical trials (Figure 1) we defined the archetypes 'clinical trial', 'trial arm', and 'study visit' which allow describing clinical trials by recording the particular meta data. For instance, the archetype 'clinical trial' defines 47 data elements like 'trial name' or 'phase' (Figure 2).

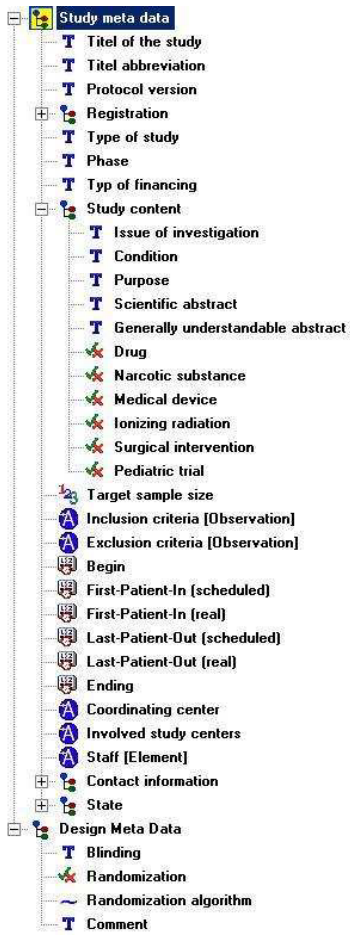

Figure 2 - Definition of the archetype 'clinical trial'

The concept 'clinical trial' is the root element of our model. One trial consists of at least one 'trial arm'. One trial arm consists of at least one 'study visit'. Within one visit at least one data item is captured or one intervention (medication, surgery...) is undertaken and recorded. While an observational study typically consists of one arm maybe with only one visit, a controlled trial consists of at least two arms.

Using the archetypes which reflect our model enables easy storage of data which describe a clinical trial in a system based on archetypes. It thus becomes possible to collect and store medical data and to assign these data to a certain trial arm, for example.

openSDMS

Our overall aim was to build a prototypical system based on *open*EHR concepts which allows electronic data capture for clinical trials not only by entering the data manually but also by reusing data which were previously stored in an EPR module in a single source approach. With openSDMS we now have a prototype for such a system. OpenSDMS is completely based on archetypes which means, that almost all data processing and storage within the system is based on archetypes.

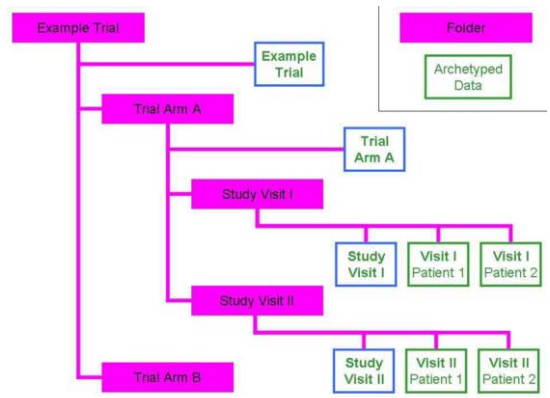

Figure 3 - Folder structure to model clinical trials

To facilitate a smooth presentation of all data items which logically belong together (for instance all data items which were captured for a certain study visit in a certain trial), we used the *open*EHR concept of 'folders' [13]. *Open*EHR folders enable logically grouping of recorded data and thus presenting the same data compositions in different folders. We used a similar mechanism in openSDMS to pool medical data not only of one patient but also of a certain clinical trial. For this, we use a virtual folder structure (Figure 3) according to our previously introduced generic trial structure (Figure 1). As a result, every folder contains – beside the medical data –some kind of meta data which describes the particular element and which is based on our newly defined archetypes. The concrete mapping of our generic trial structure to the folders is described in the following.

The 1:n relation between clinical trial and trial arm is modelled by having one folder per clinical trial which contains one dataset describing the trial itself (based on the clinical trial archetype) and a number of subfolders where each subfolder represents one trial arm. The 1:n relation between trial arm and study visit is represented analogously. The folder of each visit contains a visit description (based on the study visit archetype) and all medical datasets of different patients which have been recorded in the context of that particular visit. The single medical datasets will be visible in respective folders of the single patients together with further medical data. This means that medical data – independent of its use in a medical record or a clinical trial record – is physically stored only once in a generic way in openSDMS which complies with a 'single source approach'.

That way, it is possible to bring together all data of one study visit (of a particular trial arm in a particular trial) in one folder. The respective medical data of all patients at whom that visit took place is mapped to the respective directory. Supplemented by a description of the trial structure and other study

meta data, that results in a complete data set of one clinical trial.

Discussion

Archetypes for clinical trials

Per definition, *open*EHR archetypes are geared to comprehensively describe and structure a clinical concept in any context (cf. [14], pp. 10). Therefore, we believe that archetypes used to record medical data in EPR systems are also suitable to record medical data in the context of clinical trials. Furthermore, if an archetype was not found to be sufficient for the requirements of a clinical trial, it can be extended. It seems to be of advantage especially for clinical research that data stored in an *open*EHR based system have a 'built in' degree of validity as they have to conform to both a generic and stable information model and the models of clinical data as defined by the used archetypes.

We developed a dedicated set of archetypes to enable documentation of study meta data and to describe concepts associated with clinical trials like 'trial arm' or 'study visit' in the openSDMS. It would have been also possible to store these data just by creating additional tables in the database used by openSDMS. However, we decided to make use of archetypes because of two reasons:

1. Archetypes originally allow to systematically structure and describe the data which characterize the underlying concepts and by that, built a helpful discussion basis for the description of these concepts.
2. The archetype based representation enabled us using the same (already existing) program code which is used to process, store and transmit medical data, also for the processing of study meta data.

The archetypes we have developed for clinical trials are still draft versions. To enable their reusability in clinical trials nationally and internationally, we will bring these archetypes into a critical, public review process.

openSDMS

With our system we are able to explore technical issues associated with secondary use of medical data in EPR systems for clinical trials and to evaluate possible solutions. However, our system is still a prototype in the sense that just core functionality has been implemented. In contrast to a real study data management system further functionality is missing. For instance no plausibility checks or query management functionality have been implemented, yet.

Furthermore, Opereffa proved as a good starting point for the development of openSDMS. However, Opereffa itself is still under development and has to be improved step by step to fully implement the openEHR specifications. Therefore, we tried to implement openSDMS based on Opereffa but by observing information hiding principles as good as possible to allow for an update of Opereffa without having to adjust internal parts of the openSDMS implementation.

One relevant aspect of reusing data in EPR systems for clinical trials is data privacy protection. The underlying database of openSDMS consists of mainly one entity-attribute-value model based data table which only contains a patient id for relating the single entries to the particular patients. This seems to be an advantage, as it facilitates a separation of identifying data (like patient name) and medical data. According to the respective view and user (for instance medical record/physician or trial record/data manager) the system could display the patient name respectively only a pseudonymized patient id. We will explore whether this idea can be supported by integrating a pseudonymization software which has been developed by the German ‚Telematikplattform – Verbund zur Förderung vernetzter Medizinischer Forschung' (TMF – http://www.tmf-ev.de) specifically for scenarios like this one. The TMF crosslinks medical research in Germany as umbrella organization.

Perspective

In a next step, openSDMS will be extended by an export function for the study data based on the Operational Data Model (ODM – [15]) which has been developed by the Clinical Data Interchange Standards Consortium (CDISC). This shall enable openSDMS to export the captured trial data to other study data management systems.

However, the system shall not only facilitate storing data in an integrated EPR module and using that data for clinical trials but also to integrate data of different EPR systems for one trial. Therefore, in a further step, interoperability with other EPR systems will be established to enable importing of existing medical data into openSDMS. It is planned to make use of integration archetypes for that task.

Having openSDMS acting as a bridge between EPR and EDC systems, in a third step, the strengths and weaknesses of openSDMS will be evaluated. We plan, to evaluate the openSDMS in a real but manageable clinical trial setting.

Our approach and aims have similarities with other existing approaches – for instance the STARBRITE Proof-of-Concept Study [5] which uses the CDISC Operational Data Model and HL7 Clinical Document Architecture to integrate clinical routine and trial data in a single source approach. In contrast to these approaches we use openEHR archetypes for integrating clinical routine and trial data. Archetypes as structured models of clinical information concepts pledge to be a good basis for the future integration of different data sources which typically occur in multicenter trials. Furthermore, in contrast to other approaches, systems based on *open*EHR archetypes promise high sustainability as they strictly separate the modeling of clinical concepts (archetypes) and the technical implementation. If a concept has to be adapted to new requirements this can be done easily and not only by technicians but also by domain experts – for instance physicians.

Conclusion

Archetypes for clinical trials

*Open*EHR archetypes which have been defined to document medical data in EPR systems seem to be also suitable to document medical data in the context of clinical trials and to support single source approaches. Furthermore, the archetypes we developed make it possible to document trial metadata in an *open*EHR based system in the same way as medical data.

openSDMS

The core functionality of openSDMS has been developed. However, some fine tuning is required – for instance with regard to the graphical user interface – until the system can be evaluated in a real clinical trial scenario. This will be a further step of our research. We assume that one necessary key factor for the success of openSDMS in addition to its flexibility will be its ease of use. Especially the generation of case report forms has to be supported by easy-to-use tools.

Acknowledgments

The authors would like to thank all those who have contributed with commitment and enthusiasm to the *open*EHR project, the *open*EHR Java Reference Implementation, and the *open*EHR Reference Framework and Application. We especially thank Heather Leslie and Ian McNicoll of Ocean Informatics for their feedback in terms of the modeling of clinical trials.

Abstract

Patient medical records are often fragmented across disparate healthcare databases, potentially resulting in duplicate records that may be detrimental to health care services. These duplicate records can be found through a process called record linkage. This paper describes a set of duplicate records in a medical data warehouse found by linking to an external resource containing family history and vital records. Our objective was to investigate the impact database characteristics and linkage methods have on identifying duplicate records using an external resource. Frequency counts were made for demographic field values and compared between the set of duplicate records, the data warehouse, and the external resource. Considerations for understanding the relationship that records labeled as duplicates have with dataset characteristics and linkage methods were identified. Several noticeable patterns were identified where frequency counts between sets deviated from what was expected including how the growth of a minority population affected which records were identified as duplicates. Record linkage is a complex process where results can be affected by subtleties in data characteristics, changes in data trends, and reliance on external data sources. These changes should be taken into account to ensure any anomalies in results describe real effects and are not artifacts caused by datasets or linkage methods. This paper describes how frequency count analysis can be an effective way to detect and resolve anomalies in linkage results and how external resources that provide additional contextual information can prove useful in discovering duplicate records.

Keywords:
Record linkage, Subpopulations, Minority population

Introduction

It is common in large healthcare databases for information to be collected at different times in different places by different people. The disparate and sometimes inconsistent manner in which information is collected can lead to fragmented pieces of a person's medical information being persisted. Multiple records belonging to the same person, but mistakenly thought to belong to different people are called duplicate records. Having a single person's medical information spread across multiple records increases the time it takes to retrieve information, increases the risk of providing an incomplete patient history, and ultimately can impact patient care [1]. It therefore is important to find and eliminate duplicate records. Duplicate records are found by comparing pairs of records in a process called record linkage. The dominant method for linkage is the probabilistic approach formalized by Fellegi and Sunter [2]. This method is used in the non-trivial case where record identifiers do not match perfectly, but are close enough that they may be identified as duplicates.

Duplicate records are often found by comparing pairs of records within a single database. This paper describes an alternative situation where a second, external database exists which can be used to help identify duplicates. The enterprise data warehouse (EDW) of the University of Utah Health Sciences Center is an aggregate of medical records generated from inpatient and outpatient settings. It is routinely examined internally for duplicate records and is also linked to the Utah Population Database (UPDB), an external resource containing family history and vital records. In this second comparison, when two or more records in the EDW link to the same UPDB record, they are marked as potential duplicates. The EDW staff is notified of potential duplicates, verifies and resolves them if needed. All records, even known duplicates, are linked to the UPDB as an additional check to EDW internal deduplication processes.

In this study, we compared the frequency of name values in records in the duplicate subset with records in the full EDW and UPDB and describe instances where records in the duplicate subset are not typical of the database at large. We provide considerations for others looking at duplicate records in healthcare databases that help detect and resolve anomalies in

linkage results with population characteristics and linkage methods that are applied.

Materials and Methods

Data Sources

The University of Utah Health Sciences Center maintains an EDW that contains records for more than 1.8 million people resulting from all inpatient and outpatient visits to its hospitals and clinics since 1993. The demographic data in the EDW comes from both patient administration systems and physician billing systems. The EDW maintains a demographic record for each patient that contains fields describing a person's names, date of birth, sex, Social Security Number, addresses, phone numbers, and information about spouse and next of kin.

The UPDB is a research resource administered by the Utah Resource for Genetic and Epidemiologic Research. It was created in the mid-1970's using family histories from the Utah Genealogical Society containing the genealogy of the descendents of the Utah Pioneers [3]. The UPDB has since added records of Utah births, marriages, divorces, and deaths along with diagnosed cancers and driver license records. Each of these data sources gives extra information that can aid in the matching process. Records for each individual are grouped together into a person record - the composite of the best information available about a single person from one or more UPDB records. The more than 7 million person records in the UPDB contain demographic and family history information about individuals. Because of the scale and diversity of sources used to create the UPDB, most families living in Utah are represented in it. Birth and marriage certificates are used to expand the genealogy records and some families span as many as eleven generations. These data can only be used for biomedical and health-related research; the privacy of individuals represented in these records and confidentiality of the data is strictly protected [4]. The ability to correlate genealogy, medical, and demographic information makes the UPDB a valuable resource that has been used in many research studies [5]. For example, the UPDB was instrumental in discovering genes related to breast cancer [6,7], melanoma [8], colon cancer [9], and several other diseases.

Linkage Methods

In the interest of investigating the heritability of disease, the medical records available in the EDW are regularly linked with UPDB person records. The staff that manages the UPDB complete this activity using software that implements probabilistic record linkage.

First, middle, and last names of a patient are compared directly to the first, middle, and last name fields in a UPDB person record. Names for spouse and next of kin are compared to records linked through genealogy with the respective relationship to a particular person record. Because the EDW contains the patient's mother's maiden name, it is compared with the record linked through genealogy that is the mother of a particular person record. Both addresses in the EDW are compared with the address histories in the UPDB. Although the UPDB does not contain a history of phone numbers, the home and work phone numbers in the EDW are included since phone numbers are common identifiers used in linking at other institutions. Both the EDW and the UPDB contain more than Male and Female values for sex, including Unknown and a few other medical classifications.

Statistical Analysis

The top 2,500 most common last name values in the EDW were empirically categorized as *Founder* for Northern and Western European names; as *Traditionally Hispanic* for names typical of Latin and South America; or as *Other Ethnicities* as a collective group of Asian, Middle Eastern, and Native American names. Categorization of ethnicity based on last name was determined based using lists of names common in countries and by searching the origin of the name.

We compare frequency counts of demographic field values in the set of records identified as duplicates with the EDW generally. If duplicates occur at random within the EDW we would expect that values in these two sets would have the same relative frequencies. Comparisons that reveal notable deviations from this expectation may indicate possible areas where the matching process can be improved. Regression lines were calculated for each category comparing frequencies in the duplicate set with the EDW and the EDW with the UPDB.

Results

Of the 1,850,683 demographic records in the EDW, 1,375,704 were linked to UPDB person records. Of those, 209,852 EDW records linked to UPDB records that were simultaneously linked to by other EDW records; these were marked as potential duplicates and were used in this analysis.

Figure 1 shows the frequency of the 2,500 most common last name values in the EDW and duplicate set.

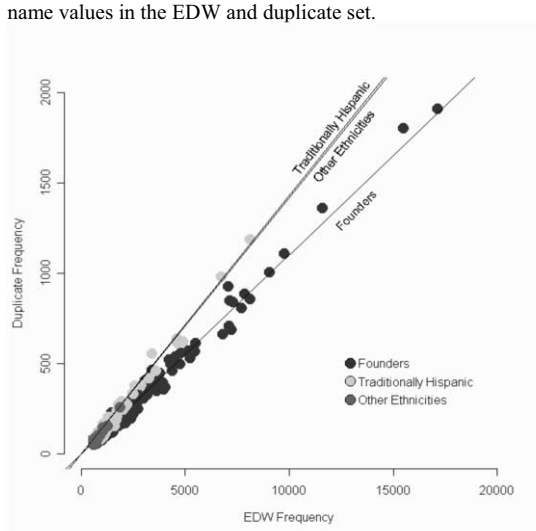

Figure 1 - Comparative frequency of ethnicity in the EDW and duplicate set

The name values are separated by assigned ethnicity with linear regression trend lines for each showing that Traditionally Hispanic names and names of Other Ethnicities are overrepresented in the duplicate set.

Figure 2 shows the frequency of the same 2,500 most common last name values in the EDW and UPDB.

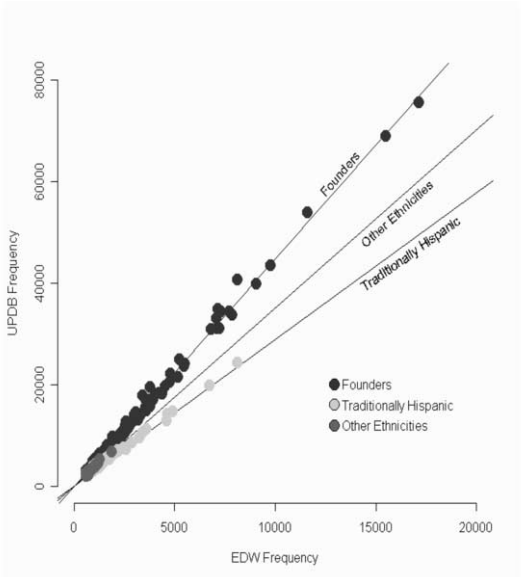

Figure 2 - Comparative frequency of ethnicity in the EDW and UPDB

The separation between Traditionally Hispanic names and those common among Founders in this comparison is even greater.

Discussion

An interesting artifact revealed in the linkage process was a division between names common among Utah founders and those common in the state today. First identified with the value Maria, a first name common in the overall population that is even more common among Hispanics, it became apparent that many of the names overrepresented in the duplicate set were traditionally Hispanic. Although less pronounced because much less frequent in the population, common Vietnamese, Korean, Chinese, Navajo, and Arabic names exhibited the same overrepresentation in the duplicate set. It was important to understand whether the higher proportion of Hispanic names existed in the duplicate record as an artifact of the linkage process or a real effect of the changing population.

The UPDB historically contains information that reflects the mostly North and West European background of the initial settlers of Utah [10,11]. The cultural face of Utah is changing, however, including a recent increase in the Hispanic population of Utah. In 1970, 95% of the Utah population was white and non-Hispanic compared to 85% in 2000 [10]. During the decade between 1990 and 2000, the Hispanic Population in Utah increased by 138% while the overall population increased by only 30% [12,13] This trend has continued since 2000 as the Hispanic population in Utah has increased at least three times faster annually than the overall population of Utah [13]. In addition to the recent increase, more than half of the Hispanic population lives in Salt Lake County, the area serviced by the University of Utah and thus represented in the EDW [14]. The recent demographic changes may not be adequately reflected in the UPDB. Temporary migrants who receive care at a hospital or clinic, but do not remain in Utah long enough to have a life event recorded in the UPDB will not have a person record created.

It is possible that by performing a single linkage with records of persons from all ethnicities, that a record linking process may not appropriately weight name frequencies. For instance, Martinez is the most common Hispanic last name in the duplicates, but only the 5th most common last name overall in the EDW and only the 19th most common name in the UPDB; Torres is the 10th most common Hispanic name in the duplicates, 59th in the EDW, and 203rd in the UPDB; and so on. As many of the common names in the EDW are found much less frequently in the UPDB, the likelihood of records being classified as duplicates when values match may artificially be inflated. Performing linkage on individual subpopulations may produce a more accurate result set, though it may be difficult to correctly decide how to classify records, particularly in cosmopolitan populations with diverse and inter-marrying ethnic populations. Other work suggests that it is not the ethnicity of an individual that causes linkage issues but the characteristics of names of certain origins that follow different naming conventions and phonetic rules than linkage tools are designed to consider [15]. Our work suggests that the uneven distribution of names between the datasets also affects linkage. Linkage artifacts caused by such a discrepancy may be less of an issue when values in both datasets are more balanced.

On the other hand, it is possible that a group may be legitimately overrepresented in the duplicate set. It is likely that names unfamiliar to registration clerks and other hospital staff would have an increased occurrence of misspellings. This could happen either during transcription, when a clerk enters information into a computer record from a paper sheet the patient filled out, or dictation, when a clerk writes or types information that a patient speaks. It may be the case for persons who do not speak English as their first language that information presented at different times and places may contain inconsistencies because of confusion, miscommunication, different traditions and feelings about record keeping, or the possible use of translation services.

Additionally, many database designs, including the EDW and the UPDB, hold that a person's name consists of a first name, a middle name, and a last name. In many cultures, this is not the case. Hispanic names often include more than one first or middle name, and it may be appropriate to use different last names in different situations. Asian names often have the last or family name presented before the first or given name. While these format variations may fool a hospital system in initially creating duplicate records, many commercial linkage systems

contain algorithms to recognize and correct these name differences. The ability of the EDW-UPDB linkage to classify these types of records as duplicates may account for their overrepresentation.

The overrepresented Hispanic names do not necessarily mean that the entire Hispanic population is overrepresented, but could be restricted to further subpopulations. The undocumented Hispanic population of Utah was estimated at between 55,000 and 85,000 in 2005 [16]. It may be less common that this group discloses complete and consistent demographic detail during medical visits [17]. Undocumented workers are more likely to be uninsured than either Hispanic or non-Hispanic legal residents and may receive care at the University of Utah which, as a state funded hospital, may have more flexibility to fund care for individuals who do not qualify for either federal or private reimbursement [18]. Care at the University of Utah indicates inclusion of records in the EDW and inconsistent information increases the likelihood of creating duplicate records. Recent immigrants are another subpopulation that may be less settled or more mobile. This may result in records being created at a number of different clinics that are later resolved as duplicates.

We found that the use of an external resource for discovering duplicate records in a healthcare database did affect which records were identified. We present the strengths and limitations of such a process along with considerations for those attempting such a linkage.

Strengths

Duplicate records are usually found by comparing sets of records within a single database and both the EDW and the UPDB undergo internal de-duplication as new records are added. Additionally, a linkage is made where the EDW is used as a database of interest and the UPDB as an external reference standard. Mistakes are made in de-duplication when dissimilar records are not matched, but are actually duplicates and when similar records are matched when they are not really duplicates. Using an external resource representing the population in the target dataset can provide the extra information and context needed to distinguish pairs that are truly duplicates and those that are not. The UPDB is such a resource that contains the majority of the population that receives healthcare from the University of Utah.

The additional information provided in links to family members and demographic field histories found in the UPDB allows duplicate records to be identified in the EDW that may not be found by other methods. For example, twins often have similar names, share a birth date, have the same parents, and may have the same address. Despite how similar these records are, the UPDB would show multiple births on each person's birth certificate and the two records could match properly to siblings instead of each other. As a further example, a woman who has recently married may have different last names and addresses on two records. Despite the records being dissimilar, UPDB person records would list her maiden name, her new last name and her husband's identity – obtained from a marriage license – a history of her known addresses, and a history of addresses for her husband. The two records could then be matched to the same person.

Limitations

Using an external reference for de-duplication may not eliminate the need for other methods of de-duplication. Duplicate records in the EDW cannot be found for individuals who do not have a record in the UPDB or where duplicates exist in the UDPB itself. Although the UPDB represents the population served by the University of Utah, it is not a true super-set. As a large academic research hospital, individuals may be referred from other states for specialized care. Others may receive care while visiting, but not living in the state. In addition, even for persons living in Utah to be included in the UPDB, they must have a life event that triggers the creation of a record.

Conclusion

The EDW and UPDB have different record characteristics and forces acting on them. Information is collected independently and for different purposes. When two different datasets are used for linkage, especially when they are collected at different times and for different purposes, a portion of the results may be explained by dataset differences. It is important to know when anomalies occur and if they describe real effects or artifacts caused by the datasets.

The changing face of the population represented in these datasets shows how subpopulations and changes in demographic trends may affect linkage. It is possible that segmenting data into homogenous demographic groups may lessen the impact that minority populations have on linkage results.

Understanding the impact of dataset characteristics and record linkage methods is a first step in improving duplicate record detection. We suggest the use of frequency count analyses as an effective way to detect anomalies in linkage results and as a tool for validating records identified as duplicates.

Abstract

In the health sector, record linkage is of paramount importance as clinical data can be distributed across different data repositories leading to duplication. Record Linkage is the process of tracking duplicate records that actually refers to the same entity. This paper proposes a fast and efficient method for duplicates detection within the healthcare domain. The first step is to standardize the data in the database using SQL. The second is to match similar pair records, and third step is to organize records into match and non-match status. The system was developed in Unified Modeling Language and Java. In the batch analysis of 31, 177 "supposedly" distinct identities, our method isolates 25, 117 true unique records and 6, 060 suspected duplicates using a healthcare system called MINPHIS (Made in Nigeria Primary Healthcare Information System) as the test bed.

Keywords:

Record linkage, Data mining, Duplicates, Databases, MINPHIS

Introduction

Many private and public organizations in the health sector capture, store, process and analyze fast-growing amounts of data with millions of records. The records are made up of patient's bio-data and health records. Linking and aggregating records that relate to the same person from several databases is becoming increasingly important as information from multiple sources needs to be integrated, combined or linked in order to allow detailed data analysis or mining or warehousing. The aim of such linkages is to match all records relating to the same entity for better informed decisions at various levels.

The basic methods compares name and address information across pairs of files to determine those pair of records that are associated with the same entity. The most sophisticated methods use information from multiple lists [7]; create new functional relationships between variables in two files that can be associated with new metrics for identifying corresponding entities [8] or use graph theoretic ideas for representing linkage relationships as conditional random fields that can be partitioned into clusters representing individual entities [4].

The main challenge in this task is designing a function that can resolve when a pair of records refers to the same entity in spite of various data inconsistencies. Data quality has many dimensions or qualities, one of which is accuracy. Accuracy is usually compromised by errors accidentally or intentionally introduced in a database system. These errors result in inconsistent, incomplete or erroneous data elements. In order to improve the accuracy of the data stored in a database system, we need to compare them either with their real world counterparts or with other data stored in the same or a different system.

Materials and Methods

This section describes the material and method that were used in achieving the desired or set goal.

MINPHIS is an acronym that stands for Made in Nigeria Primary Healthcare Information Systems; a software system that was collaboratively developed by the Health Information Systems Research and Development Unit of the Obafemi Awolowo University Ile-Ife, Nigeria and the Health Information Systems Research and Development Unit of the University of Kuopio Finland in 1989. Currently, MINPHIS has been deployed to over eleven (11) teaching and specialist hospitals in Nigeria. Over 30, 000 records were pulled out of MINPHIS database deployed at the Obafemi Awolowo University Teaching Hospitals Complex for testing the system developed.

Given databases A and B, record linkage finds or detects the common entity between them, (figure 1). Each record from A potentially has to be compared with all the records from B. The total number of potential record pair comparisons thus equal to the product of the size of the two databases.

Database B

Figure 1- Record Linkage Example

To reduce the large amount of potential record pair comparisons, our system employs a technique called 'blocking'; a single record attribute or a combination of attributes called blocking key or variable was used to split the database into blocks. Therefore, we sorted the records in our database alphabetically using surname, sex and date of birth, so that only records that falls within the same block are compared with their counterparts.

All records having the same value in the blocking key were inserted into one block and candidate record pairs are generated only from records within the same block. While the aim of blocking is to reduce the number of record pair comparisons made as much as possible by eliminating pairs of records that obviously are not matches, it is also important that no true matches are removed by the blocking process. That was why; we had to block records alphabetically to allow scalability or robustness of the blocking process and also to ensure that no true match is missed.

Two main issues are considered when blocking key is defined:

1. The error characteristics of the attributes used in blocking keys will influence the quality of the generated candidate record pairs. Therefore, attributes containing the fewest errors or missing values should be chosen as any error in an attribute value in a blocking key will potentially result in a record being inserted into the wrong block, thus missing true matches.
2. The frequency distribution of the values in the attributes used as blocking key will affect the size of block generated. So, if *m* records are in a block from database A and *n* records in the same block from database B, then *m* x *n* record pairs will be generated from this block. The largest block will dominate the execution time of the comparison step as they will contribute very large numbers of record pairs.

In order to address the problems enumerated above, we developed a string matching function that is embedded in the record linkage system algorithm to cater for strings with typographical errors as a result of keystroke mistakes or fatigue during the data entry process. This will enhance the blocking process because true matches will not fall into wrong block. The string matching function compares two strings say **JULIUS Babatunde** and **JULIUUS Babatunde; or Achimugu Philip** and **Chimugu Philip,** and calculates the number of common character and transposition. So if the total number of common characters between the two strings is more than three quarters of the length of the shorter string, then the function suspects and reports a likelihood of typographical error in the two strings, before other attributes such as Date of Birth, Sex and address information are finally compared to determine the status quo of such entities.

In this experiment, the blocking technique used for our health database allows the size of blocks to be controlled directly through parameters. All the candidate record pairs generated by the blocking process are compared by the comparison function applied to one or more (or a combination of) record attributes.

Each comparison returns a numerical similarity value called 'matching weight' (1 if the strings are similar or agreeing and 0 if the strings are not similar or disagreeing). A vector is formed for each compared record pair containing all the values calculated by the comparison function. These vectors are then used to calculate record pairs into match, non-match and possible match based on the decision model developed. Therefore, record pairs that were removed by the blocking process are classified as non-match or unique records without being compared explicitly. Figure 2 depicts the record linkage process.

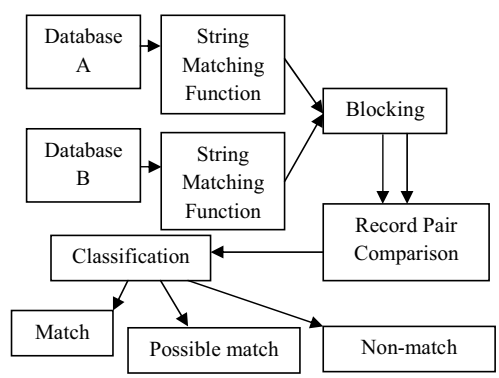

Figure 2- The Record Linkage Process

Experimental Results

To evaluate the performance of this algorithm, normalized measures such as precision and recall were used to determine the efficiency of the algorithm. The experiments performed consisted of finding matches between two data sets.

Test Data

The test used a simplified dataset containing all bio-data of patients from the MINPHIS database. The datasets contain a range of identifying information such as names, address, diagnosis, referrals, ward allotment etc for 31, 177 supposedly distinct patients.

For the purpose of this research however, the attributes that were extracted from the MINPHIS database for experimental evaluation are Hospital Number, Surname, firstNames, Sex, Date of Birth and Address information. Records representing the same entity based on the static decision rules were given the same value of 1 while those that are not were given the value 0. That was the criteria for duplicate detection.

We therefore, conclude that two records are match if they correspond in names (Surname, FirstNames), date of birth, sex and address.

Evaluation of the System

The evaluation of the algorithm encompasses two main issues: (1) the accuracy and (2) the behaviour of the similarity threshold k. First, the distances between all possible pairs of records (r_i, r_j) are computed and stored in a matrix. Then, for each value of k, the total number of true positives (TP), false positives (FP), false negatives (FN) and true negatives (TN) matches are computed using the formula below:

$$\text{Recall} = \frac{TP}{TP + FN} \quad \textbf{(1)}$$

$$\text{Precision} = \frac{TP}{TP + FP} \quad \textbf{(2)}$$

Reference Tables

We used eight blocks for the experiment. The first reference table is the combination of unique given names and surnames from the dataset giving a reference table size of 3415 unique names. The second reference table is every second name from the first reference table, starting with the first name, while the first reference table is every second name starting with the second name. The fourth reference table contains unrelated data, the unique surnames and given names from the MINPHIS database.

Table 1- Result of the System

Block	Correct Matches	Correctly Unlinked	Incorrect Matches	Precision	Recall
1	3415	302	400	0.92	0.90
2	3308	292	295	0.92	0.91
3	3936	200	225	0.95	0.94
4	3501	109	305	0.96	0.91
5	3566	190	300	0.95	0.92
6	3486	217	320	0.94	0.91
7	3299	130	178	0.96	0.95
8	3175	17	11	1.0	1.0

Analysis of the Result

As expected there is a trade-off between Precision and Recall when the threshold k is varied. Its optimum value is considered to be in the intersection of the two curves (Figure 3). The system employs a method called **blocking** in order to reduce large comparisons between potential duplicate records, so only records that falls within the same block or neighbourhood are compared and tracked for duplicate detection hence, decrease in computational time. From table 1 therefore, it is deduced that the system produced a high level of quality duplicates detection as evidenced in the values for precision and recall. In Block one, it is observed that only 400 incorrect matches was found after retrieving 3415 records, that is, matches that could not be tracked by the static decision rules embedded in the algorithm and the final match status is determined by the human expert. It goes on through all the rest of the blocks until the information retrieval process is completed. Although, the system is automated but the final decision for records that falls under the possible match category is determined by the human expert. This is important because patients in health organizations are seen as owners of their medical records; therefore, adequate care must be taken to ensure that data are not altered in any way throughout the record linkage process.

Furthermore, Figure 3 depicts the graphical representation between precision and recall. It shows a significant increase in precision as regards the quality of duplicates detected by the enhanced system. For example, it is approximately 0.18, corresponding to 0.95 of precision and recall (Figure 3). In comparison with exact record matching, which is equivalent to the case k = 0, the approximate record matching (with higher values for k) provided a good gain in Recall, without significant loss in Precision. But, when the dataset from MINPHIS database was tested on the algorithm which has embedded a string matching function that caters for typographical errors in candidate's names, exact record matching obtained a Recall of only 40% (Figure 4).

There are also large regions (0.14 < k < 0.19, for the

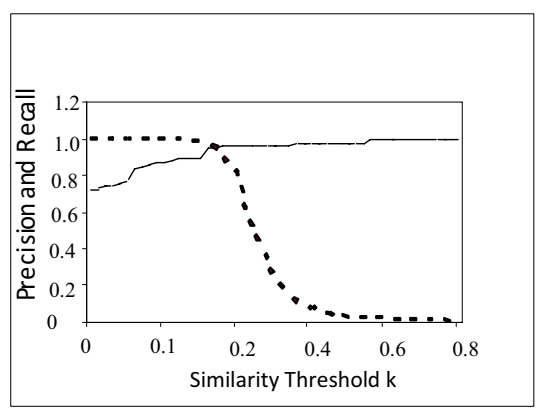

Figure 3- Tradeoff between Precision and Recall

algorithm; and $0.09 < k < 0.19$, for the tradeoff between precision and recall), where both precision and recall are high (greater than 0.9). For a while, this allows some freedom and safety in the choice of k.

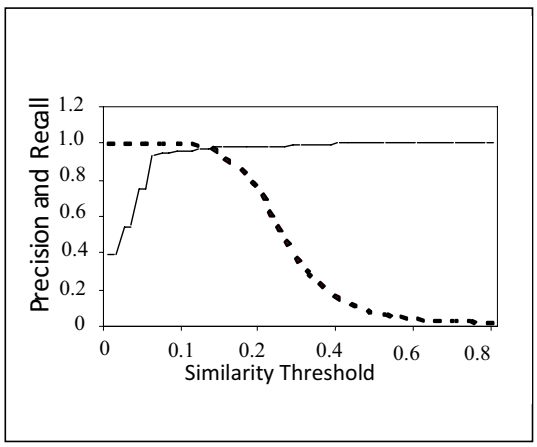

Figure 4- MINPHIS Dataset Bahaviour in the Record Linkage Algorithm

Discussion

The initial idea for record linkage was conceived by Halbert Dunn in 1946 who was the then chief of U.S. National Office of Vital Statistics. He used the term to refer to linking vital records, such as birth and death certificates, pertaining to a single individual [2]. Computerized record linkage was proposed a decade later when Howard Newcombe and colleagues used computers to link vital records in an effort to track hereditary diseases. The theory of record linkage was further expanded by Ivan Fellegi and Alan Sunter who demonstrated that probabilistic decision rules were optimal when the comparison attributes are conditionally independent [6]. Our method gives those specialists responsible for merging similar records a representative view to show them how close records in some homogenous or heterogeneous sets are. Additionally, the algorithm and underlying database support real-time detection of duplicate records. This can help to avoid the creation of duplicate records by alerting the user that several neighbour records already exist. This real-time use could also be used in multi criteria searches for identities and a simple as well as easy to use front end algorithm was employed in the implementation of the record linkage system so that short response times are achieved. Response time is closely related to optimization of the algorithm and especially the blocking part. Its improvement allows the reduction in the number of potential duplicates to be tested by the main algorithm.

Conclusion

In this paper, a record linkage system for health information systems was developed and applied to health informatics in developing countries (particularly Nigeria). The methodology implored for achieving our goal is discussed herein and we believe that the result would be useful and the system more efficient than existing ones.

Abstract

Temporal information plays a crucial role in medicine, so that in Medical Informatics there is an increasing awareness that suitable database approaches are needed to store and support it. Specifically, a great amount of clinical data (e.g., therapeutic data) are periodically repeated. Although an explicit treatment is possible in most cases, it causes severe storage and disk I/O problems. In this paper, we propose an innovative approach to cope with periodic medical data in an implicit way. We propose a new data model, representing periodic data in a compact (implicit) way, which is a consistent extension of TSQL2 consensus approach. Then, we identify some important types of temporal queries, and present query answering algorithms to answer them. We also sketch a temporal relational algebra for our approach. Finally, we show experimentally that our approach outperforms current explicit approaches.

Keywords:

Databases, Temporal information, Periodic data

Introduction

Most clinical data (e.g., patients' clinical records) are naturally temporal. In order to be meaningfully interpreted, patients' symptoms, laboratory test results, and, in general, all clinical data, must be paired with the time in which they hold (called *valid time* henceforth). In many cases, medical data concerns events that have to be repeated at periodic time. Such events include, e.g., routine activities that nurses have to perform daily on hospitalized patients, as well as intrinsically repeated activities such chemotherapy cycles, or dialysis (which is usually an *open-ended* activity, since it has to be performed for all the life of certain diabetic patients). An explicit representation of all the repetitions to be performed might be important, e.g., for scheduling purposes and resource allocation. Nevertheless, it is very costly, both in terms of storage allocation, and of disk I/O when data have to be retrieved.

Periodic data in databases

Unfortunately, the research about temporal data has widely demonstrated that the simple addition of some timestamped attributes (e.g., the START and END times for the valid time of a tuple) is not enough, since many complex problems need to be tackled. For instance, Das and Musen have identified several types of mismatches between the temporal support of standard databases and the richness of clinical data [1]; analogously, James and Goble [2] have pointed out the requirements that medical records impose on a temporal model. Designing, querying and modifying time-varying tables requires a different set of techniques. Such techniques have been studied in more than 20 years of research by the temporal database (TDB henceforth) community (consider, e.g., the overview [3]). Although TDB is still an open area of research, many researcher have already consolidated a "basic core" of results, by defining the TSQL2 consensus approach [4].

In the medical area, several temporal database approaches have been devised. For instance, Chronus [5] and Chronus II [6] have provided an implementation of a subset of TSQL2 [4], with specific focus on valid time. On the other hand, although actions repeated at periodic time are quite frequent in the medical context, no approach has been developed in order to cope with such data in an efficient way. For instance, since periodic actions are an intrinsic constituent of clinical guidelines, several approaches in the area have devised expressive languages to represent complex periodic patterns (such as, e.g., those in chemotherapy treatments). Among the others, Asbru's [7] and GLARE's [8] temporal languages have been devised to model complex cases of periodically repeated actions. However, while in Asbru's and GLARE's languages repetition patterns in the guidelines can be represented, to the best of our knowledge no medical database approach has been devised to store in a (relational) database the actual data modelling the effective execution of repeated actions (e.g., dialysis) on each specific patients on which it has to be physically executed.

Explicit vs. implicit approaches

The trivial way to store a repeated action in a database is to explicitly store all the repetitions of that action. E.g., consider the following therapy for multiple mieloma (such a therapy has been used as one of the example of application of GLARE's temporal representation language [8]).

(Ex.1) The therapy for multiple mieloma is made by six cycles of 5-day treatment, each one followed by a delay of 23 days

(for a total time of 24 weeks). Within each cycle of 5 days, 2 inner cycles can be distinguished: the melphalan treatment, to be provided twice a day, for each of the 5 days, and the prednisone treatment, to be provided once a day, for each of the 5 days. These two treatments must be performed in parallel.

While GLARE's representation language provides an high-level language to represent such a periodic pattern, a separate problem is to provide a proper support to store the time of execution the actions on specific patients affected by multiple mieloma. An *explicit* storage of all the actions (and the time when they have to be executed), although possible, is quite storage expensive. For instance, in a standard relational database approach it would consist, for each patient, of at least 90 tuples, modelling 60 melphalan applications, and 30 prednisone applications. While it is important that all such actions are recorded in some way (e.g., for scheduling purposes, and resource allocation), it is worth noticing that the main drawback of such an explicit approach is not just the waste of memory, but the increase of time devoted to physical disk I/O whenever such data need to be accessed. Additionally, from the logical point of view, an explicit storage of all the actions is not even possible in the case of open-ended repetitions, in which the end of repetitions is unknown (consider, e.g., the dialysis example). For such reasons, in the area of temporal databases, some initial approach has been devised to provide an implicit representation of periodically repeated data (consider, e.g., [9,10]). In such approaches, periodically repeated data are not explicitly elicited: on the other hand, the pattern of repetition is directly stored in the database, so that a compact representation is achieved.

However, to the best of our knowledge, no "implicit" approach to periodic data in the literature has explicitly focused on issues related to the efficient representation and management of periodical data. In this paper, we describe an approach overcoming such a limitation, with specific focus on medical data.

Methods

In this paper, we propose an "implicit" approach to cope with periodical data, which is based on the "consensus" definition of granularity taken from the TDB glossary [11], and on its extensions to cover periodical data [12]. The generality of our approach is also granted by the fact that our representation model is a "consistent extension" of TSQL2 [4], the most famous "consensus" approach to temporal relational databases. Our approach articulates as follows:

(i) We identify a (relational) data model to store periodic data in an implicit way;
(ii) we consider a "prototypical" class of queries (i.e., temporal range queries), and we address the problem of identifying a suitable query answering approach (with specific attention to the query answering algorithm);
(iii) we extend the approach (at the algebraic level) to cope with other kinds of queries
(iii) finally, we have developed an extensive experimentation of our model and methodology, showing that our "implicit" approach overcomes the performance of traditional "explicit" approaches both in terms of space and disk I/O's, and in terms of answer response time.

Temporal data model

In our approach, a periodic activities are *implicitly* represented through a new type of relation (that we term *periodical* relation), plus an additional relation, PERIODICITY, that we use to define periodicities.

Definition 1 (periodical relation): Given any schema $R=(A_1,...,A_n)$ (where $A_1,...,A_n$ are standard non-temporal attributes), a periodical relation r is a relation defined over the schema RP = $(A_1,...,A_n \mid VT_S, VT_E, Per, Per_{id})$ where VT_S, VT_E, are timestamps representing the starting and the ending point of the interval of time containing all the repetitions (called "frame time" henceforth), *Per* is an interval, representing the duration of the repetition pattern, and Per_{id} is an identifier, denoting a periodical pattern in the PERIODICITY relation.

Definition 2 (PERIODICITY relation): The PERIODICITY relation is a relation over the schema $(Per_{id}$ *Start, End),* in which Per_{id} is a periodicity identifier, and *Start* and *End* are temporal attributes (timestamps) denoting the starting and the ending points of the periods in the periodical pattern.

Example (Ex.2): As a simple example, let us suppose that an activity A1 has to be executed on a patient P1 each Monday, Wednesday and Friday for 10 weeks, starting from day 100, which is a Monday (for the sake of simplicity, here we use natural numbers instead of dates, and we assume that the base temporal granularity of the database is 'day'). Such an information is implicitly represented in our approach as shown in Tables 1 and 2 in the following.

Table 1- A periodical relation.

ACTIONS

Action	**Patient**	**VT_S**	**VT_E**	**Per**	**Per_{id}**
A1	P1	100	169	7	Id1

Table 2- PERIODICITY relation, concerning the periodicity in the example only.

PERIODICITY

Per_{id}	Start	End
Id1	100	100
Id1	102	102
Id1	104	104

In the ACTIONS relation, VT_S and VT_E states that the *frame time* is 70 days, from day 100 to day 169. The repetition period is 7 days (attribute *Per*). Per_{id} provides a link to the table PERIODICITY, in which the repetition pattern for the first week is stored. Notice that, although not explicitly stated, all the days in which action A1 has to be executed (on patient P1) can be inferred from the above implicit representation, looking at the pattern in the relation PERIODICITY as a pattern to be repeated each 7 days (*Per* attribute of the relation ACTIVITY), stopping repetitions after day 169 (see the explicit representation in Table 3) <end example>

It is important to notice that the temporal attributes of our periodical relations, in conjunction with the PERIODICITY relation, allows us to capture the implicit definitions of periodical granularities, as defined in the temporal database literature:

Property 1 (expressiveness): Our extended data model can represent periodical granularities, as defined in [12].

Moreover, it is worth noticing that non-periodical temporal data could be easily represented as a degenerate case of the periodical one, using tuples in which VT_S and VT_E model the start and the end of the valid time, and the *Per* and Per_{id} attributes are set to NULL[1]. Therefore, our approach can be seen as an extension of the "consense" TSQL2 approach [4], to cope also with periodic data.

Property 2 (consistent extension): Our data model is a "consistent extension" of TSQL2 data model.

Query answering: range queries

Here we take into account *range* queries since, according to the temporal database literature, they are particularly relevant. Specifically, the type of query we deal with is the following: given a set of periodical data (e.g., activities in the ACTIVITY table) and an interval denoting the span of time one is interested in the query (e.g., from day 120 to day 124), one wants to know which data holds during such a time period. In particular, in the context of periodical data, we identify two different types or range queries, depending on whether:

(i) one is interested in the non-temporal part of the tuples only (e.g., What activities have to be performed from 120 to 124?)
(ii) one is interested in the tuples and in their explicit time (e.g., what activities have to be performed from 120 to 124? For each of them, list all the times when they have to be performed, between 120 and 124).

For the sake of brevity, however, we will focus only on the type (i) of queries in the rest of the paper.

Given our (implicit) temporal data mode1, the process of answering such basic types of queries is quite complex, since we only have an implicit representation of data. Given a periodical relation *r* (e.g., ACTIVITY) and a query interval I_Q (e.g., [120,124]), in the following we sketch the algorithm we propose for efficiently answering queries of type (i):

(1) For each tuple $t \in r$
(2) Let P_t be the intersection between I_Q and the frame time of t
(3) IF the duration of P_t is greater or equal than the period of t (attribute Per of t) THEN return t
(4) ELSE
(4.1) get in PERIODICITY the intervals constituting the repetition pattern of t
(4.2) Using the 'module' function, "project" I_Q and the intervals retrieved at step (4.1) onto the same span of time, and check intersection
(4.3) IF there is intersection, then return t

Notice that step (3) above is simply an optimization: in case the interval of interest (i.e., $P_t \cap I_Q$) is longer than the period of t, than for sure some of the intervals in the repetition must intersect the interval $P_t \cap I_Q$, so that the tuple can be directly provided in output, avoiding other checks. In (4.2), the module function is used to check intersection between the pattern and the interval of interest in an efficient way, avoiding an explicit generation of all the intervals of repetitions.

Query answering: temporal algebra

Besides temporal range queries, all kinds of relational queries must be possible on our new data model. Codd designated as complete any query language that is as expressive as his set of five relational algebraic operators: relational union ($\cup$), relational difference (-), selection (σ), projection (π), and Cartesian product ($\times$) [13]. We propose an extension of Codd's algebraic operators to query our data model.

Several temporal extensions have been provided to Codd's operators in the temporal database literature [4,14]. In many cases, the extended temporal operators behave as standard non-temporal operators on the non-temporal attributes, and involve the application of set operators on the temporal parts. This approach ensures that the temporal algebrae are a consistent extensions of Codd's operators and are reducible to them when the temporal dimension is removed. For instance, in BCDM [4], which provides a uniform semantics underlying several temporal database approaches, including TSQL2, temporal Cartesian product involves pairwise concatenation of the values for non-temporal attributes of tuples and pairwise intersection of their temporal values. Analogously, in BCDM [4], relational union, projection and difference behave in a standard way on non-temporal attributes, and perform union (for relational union and projection) and difference on the temporal part of value-equivalent tuples. We ground our approach on such a "consensus" background, extending it to cope with periodic data. For the sake of brevity, we sketch only our definition of temporal Cartesian product. The other operators are defined in a similar way, according to the above-mentioned discussion. In the definition below, we denote by $t[X_1, ..., X_k]$ the value of the attributes $X_1, ..., X_k$ in the tuple *t*.

Definition 3 (Temporal Cartesian product $\times^T$): Given two periodic relations r and s defined over the schemas $R1^P = (A_1,...,A_n \mid VT_S, VT_E, Per, Per_{id})$ and $R2^P = (B_1,...,B_k \mid VT_S, VT_E, Per, Per_{id})$ respectively, the temporal Cartesian product $r \times^T s$ is a periodic relation q defined over the schema $R3^P = (A_1,...,A_n, B_1,...,B_k \mid VT_S, VT_E, Per, Per_{id})$ containing, for each pair of tuples ($t_r \in r$, $t_s \in r$), a new tuple t' which is the concatenation of the non-temporal attributes of t_r and t_s (i.e., such that $t'[A_1,...,A_n]=t_r[A_1,...,A_n]$, and $t'[B_1,...,B_k]=t_s[B_1,...,B_k]$), whose frame time is the intersection of the frame times of t_r and t_s (i.e., $t'[VT_S]=\max(t_r[VT_S], t_s[VT_S])$ and $t'[VT_E]=\min(t_r[VT_E], t_s[VT_E])$, with $t'[VT_S] < t'[VT_E]$), whose periodicity t'[Per] is

[1] Although such a representation is theoretically possible, for the sake of efficiency we store non-periodic data into standard TSQL2-like temporal relations, to avoid the use of unnecessary NULL values.

the least common multiple of t_r[Per] and t_s[Per], and whose periodicity identifier t'[Per_{id}] is a new system-generated identifier. The periodic pattern of t'[Per_{id}] in the table PERIODICITY is defined as the intersection of the periodic patterns associated with the identifiers t_r[Per_{id}] and t_s[Per_{id}], evaluated over a period of time which starts at t'[VT_S], and whose duration is t'[Per]. Of course, only tuples such that frame times and periodic patterns have a non-empty intersection are retained in q.

The definition of temporal Cartesian product given above can be extended to temporal definitions of theta join, natural join, outer joins, and outer Cartesian products, in a way similar that done in [15]. It is worth stressing that the consistent extension property also holds for our extended algebra:

Property 3 (consistent extension): Our temporal relational algebra is a "consistent extension" of the BCDM (and TSQL2) algebra [4].

Experimental results

In order to show the practical relevance of our implicit approach to efficiently manage periodic data, we have performed an extensive experimental evaluation. In particular, we have compared the performance of our approach with respect to the one of the standard explicit one. We remark here that, with the term "explicit" approach, we mean the approach in which periodic data are explicitly stored. For instance, the relation ACTIONS_Expl contains an explicit representation of the actions in example Ex.2.

Table 3- Explicit representation of the periodic data in Ex.2. The relation contains 30 tuples

ACTIONS_Expl

Action	Patient	VT_S	VT_E
A1	P1	100	100
A1	P1	102	102
A1	P1	104	104
A1	P1	107	107
....	....	....	....
A1	P1	167	167

Our results are computed on a four 450MHZ CPU - SUN UltraSparc II processor machine, running Oracle 10.2.0 RDBMS, with a database block size of 8K and SGA size of 100MB. At the times of testing the database server did not have any other significant load.

The RI-Tree [16] has been used to index both time intervals both in the implicit and in the explicit approach, since this indexing methodology has been proved to have has the best performance regarding interval data.

We compare our results considering space usage, CPU usage, query response time, and physical I/O, which is usually considered to be the most important parameter while evaluating efficiency of accessing data [17].
In absence of real data, based on our experience, we have generated periodic data to simulate real medical scenarios. The following parameters have been considered (we used hour as the basic granularity):

(1) Number of Patients: 16,824;
(2) Average number of periodic activities per patient: 8.30;
(3) Average number of periods in a periodical pattern: 4.86;
(4) Average duration of period of periodical patterns: 87.56;
(5) Average duration of the frame time: 1169;
(6) Distribution of the duration of periodical pattern: we have provided different durations, with a prevalence of actions to be repeated daily (about 40%), and weekly (about 30%).

In order to carry on the experiments, the same periodical activities concerning hospital patients have been represented both in the implicit and explicit model. In the implicit model, the representation of data required 353,367 records in the ACTIONS table and about 2 million records in the PERIODICITY table. In order to represent the same activities in the explicit model, more than 194 million records are required in the ACTIONS_Expl table, so that, globally, the space requirement of the explicit approach is more than 100 times greater (see Table 4).

Table 4- Comparing implicit vs explicit approach: space requirement

Table name	Number of records	Table Size (M Bytes)	Approach
ACTIONS	353,367	16.25	implicit
PERIODICITY	2,108,495	43.08	implicit
ACTIONS_Expl	194,671,463	7,331.82	explicit

Physical disk I/O's, CPU time and response time for range queries of type (i) for different query duration and different answer sizes are show in Tables 5, 6, 7, and 8. Different range queries duration are considered to investigate effect of the optimization in step (3) of our query answering algorithm. Different answer size is considered to see the effect of clustering the data, aging of database buffers and effect of trade off between Physical disk I/O and CPU usage.

Table 5- Evaluation of the implicit approach, for range queries lasting 1 hour

Answer Size	Disk I/O	CPU	Response Time
2,068	6,049	477	5
7,471	10,831	1,431	12
17,738	12,364	3,186	32

Table 6- Evaluation of the explicit approach, for range queries lasting 1 hour

Answer Size	Disk I/O	CPU	Response Time
2,068	3,031	73	3
7,471	12,872	315	30
17,738	31,904	930	154

Table 7- Evaluation of the implicit approach, for range queries lasting 1 week

Answer Size	Disk I/O	CPU	Response Time
2,887	1,838	200	3
4,620	2,114	260	5
29,455	9,490	1,375	26

Table 8- Evaluation of the explicit approach, for range queries lasting 1 week

Answer Size	Disk I/O	CPU	Response Time
2,887	7,970	601	52
4,620	12,913	1,232	116
29,455	183,073	26,460	944

As regards disk I/O (the most important parameter in the database context [17]), our approach is increasingly advantageous with respect to the explicit one. This is particularly true when the query range is bigger. This is because our approach can exploit the optimization at step (3) of the query answering algorithm. Also, with increased answer size our implicit approach outperforms the explicit method in the number of physical disk I/O's, which results in significant shorter query duration (more than 36 times shorter query response time in case of 168 hour range query and answer size of 29,455 as it can be seen comparing the last raw of Tables 7 and 8).

An extensive experimental evaluation of our algebraic operators is still ongoing. Preliminary results confirm the advantages of our approach with respect to the explicit one, similar to the advantages above as regards temporal range queries.

Discussion and conclusion

Temporal data play a fundamental role in medicine. Specifically, periodic data are frequent and important, so that their efficient treatment is a core issue in the area. We propose a new methodology based on an implicit representation, and on efficient query answering algorithms. We have experimentally shown that our approach outperforms the "traditional" explicit approach as regards disk I\O, CPU usage, and response time. The advantages of our approach increase with the increase of the answer size, and of the temporal range of the queries. As regards future work, we want to integrate our approach in GLARE (GuideLine Acquisition, Representation and Execution), a manager of clinical guidelines which strictly interacts with different databases, and devotes specific attention to the treatment of temporal data [18].

Achieving interoperability for metadata registries using comparative object modeling

Abstract

Achieving data interoperability between organizations relies upon agreed meaning and representation (metadata) of data. For managing and registering metadata, many organizations have built metadata registries (MDRs) in various domains based on international standard for MDR framework, ISO/IEC 11179. Following this trend, two pubic MDRs in biomedical domain have been created, United States Health Information Knowledgebase (USHIK) and cancer Data Standards Registry and Repository (caDSR), from U.S. Department of Health & Human Services and National Cancer Institute (NCI), respectively. Most MDRs are implemented with indiscriminate extending for satisfying organization-specific needs and solving semantic and structural limitation of ISO/IEC 11179. As a result it is difficult to address interoperability among multiple MDRs. In this paper, we propose an integrated metadata object model for achieving interoperability among multiple MDRs. To evaluate this model, we developed an XML Schema Definition (XSD)-based metadata exchange format. We created an XSD-based metadata exporter, supporting both the integrated metadata object model and organization-specific MDR formats.

Keywords:

Metadata registry, ISO/IEC 11179, Interoperability, Object model

Introduction

Metadata provide data with context and are used to facilitate the understanding, usage and management of data both by human and computers. Meta Data Registry (MDR) is a system for managing these metadata contents. For managing and describing metadata, ISO/IEC JTC 1/SC 32 established a standard for MDR, named ISO/IEC 11179 [1], on which many MDRs in various domains have been built and introduced. In biomedical domains, there are two representative MDRs, United States Health Information Knowledgebase (USHIK) from U.S. Department of Health & Human Services [2] and cancer Data Standards Registry and Repository (caDSR) from National Cancer Institute (NCI) [3]. For evaluating metadata functionality, we also developed an MDR, named Clinico-Histopathological Metadata Registry (CHMR), for describing and managing data elements related to clinical trial and research data [4].

Recently, several studies have shown semantic and structural limitations of ISO/IEC 11179 [5-7]. They are categorized into three problems. The first problem is the absence of semantic or syntactic linkage of shared concepts between components [6]. The second and third ones are structural limitations. ISO/IEC 11179 doesn't support a structure for metadata extension [5] and usage model [7]. To solve these problems and to satisfy organization-specific needs, most MDRs are built with indiscriminate extending. As a result, metadata inconsistency problem makes it difficult to support interoperability among MDRs. In other words, it results structural and semantic inconsistencies between MDRs. In this paper, we are focusing only on structural inconsistency between MDRs. To address the structural inconsistency problem, we propose an integrated metadata object model and metadata exchange format. Also we implement a metadata exporting system.

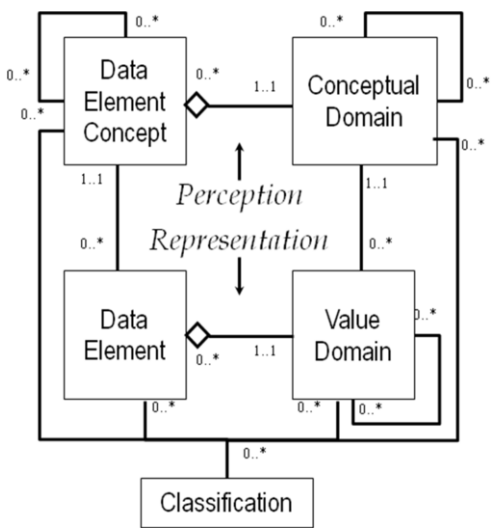

Figure 1- High-level meta-model of ISO/IEC 11179

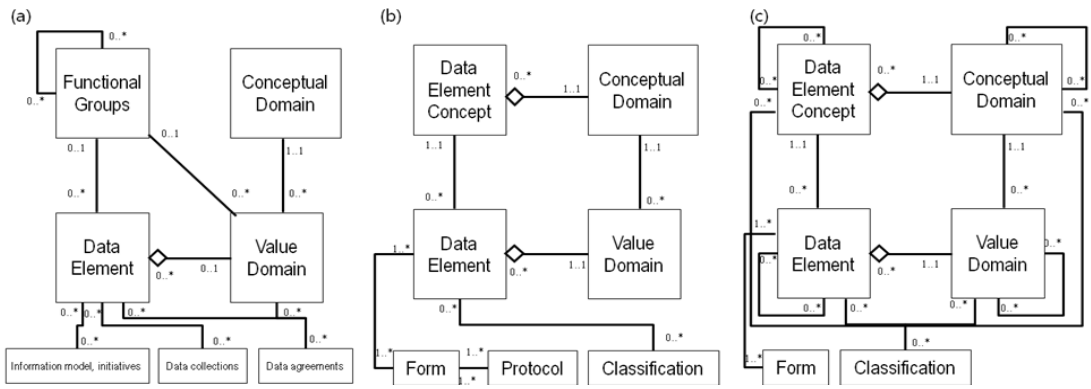

Figure 2- Reconstructed scheme for Metadata Registries (a) USHIK, (b) caDSR and (c) CHMR

Background: ISO/IEC 11179

ISO/IEC 11179 is an international standard for describing and registering metadata. Figure1 shows the most important five components of ISO/IEC 11179, Data Element, Data Element Concept, Value Domain, Conceptual Domain and Classification. The Data Element is foundational concepts in ISO/IEC 11179 model and an associated component between Data Element Concepts and Value Domain. Data Element Concept and Value domain is a set of attributes describing conceptual meaning and representational characteristics of data, respectively. Conceptual domain and Value Domain can be viewed as logical and physical code sets, respectively. Conceptual Domains support Data Element Concepts and Value Domains support Data Elements. Classification provides classification scheme to associate the components of ISO/IEC 11179.

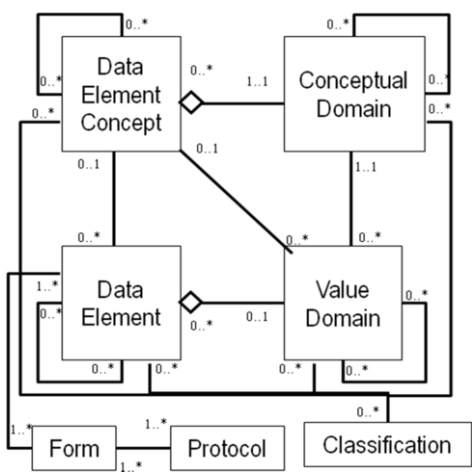

Figure 3- Integrated model

Materials and Methods

We select two public MDRs (USHIK and caDSR) with our own MDR called CHMR. USHIK and caDSR do not provide direct access to database schema or structure of metadata. For reconstructing the scheme of MDRs, we analyzed the XML files exported from caDSR and the metadata content structure of USHIK. Finally, we designed an integrated metadata object model (IMOM) and XML Schema Definition (XSD) to solve the structural inconsistency among MDRs. We downloaded 14,331, 39,572 and 13,835 data elements from USHIK, caDSR and CHMR, respectively, and stored them in an IMOM-enabled database, having 67, 738 data elements in total. We also implemented a system exporting metadata as XML files in organization-specific and IMOM formats regardless of the source of the metadata.

Results

Structural differences among MDRs

We reconstructed the scheme of MDRs (Figure 2) and compared the differences between MDRs. Relatively large number of modifications from the ISO/IEC definitions were found in USHIK and caDSR. Two of the most common modifications are as follows. First, most self associations are eliminated in USHIK and caDSR (Figures 2(a) and (b)). Second, newly defined component, named "Form," which is a set of data elements, is added in caDSR and CHMR (Figure 2(c)). Organization-specific modifications are as follows. USHIK renames Data Element Concept as "Functional Groups" and changes required associations to optional ones between Data Element and Functional Groups and Data Element and Value Domain. New associations were added between Functional Groups and Value domain (Figure 2(a)). caDSR added "Protocol" that represents a collection of "Form" (Figure 2(b)). CHMR added a self association in Data Element to describe the relationship between Data Elements (Figure 2(c)).

Integrated metadata object model and metadata exchange format

For covering all of the modifications in the three MDRs, we designed IMOM illustrated in Figure 3. The full object model represented in UML is available at http://bmesh.snubi.org/MetadataExchange/. There are two basic concepts of IMOM design. First, "do not eliminate organization specific extensions." Second, "basic attributes of ISO/IEC 11179 should be maintained." As a result, IMOM has 64 classes including five new classes related to the "Form" and "Protocol" components. Cardinalities of several associations were modified and four new associations were added.

To support metadata sharing among MDRs, we designed two types of XSD-based metadata exchange formats, one based on the full IMOM covering the entire attributes including organization-specific ones and the other covering the basic attributes only. The basic attributes are minimum specification for describing metadata defined by ISO/IEC 11179. Figure 4 shows a part of IMOM-based XSD file for metadata exchange. Both types of XSD files are available at http://bmesh.snubi.org/MetadataExchange/

Metadata Exporter

To evaluate IMOM and metadata exchange formats, we developed a metadata exporter (available at http://bmesh.snubi.org/MetadataExchnage/), supporting five XSD formats including the three organization-specific MDR formats and the two XSD formats based on IMOM and basic attributes.

Conclusion and Discussion

Recently, many organizations and research groups pay attention for extending and improving metadata contents [8-10]. Most efforts have been made for only one MDR or a domain. Achieving interoperability is important not only for an MDR but also for between MDRs. However, until now, research trends on metadata managing have been focused on just one MDR. The problem related to achieving interoperability among multiple MDRs should be researched.

In this paper, we proposed an integrated metadata object model and exchange format to solve the problem related to the structural inconsistencies among MDRs. We also implemented a metadata exporting system to support exchanging in multiple MDRs. To the best of our knowledge, none of the previous works have considered the interoperability among multiple MDRs. Our effort provides a basic framework to solve the structural inconsistency problems for achieving interoperability among multiple MDRs. In the next step of our research, we will focus on semantic inconsistency problems in multiple MDRs.

Abstract

To implement a knowledge-based clinical decision support system for clinical information systems, it is crucial to verify and validate the knowledge base. This study developed and tested the hypertension management CDSS, named LIGHT. This study used a knowledge representation framework based on SAGE and developed a knowledge converter to translate knowledge encoded into the knowledge engine. To verify knowledge converted through the knowledge converter that is included in the knowledge representation framework, expected recommendations were made according to the knowledge encoded based on 201 test cases. The expected recommendations were compared to those generated by the knowledge engine. To validate the knowledge base, two physicians reviewed the test cases and made medication orders according to the knowledge base. These medication orders were compared to recommendations generated by the LIGHT. The concordance rates for compelling indication and absolute contraindication were 85% and 100%, respectively. Another senior physician reviewed and analyzed the discrepancy cases between the orders of the two other physicians and system recommendations. Accordingly, the authors conclude that the knowledge base for hypertension management became more accurate and practical through the testing process.

Introduction

Knowledge based-CDSS integrated with an electronic medical record can provide clinicians with evidence-based patient-specific recommendations at the point of care [1]. Clinical practice guidelines (CPGs) are usually used as resources of evidence based knowledge for Knowledge based-CDSS. However, in order to use CPGs for CDSS, there are a lot of tasks such as non-computer interpretable and non-executable narrative CPGs are translated into executable knowledge.

Research has been done on guideline ontology for knowledge representation to support more efficient knowledge authoring of computer interpretable guidelines (CIGs). There are several guideline modeling methods, such as EON, Asbru, GEM, GUIDE, PROforma, PRODIGY, GLIF, SAGE. SAGE is built upon previous work on another guideline modeling and has been evaluated as an effective guideline modeling framework, which provides a systemic way to create sharable clinical interpretable guidelines and standardized vocabularies [2, 3].

A knowledge based CDS service, named Lightening pressure with computer-Implemented Guidelines on Hypertension Treatment (LIGHT), as a part of the EHR project in Korea. The LIGHT system provides recommendations for hypertension management, and integration into a hospital information system as an interoperable and sharable CDSS [4]. An EHR knowledge representation framework based on SAGE was used. However it was not possible to use a practical execution engine for SAGE-based guidelines. To execute SAGE-based guidelines, the u-BRAIN execution engine is developed as a knowledge engine that is an integrated process engine and rule engine. In addition, a knowledge converter to translate SAGE based guidelines into u-BRAIN is also developed, which is applied as an "Export" plug-in on Protégé (Figure 1) [5. 6].

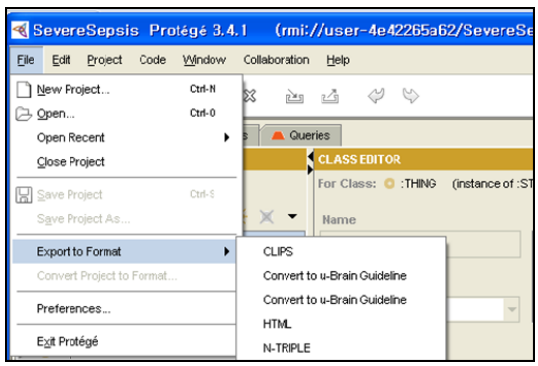

Figure 1 - The framework of EHR knowledge representation framework

It is possible to make wrong representation during the translation from narrative CPGs into computer interpretable guidelines. Clinical guidelines are often vague and incomplete with possible serious omissions and inconsistencies [7]. As well, newly developed software may have errors. It is essential to ensure that the recommendations generated by CDSS are accurate. One of the reasons for testing a system is to discover problems. The testing of the accuracy of the KB should be required at every step of the development of the system to ensure qualified software and to discover problems [8, 9].

The testing process was conducted in three phases (Figure 2). This paper focused on verifying knowledge converted (second phase) and validating the KB (third phase). Preece (2001) explained that *verification* is the process of checking whether the software system meets the specified requirements of the users, while *validation* is the process of checking whether the software system meets the actual requirements of the users [10].

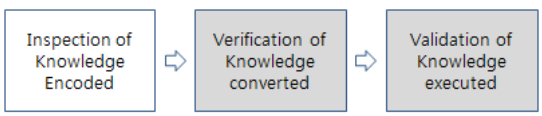

Figure 2- The process of testing the KB

The knowledge module for the LIGHT system is based on The Seventh Report of the Joint National Committee on the Detection, Evaluation, and Treatment of High Blood Pressure (JNC7) [11]. The knowledge module has 256 rules including the criteria of compelling indication and absolute contraindication for hypertensive medication. The LIGHT system makes recommendations for drugs of compelling indication or absolute contraindication. If blood pressure is not controlled (over goal BP), the system gives information about the maximum dose of the current medication.

The testing process in the development of the LIGHT system is described in this paper.

Materials and Methods

Test cases selection

This study used a set of 201 test cases selected from a data set of 430 patients with hypertension diagnosis (ICD 10 code; I10, Essential (primary) hypertension) in a general hospital. The inclusion criteria for the patient were history of two encounters from Dec 2007 to Dec 2008.

Verification of knowledge converted

The purpose of verification for the knowledge converted is to ensure that the knowledge converter correctly translates knowledge encoded into the u-Brain knowledge engine. The functional (black box) testing paradigm was used to verify the knowledge converted (Figure 3). Functional testing is concerned with the inputs and outputs of the LIGHT system [8].

The knowledge encoded based on our representation framework was inspected prior to the verification of knowledge converted. The semantic correctness and completeness was checked by two knowledge engineers who did not participate in the knowledge encoding. The research team including the knowledge encoders made the expected results in 201 real test cases, and compared them to the outputs of the generated knowledge executed through the knowledge converter in order to find errors of the knowledge converter.

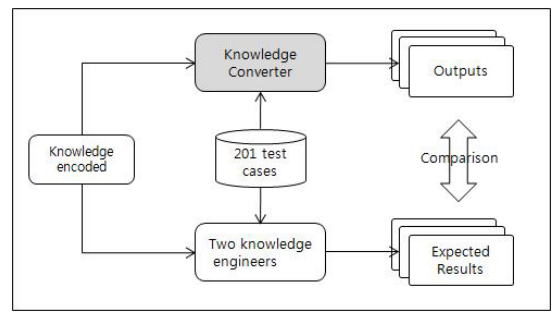

Figure 3 - The process to verify knowledge converted

Preparation of physicians for validation

Three physicians (internists) from a university hospital were involved in this phase. One physician had more experience and was regarded as the advanced physician. They had no previous involvement in the development of HT management KB. The document written 256 rules and the knowledge source of JNC7 were explained [9]. The documents were a semi-formal representation type such as excel and visio files. This study represented knowledge more explicitly on the documents than the CPGs.

Figure 4 - Screenshot for retrieving patient information and selecting medication for physicians

The LIGHT system was developed to present patient information and to obtain the recommendations from physicians. They reviewed patient information and prescribed medication according to information provided by the LIGHT system that would allow them to change the prescription after seeing the recommendation of system (Figure 4).

Patient information included age, most recent blood pressure measurement, previous blood pressure measurement, combined disease, signs and symptoms, most recent results of laboratory tests (potassium, sodium, glucose, urinalysis, lipid profile, creatinine, white blood cell count) and current medication. Physicians selected ADD, MAINTAIN, INCREASE and REMOVE 6 classes (thiazide, DHP and NDHP calcium channel blocker, ACE inhibitor, ARB, beta blocker) of hypertensive medication according to the current medication and the condition of the patient. These 6 classes of antihypertensive drugs were chosen because they were most frequently used in primary health care in Korea, according to the research that was conducted from May 2005 to Feb 2006 by R&D Center for Interoperable EHR.

Validation of knowledge executed

The medication recommendations generated by the CDSS were compared first with the medication selection made by physicians and then cases were searched for discrepancies. The advanced physician reviewed the cases and presented a third opinion about each test case. The KB was refined by consensus if the reason of the discrepancy originated form the HT management KB (Figure 5).

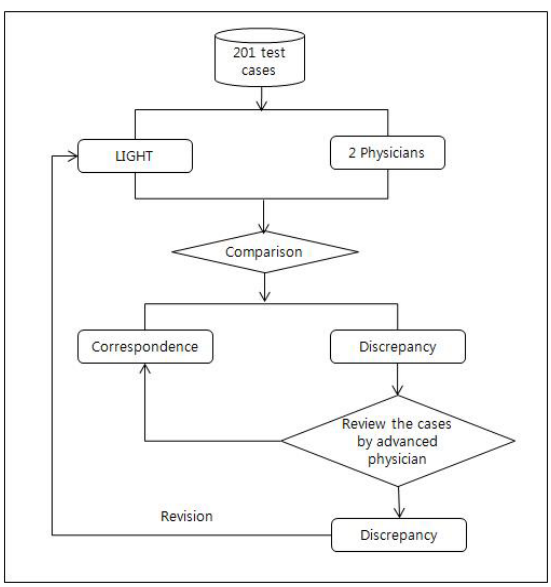

Figure 5 - The process to validate knowledge base

Framework to compare medication recommendations

An analysis of correspondence was made by compelling indication or absolute contraindication related to the condition of the patient.
The cases that were not matched according to the correspondence framework were regarded the cases as a discrepancy.

Table 1 - Framework of correspondence analysis

	Physician	LIGHT
Correspondence	Add	Compelling indication
	Maintain	Compelling indication
	Increase	Compelling indication and Not controlled BP
	Remove	Absolute contraindication

Evaluation of usefulness of recommendations

Two physicians were required to evaluate the usefulness of the patient specific recommendations generated by the LIGHT system. After the physicians prescribed medications for each patient, the system provided recommendations for the patient. And the system allowed them to change the prescription after seeing the recommendations and gave a user interface to evaluate the usefulness of recommendations.

Results

The correctness of knowledge converted

Outputs from the knowledge converter and expected results from the knowledge engineers based on knowledge encoded were exactly corresponded. The result showed that the knowledge converter could convert all knowledge elements used in SAGE into the knowledge engine [6]. To represent knowledge elements of CPGs, elements on SAGE were used such as activity graphs to represent the procedural knowledge, expression to represent rule based knowledge and virtual medical record (vMR) to identity the data of patients [2]. The knowledge converter used in this study can accept all these elements and convert correctly into the execution engine.

Analysis of the medication choice by physicians

For the 201 test cases, the LIGHT system made 537 medication recommendations with an average of 5.3 recommendations per test case (median 2, range 0-9). Physician A and B chose 279 hypertensive drug classes with an average of 2.8 for same test cases, respectively (physician A and B; median 1, range 0-4).

Among 279 drug classes, 164 classes selected from physician A and 176 selected classes from physician B came under the scope of the LIGHT system. The type of medication choice by physicians is shown in Table 2.

Table 2 – Type of prescription choice by physicians

	Type of Prescription			
	Add	**Maintain**	**Increase**	**Remove**
Physician A	30 (18.3%)	114 (69.5%)	17 (10.4%)	3 (1.8%)
	Subtotal		164(100.0%)	
Physician B	42 (23.9%)	116 (65.9%)	17 (9.6%)	1 (0.6%)
	Subtotal		176(100.0%)	

Result of comparison

In the case of compelling indication, correspondence rate for each physician was 85.1% respectively. In absolute contraindication, the rate was 100% respectively (Table 3). Two physicians were followed well by absolute contraindication from CPGs.

There were 27 test cases, when the medication recommendation discrepancies were classified by test case. These cases were characterized in three types; 1) A patient needed to increase the dose of a current medication or to add another medication, physicians did not choose a medication of compelling indication for ADD, INCREASE, 2) System recommended a medication of absolute contraindication, but physicians decided to ADD, MAINTAIN the medication or INCREASE dose, 3) The system recommended a medication of compelling indication, but physicians decided to remove the medication.

Table - 3 Correspondence rate of compelling indication

Classification	Physician A	Physician B
Correspondence	137 (85.1%)	149 (85.1%)
Discrepancy	24 (14.9%)	26 (14.9%)
Total	161 (100%)	175 (100%)

The reasons that led to discrepancies were analyzed through a review of the knowledge base and the opinion of an advanced physician. Medication recommendation discrepancies between physicians and the LIGHT system originated from the two reasons as follow; 1) The rule was on the document for semi-formal representation, however the rule was not encoded in the knowledge base. The relationship of a DHP-calcium channel blocker and angina was missed. The knowledge base was refined according to the results. 2) A physician did not recognize the condition of absolute contraindication. In this case, feedback was provided to the physician. 3) When blood pressure is controlled and the current medication is not absolute contraindication, physicians have a tendency not to change medications. This study did not regard as a discrepancy when the recommendation between them didn't correspond exactly.

Usefulness of recommendations of LIGHT

After physicians first chose recommendations were provided generated by the LIGHT system that gave the physicians a chance to change the selected medication. Physician A changed the choice in 14 cases and physician B did in 8 cases. In the evaluation of the usefulness of the recommendation given, physician A and B showed 96.1%, 77.4% respectively.

Physicians commented that the recommendation of the system would be very helpful for patients who required hypertension medication for the first time. However, in the case of a very complex patient, the LIGHT system did not consider all the parameters.

Discussion

It is difficult to make computer interpretable guideline in narrative CPGs when there are ambiguities and omissions [5, 7]. Newly developed software may contain errors [6]. The procedural testing method was conducted in order to search for errors in the knowledge base.

The EHR knowledge representation framework was used based on SAGE to make computer interpretable guidelines. The framework includes a knowledge converter that converts computer interpretable guidelines into knowledge execution engine. This study verified that the converter correctly all knowledge elements used in the SAGE framework with the converting knowledge base of HT management.

The validation of knowledge base is whether the content of the knowledge base accurately includes the knowledge of human experts [8], it is essential for human experts to participate. We could search one missing error and refined in the knowledge base through the testing process.

One of the limitations of this study is that the knowledge base didn't contain rules to cover all antihypertensive medications.

Conclusion

This study was conducted to verify and validate the knowledge base in every phase of developing CDSS. Through the verification and validation process, one omission in the knowledge base was found and refined to improved accuracy. The result showed that the testing process in every development phase contributed to an accurate and useful knowledge base and is useful for evaluating for other knowledge bases.

Abstract

Gestational diabetes mellitus (GDM) makes women at risk of type 2 diabetes during their life. In order to predict this later abnormal glucose intolerance, several antepartum and postpartum predictors have been identified. In this study we conjecture that future evolution is predictable from morphology of the oral glucose tolerance test (OGTT) curves at baseline. To test our hypothesis, as a first step we evaluated the association between the curve morphologies of normal and diabetic patient condition at baseline. In particular, we analysed glucose and insulin curves of a group of women with a history of GDM. A Self-organizing map (SOM) was proposed to evaluate shape differences among control, normal, impaired glucose tolerance and diabetic curves shape. We compared our results with the currently applied clinical classification. We found that morphology contains information about the current status of the patient, because the SOM analysis clearly allows to discriminate subjects belonging to healthy or diabetic group. Moreover, SOMs highlighted additional information that could be used for prognostic purposes.

Keywords:

Gestational Diabetes Mellitus, Self-Organizing Map, Morphological analysis, Oral Glucose Tolerance Test

Introduction

Gestational diabetes mellitus (GDM) is defined as the diabetic condition with onset during pregnancy [1]. The prevalence of GDM seems to be proportional to the prevalence of type 2 diabetes; however, in general, GDM prevalence ranges from 1% to 14% of all pregnancies depending on the population studied [2]. In most cases, the onset of GDM is characterized by the symptoms of type 2 diabetes, i.e., an increased insulin resistance, and a decline in insulin secretion [3,4]. For this reason, gestational diabetes is often considered to be type 2 diabetes unmasked by pregnancy, also because they share common risk factors, such as obesity. In general, shortly after delivery, glucose homoeostasis is restored to the antepartum condition, but women with a history of GDM often show high blood pressure, atherogenic lipid profiles [5,6], and have a high risk of developing type 2 diabetes [7]. A systematic review showed that the incidence of diabetes among women with a history of GDM ranges from 3% to 65%, because of differences in the duration of the follow-up period and ethnicity [8]. This means that women who had gestational diabetes have at least a seven-fold increased risk of developing type 2 diabetes compared with those who had a normoglycaemic pregnancy [9]. Hence, women with a history of GDM represent a high-risk population and, since the risk of type 2 diabetes seems to be maintained for several years, they should attend regular assessments of their glucose tolerance condition. For these reasons, there is the need to develop appropriate preventive strategies and to identify reliable prognostic factors. In the last years, different antepartum and postpartum independent predictors of later abnormal glucose tolerance have been identified [10-14]. Several studies considered parameters or variables derived from the oral glucose tolerance test (OGTT) data as possible predictors of diabetes risk in the former GDM population, but a few studies considered the entire morphology of those curves.

In this study we hypothesize that the future evolution to a condition of normal glucose tolerance or type 2 diabetes is predictable from the morphology of the OGTT curves at baseline. In order to evaluate this potential predictor capacity, the first step is to evaluate if additional and useful information is contained into curves shape besides the two specific values used for current diagnosis of normal/diabetic condition. For this reason, we used a Self-organizing map (SOM), that is a neural network able to reduce high dimensional data into a low-dimensional topological map and display similarities, in order to cluster OGTT curves basing on their shape. Glucose and insulin curves derived from OGTTs of women with former GDM were considered. The SOM-based analysis was compared with the clinical, shape-independent classification of the glucose tolerance condition (i.e. the gold standard), in order to assess whether the morphology of the OGTT curves are (i) correlated to such condition, and (ii) maintain memory of the previous disease (GDM condition). Moreover, having a small number of curves at disposal, the other aim of this study is to find out an efficient method able to guide data mining in presence of small datasets.

Materials and Methods

Subjects

A group of 127 Caucasian women with GDM was investigated together with a control group (CNT) of 40 women without known risks for diabetes, and with normal glucose tolerance both during pregnancy and at the time of study. Gestational diabetes was diagnosed according to American Diabetes Association (ADA) criteria [15].

All women were recruited during pregnancy from the outpatient department of the University Clinic of Vienna, and gave written informed consent for participation in the study, which was approved by the local ethics committee. They were studied for a maximum of 5 years after delivery. All women underwent a standard 75-g OGTT every year. For each OGTT venous blood samples were collected at fasting and at 10, 20, 30, 60, 90, 120, 150 and 180 min afterward. In this preliminary analysis, however, only OGTT data at the baseline condition were used. According to the criteria proposed by ADA in 1997 [16], summarized in Table 1, the population was divided into a normotolerant group (NGT), a group with impaired glucose tolerance (IGT), and a group with type 2 diabetes (T2DM).

Table 1 – ADA classification of diabetes. G is the glucose concentration in blood measured at the beginning of the test and after 120 min

Glucose Values [mg/dL]	Clinical Classification
[G(0) < 100]	NGT
100 ≤ [G(0)] < 126 **OR** 140≤ [G(120)] <200	IGT
[G(0)] ≥ 126 **OR** [G(120)] ≥ 200	T2DM

As an example of the OGTT data, Figure 1 displays the measured mean glucose curves of NGT, IGT and T2DM subjects.

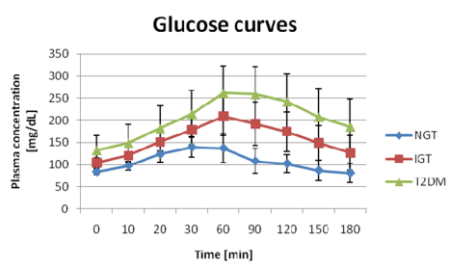

Figure 1 – Mean glucose curves and standard deviations of NGT, IGT and T2DM subjects

Morphological analysis

The Self-organizing map (SOM) is a subtype of artificial neural networks which uses a competitive learning technique to train itself in an unsupervised manner [17]. Competitive learning is an adaptive process in which the neurons of the neural network gradually become sensitive to different input categories, i.e., sets of samples in a specific domain of the input space. A division of neural nodes emerges in the network to represent different patterns of the inputs after training. The division is enforced by competition among the neurons: when an input x arrives, the neuron which is able to represent x better than the others wins the competition and is allowed to learn it even better. If there exist an ordering between the neurons, i.e. the neurons are located on a discrete lattice, the competitive learning algorithm can be generalized. Not only the winning neuron but also its neighbouring neurons on the lattice are allowed to learn: the whole effect is that the final map becomes an ordered map in the input space. This is the essence of the SOM algorithm. Technically, a SOM is made of m neurons located on a regular low-dimensional grid, usually one or two-dimensional. Each neuron i has a d-dimensional feature vector $w_i = [w_{i1},...,w_{id}]$, called prototype vector. At each training step t, a sample data vector $x(t)$ is randomly chosen for the training set, and the "distance" between $x(t)$ and each feature vector is computed. The winning neuron, denoted by BMU (Best Matching Unit), is the neuron with the feature vector closest to $x(t)$:

$$BMU = arg\min_i \| x(t) - w_i \|, \qquad i \in \{1,\ldots,m\}.$$

Once the winning neuron emerges, the weights of the neurons which are close to it are adjusted: because of the neighbourhood relationships, neighbouring neurons are pulled to the same direction, and thus prototype vectors of neighbouring neurons resemble each other. After the training is over, the map should be topologically ordered: this means that n topologically close input data vectors map to n adjacent map neurons or even to the same single neuron.

The morphological analysis was performed over all the glucose and insulin curves made available by the OGTT test. The analysis was conducted both on measured curves, and on curves obtained by the measured ones by removing their mean value. This was done in order to investigate whether curves can be someway classified exclusively in terms of their morphology, or the classification is biased by the exact value of each sample of the curve. For the SOM design, a hexagonal lattice map, a linear initialization of prototype vectors and a batch training algorithm was chosen, while the dimension of the grid depended on the size of the training sets used. The input sets were different, depending on what information we wanted to extract from the morphology of the considered curves. In detail, we investigated two different aspects:

- Curves belonging to CNT ($n = 40$) and NGT groups ($n = 43$) were used to construct a SOM with the aim of discovering whether a sort of memory of the previous disease (the GDM condition) is maintained in the morphology of the NGT curves (memory-of-disease-driven shape)
- Combination of curves belonging to CNT, NGT, IGT and T2DM groups (see Table 2) were used for training SOMs, aiming at evaluating whether there are substantial morphological differences among curves of subjects classified as having different glucose tolerance condition according to the ADA 1997 criteria [16].

Table 2 – Combination of curves used for training SOM

Combination of curves	Sample dimension
NGT vs. T2DM	($n_{NGT} = 43$) vs. ($n_{T2DM} = 37$)
NGT vs. IGT	($n_{NGT} = 43$) vs. ($n_{IGT} = 47$)
NGT vs. IGT vs. T2DM	($n_{NGT} = 43$) vs. ($n_{IGT} = 47$) vs. ($n_{T2DM} = 37$)

After training, the natural clustering tendency of curves was evaluated. Moreover, the available a priori knowledge about the input dataset was then used: each neuron was, in fact, afterwards labelled with class of the most numerous group of curves represented by that node. In this way, it was possible to understand how the current classification is represented by curves morphology and if SOM makes additional information come out.

The entire analysis was performed inside Matlab environment (The Mathworks, Inc., Natick, USA).

Results

First of all, there was any significant difference between results obtained with measured curves and those obtained with curves subtracted of their mean value (data not shown). For this reason, the following results are referred only to zero-mean curves.

A visual depiction of the analysis performed over glucose curves belonging to CNT and NGT groups is shown in Figure 2, where each colour is the result of the waveform classification performed by the SOM, i.e.: blue colour is associated to neurons representative of only CNT curves; yellow colour is associated to neurons representative of only NGT curves; green colour is associated to neurons with prototype vectors morphology is very close to both CNT and NGT curves. Notably, colours do not identify well separated regions in the map. This means that SOMs were not able to assign CNT and NGT curves to distinct regions of the map: neurons representative of only CNT curves were not confined in a particular region well separated from regions with neurons that recognized only NGT curves. Furthermore, about the 35% of prototype vectors was very similar both to CNT and NGT curves, and the corresponding neurons were quite randomly distributed in the SOM space. Also comparing different type of curves combined together (glucose and insulin) did not improve the SOM capability in discriminating among CNT and NGT curves (data not shown).

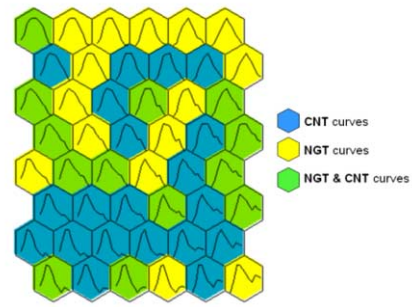

Figure 2 – CNT vs. NGT curves SOM: each neuron (hexagon) is characterized by its prototype vector (curve drawn inside the neuron). In this case, neurons representative of only CNT curves were not confined in a particular region well separated from regions with neurons that recognized only NGT curves

Concerning the morphological differences between NGT and T2DM groups, the SOM based analysis put in evidence a clear division in the morphology of the OGTT measured waveforms, as showed in Figure 3, in particular when only glucose curves were considered.

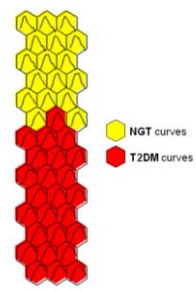

Figure 3 – NGT vs. T2DM curves SOM: upper region recognized only NGT patients, while lower area only T2DM curves

When the IGT group was included in the analysis, SOM analysis identified specific regions in the map referable to NGT, IGT and T2DM curves (Figure 4: glucose and insulin curves combined). However, when IGT curves were intro-duced in the analysis, the clear distinction observed between different group, such as Figure 3, was partially lost: transition regions appeared in the map because their prototype vectors were close enough to two different types of curve morphol-ogy. This is due to the fact that the inclusion of IGT curves in the analysis made less clear the distinction between NGT and T2DM curve morphology.

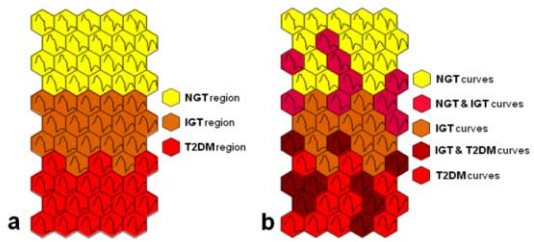

Figure 4 – NGT vs. IGT vs. T2DM curves SOM: it was possible to identify regions corresponding to different groups (a), however, some neurons had prototype vectors closed to two kind of curves, i.e. NGT and IGT or IGT and T2DM (b)

The distribution of the curves within neurons when the three clinically defined groups are included in the SOM analysis is summarized in Table 3. Notably, the number of NGT and T2DM curves falling into regions different from their clinical diagnosis was only the 2% and the 16%, respectively. In both the two cases, this happened because they were considered to belong to the same neurons as IGT curves.

Table 3 – Classification of curves using regions identified by SOM

Glucose tolerance condition	Areas identified by the SOM		
	NGT region	IGT region	T2DM region
NGT	42 *(98%)*	1*(2%)*	0
IGT	8 *(17%)*	30 *(64%)*	9 *(19%)*
T2DM	0	6 *(16%)*	31 *(84%)*

Discussion

To our knowledge, a few studies are present in the literature addressing the problem of the possible information contained in the shape of the OGTT curve [18]. In particular, in a population of women with a history of gestational diabetes, only a preliminary study [18] was carried out so far, based on a totally different approach from the SOM analysis used in this study.

Our results show that the whole morphology of the OGTT measured curves contain information about the current status of the patient with a history of GDM, because the SOM-based clustering clearly allows to discriminate subjects belonging to healthy or diabetic group even when the mean values is removed from the measured curves. Moreover, there are additional information that lead SOM to map nearer or not curves that currently belong to different groups. Exactly this topographic arrangement could be predictive of future evolution of patients.

Concerning the previous status of patient, OGTT measured curves of NGT women seem not to contain any memory of the previous GDM condition (that is, at this stage of analysis our method seems not to distinguish between NGT with former GDM and CNT). However, the other results presented here make us confident about the possibility of proceeding in our hypothesis verification: in fact, our preliminary findings show that OGTT curves morphology contains additional information about the current glucose tolerance condition that can be used for prediction of patient status evolution.

Conclusion

In conclusion, we succeeded in mining novel knowledge from our dataset even if it is relatively small: having not a large number of curves, through SOM, we have however extracted shape information that could be used for pattern recognition and feature selection in the next step, in which a relation between morphology characteristics and follow-up will be sought.

We also demonstrated the presence of additional information that, for example, leads some normal curve to be more similar to a diabetic one. The next phase will be to validate the hypothesis that these similarities or dissimilarities, recognized and underlined by SOM, are effectively prognostic factors of glucose tolerance evolution.

These results will be used to improve the follow up of women with a history of GDM. The fact that the whole morphology of the OGTT curves, and not only the absolute value of some glucose or insulin OGTT samples, depends upon the normal or diabetic condition of a subject allow for a more reliable identification of women that will develop type 2 diabetes.

Abstract

Blood Glucose (BG) analysis and control in critically ill patients became an important research challenge in the last few years. Despite the big improvements that have been achieved both in research and in clinical practice, there are still many aspects that need to be elucidated. A first step towards a better comprehension of the phenomena underlying BG dynamics is represented by the study of retrospectively collected data. In this paper we propose an analysis of blood glucose time series through a combined temporal clustering and standard statistical analysis approach. The ultimate goal of the analysis is the identification of groups of patients showing different BG dynamics and evaluate their risk profiles, which is a very important issue in the Intensive Care Units. The method is applied to a set of patients treated at the Mediterranean Institute for Transplantation and Advanced Specialized Therapies in Palermo, Italy. We show that it is possible to identify two groups based on the initial blood glucose trends, and that the two groups significantly differ in terms of their future BG behaviour.

Keywords:

Blood glucose analysis, Temporal data mining, Clustering, Intensive care units.

Introduction

Blood Glucose (BG) analysis in critically ill patients has become a crucial issue over the last few years [1,2]. Recent studies have demonstrated that a tight glycaemic control in Intensive Care Units (ICUs) causes a significant reduction in mortality and in the development of post-operative morbidities in surgical ICU patients [3-5]. The use of standardized protocols is leading to better patients' outcomes, so that many tools have been proposed to improve the compliance of ICU departments to current guidelines [6]. Several "ad hoc" glucose variability indexes have been proposed in the literature to evaluate and compare the quality of BG control algorithms among patients [7-9]. Although a lot of progresses have been achieved in this field, many aspects of BG control in ICU patients still have to be deeply understood and there is certainly room for large improvement.

A first step towards a better comprehension of the phenomena underlying BG dynamics is represented by the analysis of retrospectively collected data resorting to statistical and data mining methods. In particular, since BG monitoring data are naturally collected over time, an interesting application is to study such data by exploiting Temporal Data Mining techniques. This can be useful for example to detect different risk profiles in the patients and to plan different therapies for different groups. To this end, temporal clustering techniques are particularly suitable to identify groups of patients showing similarities in glycaemic profiles. However, since ICU patients are usually characterized by severe conditions, the collected time series are often very noisy and irregular. Moreover, they are characterized by uneven sampling time and missing data. To tackle these problems, many researchers are starting to move towards methods that resort to a qualitative and abstract representation of temporal profiles, which are often based on the Temporal Abstraction (TA) technique [10-12].

In this paper we present a combined analysis through TA-based clustering [13] and classical statistical methods applied to ICU patients who underwent cardiovascular surgery at the Mediterranean Institute for Transplantation and Advanced Specialized Therapies (ISMETT) in Palermo, Italy. We show that it is possible to identify two risk groups based on the initial blood glucose trends, and that the two groups significantly differ on some important aspects of their future behavior.

The paper is structured as follows: in the Methods Section we describe the algorithms and analysis approach we used; in the Results Section we introduce the ISMETT ICU data set and we show the results obtained on the patients. The results are further commented in the Discussion Section. In the last Section we draw some final conclusions.

Methods

The analysis approach we adopted in this work is mainly characterized by three methodological issues. The first part of the

analysis deals with the extraction of a suitable representation of BG time series through Temporal Abstractions. Such representation serves as a preparation for the second step, which is temporal clustering. The third phase deals with knowledge extraction from clustering results. The aim of this last phase is to find significantly different groups of patients, focusing in particular on the risk of hypo and hyper-glycaemic events during ICU stay. The different analysis steps are described in the following sections.

Knowledge-based Temporal Abstractions

Knowledge-based Temporal Abstractions (TAs) were first introduced in [14]; they are a formalism that allows to move from a time-point to an interval-based representation of time series data. Such technique provides a description of a (set of) time series through sequences of temporal intervals corresponding to relevant qualitative patterns detected in their time courses. Following the model proposed in [15,16], TAs can be classified into two main categories, depending on the input and output data that are provided. *Basic* TAs are used to transform time-stamped data into a sequence of intervals, while *Complex* TAs are used to abstract intervals into other intervals applying suitable temporal operators [17]. In this paper we will mainly refer to Basic temporal abstractions, that we herein exploit to extract Increasing, Decreasing and Stationary trend patterns from blood glucose time series.

The algorithms that are used to detect TAs are known as TA mechanisms. We herein use a segmentation-and-labeling methodology to extract trends from the raw blood glucose time series. Time series are first processed through a stepwise linear segmentation and then a label is assigned to each segment on the base of its slope. For time series segmentation we use a bottom-up approach [18] suitably designed to deal with unevenly sampled and missing data. Once segments are extracted, the following step is to assign a label to each of them according to the slope of the segment itself. In this work we use a purely data-driven labeling approach, where a two-tailed t-test is performed on the slope parameter of the linear regression used for segment definition. A significance level α is established for the test, and the labeling criterion is the following:

- if |p-value|$\leq\alpha$ AND slope>0 then label = *Increasing*
- if |p-value|$\leq\alpha$ AND slope<0 then label = *Decreasing*
- if |p-value|>α then label = *Steady*

An alternative solution to the labeling issue is the knowledge based definition of a minimum slope threshold to which the segment slope value is compared.

As a result of this first analysis step, BG time series are represented by a qualitative label (or abstract pattern) made up of a set of consecutive basic trend TAs.

Temporal Clustering

The second analysis step concerns the application of a novel method to cluster time series data according to their qualitative behavior [13,19]. This method is called TA-clustering and, although designed to deal with gene expression data, well adapts to any time series with irregular sampling time. The TA-clustering technique is a generalization of template-based clustering [20] and it is based on a qualitative representation of profiles derived exploiting trend TAs (as described in the previous section). One of the most relevant features of TA-clustering is that it is based on a multi-level strategy that works on qualitative labels. In particular, we originally defined three abstraction levels for time series representation, that reflect different label aggregation. As a starting point we take the label deriving from the segmentation-and-labeling step; we will call this label the L_2-level label, since it represents the intermediate level from which the other two are then derived. L_1-level labels are obtained by removing all the *Steady* elements from L_2 labels and re-aggregating consecutive equal labels when needed. L_3-level labels are low-level abstractions obtained by assigning to each time interval of the original time series the corresponding qualitative label (consecutive labels can be duplicated in such representation). An example of the multi-level labeling system is depicted in Figure 1.

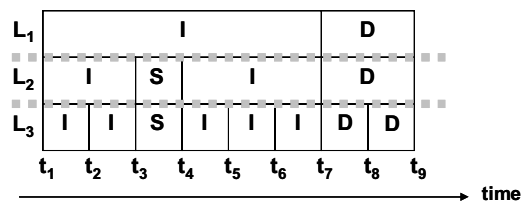

*Figure 1 – Example of the multi-level labeling scheme used for temporal clustering. Herein **I** stands for Increasing, **D** for Decreasing and **S** for Steady. At the bottom of the picture the time line is reported.*

Considering the high heterogeneity in sampling time, number of measurements and length of stay characterizing critically ill patients, in this work we will only refer to the most abstracted levels (L_1 and L_2).

Once the abstracted labels are created, the aggregation procedure for the two top levels is straightforward: time series with the same label are grouped into the same cluster. For L_3 labels a distance function is instead defined to group together time series that show similar qualitative behavior [13].

Evaluation and Comparison of Patients' Risk profiles

Relying on clustering results it is often possible to identify patients groups and to evaluate the clinical profiles of the members of such groups on the base of interesting characteristics. As regards BG monitoring, an interesting index to assess a patient's condition is to evaluate his/her risk of experiencing hyper or hypo-glycaemic episodes during the ICU stay.

To this end, for each patient we compute the risk profile following the indications proposed in [8]. In particular, for any BG measurement (*bg*) expressed in mg/dl, the risk function(*r(bg)*) is defined as follows:

$$r(bg) = 10 \times \left\{1.509 \times \left[(\ln(bg))^{1.084} - 5.381\right]\right\}^2 \quad (1)$$

Exploiting equation (1) it is possible to derive a risk time series for each patient. From this time series the average risk can then be calculated on a specific time window as required by the analysis purposes. We will exploit such solution on the groups of patients extracted through clustering. As we will show in the next section, comparisons between groups are performed towards standard statistical methods.

Results

Data Set Description

In this study we considered a group of 596 ICU patients treated by the Mediterranean Institute for Transplantation and Advanced Specialized Therapies in Palermo, Italy, from August 2006 to February 2008. The patients belonging to our sample underwent various types of cardiac surgery, as reported in Table 1. For 11 patients the information related to the type of intervention was not available.

Table 1 – Type of surgery and number of patients in our data set

Type of surgery	Number of patients
Single valve	216
Multiple valves	47
Aortic surgery	16
Ventricular surgery	24
Bypass	180
Bypass and Valve	78
Transplantation	15
Minor cardiac surgery	9

A set of 22 parameters was monitored over time for all the patients during the ICU stay. In this study we will consider blood glucose time series. BG was monitored for all the patients by means of BG fingerstick and venous measurements. The median of ICU stay was of 3 days (minimum: 1 day, maximum 31 days), with an average number of 14 measures per patient and an average inter-measurement time of 3.7 hours.

Data Analysis

Considering the median length of stay and the fact that patients staying at the ICU for 3 or more days usually show the most critical illness conditions, in our analysis we chose to take into account the first 3 monitoring days. As a first analysis step we performed TA-clustering using L_1 and L_2-level labels. The result of this step was a set of 14 L_1 clusters, that we further joined to form two macro-groups based on the initial trend of the glucose monitored values (*Increasing* and *Decreasing*)

In particular, we identified 300 patients starting with an initial increasing trend and 286 patients starting with a decreasing glucose trend. Figures 2 and 3 represent the two clusters with the average profile of the initial trend.

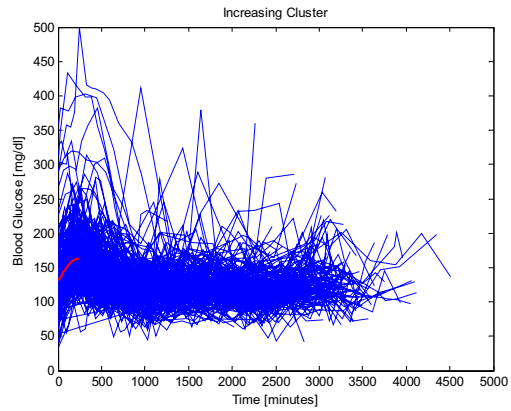

Figure 2 – Cluster of patients with an initial increasing trend

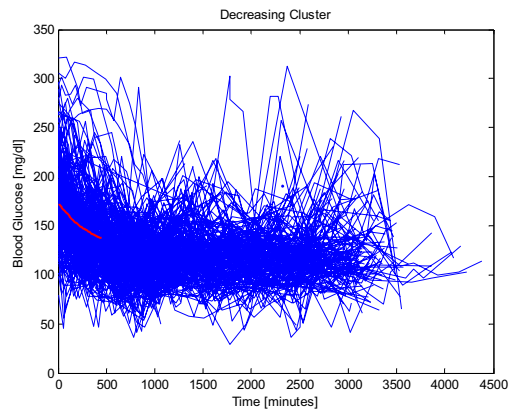

Figure 3 – Cluster of patients with an initial decreasing trend

The median time span of the initial increasing interval was found to be 4.03 hours, with an interquartile range of [1.9 - 8.4] hours. The median duration of the initial decrease was found to be 14.4 hours, with interquartile range [7.98–21.15] hours. The two medians are significantly different ($p << 0.01$). The duration of the increasing trend is significantly shorter than the duration of the decreasing BG trend ($p << 0.01$).

We also found a significant difference ($p < 0.05$) between the initial BG values in the two groups. Rather interestingly, the higher BG basal value is associated to the decreasing group, as it can be noticed by the boxplot in Figure 4.

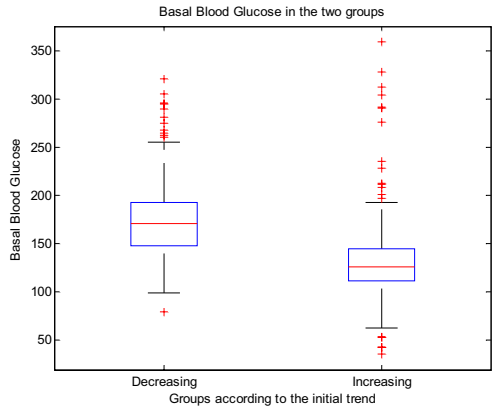

Figure 4 – Boxplot of the distributions of the basal BG value in the two groups

As a next analysis step, we have subdivided the BG time series for each patient into two periods to evaluate the patients' risk profiles. The first period was set to finish at the end of the initial trend (i.e. the increasing or decreasing period), while the second period was defined by the remaining monitoring time.

For each patient we computed the time series of the risks, and we calculated the average risk index on the two periods. We compared the average risk distributions for the second period in the two clusters, and we obtained a significant result ($p << 0.01$), being the decreasing group less risky. Besides the average risk index we also evaluated the standard deviation of BG measurements in the second period and compared it in the two groups. Also in this case the result showed a significant difference (p-value<<0.01) with higher values for the Increasing group. In particular the median value for standard deviations in the Increasing group was of 25.03, while for the Decreasing group it was 20.6.

To better evaluate the instability scenario that clearly characterizes the patients belonging to the Increasing group, we also analyzed the insulin intake in our set of patients with the goal of comparing the two groups. In particular, we compared the medians of the standard deviation of the insulin intakes after the initial trend in the two groups. The result is significant (p-value <<0.01), with a lower value for the Decreasing group. The median value of the insulin intake standard deviation for the Increasing group was found to be 1.24, while for the Decreasing patients it was found to be 0.95.

A further analysis also revealed that the duration of the increasing period is significantly positively correlated with the risk in the second period and that the duration of the decreasing period is negatively correlated with the risk in the second period ($p < 0.05$).

To better elucidate if the difference between the two groups is due to some clinical reasons not related to BG control, we performed an additional analysis to check the frequency of the surgery type and risk factors (comorbidities) in the two groups of patients. We didn't find clinically interesting differences in the distribution of clinical interventions; however, we found that in the Decreasing group there are significantly more Diabetes mellitus patients (76 vs 52, $p < 0.05$) while in the Increasing group there are more Valvular Heart Disease patients (148 vs 193 $p<0.05$)

Finally, we analyzed the distributions of clinical morbidities of the two groups, that showed significant differences only concerning Bleeding (Decreasing 15, Increasing 26, $p<0.01$) and the need of an Intra Aortic Balloon Pump (Decreasing 15, Increasing 3, $p<<0.01$).

Discussion

In the previous section we have shown that it is possible to divide ICU patients into two groups related to the initial BG trend and that these groups show significant differences in their risk profiles and in insulin treatment.

In particular, we have demonstrated that the basal BG values are significantly higher in the Decreasing group. This can be motivated by analyzing the post-operative patient management. Each patient gets an insulin drip starting immediately after surgery until they start to eat. If an high basal glycaemic level is observed, it is immediately treated to return to normal values, thus originating a decrease in BG time series. Higher basal glycaemic values lead thus to a more aggressive treatment in BG control at least in the first period.

Similarly, the resulting shorter duration of the increasing trend is clinically motivated by the fact that an increase in BG is often considered as an alarm. The procedures to go back to a normoglycaemic pattern are performed quite quickly in order to stop the increase and to avoid severe complications.

Broader glycaemic oscillations and higher average risk indexes were also found for the Increasing patients. This was coupled to an higher variability in the associated insulin therapy for such group, highlighting a clear relationship between the glycaemic temporal patterns and the clinical management of the patients.

Trying to further characterize the two groups of patients on the base of their clinical characteristics, we also compared the frequencies of surgery type and risk factors in the two samples. The aim of this analysis was to verify whether the group characterized by the higher instability and risk index (the Increasing group) was made up of patients who underwent major surgeries or characterized by important risk factors. However, our tests resulted in almost no significant differences into the distributions of surgeries and comorbidities among patients. Also the number of diabetic patients, that are usually characterized by a more aggressive insulin therapy and were thus expected to fall into the decreasing group, was only slightly higher in such group. The same conclusion can be drawn if we observe the distribution of the morbidities in our two samples. Besides the increase of the risk index and in the incidence of bleeding, the patients of the Increasing group don't show major morbidities if compared to the Decreasing group.

We might thus conclude that, at least in the clinical center under study, an increase of BG after surgery is a useful marker of

metabolic instability and of a critical evolution of the patient's condition which requires more frequent intervention of the health care providers. A further step of the analysis will be to include in the study also the other parameters that are monitored during the ICU stay.

Conclusion

In this paper we have presented a temporal data mining approach to the problem of analyzing blood glucose monitoring time series in ICU patients. In particular, we have applied a TA-based clustering technique to identify groups of patients showing similarities in their glycaemic profiles. We have been able to identify two macro-groups of patients characterized by a different initial trend in BG, namely Increasing and Decreasing trends. Such groups were found to significantly differ on some important characteristics, and in particular we found that the patients showing an initial increase in BG have an higher future BG risk and higher future oscillations. Moreover, the risk in the second period results to be correlated with the duration of the initial trend. These promising results lead us to conclude that evaluating the initial BG trend can be predictive of the future behavior of the patients' risk profile.

This paper showed that temporal data mining is a useful tool to better understand the data collected in routine clinic and to provide health care providers with useful advice and caveats.

Abstract

Women with gestational diabetes mellitus (GDM) are at increased risk of developing type 2 diabetes (T2DM). However, the degree of risk and the timing of progression from normal to a pre-diabetic or diabetic state have not been clearly quantified. In this study we analyzed data from a longitudinal study on a group of women with a history of GDM, that were inserted in an oral glucose tolerance test (OGTT) annual screening program and followed up for 5 years after partum. A three state Markov chain model was proposed to represent the dynamics of changes between metabolic states. We used the data to empirically estimate the one-year transition parameters of the model and make predictions about the possibility that women with normal glucose tolerance or impaired glucose metabolism just after partum will develop overt T2DM in three or five years. Results show that subjects with an impaired glucose metabolism few months after partum will hardly (10%) be in the same state after three years. Women with normal glucose tolerance after partum will have a high probability (0.80) to be in the same state three years after.

Introduction

Gestational diabetes mellitus (GDM) is the specific type of diabetes that may develop during pregnancy [1]. GDM is a quite common condition with a prevalence ranging from 1 to 14% of pregnancies, depending on the population under study. GDM represents nearly 90% of all pregnancies complicated by diabetes. The incidence of gestational diabetes is rising throughout the world [2,3], and the same holds for type 2 diabetes [4]. Women with previous gestational diabetes, after delivery (pGDM), often normalize their glucose levels, but they are at increased risk of developing type 2 diabetes [5,6], especially if they have other risk factors (i.e. obesity, hypertension, family history of type 2 diabetes). In this context, it is important to undertake follow up studies that can provide some insights about the actual risk and timing of possible onset of type 2 diabetes. Data analyzed in this paper refers to a 5 year follow up study of glucose tolerance in pGDM women. The analysis of the data was carried out using a three state Markov chain model to study the transition between different glucose tolerance conditions and making predictions about the onset of type 2 diabetes in the population after three years from the delivery. Markov chains have often been used to model disease's natural history, see [7] for an example of application in the context of diabetes.

Subjects

A group of 116 women participated in the study. They were selectively recruited from the outpatient department of the University Clinic of Vienna. Written informed consent was obtained from all subjects and the protocol was approved by the local ethics committee. For all women, GDM was found in their first pregnancy; repeated pregnancies were excluded.

Table 1 – Characteristics of the studied pGDM women at the basal state (mean ± SE).

	NGT	IGM	T2DM
Number of subjects	87	21	8
Age (years)	32.91 ± 0.51	34.66 ± 0.93	33.88 ± 2.25
BMI (kg m^{-2})	26.57 ± 0.55	30.97 ± 1.00	31.35 ± 2.15
Fasting plasma glucose (pmol L^{-1})	4.82 ± 0.05	5.89 ± 0.18	6.91 ± 0.35
Plasma glucose at 120 min (pmol L^{-1})	5.88 ± 0.11	9.77 ± 0.36	11.85 ± 0.63

GDM was diagnosed in all the participants according to the criteria of the 4th Workshop Conference of Gestational Diabetes [5], through a 75-g oral glucose tolerance test (OGTT). During pregnancy the GDM women were not subjected to any treatment; they received only dietary and physical exercise advertisements. The study started with a basal OGTT screen-

ing taken 4 to 6 months after partum and then the women were followed, with an annual OGTT screening program, up to 5 years later on. The characteristics of the pGDM women immediately after partum are described in Table 1. Subjects' conditions (or metabolic states) were classified, according to the American Diabetes Association (ADA) 1997 criteria, as: normal glucose tolerance (NGT); impaired glucose metabolism (IGM), including subjects with impaired glucose tolerance (IGT) and/or impaired fasting glucose (IFG); and type 2 diabetes (T2DM). A complete depiction of the data is given by Figure 1, where the distribution of the metabolic states at each year is reported.

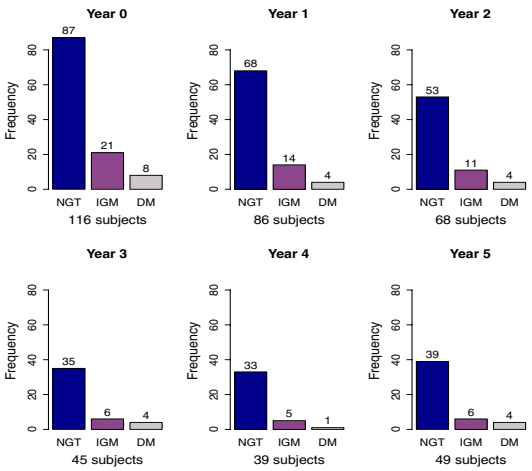

Figure 1- Frequency distribution of the three states (NGT, IGM, T2DM) at each year.

There were two main causes for ending the program: the natural deadline (5 years after partum), or the onset of type 2 diabetes. The data expected from the protocol are not complete, because some participants skipped one or more visits and then reentered the program subsequently.

Methods

Oral Glucose Tolerance Test

After an overnight fast, all women underwent a standard 75-g OGTT. Venous blood samples were collected immediately before glucose ingestion (fasting sample, $t=0$) and at 10, 20, 30, 60, 90, 120, 150 and 180 min afterwards for glucose, insulin and C-peptide measurements.

Data analysis

Markov chains

A Markov chain (MC) is a simple stochastic process often used to model uncertain phenomena evolving in time. In a stochastic process changes of state (value of the process) are governed by probabilistic laws. The laws describing present and future values of the process in terms of its past state history are called transition laws. A Markov chain, specifically, is characterized by transition laws depending only the most recent past state and not on the whole past history. More formally, consider a stochastic process $\{X_t, t=0,1,2,\ldots\}$ that takes values on a finite set S, called state space. Let the state space size be N, with $S=\{s_1,s_2,\ldots,s_N\}$. If $X_t=s_i$, then the process is said to be in state s_i at time t. Suppose further that the Markov property holds:

$$\Pr(X_{t+1}=s_j \mid X_t=s_i, X_{t-1}=s_{t-1},\ldots,X_0=s_0) = \\ = \Pr(X_{t+1}=s_j \mid X_t=s_i) \quad \forall s_0,\ldots,s_{t-1},s_i,s_j;\forall t. \quad (1)$$

Such a process is known as a Markov chain, and the above property reads that for a MC the conditional distribution of any future state given the past states and the present state is independent on the past states and depends only on the present state. If $X_t=s_i$ and $X_{t+1}=s_j$, then we can write

$$\Pr(X_{t+1}=s_j \mid X_t=s_i)=p_{ij}^{t+1} \qquad \forall t. \qquad (2)$$

The value p_{ij}^{t+1} represents the probability that the process, when in state s_i at time t will make a transition to state s_j at time $t+1$. Clearly we have that $p_{ij}^{t+1}\geq 0 \quad \forall i,j;$ and $\sum_{j=1}^{N} p_{ij}^{t+1}=1 \quad \forall i.$ We can arrange the transition probabilities into a $N\times N$ matrix, $P^{t+1}=\left\|p_{ij}^{t+1}\right\|$, obtaining the one-step transition matrix of the MC from time t to $t+1$. As the transition probability between any two states of the chain does depend of t, the chain is called time-inhomogeneous Markov chain.

Once the one-step transition probabilities are known it is possible to compute the conditional probability that the chain at time $t+T$ will be in state s_j given that at time t was in state s_i. As an example, we report the formula for the case $T=3$:

$$\Pr(X_{t+3}=s_j \mid X_t=s_i)=\sum_{k=1}^{N}\sum_{l=1}^{N} p_{ik}^{t+1} p_{kl}^{t+2} p_{lj}^{t+3}, \qquad (3)$$

$\forall s_i,s_j;\forall t.$

A state of the chain, say s_i, is called an adsorbing state if $p_{ii}=1$, that is once the process is entered in that state it will never leave it. A state is called transient, if, starting the process from that state, there is a positive probability that the process will never reenter that state. For further details on the basic concepts introduced in this paragraph, we refer the reader to

any book including an introduction on discrete time Markov chain, i.e. [7].

A Markov model for the transitions between metabolic states

Metabolic (or glucose tolerance) states can be defined for each subject - using ADA 1997 criteria - as NGT, IGM, and T2DM. We consider this simplified three state classification, even if the intra-class variability may be large in the IGM class (including both IFG and IGT subjects). Furthermore, we hypothesize that the dynamics of the glucose tolerance derived from the OGTT depends on the past screenings only through the previous year dynamics. Under this hypothesis and recalling that the subject state classification depends on the fasting and on the 2-h plasma glucose level during the OGTT, the future and the past subject's metabolic states are conditionally independent given the state in which the subject is at present, so the Markov property holds. Thus, we model the transitions between subject's glucose tolerance states as a one order time-inhomogeneous Markov chain with categorical state space $S = \{NGT, IGM, T2DM\}$. Let X_t be the metabolic state at year t, if $X_t = s_j$ and $X_{t-1} = s_i$, then $\Pr(X_t = s_j \mid X_{t-1} = s_i) = p_{ij}^t \quad \forall t.$

From the screening protocol, we know that women entering the T2DM state are no longer followed up because they might be treated with anti-diabetic drugs. This information allows us to define a Markov chain model with two transient states (NGT and IGM) and one absorbing state (T2DM). Thus the transition matrix, from year $t-1$ to t, has the following structure:

$$P^t = \begin{Vmatrix} p_{11}^t & p_{12}^t & p_{13}^t \\ p_{21}^t & p_{22}^t & p_{23}^t \\ 0 & 0 & 1 \end{Vmatrix},$$

where state 1 correspond to NGT, state 2 to IGM, and the absorbing state 3 to T2DM. In Figure 2 the graphical representation of the transition probabilities between any couple of states of the chain is reported.

Alternative Markov chain models with longer memory of the chain or with higher number of states might also be considered, but such models would not be suitable in the case of sample size of 116 (that is our case) because they would lead to many transition parameter estimates being zero for lack of empirical data.

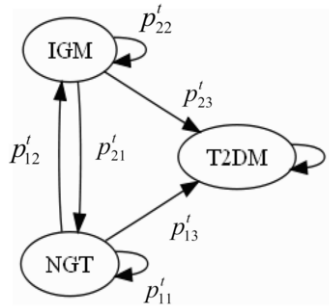

Figure 2 - One-step transitions between the states of the chain; labels on arrows are the transition probabilities.

Estimation of transition probabilities

Let denote by n_{ij}^t the number of women that were in state i at year $t-1$ and are in state j at year t after partum. We can empirically estimate the probability of a woman being in state j at year t after partum given that she was in state i at year $t-1$, $\hat{p}_{ij}^t$, using the formula

$$\hat{p}_{ij}^t = \frac{n_{ij}^t}{\sum_j n_{ij}^t}, \tag{4}$$

that corresponds also to the maximum likelihood estimator. This estimator is showed to be consistent but biased, with bias tending to zero as the sample size increases [9]. For the reader interested in further statistical properties of the transition probability estimator of a MC the paper just cited is a very good reference.

Thus, Equation (4) states that the estimated transition probability from any given state i to state j is equal to the proportion of women that started in state i and ended in state j with respect to all women that started in state i. As we are considering inhomogeneous Markov chains, these probabilities are different for different times.

Results

One year transition matrices

By using the procedure described in the data analysis section we have estimated the one year transition matrices for each possible transition (0 to 1, 1 to 2, 2 to 3, 3 to 4, 4 to 5). Due to the incompleteness of the longitudinal data (some screenings were skipped by the women or they had developed T2DM, thus they were excluded from further analysis) for the last two transition we had only few cases available to estimate some of the transition probabilities. Therefore we decide to stop our analysis at the third year.

As regards the estimated transition matrices for the transitions from 0 to 1, 1 to 2 and 2 to 3, we found the following results:

$$\hat{P}^1 = \begin{Vmatrix} 0.89 & 0.10 & 0.01 \\ 0.33 & 0.47 & 0.20 \\ 0 & 0 & 1 \end{Vmatrix},$$

$$\hat{P}^2 = \begin{Vmatrix} 0.88 & 0.12 & 0.00 \\ 0.36 & 0.45 & 0.18 \\ 0 & 0 & 1 \end{Vmatrix},$$

$$\hat{P}^3 = \begin{Vmatrix} 0.90 & 0.10 & 0.00 \\ 0.50 & 0.10 & 0.40 \\ 0 & 0 & 1 \end{Vmatrix}.$$

As can be appreciated, the transition from year 0 to 1 and from year 1 to 2 lead to approximately the same estimated transition matrix. In other words, we can claim that the differences in the first two transition matrices are negligible from a clinical point of view. In the transition from year 2 to 3 we notice a strong change in the behavior of IGM subjects. The percentage of women passing from IGM to T2DM is doubled with respect to the transitions occurred in the first 2 years after partum.

Predictions

The estimated transition matrices allow us to make predictions about the possibility that women with previous GDM will develop T2DM in three years after partum. Inserting into Equation (3) the estimated transition probabilities above, the ensuing conditional distributions of the metabolic state at year 3, given that the basal state was either NGT or IGM, are

$$\Pr(X_3 \mid X_0 = NGT) = (0.8, 0.1, 0.1),$$

$$\Pr(X_3 \mid X_0 = IGM) = (0.5, 0.1, 0.4).$$

Thus, a woman with pGDM who is NGT after partum, after three years from the delivery will remain NGT with probability 0.8, will become IGM with probability 0.1 and will develop T2DM with probability 0.1. The IGM condition appears as a temporary condition: in fact, in three years we expect that only the 10% of IGM subjects will remain in the same condition, while the remaining 90% will be split between the return to a condition of normal glucose tolerance (50%) and the development of the pathological condition of type 2 diabetes (40%).

Discussion

In this study we presented a Markov chain approach for population predictions about the transition between metabolic states of women with a history of gestational diabetes. The parameters of our model were estimated using data from a follow up study. We found that a woman in NGT condition immediately after partum has high probability (0.8) to be in the same condition three years later and will move to the condition of impaired glucose metabolism or become diabetic with the same probability: 0.1. The IGM condition appears to be a splitting condition from the normal and the pathological states. This may be due to the fact that in the IGM condition reversibility to the NGT condition is still possible, provided that the subject undergoes a change in the lifestyle, especially in terms of dietary habits and physical fitness. The quantification of the suitable energy intake and the possible degree of exercise are beyond the aims of this report; therefore, no specific suggestion is provided here. On the other hand, if no action is taken, it is known that the worsening of the metabolic condition with possible development of diabetes is likely to happen. Thus, in both cases, the IGM condition does not hold for long periods. Our results appear in fact consistent with this explanation: the 50% of IGM reversing to NGT may be the subjects that did take some actions for their health, whereas the 40% progressing to T2DM may be those not taking any significant action. Another interesting result was that, based on the estimated transition matrices, relevant changes in the probability of transition were noticed only between the second and the third year after partum. This observation indicates that in post-gestational diabetic women screening programs shorter than three years after the delivery may not be sufficient, since possible changes (worsening) in the metabolic condition are unlikely to happen before a period of at least three years after partum.

Conclusion

In this study we used a three state Markov chain model to analyze the dynamics of changes in the metabolic condition of women with a history of gestational diabetes. We found that possible transitions of the metabolic condition might not occur until three years after partum. We also found that the condition of impaired glucose metabolism is not likely to be maintained for a long time. The clinical implication of this finding is that a pGDM woman with IGM (easily detectable with a simple metabolic test) must be carefully followed in terms of lifestyle and perhaps appropriate pharmacological agents to yield in the following years a status of NGT. It will be necessary however the assessment of other parameters (such as for instance, insulin resistance, pancreatic secretion, lipid profile) to precisely identify the target for the intervention. With this regard, future works will be devoted to extend these preliminary results including considerations based on other measured variables (like plasma insulin and C-peptide), as well as on metabolic parameters describing fundamental processes such as insulin sensitivity and beta cell function.

Acknowledgments

The study was partially supported by a grant from Regione Veneto (Azione Biotech) to ISIB-CNR and by a grant from the Austrian Nationalbank Jubiläumsfonds (n. 11198) to AKW. The study is part of an ongoing scientific cooperation on gestational diabetes between ISIB-CNR and Medical University of Vienna (former Progetto Bilaterale CNR).

Development and Validation of Data Specifications for Nursing Problems in Maternal Nursing Care

Younglan Kim, Hyeoun-Ae Park, Yul Ha Min, Myung Kyung Lee

College of Nursing, Seoul National University, Seoul, Korea

Abstract

The aims of this study were to develop data specifications for nursing problems related to maternal nursing care and to test the applicability of those data specifications. First, we identified focus concepts and characterizing concepts of nursing problems by analyzing nursing-problem statements from nursing records, reviewing the literature, and interviewing experts. Second, we identified relationships between the focus concepts and characterizing concepts. Third, value sets of characterizing concepts were identified and types and cardinalities of the characterizing concepts were defined based on those value sets. Finally, data specifications were evaluated by a group of experts and by applying them to published case reports. The adequacy of the characterizing concepts and value sets, and the types and cardinalities of the characterizing concepts were validated. In total, 58 data specifications were developed with 53 characterizing concepts, relationships, and value sets. Their validity was established by the experts and by their application to case reports. The data specifications developed in this study can ensure that electronic health records contain meaningful and valid information, and support the semantic interoperability of nursing information.

Keywords:

Medical information standards, Nursing diagnosis, Knowledge representation.

Introduction

The potential benefits of electronic medical records include improvements in patient safety and quality of care, and reducing the number of medical errors. These benefits depend on data interoperability; exchanging and sharing data is most effective if the data are exchanged and shared in a semantically interoperable manner.

Semantic interoperability means ensuring that the precise meaning of exchanged information is understandable by other systems or applications not initially developed for this purpose [1]. Data being exchanged must be structured and coded to facilitate their complete understanding by computer systems. Complete interoperability depends on a detailed clinical data model that is bound to terms and codes from a standard coding system.

Several different approaches have been used in the development of interoperable models. Intermountain Healthcare has been developing Clinical Element Models for over 15 years [2]. The Research and Development Center for Interoperable Electronic Health Records (EHRs) in Korea is developing a Clinical Contents Model [3]. The developers of the openEHR used archetypes and templates as interoperable models [4]. A group in the UK National Health Service is developing models using a process called the Logical Health Record Architecture. Within the Health Level Seven community, a detailed Clinical Document Architecture is being developed as an interoperable model [5]. However, these efforts in model development are limited to the domain of medical knowledge.

Whilst the importance of developing a nursing constraint model has been addressed by nurse informaticists [6], there are few reports on this topic in the nursing literature. Arche-types of nursing problems for breast cancer patients have been developed and tested in Korea [7], and data specifications for stroke patients have been developed in The Netherlands [8].

The aim of this study was to develop data specifications to represent clinical information in a meaningful way so that data can be accumulated and integrated in a clinical practice environment where the level of nursing-problem do-cumentation varies. We looked at the nursing problems of pregnant women who were hospitalized to give birth since this cohort is homogeneous in terms of gender and age and exhibits comparatively few comorbidities and complications. Once data specifications are developed, we plan to explore the possibility of expanding this work and applying it to other areas of nursing.

Materials and Methods

Extraction of focus concepts of nursing problems

We extracted nursing statements describing patient signs and symptoms, and nursing diagnoses from the electronic nursing records of the 118 women who were hospitalized to give birth from October 1 to October 31, 2008 at a tertiary teaching hospital in Korea. We identified focus concepts from these statements. For example, we extracted a focus concept ‘pain’ from

the nursing-problem statements 'mild back pain' and 'continuous back pain'. We also reviewed the maternal nursing literature to supplement the focus-concept list. The extracted focus-concept list was evaluated and confirmed by a group of experts that comprised a head nurse in maternal nursing, three nurses with master's degrees in maternal nursing, and four nurse experts each with more than 7 years of clinical experience in maternal nursing.

Identification of characterizing concepts

We identified the concepts needed to describe the focus concepts in more detail by analyzing nursing statements, reviewing the literature, and consulting staff nurses. For example, characterizing concepts such as 'anatomical site', 'severity', and 'frequency' were identified from the nursing statement 'continuous mild back pain'. These characterizing concepts were confirmed by 8 nurse experts and named using The Conceptual Framework for Patient Findings and Problems in Terminologies published by the ISO/TC 215 [9], Archetype by the *open*EHR [4], Attributes of SNOMED CT [10], and the Clinical Contents Model developed by the Research and Development Center for Interoperable EHRs [3].

Development of data specifications

Data specifications were developed using focus concepts, characterizing concepts, the relationship between focus concepts and characterizing concepts, and the types, value sets, and cardinalities of characterizing concepts.

Validation of data specifications

Data specifications were validated by experts and by their application to published case reports. A group of experts was asked to evaluate whether the focus concepts were adequate, the characterizing concepts were clearly represented, the relationships between core concepts and characterizing concepts were adequate, the value sets were complete, and the types and cardinalities of the characterizing concepts were correct. The expert group comprised three doctoral students in nursing informatics, one head nurse with experience in informatics and maternal care, two informatics nurse specialists, and two maternal nurses each with more than 7 years of clinical experience.

Data specifications were also evaluated using two case reports published in an academic journal. We identified focus concepts, characterizing concepts, and value sets from the case reports, and mapped them with the developed data specifications to evaluate their coverage. The cases we used for validation were aplastic anemia in pregnancy [11] and stimulating the onset of labor [12]. Data specifications of menstrual history, gravida, parity, abortion, Bishop Score, uterine contraction, and rupture of membranes were validated with the case reports.

Results

Extraction of focus concepts of nursing problems

Forty-one core concepts were extracted from 711 days of nursing records related to 118 pregnant women who were hospitalized to give birth. Examples of focus concepts identified from the nursing records included concepts unique to maternal nursing such as uterine contraction and lochia, and general nursing concepts such as gas emissions, constipation, and pain. In addition, 12 core concepts were identified from a literature review. Concepts such as Bishop Score, guilt, and inverted nipples were identified through a literature review. Five more concepts were identified from the experts' evaluation: two experts suggested body weight and abdominal circumference, and one expert suggested abscess, falling, and arrhythmia.

In total, 58 focus concepts were identified. These focus concepts included not only physical signs and symptoms such as dyspnea and seizure, but also psychosocial problems such as grief, guilt, depression, and parent role. Furthermore, there are complex focus concepts that comprise more than one focus concept, such as vital signs, which comprise systolic blood pressure, diastolic blood pressure, pulse, respiration, and body temperature.

Identification of characterizing concepts

Thirteen characterizing concepts were identified by analyzing nursing statements. For example, we identified 'severity' with a value set of 'absent', 'mild', and 'severe' by analyzing nursing statements such as 'severe pain', 'mild pain', and 'no pain'. The characterizing concept 'pain character' was identified with the value set of, for example, 'sharp', 'burning', and 'fulgurating', by analyzing nursing statements such as 'burning pain', ' sharp pain', and 'fulgurating pain'.

Thirty-four characterizing concepts were identified from a literature review, such as 'intensity' with a value set of 'strong' and 'weak'. In addition, six characterizing concepts were identified by the expert group, such as 'level' with a value set of '–', '±', '+', and '++' to describe the presence and amount of protein or ketone in the urine. In total, 53 characterizing concepts were identified.

Development of data specifications

Data specifications for 58 focus concepts were developed by relating focus concepts to characterizing concepts with data types, cardinalities, and value sets. The lochia data specification is listed in Table 1 and presented diagrammatically in Figure 1. Lochia has a 'has_amount' relationship with the characterizing concept 'amount,' and a 'has_odor' relationship with 'odor'. Data types of these characterizing concepts are coded text; cardinalities for 'amount' and 'odor' are optional.

Table 1 - Lochia data specification

Characterizing concept	Relationship	Type	Cardinality	Value
Amount	has_amount	Coded text	Optional 0..1	[almost none | a little | moderate | a lot]
Odor	has_odor	Coded text	Optional 0..1	[foul | none]
Color	has_color	Coded text	Optional 0..1	[rubra | serosa | alba]
Subject of information	has_subject of information	Coded text	Mandatory 1..1	[patient]

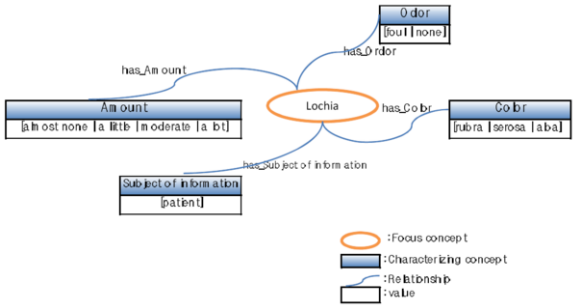

Figure 1- Schematic of lochia data specification

Validation of data specifications

Data specifications were validated by a group of experts, as described above, and tested by applying them to published case reports. Based on the recommendation of one expert, 'greenish' was added to the value set of the characterizing concept 'color' in the data specifications rupture of membranes and abscess. The characterizing concept 'interpretation' was removed from blood sugar, body weight, and pulse data specifications because two experts pointed out an overlap of information between the characterizing concepts 'numerical quantity' and 'interpretation' for the blood sugar, body weight, and pulse data specifications.

With the aid of case reports from the literature, data specifications unique to maternal nursing such as menstruation history, gravida, parity, abortion, Bishop Score, uterine contraction, and rupture of membranes were validated. In this validation, we verified whether the data specifications developed in the study cover data elements in the two case reports. Table 2 indicates how the section describing rupture of membranes was decomposed and mapped to values of characterizing concepts in the rupture of membranes data specification.

In this description, values of characterizing concepts of the data specification rupture of membranes, such as 'interpretation', 'occurrence', 'color', 'instrument', and 'subject of information' were identified. For example, 'M.S. reported a gush of clear fluid at 6:30 p.m.' has information about the time of rupture, the color of the fluid, and the subject associated with the information. All of these values were covered by the value sets of the characterizing concepts of data specification of 'rupture of membranes' developed in this study.

Table 2 - Validation of rupture of membranes data specification using case reports

Description of rupture of membranes in the case report	Extracted value	Characterizing concept
M.S. reported a 'gush of clear fluid' at 6:30 p.m. Ruptured membranes were confirmed by sterile speculum exam.	Were confirmed (positive)	Interpretation
	At 6:30 p.m.	Occurrence
	Clear (none)	Color
	Speculum exam	Instrument
	M.S. (patient)	Subject of information

Discussion

We developed data specifications to model the nursing problems of pregnant women who were hospitalized to give birth. These data specifications were validated by a group of experts and tested by applying them to case reports published in the literature. We identified focus concepts and characterizing concepts by analyzing electronic nursing records, reviewing the literature, and consulting nurse experts. We identified 58 focus concepts. Most of those identified by analyzing electronic nursing records were concepts describing physical problems such as pain, diarrhea, and constipation. Psychosocial concepts such as grief, guilt, and parent role were identified from the literature review and by consulting nurse experts. This implies that nurses do not document the psychosocial problems of their patients in their nursing notes as frequently as they document their physical problems. This concurs with what Min found in her work developing archetypes of nursing problems for breast cancer patients [7].

We found 53 characterizing concepts to describe focus concepts in more detail, of which only 13 were identified through analysis of the electronic nursing records. Most (54%) were identified from a literature review, and the remainder were suggested by the nurse experts. This implies that nurses do not document nursing problems in a structured way or as precisely as found in the literature or recommended by experts.

The data specification of nursing problems can be classified based on the characterizing concepts with value sets. For example, data specifications for flat nipple and inverted nipple have the same characterizing concepts ('anatomical site' and 'subject of information') with the same value sets. Other examples with the same characterizing concepts and the same value sets are the data specifications of constipation and diarrhea. However, there are similar focus concepts with different characterizing concepts. For example, after pain and labor pain are both types of pain, but they have different characterizing concepts from those of the data specification pain. For example, the data specification of pain has a characterizing concept 'anatomical site', whereas the data specifications of after pain and labor pain do not. If two focus concepts have different characterizing concepts and value sets, we classified them as different types of data specification.

Data specifications were modeled by linking the characterizing concepts to the focus concepts and specifying value sets, data types, and cardinalities of the characterizing concepts. There are two different types of relationship between the focus concepts and the characterizing concepts: associated and partitive. An example of an associated relationship is 'has_severity' linking the characterizing concept 'severity' to a focus concept such as pain. An example of a partitive relationship is 'has_part' linking a simple focus concept such as body temperature to a complex focus concept such vital signs.

A list of values for a characterizing concept was identified and presented in the data specification. For example, the characterizing concept 'severity' has a value set of 'mild', 'moderate', and 'severe'. The data type of the characterizing concept was also suggested in the data specification based on the value set. The cardinality of the characterizing concept, which indicates whether a specific characterizing concept is mandatory or optional to describe a focus concept, was also suggested in the data specifications.

The data specifications developed in this study can be used to guide the structured documentation of nursing records. If data are collected in a structured way using data specification, a richer and more granular database will be developed for use in research and education. In addition, if data are collected in a structured way using a value specified in the value set, data can be shared and exchanged between different information systems and different health-care institutions.

The data specifications developed in this study can ensure that electronic medical records contain meaningful and valid information, and support the semantic interoperability of information. The procedures and methods used here to develop data specifications could be expanded to other areas of nursing.

Abstract

A core challenge in biomedical data integration is to enable semantic interoperability between its various stakeholders as well as other interested parties. Promoting the adoption of worldwide accepted information standards along with common controlled terminologies is the right path to achieve this. Our paper describes a solution to this fundamental problem by proposing an approach to semantic data integration based on information models serving as a common language to represent health data coupled with technology that is able to represent the data semantics. We used the HL7 v3 Reference Information Model (RIM) [1] to derive a specific data model for the integrated data, the Web Ontology Language (OWL) [2] to build an ontology that harmonizes the metadata from the disparate data sources, the Unified Modeling Language (UML) [3] to model the data representation, and the Object Constraint Language (OCL) [4] to specify UML model constraints. To illustrate the approach, we use the Essential Hypertension Summary CDA document and related models from Hypergenes, a European Commission funded project [5] exploring the Essential Hypertension disease model.

Keywords:

CDA, Ontology, OWL, Modeling, UML, OCL

Introduction

Biomedical information repositories typically contain data related to a specific clinical domain with semantics unique to the originating systems [6]. These disparate data sources pose a challenge for data integration [7] that is paramount for improved patient-centric care [8], as well as for secondary use of the data for analysis of aggregated data in context of clinical research, public health surveillance, and decision support [9].

In this paper, we depict a complete solution to this fundamental problem by proposing an approach to semantic data integration using healthcare standard information models, ontology-based metadata harmonization, technology for creating and constraining data models, and an engine for instance generation.

The solution we present, as depicted in Figure 1, starts with a clinical domain expert creating an ontological representation of the information elements or variables of interest needed for a particular study. Based on past experiences, the clinical domain expert does not care about explicit data format, but only that certain data elements are required for further analysis.

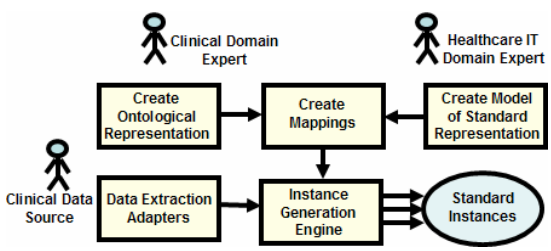

Figure 1 – Solution Activity Diagram

Our approach is intended to work over multiple, heterogeneous data sources by using models based on international standards for healthcare semantics and interoperability. Using standard exchange formats, along with a set of constraints, serves to unify data into a semantically unambiguous format that makes operations on the data straightforward from a technological standpoint. The healthcare IT domain expert, familiar with healthcare data representation methods and standards, creates healthcare interoperability models. Mappings between the ontological representation and healthcare interoperability models enable the instance generation engine to produce the standard instances in the last step.

IT industry-standard modeling languages form the bridge between the clinical and healthcare IT domains and user roles required for proper integration of healthcare data. The clinical domain expert works with a "more intuitive" ontology-based approach using semantic web technologies to represent the metadata needed for harmonization, while the healthcare IT domain expert uses software modeling languages to create model-based representations of the standard format, apply constraints to this format for a domain of interest, and, in collaboration with the clinical domain expert, create mappings between the ontological representation of the variables of interest and the standard-based information models. The annotated model created by the healthcare IT domain expert at design time, is then used by the instance generation engine at

runtime in order to transform the data to the standard format that conforms to the constrained model.

Background & Related Work

The HL7 v3 Reference Information Model (RIM) is used to derive consistent health information standards such as laboratory, problem and goal-oriented care, public health, and clinical research. It is an ANSI and ISO-approved standard that provides a unified health data 'language' to represent associations between entities who play roles that participate in acts. For example, a person entity plays a role of a surgeon who participates in a procedure act, and so forth. Acts may relate to other acts through "act relationships", thus providing a mechanism to describe complex actions.

Clinical Document Architecture (CDA) [10] is a constrained subset of the RIM that specifies terminology-encoded structure and semantics for clinical documents. These documents can be serialized to XML that conforms to a published W3C XML Schema. In most applications, the general CDA structure is further constrained by a set of templates that are standardized and published in an implementation guide, such as the Continuity of Care Document (CCD) [11]. Healthcare applications that produce or consume XML instances for CDA must include the appropriate template identifiers, as specified in the implementation guide. For example, a CDA instance that includes the template identifier "2.16.840.1.113883.10.20.1.28" indicates that the instance conforms to the CCD problem observation.

Most CDA template specifications, such as CCD, are written using structured English expressions that are based on the XML schema element relationships. These conformance statements are usually implemented using Schematron rules to augment the CDA XML schema. Our work, however, includes methods and open source software tools for representing CDA documents and template constraints using the Unified Modeling Language (UML) and the Object Constraint Language (OCL). Details and examples of this approach are described in the Methods and Results sections of this paper.

The UML modeling language is dominant among IT domain users, whereas clinical domain experts often work with formal ontology definitions. The Web Ontology Language (OWL) is a semantic markup language for publishing and sharing ontologies on the World Wide Web. It is endorsed by the World Wide Web Consortium (W3C) [12]. OWL is often used as the framework for converging distinctive terminologies into a single coherent ontology; many successful examples exist in clinical research and medical informatics domains [13, 14].

There has been some prior work in both using OWL ontologies in conjunction with instance generation [15], and in using OWL to add semantic annotations to UML information models [16]. These methods are applied and extended to support ontological mapping, representation modeling, formal constraining, and instance generation in our research.

Methods

Users

The use case diagram in Figure 2 illustrates the primary activities involved in our approach and the user roles required to perform these activities.

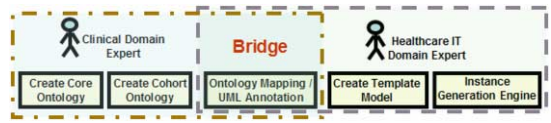

Figure 2 – Use Case Diagram

The clinical domain expert is responsible for creating the core ontology. The core ontology contains conceptual abstractions for a given clinical research domain and includes all the data elements required for secondary use by clinical researchers. The cohort ontology contains data elements and terminology specific to a data source. The cohort ontology is created by the clinical domain expert for each cohort that wishes to participate in the data integration. Using common ontology development tools such as Protégé [17], mappings are created between these cohort ontologies and the core ontology. This process is described in greater detail in the next sub section.

The healthcare IT domain expert is responsible for creating the CDA template model using a UML tool. The CDA template model contains classes, attributes, and relationships that are used to further constrain the CDA model to a particular clinical research domain. There are implicit relationships between classes in the template model and concepts in the core ontology. These relationships are made explicit by creating mappings on the CDA template model as UML annotations, providing the basis for generating the annotated template model.

The artifacts produced by these different users and the relationships between them are captured in Figure 3 below.

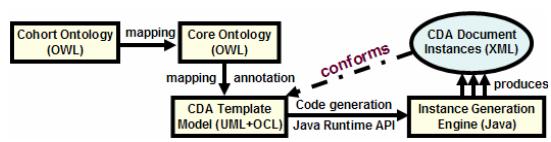

Figure 3 – Artifact Relationships

Data Integration

Healthcare data integration involves harmonization, validation, normalization, and transformation into standard structures that are accepted by the healthcare and medical research communities. Relationships between data items are often defined implicitly, e.g., in documentation or as tacit knowledge of experts. These implicit relationships must be expressed in an explicit and standard way so that analysis algorithms not aware of the implicit semantics can use them effectively.

Harmonization

Integration of data from dissimilar data sources must first undergo a process of conceptual harmonization, i.e. convergence of the sources metadata to a single and agreed-upon terminology. For example, blood pressure measurements from three different cohorts of essential hypertension are outlined in Figure 4. This outline depicts the underlying data model for the blood pressure measurements taken by the three cohorts.

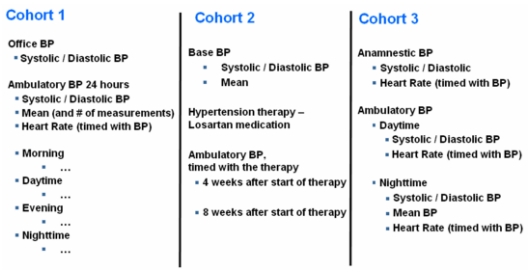

Figure 4 – Various blood pressure measurement schemes

Comparing data between the different cohorts is not a trivial task. The metadata is named differently, so how can one deduce that: Cohort 1 "Office BP", Cohort 2 "Base BP", and Cohort 3 "Anamnestic BP" all refer to the same conceptual data? Furthermore, looking at Ambulatory Blood Pressure findings one can see that Cohort 1 temporal divisions are to "Morning, Daytime, Evening, and Nighttime", whereas in Cohort 3 we find "Daytime and Nighttime" only; Cohort 2 blood pressure observations relate to four and eight weeks after start of therapy, thus completely incomparable to the above data.

Using OWL, we leveraged technology used for semantic web representation, to map all cohort variables to a core ontology able to represent the base conceptual terms for the target domain, e.g. Essential Hypertension. A schematic diagram is shown in Figure 5.

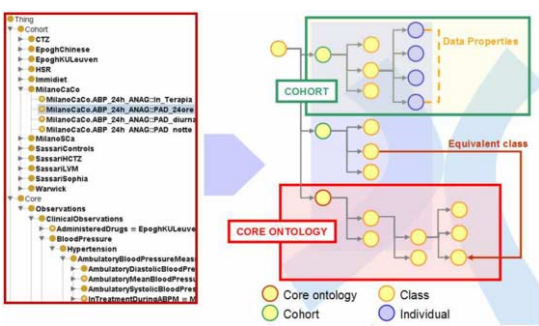

Figure 5- Ontology schematic diagram, left side is a screen capture of ontology using Protégé

The process starts by creating a cohort class (OWL class) for each metadata variable, thus each cohort contains a flat list of cohort classes. We then map each cohort variable in accordance with harmonization effort to a core ontology class by specifying an equivalent class relationship. In case of n:1 mapping, cohort instances (OWL individuals) are created, allowing the class to maintain 1:1 mapping, and additional parameters (as Data Properties) are added to capture the instance disparities. Thus, following the example shown in Figure 4, Cohort 2 Ambulatory Blood Pressure would contain one class with two individuals, having a temporal parameter to specify for four or eight weeks after therapy.

Normalization & Validation

Having crossed the hurdle of defining metadata in comparable terms, one is left with the challenges of deducing and validating data values for each metadata variable under the cohort's data model, as well as normalizing values in correspondence to harmonized standard units. This task is a complex one due to differences in units of measurement, classifications, and diversity of protocols. We do not elaborate here on these efforts.

Transformation to Intermediate Data Representation

Data is first extracted via a suitable adapter from data source proprietary formats, such as an excel file or MySQL database, and copied into a generic *data container*. The data container is conceptually a map where the *key* is a cohort variable and the *value* is the matching value. Additional inference is performed by the instance generation engine receiving both the data container and the ontology as input.

Capturing Data Semantics

Having similar sets of metadata represented in an agreed-upon terminology provides the basis for semantic interoperability [18]. Biomedical data is typically complex, consisting of associations and dependencies between discrete data items as well as between common structures. Consider the example in Figure 4. In Cohort 2, the Ambulatory Blood Pressure is measured while the subject is treated by a medication called Losartan. Associating the act of observing the blood pressure and the act of administering the drug will explicitly represent the semantics. This relationship is crucial to physician as the significance of high blood pressure while under a Losartan regimen is different than under other circumstances. To capture the full context of the data, these kinds of associations should be established during the data integration process when the experts responsible for the data source can provide the implicit semantics often hidden in unstructured documentation or in their minds.

As described in the background, the HL7 v3 RIM provides a unified 'language' to represent such relationships and context. CDA, as a RIM-derived domain specific standard, facilitates the explicit representation of the rich semantics of healthcare data. Referring back to the examples discussed above, the blood pressure measurements are represented as CDA observations and, when appropriate, these observations are associated with a substance administration of Losartan.

CDA Model

The CDA UML model was created as an implementation model that is primarily based on two artifacts: (1) the CDA Refined Message Information Model (R-MIM) from HL7 and

(2) the CDA XML Schema. This implementation model was developed to support the existing code generation and serialization mechanisms present in the Eclipse Modeling Framework (EMF) [19]. The model was imported into an EMF model and ultimately transformed into a set of Java classes. The Java classes in conjunction with a set of additional utility classes make up the base runtime API that can be used to produce, consume and validate instances of CDA.

Template Modeling &Annotation

The template model is a domain-specific model that constrains the CDA model. Classes in a template model extend those in the CDA model. Constraints are modeled using directed associations, property redefinitions, and OCL expressions. The CDA Profile for UML is used to capture additional metadata needed during model transformation and at runtime. Annotations on template model elements including UML classes and properties are used to describe all core ontology variables and their possible parameterizations, each appearing at a unique location in the template model. Annotations are used to map between the core ontology and the CDA template model. After an annotated template model has been created, it is transformed into an implementation model which leads to the generation of a domain-specific API for constructing and validating instances.

Instance Generation Engine

The instance generation engine takes a data container that contains data values corresponding to variables in the cohort ontology as input and produces CDA document instances that conform to the template model. Using the ontology mappings, which were specified by the clinical domain expert at design-time, it resolves each variable in the data container to a corresponding variable in the core ontology. Annotations from the template model are then used to map core ontology variables to unique paths in the output tree and store data values in the leaves of the tree. Values that were specified as default or fixed in the template model such as template identifiers and coded attributes are also generated automatically. Additionally, we support a registry of CDA templates that enables instance validation.

Results & Discussion

In the frame of Hypergenes, an FP7 European Commission funded project exploring the Essential Hypertension disease model, we had to deal with 18 historical cohort data sources with diverse clinical and environmental data. We chose HL7 v3 RIM meta-model and data types for data representation and CDA as our data model. Additionally we needed to apply a template to constrain CDA to a document specialized for describing an Essential Hypertension Summary document (EH-CDA). Needless to say it was a perfect opportunity to put theory to test. In this section we will describe how the technology was used as well as illustrate a concrete example based on work done for Hypergenes project.

Essential Hypertension Ontology

Hypergenes project assimilated clinical data from 18 cohort data sources. The harmonization process involved consulting with scientific experts in order to elucidate exact intention in each data element. The metadata was discussed at length in order to identify the list of variables, their meaning, variable associations, value ranges, and additional parameterization. The core ontology taxonomical structure was built based on data analysis of preliminary results and the macro-classes of intermediate phenotypes and environmental risk factors defined for Essential Hypertension. The core ontology was used as a reference for mapping the variables in each of the cohorts.

Essential Hypertension Template Model

Once metadata was fully accounted for, we created a template model that constrains CDA to Essential Hypertension report. Figure 6 depicts an excerpt pertaining to Blood Pressure Finding; the full model comprising of several hundred templates.

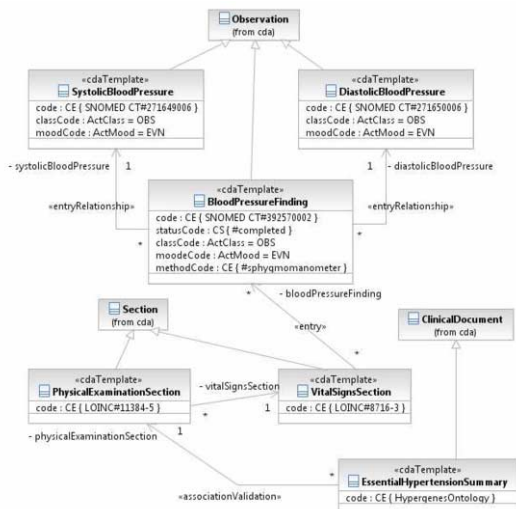

Figure 6 – Blood Pressure Observation in template model

The *BloodPressureFinding* class in the EH-CDA template model *extends* the *Observation* class from the CDA model. The template identifier was specified in a property of the <<cdaTemplate>> stereotype. Additionally, the code attribute was used to capture metadata about the specific code in SNOMED-CT. This gives the template precise semantics from a clinical perspective. The directed associations in the diagram (e.g. *VitalSignsSection* to *BloodPressureReading*) were converted into equivalent OCL constraints during the model-to-model transformation.

Instance Generation for Essential Hypertension

The model in Figure 6 was used to generate a runtime API that enabled the creation of the CDA XML instance of a Blood Pressure finding depicted in Figure 7 below.

```
<observation classCode="OBS" moodCode="EVN">
    <templateId root="2.16.840.1.113883.3.18.99.1.1.8.1"/>
    <code code="..." codeSystem="..." codeSysName="SNOMED CT" displayName="Blood pressure finding"/>
    <statusCode code="completed"/>
    <methodCode displayName="sphygmomanometer"/>
    <entryRelationship typeCode="COMP">
        <observation classCode="OBS" moodCode="EVN">
            <templateId root="2.16.840.1.113883.3.18.99.1.1.8.2"/>
            <code code="..." codeSystem="..." codeSysName="SNOMED CT" displayName="Systolic BP"/>
            <value unit="mmHg" value="171" xsi:type="PQ"/>
        </observation>
    </entryRelationship>
    <entryRelationship typeCode="COMP">
        <observation classCode="OBS" moodCode="EVN">
            <templateId root="2.16.840.1.113883.3.18.99.1.1.8.3"/>
            <code code="..." codeSystem="..." codeSysName="SNOMED CT" displayName="Diastolic BP"/>
            <value unit="mmHg" value="109" xsi:type="PQ"/>
        </observation>
    </entryRelationship>
</observation>
```

Figure 7 – EH-CDA Blood Pressure finding Observation

As the hypertension model contained hundreds of templates to model we used the Jena API, Eclipse UML2 API, and models for CDA, data types, and vocabulary from the MDHT project to programmatically generate the template model from a minimal complete, conforming instance [20]. The template model was decorated with annotations that map variable names from the core ontology to relative paths in the instance. We used a depth first traversal of the template model to convert these relative paths into a map of variable to absolute paths. Given an incoming record (i.e. data container), variables were extracted and used to look up the absolute path which was in turn used to construct the corresponding path of objects in the instance. We followed this approach for 11,472 records coming from 4,000 patients deriving from 18 historical cohorts of Hypergenes project. Each record contained up to 1500 unique data elements or variables that mapped to the same number of paths in the output instance.

Conclusion

In this paper we discussed a model-driven approach for integrating biomedical data using three complementary technologies. We used semantic technology in the form of an ontology definition language (namely OWL) to describe data elements of interest for a particular clinical research domain. We discussed the use of XML-based healthcare interoperability standards for clinical data and the role they play in semantic interoperability across multiple data sources. Finally, we discussed the use of UML to bridge the gap between the clinical domain expert and the healthcare IT domain expert and to facilitate the generation of a runtime that produces conforming instances. We validated our approach by using it to integrate clinical data in the EU-funded Hypergenes project.

Acknowledgments

The research leading to these results has received funding from the European Community's Seventh Framework Program FP7/2007-2013 under grant agreement n° 201550.

Abstract

Continuity of care is a concept that is defined as the uninterrupted and coordinated care provided to a patient and that includes an informational dimension which describes the information exchange between the parties involved. In nursing, the nursing summary is the main instrument to ensure informational continuity of care. The aim of this paper is to present an HL7 Clinical Document Architecture based document standard for the eNursing Summary and to discuss the need for harmonizing these results at international level. The eNursing Summary proposed in this paper was developed on the basis of several internationally accepted concepts, primarily the nursing process, the ISO 18104 Reference Terminology Model for Nursing and various data sets. The standardisation process embraced several phases of involving nursing experts for validating its structure and content. It was finally evaluated by a network of 100 healthcare organizations. We argue that the eNursing Summary is a good starting point for standardising nursing discharge and transfer documents on a global level. However, further work is needed to bring together the different national and international strands in standardisation. .

Continuity of care, Nursing summary, HL7 Clinical Document Architecture, ISO 18104 Reference Terminology Model for Nursing

Introduction

Decreased length of stay in hospitals, early discharges from hospitals and the proliferation of fragmented healthcare services have contributed to a renewed interest in continuity of care as a concept for ensuring quality of care. Defined as the delivery of care to a patient by care providers "in an uninterrupted and coordinated manner" [1], it aims at bridging gaps between settings, institutions, healthcare professionals and between shifts. The non-attendance to continued care may lead to severe hazards for the patient such as adverse drug events [2] and is a clear risk factor in patient safety [3]. Continuity of care is a multi-dimensional concept which comprises of different levels referring to information, management, relationship and contact issues [4]. The informational dimension typically addresses the need for consistent, complete, up-to-date and timely patient information to be transferred between healthcare institutions or healthcare professionals in charge of providing care for the patients. New studies give insight into how technology and electronic health records (EHR) in particular can support a seamless flow of information within [5] and across institutions [6] without compromising privacy [7]. Sharing data between healthcare providers by means of an EHR is one approach of transmitting relevant information. In addition, messages can be exchanged between the health information systems concerned [8] or summary documents can be sent via electronic networks. Finally, summary documents can be also made available through shared document repositories with IHE XDS [9].

Nurses have had a long-standing interest in implementing continuity of care in their daily work [10], in particular in their role as discharge managers, case managers and community nurses. Their information needs have been clearly stated early on [11]. Only with the increasing prevalence of electronic nursing information systems in healthcare institutions [12] electronic exchange of nursing information across institutions becomes possible. National eHealth initiatives in many industrialized countries in addition have given momentum for including nursing information in the electronic healthcare information chain [13, 14]. Despite the definite need for an electronic nursing summary in many countries, national standards are rare (e.g. there is one in Finland [15]) and an internationally coordinated approach for standardising the nursing summary does not yet formally exist.

The aim of this paper is therefore to present the results of a standardisation process for the electronic nursing summary in Germany and hereby to stimulate the corresponding discussion at international level.

Materials and Methods

Defining the nursing summary and its core elements

By nursing summary we mean a document which summarizes all major health events of a given patient from the nursing perspective of the discharging or transferring institution. It makes use of the wealth of information from the maximum data set (nursing record) and is distinct from the nursing minimum data set. It is less aggregated than the minimum data set and focuses on the continued care of an individual patient.

A proposal for core elements of the nursing summary was derived from relevant standards, in particular the Continuity of Care Record [16], the Swiss "NURSING data" data sets [17], the Reference Terminology Model for Nursing [18] and the definition of HL7 nursing meta-observations [19]. The proposal also drew from our own previous work [20, 21]. It was further refined by members of the "Continuity of Care Network in the Osnabrück Region" (www.netzwerk-os.de) who established an eNursing Summary working group in 2006. The Network consists of healthcare institutions which represent the primary, secondary and tertiary healthcare sector and thus could provide a comprehensive overview of the information needs across the care continuum. Consensus was reached by means of a nominal group process. In 2007 and 2008 the results were presented in workshops at regional, national and multinational conferences (e.g. European Nursing Informatics ENI 2008 in Münster, Germany). Suggestions for modifications, e.g. biographical patient information, were incorporated in an updated version of the nursing summary. The developments took place under the auspices of the German Council of Nurses.

Building an information model of the nursing summary

HL7's Clinical Document Architecture (CDA) Release 2 [22] and the corresponding Reference Information Model (RIM) were utilized to structure the relevant data into a header and body section and to model the information. The document header was adopted to a great extent from the German discharge letter [23]. HL7 CDA classes, elements, data types and attributes were specified and modelled with the help of HL7-RIMDesigner in Microsoft Visio and RoseTree. LOINC-codes were used for coding the document sections. XML instances were created, drawn from the model and populated with example data.

Standardising and evaluating the nursing summary

The eNursing Summary undergoes the formal standardisation process of the HL7 German User Group in autumn 2009 and will subsequently be made available via its website (www.hl7.de). In parallel, contacts were established in 2009 to the Nursing Network Heilbronn, Germany, a regional network composed of 100 nursing care institutions, for evaluating the eNursing Summary data set and its structure by cross-mapping them to their paper-based nursing discharge letter. This discharge letter is the result of an internal standardisation process among the member institutions which all use it for exchanging patient information. The cross-mapping was performed by four experts (two of the authors [UH, DF], the chairman of the Heilbronn Network and a nursing expert from a software company).

Results

Information model of the eNursing Summary

The HL7 CDA based eNursing Summary is a structured clinical document. In contrast to its header, its body is specific to nursing. It has been broken down into the following sections (fig. 1): a) nursing process, b) social information, c) reference to legal documents, d) home care status and e) medical information. The "NursingProcess" section is the central part of the eNursing Summary (fig. 2). Nurses use the nursing process as fundamental concept to assess, identify nursing diagnoses, determine expected outcome plans, implement and evaluate patient responses to provide effective care [24]. The section is subdivided into the concepts *Nursing Score*, *Nursing Diagnosis*, *Nursing Goal*, *Nursing Procedure* and *Nursing Outcome*. *Nursing Score* summarizes the results of assessment scales used in the diagnostic process. The nursing diagnoses are described in *Nursing Diagnosis* which is further specified by the subconcepts *Etiology*, *Symptoms* and *Resources*. *Nursing Procedure* is always triggered by other nursing concepts, such as *Nursing Diagnosis*, and can be followed by a *Nursing Outcome*. Groups of scores, nursing diagnoses, nursing goals, nursing procedures and nursing outcomes may be clustered by themes, such as the activities of daily living (ADL), or by user-defined themes. The use of ADLs is not mandatory, neither is any other taxonomy because any predefined scheme would imply a specific nursing theory as default. Furthermore, studies showed a considerable amount of disagreement among specialty practice groups on what information was critically important for continuity of care [11]. We therefore favoured a more formal approach, i.e. using the nursing process as guiding structure, and left clusters of themes open for definition by user groups.

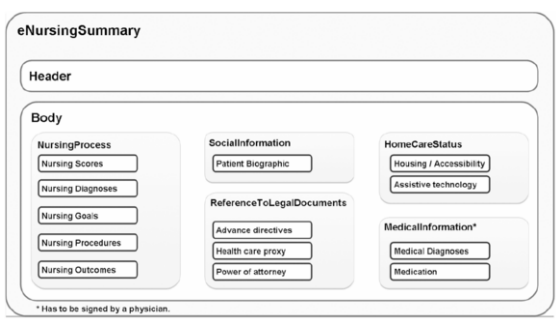

Figure 1- Structure of the eNursing Summary Body

Also at the level of entries the "NursingProcess" section does not propose any particular nursing terminology but is open to different controlled vocabularies. The eNursing Summary, however, recommends at least regional specifications of the terminologies preferred by the healthcare providers in that area.

The "SocialInformation" section covers a short non-structured note on the patient's or client's biography (CDA level 1 and 2). The "ReferenceToLegalDocuments" section allows legal and official documents to be referenced, i.e. meta-data of these documents to be communicated, such as date of issue, the depository and contact persons.

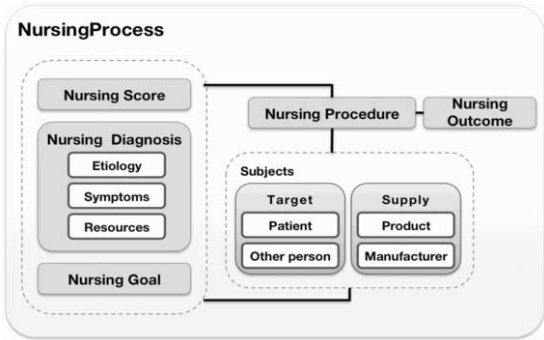

Figure 2- Concepts of the NursingProcess

These two sections were added pursuant to special requests from institutions that are in charge of the care of the elderly, in particular of dementia patients, e.g. nursing homes, geriatric clinics, geriatric hospital departments and ambulatory care services, and from psychiatric care institutions. The "HomeCareStatus" section describes the private and social environment where the patient lives, constructional issues of the home and the assistive technology that is available. Rehabilitation centers, home care providers (nurse specialists) and ambulatory nursing services particularly benefit from information of this section but also therapists in hospitals and other organisations. Information for the sections "SocialInformation", "ReferenceToLegalDocuments" and "HomeCare-Status" may be provided either by nurses or social workers depending on who is in charge of social care issues. Finally, the section "MedicalInformation" is a data container for medication data and medical diagnoses. It is copied from the medical summary or provided by physicians who are the authors and the signatories of this section.

The information model was checked for consistency and mapped into the proper CDA structures and corresponding domain message information models. The eNursing Summary concepts were represented by the use of specific terminology in the generic CDA classes.

Evaluation of the eNursing Summary

The results of the cross-mapping showed that all data fields of the Heilbronn nursing discharge letter could be translated into the eNursing Summary standard. The discharge form, however, differed from the standard with regard to the relations between diagnoses and interventions. Whereas the standard requires interventions to be linked to the cause of the intervention, typically the nursing diagnosis, the Heilbronn discharge letter consisted of a loose enumeration of unrelated problems and interventions. Furthermore, it did not specify any standardised nursing terminology to be used but rather preferred free text fields. Both can be represented in CDA documents and thus also in the eNursing Summary.

Discussion

The multidisciplinary nature of the nursing summary

The eNursing Summary is a communication instrument in ICT supported care delivery scenarios (fig. 3). Its main purpose is to warrant informational continuity of care across the spectrum of settings. The results of the standardisation process demonstrate that the nursing summary can be structured in a general way if the nursing process is utilized as the major guideline. Only then it is independent of the setting and the nursing specialty. When used in the context of the nursing summary the nursing process refers to critically important information and the patient status at discharge or transfer. It therefore does not contain the nursing assessment which is again carried out by the nurses who continue the care. In addition to the nursing process, the eNursing Summary also consists of medical, social and legal information that is needed by the institution or healthcare professional in charge of the follow-up care. As figure 3 shows the eNursing Summary may also contain information that is shared between nurses and therapists, e.g. information concerning the mobilization of a stroke patient. This fact hints at the interdisciplinary nature of the nursing summary and the role of nurses as generalists in the healthcare arena. It also raises the question of whether there is the need for a multi-professional summary to guarantee informational continuity of care. There is indeed critical overlap of information, notably in the medical area. There have been aivid discussions during the definition phase of the nursing summary on the need to know the medication and the medical diagnoses of a patient. This requirement can be met by two ways: either by referring loosely to the medical summary which would be (hopefully) sent in parallel or by copying these parts into the eNursing Summary. We finally decided for the latter solution in order to closely couple these pieces of information that need to be available at the same time for continuing the care. In the long run, the goal, however, should be to establish a multi-professional summary document. We made a first step towards this direction when adopting the content of the header from the medical summary.

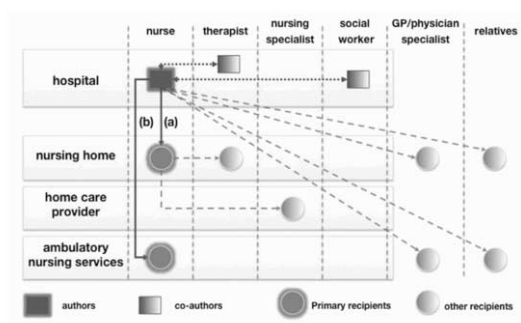

Figure 3- Continuity of care scenario; legend: patient discharged to (a) home, (b) nursing home

The need for harmonization at international level

There are several reasons that speak in favour of seeking to standardise the nursing summary at international level. First of all, the nursing process, which constitutes the backbone of the eNursing Summary, is an internationally accepted concept that is used – with variations – in many countries [25]. The second major contributor to the eNursing Summary is the Reference Terminology Model for Nursing [18], which is an ISO standard and ensures a common understanding of what is the essence of a nursing diagnose and a nursing intervention. Both approaches, the nursing process and the ISO standard, give the eNursing Summary a formal structure that makes it independent of a structure defined by content, e.g. by ADLs. This is paramount in an international context because the content may vary from country to country according to the culture and to the different task profiles of the nurses in different countries. The eNursing Summary allows so called themes to be included on an optional basis to make it flexible to the various demands and to enhance its readability.

There is also a need for standardising discharge and transfer documents from a European perspective. The European eHealth Action Plan [26] and the proposed European Directive on cross-border healthcare [27], both call for standardised procedures each from their own point of view. The eHealth Action Plan [26] addresses the need for developing interoperable health information systems, in particular electronic health record systems, as one of the most urgent challenges to be tackled. Interoperability is inseparably linked with the availability of accepted standards, also in nursing. The proposed EU Directive on cross-border healthcare [27] states that "ensuring continuity of cross-border healthcare depends on timely transfer of data concerning patient's health".

Finally, there is a growing interest among the health-IT vendors in internationally accepted standards as clinical health-IT-solutions are increasingly marketed on a global level, e.g. by international companies..

Need for action

Due to the critical importance of the electronic nursing summary in eHealth scenarios activities of international bodies for standardising the summary document are emerging. The concept and current implementation status of the eNursing Summary was presented at the 10th International HL7 Interoperability Conference 2009 in Kyoto [28] and HL7 is interested in further promoting the topic at international level. IHE (Integrating the Healthcare Enterprise) has taken the position that nursing is central to all patient care activities in terms of consistently providing and coordinating care. The IHE Patient Plan of Care (PPOC) profile is an individualized, framework intended for nurses to provide continuity of care across care settings and time [29]. These different strands which have emerged recently need to be integrated and participation from healthcare providers and industries must to be assured. International harmonization of an eNursingSummary should be addressed in the Joint International Council, where standardisation bodies and organisations like HL7, ISO, CEN, IHTSDO and others work together.

Limitations

The eNursing Summary standard we propose was developed using different international sources but has been evaluated so far in Germany only. Further work on mapping the structure and data fields with nursing and discharge letters used in other countries is necessary.

Conclusions

Implementing a standardised electronic nursing discharge and transfer document promises benefits for patients, relatives and healthcare professionals alike. Not only may patients with comorbidities [30], who frequently see different healthcare professionals during an acute episode of their illness, profit but also many other types of patients including elective [31] and emergency patients [32].

Acknowledgments

This work was kindly funded by the EFRE programme (FA-2007.8125). We would like to thank the members of the Continuity of Care Network Osnabrück, in particular U. Strotmann and C. Giehoff, and of the Nursing Network Heilbronn, particularly A. Haupt, for their most valuable contributions.

Abstract

To support the practice of evidence-based medicine (EBM), clinically relevant and scientifically sound articles should be easily accessible. Due to the huge volume of medical literature and the low performance of present retrieval models, clinicians could only get relevant documents in the order of publication time. This study propose a new clinical task-specific retrieval technique that improves retrieval accuracy by exploiting clinical task-specific EBM terms to query expansion using co-occurrence analysis technique. The idea is aimed at selecting query expansion terms that are relevant to a specific clinical-task using task-specific EBM terms. Focusing on treatment and diagnosis tasks, the new method which was performed on the OHSUMED collection showed a further improved result than the existing method.

Keywords:
Evidence-based medicine, Clinical task-specific query expansion, Local context analysis

Introduction

Evidence-based medicine (EBM) is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients[1]. The exponential increase of the volume of medical literature requires the development of effective information retrieval strategies. Clinically relevant and scientifically sound articles (i.e., high-quality) should be accessible in a fast and easy manner, especially to support the practice of EBM.

In terms of clinical activity there are four main clinical task categories: treatment, diagnosis, etiology, and prognosis. EBM defines methodological criteria for the task categories in order to identify high-quality articles. For example, methodological criteria for treatment task is defined as "*random allocation of participants to comparison groups; Outcome assessment of at least 80% of those entering the investigation; analysis consistent with study design*" [2]. Based on the definition the main task of the information retrieval strategy is to search articles that meet the criteria for each clinical task.

Aiming at retrieving ranked relevant articles of high quality for a given clinical query, this paper describes a new information retrieval technique that uses EBM-related terms to improve retrieval accuracy in a clinical task-specific ranking system. Focusing on a treatment and diagnosis task, we suggest a new query expansion strategy based on co-occurrence analysis with clinical task-specific EBM terms as well as all query terms to restrict query expansion to terms that are relevant to a given clinical task in the principle of EBM.

Related Work

There have been different approaches to clinical task-specific retrieval.

Haynes and colleagues [2-7] developed optimal MEDLINE search strategies, called clinical query filters targetting four clinical task areas: treatment, diagnosis, etiology, and prognosis by validating diagnostic tests using proposed search terms and their manually-constructed gold standard. The filters were Boolean query strategies optimized for sensitivity and specificity that were added to the original user query. They were adopted by the U.S. NLM strategies for use in the Clinical Queries feature [8] in PubMed. However, since the query filter is Boolean form, it still retrieves thousands of articles from MEDLINE when a common clinical term is given as a user query ("*breast cancer*" for treatment task category, for example). It displays too many or too small number of articles depending on the user query. It also does not support ranking of the retrieved articles according to relevance to the user query.

Chu and colleagues [9, 10] proposed a knowledge-based query expansion to support clinical task-specific retrieval. In their retrieval system, the authors tried to expand the original user query with additional terms that are specifically relevant to the query's task using domain knowledge source such as UMLS Metathesaurus and semantic structure. Focusing on five types of tasks such as treatment, diagnosis, prevention, cause, and indication, they evaluated their approach on the OHSUMED test collection for a subset of 40 queries explicitly mentioning the tasks in the OHSUMED. Comparison of their approach with no-expansion and statistical expansion approach based on a co-occurrence thesaurus showed the effectiveness of their approach over the traditional approaches. Rather than using a knowledge source, we exploit clinical task-specific EBM terms to restrict query expansion to task-specific terms in the principle of EBM.

Recently, some researchers dealt with clinical task-specific retrieval using a text classification technique.

Aphinyanaphongs et al. [11] applied machine learning techniques to identify high-quality articles in internal medicine for the areas of treatment, diagnosis, etiology, and prognosis. Using inclusion or citations by the *ACP Journal Club*[12] for one specific time period as a gold standard, the authors constructed test corpus and automatically built machine learning models. They found support vector machine (SVM) classifier shows the best performance and machine learning techniques have better or comparable performance than the 1994 PubMed clinical query filters [13]. The results obtained by Aphinyanaphongs et al. [11] were tested for the generalizability to other gold standard used in the development of PubMed clinical query filters by the work of Kilicoglu et al. [14]. The authors confirmed that machine learning approaches can be used to recognize high-quality articles.

Materials and Methods

Text Corpus

We used OHSUMED [15] as a test collection. It is a subset of the MEDLINE database. It consists of 348,566 MEDLINE references from 1987 to 1991, and 106 topics (queries) generated by actual physicians in the course of patient care. Relevance judgments to each query are provided, with the scale of 'definitely relevant', 'possibly relevant', and 'not relevant'. In this study, we limit relevant documents to those judged as 'definitely relevant' to retrieve high-relevant documents.

For the new clinical task-specific retrieval, we reviewed the OHSUMED queries and selected 60 treatment-specific queries and 26 diagnosis-specific queries according to the definition of treatment and diagnosis task [2]. Among the 60 treatment-specific queries, we use 57 queries with at least one definitely relevant document for our treatment-specific experiments (see Table 1).

Table 1 - Queries used for our experiments

Task	Query IDs
Treatment	1,2,5,10,13,15,16,18,19,22,24,27,29,30,31,32, 33,35,37,38,39,40,42,43,45,52,53,56,57,58,60 ,61,62,63,64,67,69,71,72,73,74,75,76,77,78,7 9,81,84,85,88,89,91,94,98,100,102,104
Diagnosis	14,15,21,23,37,41,43,47,51,53,57,58,65,69,70 ,72,74,76,80,81,82,92,97,99,101,103

Text Representation

For the document representation, MeSH, title and abstract fields of each MEDLINE reference are used. For the index generation, we parse the three fields from each MEDLINE document as follows. First, all the texts in each field are tokenized into single words. Each word is then processed by the removal of stopwords identified by SMART stopwords. It is further stemmed by the Lovins' stemmer [16] and is case-folded. Finally, all single-stemmed terms are indexed in the form of inverted file.

A user query is represented by using *information need* field from OHSUMED queries since it is the most likely user queries issued in the information retrieval system, and is processed by the same text processing method mentioned above.

Document Ranking Model

As our baseline retrieval model for ranking retrieved documents according to relevance to the query, we implemented the well-known Okapi BM25 weighting scheme [17], which is a highly effective retrieval formula that represents the classic probabilistic retrieval model [18, 19].

In the Okapi BM25 formula, the top-ranked documents are retrieved by computing a measurement of similarity between a query, q, and a document, d, as follows:

$$sim(q,d) = \sum_{t \in q \wedge d} w_{d,t} \cdot w_{q,t} \quad (1)$$

$$w_{d,t} = \frac{(k_1 + 1) \cdot f_{d,t}}{K + f_{d,t}} \quad (2)$$

$$w_{q,t} = \frac{(k_3 + 1) \cdot f_{q,t}}{k_3 + f_{q,t}} \cdot \log \frac{N - n + 0.5}{n + 0.5} \quad (3)$$

where t is a term of the query q, $w_{d,t}$ is the weight of the term t in the document d, $w_{q,t}$ is the weight of the term t in the query q, n is the number of documents containing the term t across the document collection that contains N documents, $f_{d,t}$ is the frequency of the term t in the document d and $f_{q,t}$ is the frequency of the term t in the query q. K is $k_1((1-b) + b \cdot dl/avdl)$. k_1, b, and k_3 are tuning parameters set to 1.2, 0.75, and 1,000, respectively, by default. We use the default setting in this study. Document length and average document length, *dl* and *avdl* respectively, are measured in suitable units such as the number of terms or the number of bytes (in this study byte length is used).

Clinical Task-Specific Query Expansion by Exploiting EBM Terms

To retrieve topically relevant documents that pertain to a specific clinical-task and contain clinical evidence of high-quality, we use clinical task-specific EBM terms.

We focus on treatment and diagnosis task for this study. By employing and evaluating each task-specific EBM terms used in the PubMed Clinical Queries and their combinations in our preliminary experimentation, we define task-specific EBM terms *TASK-EBM* as follows.

Treatment: "clinical trials therapeutic"

Diagnosis: "sensitivity specificity diagnosis diagnostic"

The EBM terms are utilized following two ways in this study.

Method 1. Simple expansion with EBM terms (*SE-EBM*): The simplest way to use the EBM terms is to add these terms to the

original query before the query is submitted to the system. We refer this approach to *SE-EBM*.

Specifically, given a query q for a specific clinical- task such as treatment or diagnosis, input query to the system is built by appending the query q with the *TASK-EBM* terms of the clinical task that are not found in the query, and then submitted to the system. For the input query, the ranked retrieved documents are returned according to the score of Okapi BM25.

Method 2. Co-occurrence analysis with EBM terms (*CO-EBM*): By extending the local context analysis (*LCA*) [20], we propose a new query expansion approach to expand query with additional task-specific terms using task-specific EBM terms.

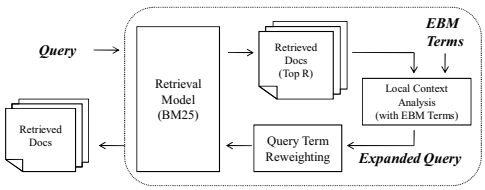

Figure 1 - Co-occurrence analysis with EBM terms

Given a query q for a specific clinical-task, our new query expansion is performed as follows. Let R be the number of pseudo-relevant document, and let E be the number of expansion terms that are appended to the original queries. First, query q is submitted to the system and documents are retrieved based on the Okapi BM25 for the given query. Then, the top-ranked R documents retrieved for the query q are assumed to be relevant and are used as a source of expansion terms. After extracting and merging all indexing terms from the top-ranked R documents, each term t is scored by:

$$score(t) = \prod_{k_i \in q \cup TASK-EBM} \left(\delta + \frac{\log_{10}\left(f(t,k_i)+1\right) \times idf_t}{\log_{10} R} \right)^{idf_i} \quad (4)$$

where the function $f(t,k_i)$ measures the degree of co-occurrence of term t with term k_i in the query q and the *TASK-EBM* terms of the clinical task, and idf_t and idf_i are inverse document frequency of term t and term k_i , respectively. Each factor is calculated by:

$$f(t,k_i) = \sum_{j=1}^{R} tf_{t,j} \cdot tf_{i,j} \quad (5)$$

$$idf_t = \min\left(1, \frac{\log_{10} N/n_t}{5}\right) \quad (6)$$

$$idf_i = \min\left(1, \frac{\log_{10} N/n_i}{5}\right) \quad (7)$$

where $tf_{t,j}$ is the frequency of term t in document j, $tf_{i,j}$ is the frequency of term k_i in document j, N is the number of documents in the collection, n_t is the number of documents in the collection containing term t, and n_i is the number of documents in the collection containing term k_i. The tuning parameter δ is set to default 0.1. The *TASK-EBM* terms are employed to reflect co-occurrence degree with those terms. All terms are then sorted in descending order by their scores. Lastly, the highly scored E terms are selected and added to the query q. The expanded query is automatically submitted to the system to get the final results. We refer this approach to *CO-EBM*. It is compared with the existing *LCA* method based on co-occurrence analysis with only query terms.

Query Term Reweighting

The expanded query produced by *CO-EBM* method is reweighted in the second-pass retrieval.

The standard Rocchio's feedback formula is a commonly used for (pseudo-) relevance feedback and term reweighting. It reweights terms in the expanded query by adding the weights from the actual occurrence of those query terms in the relevant documents and subtracting the weights of those terms occurring in the non-relevant documents [21]. In this study, we modify the formula so that all expansion terms are given the same weight for fair comparison of different query expansion approaches. Based on the positive feedback form of the standard Rocchio feedback formula, the new weight $w'_{q,t}$ of term t in the expanded query is assigned as:

$$w'_{q,t} = w_{q,t} + c \quad (8)$$

where $w_{q,t}$ is the weight of term t in the unexpanded original query q submitted to the system initially and c is a constant to give the same weight to all expansion terms (c is set to 1 in this study).

Results

We evaluate our experimental results using mean average precision (MAP), precision at given document cutoff value X (P@X). MAP is an average overall precision measurement for each relevant document in the ranking. It serves as a good measurement of the overall ranking accuracy. We measure the performance for the top-ranked 100 documents retrieved in our experiments. P@X is the percent of retrieved documents that are relevant after X documents have been retrieved. Since most users are interested in a few top-ranked documents, it is a good measurement in terms of users' perspective.

Table 2 - Performance of SE-EBM compared with no expansion for each treatment and diagnosis task.

Treatment (Average over 57 Queries)		
	No expansion	SE-EBM
MAP	0.2269	0.2175 (-4.14%)
P@5	0.3439	0.3333 (-3.08%)
P@10	0.2982	0.2772 (-7.04%)
Diagnosis (Average over 26 Queries)		
	No expansion	SE-EBM
MAP	0.2155	0.1877 (-12.9%)
P@5	0.3385	0.3462 (+2.27%)
P@10	0.3462	0.2885 (-16.67%)

Table 2 shows the performance of *SE-EBM* method compared with the one of unexpanded run for two clinical tasks of treat-

ment and diagnosis. As can be seen in the table, *SE-EBM* approach generally makes the performance decreases for both treatment and diagnosis tasks. It indicates that clinical task-specific EBM terms are not useful as additional expansion terms to retrieve task-specific relevant articles. Rather, these terms make relevant articles be retrieved in a lower rank. EBM terms would be not used as expansion terms in a ranking system.

On the other hand, the effectiveness of clinical task-specific EBM terms on improving retrieval accuracy is evaluated for selecting expansion terms. The performance of *CO-EBM* method is evaluated for a wide range of *R* (5 to100 by 5) and *E* (5 to 100 by 5) settings to see the sensitivity of the parameter settings, and is compared with *LCA* method based on co-occurrence with only query terms. Since 15 expansion terms generally provided a good performance on OHSUMED collection in our previous study [22], we present the performance of *CO-EBM* and *LCA* over a different parameter of *R* at a fixed E parameter of 15 in this paper. Figure 2 and Figure 3 display MAP percentage change of *CO-EBM* and *LCA* methods over unexpanded run for treatment and diagnosis task, respectively.

As can be seen, the maximum performance improvement is achieved using our *CO-EBM* method for both treatment and diagnosis tasks. On treatment-task experiments (Figure 2), our *CO-EBM* shows better performance than *LCA* when more than 50 documents retrieved are used for co-occurrence analysis. On diagnosis-task experiments (Figure 3), our *CO-EBM* shows better performance than LCA regardless of the number of pseudo-relevant documents used. It indicates that task-specific EBM terms can be effectively used for restricting query expansion to terms that are relevant to a given clinical task.

Conclusion

In order to support the practice of EBM, we have proposed a new information retrieval technique that exploits clinical task-specific EBM terms for the query expansion using co-occurrence analysis. Focusing on treatment and diagnosis tasks, our experimental results on the OHSUMED collection showed that our proposed method was performed best. The co-occurrence analysis with clinical task-specific EBM terms can select expansion terms more specific to a given clinical task. We believe that our method can be effectively used for clinical task-specific ranking system.

We plan to evaluate our approach for other clinical tasks including etiology and prognosis by preparing for new test collections since OHSUMED does not provide sufficient test queries for evaluation of other clinical tasks.

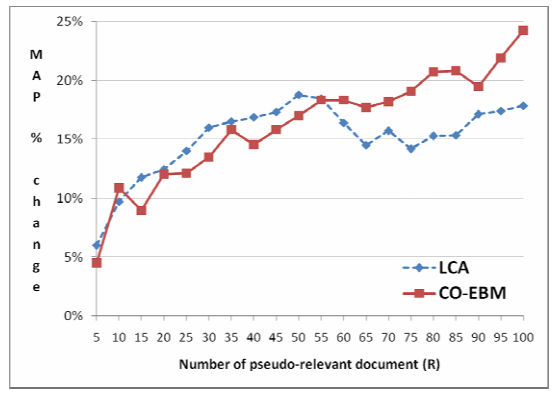

Figure 2 - Performance change of CO-EBM from no expansion compared with LCA when 15 terms are expanded using different number of pseudo-relevant documents for a treatment task.

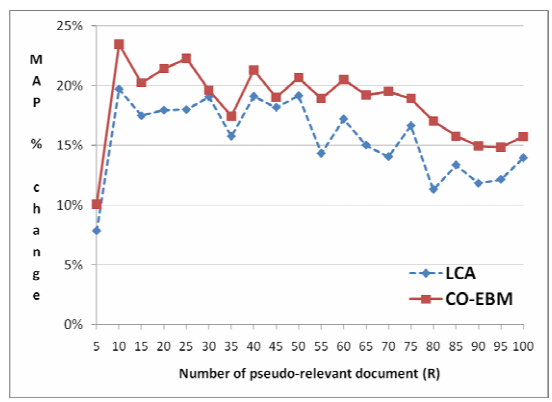

Figure 3 - Performance change of CO-EBM from no expansion compared with LCA when 15 terms are expanded using different number of pseudo-relevant documents for a diagnosis task.

Abstract

Background: The process of moving research into practice has a number of names including knowledge translation (KT). Researchers and decision makers need to be able to readily access the literature on KT for the field to grow and to evaluate the existing evidence. Methods: To develop and validate search filters for finding KT articles in the database Cumulative Index to Nursing and Allied Health (CINAHL). A gold standard database was constructed by hand searching and classifying articles from 12 journals as KT Content, KT Applications and KT Theory. Main outcome measures: Sensitivity, specificity, precision, and accuracy of the search filters.
Results: Optimized search filters had fairly low sensitivity and specificity for KT Content (58.4% and 64.9% respectively), while sensitivity and specificity increased for retrieving KT Application (67.5% and 70.2%) and KT Theory articles (70.4% and 77.8%). Conclusion: Search filter performance was suboptimal marking the broad base of disciplines and vocabularies used by KT researchers. Such diversity makes retrieval of KT studies in CINAHL difficult.

Diffusion of innovation, Information dissemination, Evidence-Based Medicine

Introduction

Getting research into practice has become a focus for medical researchers and decision makers globally [1]. How to accomplish this is less clear. The field of research studying how best to implement new research findings is fairly new, with its origins in Roger's diffusions of innovations work in the field of agriculture[2]. Many disciplines are actively investigating theories, methods and frameworks to facilitate the movement of research into practice[3,4], each discipline with its own vocabulary and methods [5].

The process of getting research into practice in health care is often termed knowledge translation (KT). This is defined by the Canadian Institutes of Health Research (CIHR) as "*the exchange, synthesis and ethically-sound application of knowledge - within a complex system of interactions among researchers and users - to accelerate the capture of the benefits of research for Canadians through improved health, more effective services and products, and a strengthened health care system*" [6]. Terms used to refer to moving research into practice by other funding agencies include knowledge transfer, knowledge exchange, research utilization, uptake and dissemination [7].

Developing search filters for large databases can help researchers and decision makers optimize search retrieval, capturing articles of interest (true positives) and reducing the number that are not of interest (false-positives). Such search filters have been developed for methodological aspects of studies [8, 9], and also for content [10, 11].

We approached the KT literature as having 2 natural sub groups of articles, those related to interventions designed to change behaviors (KT Applications) and those related to the theory and understanding of KT (KT Theory). In this study, we sought to develop and validate search filters to retrieve articles with content related to KT in general as well as KT Applications and KT Theory. A large body of KT literature exists within the field of nursing so in this instance we focused our search strategy development for use in the CINAHL database via EBSCOhost.

Materials and Methods

To develop and validate the search filters, we used a diagnostic testing assessment framework. We created a gold standard database by hand searching the literature and classifying content as of interest to KT (KT articles) or not of interest to KT (non-KT articles). Search terms were tested using the database and the sensitivity, specificity, precision and accuracy with

which the terms retrieved the target articles (KT articles) were calculated. Sensitivity is the proportion of target articles retrieved, while specificity is the proportion of non-target articles that were not retrieved. Precision measures the proportion of retrieved articles that were on target, and accuracy measures the proportion of articles that were classified correctly.

Table 1 –Abridged inclusion criteria for articles with KT Content, KT Applications and KT Theory

KT Content includes the more specific areas of • Educational interventions • Peer-to-peer knowledge brokering • Finding information • Articles outlining barriers to providing care by clinicians • Application of Evidence-Based Medicine/practice • Quality of care and quality improvement strategies • Production of systematic reviews, guidelines, and other knowledge syntheses • Implementation of knowledge syntheses, guidelines or research findings • System modifications based on evidence • Setting policy using evidence • etc
KT Application: articles that are identified as KT and then describe a study or project in a specific setting or settings to implement a KT strategy eg. strategies that increase implementation, or a project to improve uptake of a specific intervention or knowledge area such as vaccinations, screening procedures, smoking cessation approaches, etc.
KT Theory: articles that describe or develop the general understanding of the KT process or theory. • Theories, models or frameworks of KT • Processes of KT • KT across disciplines, vocabulary and scope • Other theories contributing to our understanding of KT

Our gold standard database was constructed by careful reading of all articles published in 2006 in 12 journal titles. Our required sample size of on-target articles (KT articles) was between 110 and 150 [12] . To get a representative sample of the health literature, journals expected to have a high yield and a low yield of KT articles were included [12]. The method of journal selection is reported elsewhere [13].

Using a clear reading guide (developed with input from all authors who have KT expertise -NW, RBH, DC, MD, DAD, SES) articles were tagged as having KT content; those assessed as having KT content were further tagged as relating to a KT Application or KT Theory if applicable (abridged inclusion criteria -see Table 1). The reading guide was based on the full CIHR definition of KT [6] (the reading guide is available from the authors). Articles were read in duplicate by KAM and CL. Disagreements were adjudicated with consensus.

Table 2 – Number of articles classified as KT Content [KT Content- not instruments in square brackets], KT Applications (KTA) and KT Theory (KTT) in the 12 journals hand searched in 2006 (all 12 were indexed in CINAHL)

Journal	# Read	KT Content	KTA	KTT
High KT-yield journals				
BMJ	518	150[82]	31	23
Annals of Internal Medicine	260	109[39]	22	7
JAMA	310	87[28]	18	4
Social Science and Medicine	530	87[86]	47	57
Journal of Advanced Nursing	265	47[47]	35	27
Health Affairs	199	39[39]	15	11
Low KT-yield journals				
Journal of the Medical Library Association	59	16[16]	8	2
Addiction	168	13[13]	9	7
International Journal of Nursing Practice	48	9[9]	5	5
Journal of Occupational and Environmental Medicine	148	8[7]	4	1
Nursing Research	49	7[7]	6	7
Nursing Inquiry	31	1[1]	0	1
Totals	**2585**	**573[374]**	**200**	**152**

A posteriori we determined that a number of articles that were classified as KT Content only (not further classified at KT Application or KT Theory) presented information (ie content) for patient or clinician education. These articles included *JAMA*'s "Patient Page", *Annals of Internal Medicine's* "Summaries for Patients" and *BMJ*'s "ABC of [disease]" These tagged articles do not describe a KT intervention or theory, rather they are essentially a KT instrument for clinicians that can be printed and given to patients or articles educating clinicians on specific topics. As such, they represented a further subset of KT Content –articles to be used as KT instruments. We therefore created a further subset of articles for 'KT Content-not instruments' in an effort to improve the performance of search terms retrieving general KT Content articles. See Table 2 for the classification of articles.

Using KT published terms, Medline and CINAHL indexing terms, frequent terms in tagged articles (PubReminer (http://bioinfo.amc.uva.nl/human-genetics/pubreminer/) and terms suggested by KT researchers, we compiled a list of 3423 index terms and textwords to test their retrieval characteristics. The terms were submitted to CINAHL via EBSCOhost. Multiple spellings and endings were applied. Terms were tested as keywords and text words (TX). Keyword searches require no field codes and search title, abstract and subject headings. Textword searches are coded with TX and search all indexed fields and full-text. Index terms were searched using the MH field code. The retrieval characteristics were calculated for

each search term. All calculations were done by an automated online system developed at McMaster University. The system allows for the performance of single terms to be viewed as well as 'OR'ed combinations of terms that are computer generated. The system also allows the researcher to combine single terms using the Boolean 'OR'. Terms are 'OR'ed to maximize sensitivity and specificity.

The system generated 'OR'ed combinations of all terms and we selected the highest performing combinations to generate the 'best' search filter for detecting articles that were classified as (a) KT Content, (b) KT Content – not instruments, (c) KT Application and (d) KT Theory, while trying to keep the number of terms to a minimum. We report the best sensitivity filter keeping specificity ≥50%, best specificity filter keeping sensitivity ≥ 50% and best filter optimizing sensitivity and specificity using four term combinations (abs[sensitivity-specificity]<1%).

Our sample size was adequate for the KT Content and 'KT Content-not instruments' searches; for these we randomly divided the database into a 60:40 development/validation set of 1551 and 1034 articles respectively. Search strategies for KT Content, both with and without instruments, were developed in the development set and tested in the validation set. The proportions for sensitivity, specificity, precision and accuracy were compared between the two datasets as independent proportions using Arcus QuickStat.

Results

Our sample included 2585 articles, 573 tagged as KT Content, 374 KT Content-not instruments, 200 KT Applications and 152 KT Theory. Journals expected to have a higher yield of KT articles had a mean of 25.4% KT Content (95%CI 15.3 to 35.6) while low yielding journals had a mean of 12.8% (95%CI 3.2 to 22.3). The two groups of journals however were not statistically different in the proportions of articles tagged as KT Content, KT-not instruments, KT Application or KT Theory.

Table 3 – Combinations of Four Terms with the Best Sensitivity (keeping Specificity ≥50%), Best Specificity (keeping Sensitivity ≥50%), and Best Optimization of Sensitivity and Specificity (based on abs[sensitivity-specificity]<1%) for Detecting KT Content in CINAHL. Articles were assessed as all KT Content and then as KT Content with instruments removed. Values for the development data, the validation data, their absolute difference are given.

Search Strategy for KT content (EBSCOhost CINAHL)	Sensitivity (%) Development Validation Diff (95% CI)[a]	Specificity (%) Development Validation Diff (95% CI)[a]	Precision (%) Development Validation Diff (95% CI)[a]	Accuracy (%) Development Validation Diff (95% CI)[a]
KT Content including instruments

[a] Comparing the development and validation data sets. [b]Statistically significant differences at p<.05. EBSCOhost CINAHL fields: TX=text words, searches all searchable fields in full-text and citation record; ?=wildcard; *=truncation character; no field code=default title, abstract and subject heading search.

Table 4 – Combination of Terms with the Best Sensitivity (keeping Specificity ≥50%), Best Specificity (keeping Sensitivity ≥50%), and Best Optimization of Sensitivity and Specificity (based on abs[sensitivity-specificity]<1%) for Detecting KT Application and KT Theory Content in CINAHL

Search Strategy for KT content (EBSCOhost CINAHL)	Sensitivity (%) (95% CI)	Specificity (%) (95% CI)	Precision (%) (95% CI)	Accuracy (%) (95% CI)
KT Applications				
Best Sensitivity – evaluation OR evidence based practice (TX) OR health services (TX) or patient (TX)	78.5 (72.8 to 84.2)	50.7 (48.7 to 52.7)	11.8 (10.0 to 13.5)	52.9 (51.0 to 54.8)
Best Specificity – randomized controlled trial OR pretest-posttest design OR decision making OR evaluation	50.5 (43.6 to 57.4)	80.0 (79.3 to 82.4)	18.1 (14.9 to 21.3)	78.5 (76.9 TO 80.0)
Best Optimization of Sensitivity and Specificity- physician OR utilization OR evaluation OR evidence based practice	67.5 (61.0 to 74.0)	70.2 (68.3 to 72.0)	16.0 (13.5 to 18.4)	70.0 (68.2 to 71.7)
KT Theory				
Best Sensitivity – research OR evaluation (TX) OR evidence based practice (TX) OR social work (TX)	80.3 (73.9 to 86.6)	52.0 (50.0 to 54.0)	9.5 (7.9 to 11.1)	53.7 (51.8 to 55.6)
Best Specificity- change* OR evidence-based medicine OR decision making OR knowledge	53.9 (46.0 to 61.9)	85.1 (83.7 to 86.5)	18.4 (14.8 to 22.0)	83.2 (81.8 to 84.7)
Best Optimization of Sensitivity and Specificity- theoretical OR decision making OR change* (TX) OR evidence based practice	70.4 (63.1 to 77.7)	77.8 (76.1 to 79.4)	16.5 (13.7 to 19.4)	77.3 (75.7 to 79.0)

Search Filters

No single terms were able to retrieve KT, KT Application or KT Theory articles with 50% sensitivity and 50% specificity. Multiple term filters were derived by 'OR'ing top performing single terms together to form 4-term combinations.

For KT Content articles, sensitivity of filters ranged from 50-62%, specificity from 56-70%, precision from 30-33% and accuracy from 57-66% (Table 3). Development and validation sets did not differ in search performance. When KT instruments were removed, sensitivity increased by ~10%, but the other performance measures did not change or were lower (Table 3). Development and validation sets performed similarly except for sensitivity of the optimal search.

KT Application filters peaked at 80% specificity, but with low sensitivity of 50% (Table 4). Similarly, sensitivity peaked at 78.5% but with low specificity. Overall the KT Application filters performed better than the general KT Content search. Performance of KT Theory filters were similar to KT Applications, maximizing sensitivity or specificity at the expense of the other, The optimal search performed with 70% sensitivity and 78% specificity, the best overall (Table 4).

Precision was low, which is not surprising since it is dependent on the prevalence. KT Application and KT Theory filters also had low precision. Accuracy improved for the KT subsets (Application and Theory) compared to the KT content filters.

The search terms that are included in the best performing filters tend to be fairly common and widely used (evaluation, evidence-based medicine or practice, research or patient) and not necessarily KT specific.

Discussion

Ideally a search filter will allow retrieval of a large proportion of the target articles with a minimum number of non-target articles, maximizing sensitivity while maintaining specificity. Our research group has published a number of such filters, relating to methodological aspects and content. Generally speaking, performance values of 90% sensitivity and 90% specificity are markers of effective search filters.

In the case of KT, we find that sensitivity and specificity do not reach high levels. For the filters focusing on the KT subsets, we were able to develop filters that performed slightly better than the general content area of KT.

From the search terms, we see that the content purpose of the search is often reflected in the filter search terms, for example, the term 'theoretical' in the optimal KT theory filter. KT Application filters included more methods terms like "randomized controlled trial" and "pretest-posttest design". But many of the other terms are not specific to the field of KT (research, patient, evaluation) and this likely explains the poor performance of the filters. Yet few KT related terms that we compiled were able to effectively detect KT articles. For example, research utilization, dissemination, and translational research did not contribute to effective retrieval of KT material Also, when maximizing specificity, sensitivity is compromised, at times leaving many target articles undetected.

Given the range of disciplines engaged in KT and the lack of a consistent vocabulary, the low performance of the search filters is not surprising. When moving forward it is important for those in the field of KT consider how we can improve our communication and understanding, for example, by agreeing on our use of KT terms. Perhaps then more effective search filters could be devised.

Alternatively, other approaches to data mining such as semantic web technologies could be studied in relation to KT litera-

ture search and retrieval. Use of these technologies could circumvent the call for a standardized terminology for the field.

Strengths

Our study sample of 2585 articles represents a sufficient sample to develop and validate KT search filters. Our journal titles cover a broad range of health fields from nursing to internal medicine, and library science to environmental science and business. The search filters performed similarly in the development and validation datasets suggesting that the performance of these searches can be generalized for use in the entire CINAHL database or other similar subsets.

Limitations

Classifying articles as KT is not a simple task. The development of the reading guideline went through many iterations with continuing input from all authors. We tried to be as systematic and consistent as possible, but it is possible that other researchers would classify some of the articles differently based on their own views and values for KT.

Statistical limitations include not having development and validation data sets for the KT Application and Theory categories. Also we were unable to perform cross-validation studies on the KT Content dataset.

Conclusions

Retrieval of KT literature from large databases remains a challenge. Our search filters do not have high enough sensitivity and specificity to allow a researcher to effectively retrieve KT articles of interest. They would be left with too many non-target articles to sort through and miss many target (ie KT) articles. A consensus regarding the use of KT terms would be one way to improve retrieval going forward. In addition, work with the large database producers such as CINAHL would likely show benefits from implementing new index terms related to KT and their consistent use.

Pediatric Pain Management Knowledge Linkages: Mapping Experiential Knowledge to Explicit Knowledge

Sam Stewart[a], Syed Sibte Raza Abidi[a], Allen Finley[b]

[a] *NICHE Research Group, Faculty of Computer Science, Dalhousie University, Halifax, Canada*
[b] *IWK Health Centre/Dalhousie University, Halifax, Canada*

Abstract

The goal of this project is to augment clinician communication by connecting it to evidence-based research, providing explicit knowledge to corroborate the experiential knowledge shared between health care practitioners. The source of tacit knowledge sharing is the Pediatric Pain Mailing List (PPML), a forum for practicing clinicians to contact peers on the subject of pain in children. The messages, dating back to 1993, are processed for pertinent information and gathered together into threads. They are then parsed and connected to a set of MeSH keywords, which is used to search Pubmed and return a set of papers that correspond to the subject being discussed. The results are presented in an online forum, providing clinicians with an arena in which they can browse the archives of the PPML and connect those conversations to pertinent medical literature.

Information retrieval, MeSH headings, Natural language processing, Pediatrics, Pain, UMLS

Introduction

Pediatric pain management is a complex subject, as children lack the cognitive ability to properly express their pain [1], which at times leads to incorrect interventions. The problem is exacerbated due to lack of specialized knowledge and formal training in pediatric pain management [2]. The emergence of Web 2.0 technologies has provided alternate knowledge dissemination mediums, such as online discussion forums, mailing lists, social networks and so on, that allow pediatric pain practitioners to converge and share their knowledge through problem or topic specific discussions. One successful initiative is the Pediatric Pain Mailing List (PPML) which brings together over 700 pediatric pain practitioners from around the world to share their clinical experiences and seek clinical advice. The PPML not only overcomes temporal and geographical barriers to connect pediatric pain practitioners, but the archives of the mailing list, containing over 13,000 messages, represent an invaluable resource of the experiential knowledge of the pediatric pain management community spanning more than 15 years. The archives contain experience based recommendations, educational materials, tools, case solutions, practice critiques and research ideas.

Experiential knowledge is not evidence-based rather it is practice-based, nevertheless it provides vital and pragmatic insights into *what worked*, *what did not work* and *what are the best practices* in specific clinical situations, especially beyond the realm of accepted norms and established beliefs. We argue that to generate comprehensive healthcare knowledge for a specialized health topic it is important to augment this tacit experiential knowledge with evidence based explicit knowledge, i.e. to establish knowledge linkages between online discussions with published medical literature.

In this paper, we present our approach to establish knowledge linkages between pediatic pain management discussions in the PPML and corresponding published literature at Pubmed. The rationale for the project is driven by the observation that practitioners need to reaffirm the practice-related recommendations on the PPML with evidence reported in the medical literature. The exercise of finding evidence corresponding to the exact theme and content of a PPML discussion is challenging for practitioners, as the incorrect choice of keywords (as per the PPML discussion) results in sub-optimal research articles, which in turn affects the perceived validity of the PPML messages and the subsequent uptake of the experiential knowledge at the PPML.

Our solution is a knowledge management framework that leverages (a) Web 2.0 based communication and collaboration to gather clinical experiential knowledge through an active interaction within a virtual community of practice, and (b) knowledge interoperability to establish linkages between the unstructured experiential knowledge and structured explicit knowledge stored in an accessible knowledge repository. The research challenge is (i) to organize the unstructured email messages containing the experiential knowledge into meaningful topics/discussion threads so that specific knowledge items can be easily found and used by the practitioners; and (ii) to process the content of the email messages to derive medically salient keywords to search a medical literature repository for related research articles.

In this paper, we present our knowledge linkage framework featuring our literature search strategy that implements an ex-

tended Boolean Information Retrieval (eBIR) algorithm [3]. Our framework allows users to (i) search through the PPML archives to find interesting discussion topics, (ii) select interesting discussions threads within the discussion topics, and finally (iii) retrieve a set of related research articles from Pubmed, through a 'single-click' evidence retrieval mechanism, based on our literature search strategy.

Methods

Our knowledge linkage framework followed the following steps: (i) Filter the email archives to extract medically useful email messages; (ii) Associate a series of emails to realize a *thread* that represents an online discussion between multiple practitioners around a specific topic; (iii) Parse the discussion thread to identify its constituent medical terms in terms of the MeSH lexicon (because Pubmed is indexed using MeSH); (iv) Apply the search strategy to find related research articles; (v) Present the search results to the user.

The task of processing free text and connecting it to a formal medical lexicon is an active research subject in the medical community [4-6]. Previous projects have approached the problem using natural language processing (NLP) algorithms to try and extract the semantics of the text, representing the semantics using a formalized lexicon. One example is the program Metamap [7], a NLP based medical language processing system that scans medical text and links it to formal terms from MeSH. However, Metamap's precision and recall in previous projects have varied depending on the format of the text being processed, from values as high as 0.897 and 0.930 respectively [6] to values as low as 0.56 and 0.72 [4]. Projects that reported low recall and precision with Metamap acknowledged that many of the problems come from the inherently ambiguous nature of the text being processed: in processing medical residents' voice recordings, it was noted that Metamap failed to recognize abbreviations, acronyms or complex phrases that omitted key terms [5].

For this project, we expect some degree of inaccuracy in the list of medical terms returned by Metemap given the unstructured nature of the PPML. We decided to use Metamap as the medical text processing application due to its ability to provide MeSH terms together with concept and semantic types. We improve the output of Metamap through our literature search strategy that uses a modified eBIR algorithm to rank the MeSH terms by assigning them a score, and then determining the optimal subset of terms based on their scores. Below, we discuss the workings of the individual steps of our knowledge linkage framework.

Processing the PPML Archives

The archives are stored in simple ASCII text files, organized by month, starting June 1993, and ending December 2008. The messages were processed to extract the sender, date, subject line and content of the message. The extracted information was used to filter out irrelevant and noisy messages. For experimental purposes we selected the set of emails from 2007 and 2008; we believe that the recent two years of the PPML reflect the current nature of the mailing list.

The goal of the project is to extract the substantive content of the messages and use that to link pertinent literature. This means that the messages need to be parsed to remove content such as user signatures, replies and useless messages. The purpose of parsing these elements is to restrict the recorded content of the message to the subject being discussed, in order to properly link the conversation to literature. Any medical terms in the user's signature, or the content of the previous messages, could confuse the mapping process and ultimately lead to inaccurate results.

Discussion Thread construction

Using the extracted data the messages are assigned to discussion *threads* that are the embodiment of experiential knowledge in the PPML. A thread can be thought of as a conversation, or a series of messages around a certain topic. It generally contains a question, problem or novel idea posed by a list member, and is followed by a series of responses that attempt to solve the problem. Within a thread experts in the field can provide their own knowledge or recount their own experiences in response to a certain problem. A thread is built using the subject line of the email messages—all messages with a matching subject are grouped within a thread.

Converting Threads to MeSH Vocabulary

Given that the Pubmed database is indexed by the MeSH vocabulary, to optimize the search results we convert the content of the PPML messages to the MeSH vocabulary via the Metamap program [7].

Connecting Threads to MeSH terms

Metamap uses a special NLP parser called SPECIALIST [7] to find all the nouns and noun-phrases in a discussion thread, and maps them to one or more MeSH terms. Each mapped MeSH term is assigned a score that is a measure of how strongly the actual term mapped to the MeSH vocabulary. The score is a weighted average of four metrics measuring the strength of the matching, with an overall range in [0,1000], with higher scores indicating a better match. The formal equation for calculating the scores is:

$$1000\text{x}(\textit{Centrality}+\textit{Variation}+2\text{x}\textit{Coverage}+2\text{x}\textit{Cohesiveness})/6 \quad (1)$$

1. *Centrality*: An indicator of whether the matched (source) term is the head of the phrase. The head of the phrase is the root; in the phrase *pain medication medication* is the head and *pain* is a modifier.
2. *Variation*: A measure of the distance between the matched term and the root word. For example, if the source word is eye and the match is to the term ocular, the distance is 2, as ocular is a synonym for eye
3. *Coverage and Cohesiveness*: Measures of how well the source term and the MeSH term match each other: if the source and MeSH terms are both "pain" then the match is perfect, but if the source term ocular matches to the MeSH term Ocular Vision then the coverage and cohesiveness are less than perfect.

For our purposes, the Metamap scoring system provides a baseline measure of how well the mapped MeSH term represents the original term in the PPML discussion thread.

Managing MeSH Terms

Metamap produces certain MeSH terms that are not appropriate for this project, either due to generality or complexity of the phrase being mapped. The problem of generality arises when the MeSH term provided is not a formal member of the MeSH lexicon. Metamap returns the MeSH term *stress*, which is not technically part of the MeSH vocabulary. MeSH contains many terms that are more specific forms of stress, but the term itself is not present. These terms must be dropped from the MeSH mapping, as their generality makes them useless in connecting the content to literature.

The second problem relates to complex matches, and can be best explained using a sample message. Consider the following message "*The report stated that when* ***music therapy*** *is used,* ***the babies*** *required* ***less pain medication****. Does anyone know* ***of any published reports*** *of* ***empirical research*** *demonstrating the effect?"* Table 1 lists the mappings and their associated scores for this example.

Table 1- Sample message and its associated MeSH mappings

Source	MeSH	Score
music therapy	Music Therapy	1000
the babies	Infant	966
less pain medication	Pain	660
less pain medication	Pharmaceutical Preparations	827
of any published reports	Publishing	694
of empirical research	Empirical Research	1000

Consider the two mappings in table 1 for "less pain medication" which is an example of a *Complex Match* [7], where a single noun-phrase maps to a combination of MeSH terms. In this case the word "pain" maps to *pain* and "medication" to *pharmaceutical preparations*. The formal solution proposed by Metamap for complex matches is to combine these two mappings and take the average of their scores, resulting in the term "less pain medication" mapping to two MeSH terms, with a score of (827+660)/2=743.5. This is a logical solution, but for this project we do not use such a strategy, as it requires two MeSH terms to represent a single concept. Our strategy for complex matches is to leave the multiple mappings separate and allow their reduced scores to reflect the fact that neither MeSH term completely represents the concept in the message.

We also incorporated a filtering strategy to remove undesired MeSH terms. This is achieved through a *stop* list (a set of noun-MeSH combinations) that is based on terms that are consistently mapped incorrectly. Terms appearing in the stop list will be removed automatically from the list of MeSH terms produced after parsing the PPML message. In Table 1, the last two mappings belong to the stop list and will be removed.

At the end of the step, we have a set of MeSH terms (with a score evaluating the strength of each mapping) corresponding to the terms in a discussion thread.

Literature Search Strategy

The first step in the literature search process is to generate a *literature search vector* from the set of MeSH terms found in previous step. This is done by combining any duplicate MeSH terms in the set and adding their scores together. The result is a set of k unique MeSH terms, each of which has a *MeSH Score* associated with it. Let M be the unique set of MeSH terms from the thread, and let s_i be the MeSH score for term i.

$$\{m_1, m_2, m_3, \ldots, m_k\} \in M \quad (2)$$

M can potentially be used to query Pubmed through a simple Boolean Information Retrieval (BIR) algorithm that would perform a search of Pubmed for all the MeSH terms, and return a set of papers that feature each term in M. The problem with this approach is that if we keep the size of M unrestricted (and often quite large) Pubmed may have no papers that have all the associated MeSH terms. A modified BIR solution would be to drop the lowest scoring MeSH term(s) from the search vector and redo the search, reiterating until a set of papers is returned. Let $M_{(j)}$ be the MeSH search vector with the lowest j scores removed ($M_{(0)}$ is the full set), let $f(q)$ be the number of papers in Pubmed with the set of MeSH terms q, and let Q be the set of papers returned. The set of papers returned would be:

$$Q = min_j(f(M_{(j)}) > 0) \quad (3)$$

Again, there are several problems with the above search strategy: (i) it provides no ranking of the returned papers; (ii) it uses the MeSH scores only to sort the MeSH terms, and not as absolute values; (iii) it does not differentiate between those papers that contain all but one of the terms in the search vector from those that contain none; and (iv) it does not address the most pressing issue of this project, the potential inaccuracy of the MeSH terms.

To address these limitations, we developed an algorithm similar to the extended BIR algorithm (eBIR) [3]. Our algorithm differs from the BIR algorithm by using the MeSH scores as weights for each of the MeSH terms in M. For each MeSH term Pubmed has a set of papers that use that term as a keyword. Let p_j be an individual paper, P_i be the set of papers associated with MeSH term i, and l_i be the number of papers in P_i.

$$P_i = \{p_1, p_2, \ldots, p_{li}\} \in m_i \quad (4)$$

For every MeSH term there is now a vector of associated papers along with the MeSH score. A *paper score* is derived from these MeSH scores, and we use the paper score to order the results. Let t_i be the paper score for paper i. The paper score can be calculated using the following:

$$\forall m_i \in M(\forall p_j \in P_i | t_j = t_j + s_i) \quad (5)$$

Take every MeSH term m_i in the set of MeSH terms M, and for every paper p_j associated with that MeSH term, add the MeSH score, s_i, to the paper score t_i. Paper j has a score that is the sum of its MeSH terms' scores. Finally, let the set Q be the union of all the papers, and return the set Q sorted by the paper scores.

$$Q = \bigcup_{i=1}^{k} P_i \quad (6)$$

We argue that our literature search algorithm is superior to a traditional BIR algorithm as it provides an absolute ordering of the papers, and is not a susceptible to high scoring MeSH terms that are incorrect mappings.

PPML Forum: Linking Explicit and Experiential Knowledge

We have developed a PPML forum that allows practitioners to interact with the PPML discussions and review the retrieved research articles for a selected discussion thread. The forum allows the following functionalities:

(a) Navigating the discussions using a standard search function that allows users to perform a search of discussion threads for desired content, returning a list of threads sorted by relevance to the search query.

(b) Navigating the discussions using search functions based on MeSH terms. Two search algorithms have been provided for the MeSH-based search. The first search method uses a simple BIR algorithm and takes MeSH terms as input and returns all the discussion threads that contain all those terms, sorted by the date they were posted in the thread. This method has the advantage that it returns recent messages first, as it is expected that recent messages are what clinicians are most interested in. The second search method uses our search algorithm (i.e. terms with their MeSH scores) to retrieve discussion threads. The threads are assigned a score that is a sum of the MeSH terms that match the terms in the query. If we define C as the set of MeSH terms in the query, and M_i as the set of MeSH terms for thread I, then the query score e_i for each thread is calculated as follows:

$$e_i = \sum_{j \in C \cap M_i} s_j \quad (7)$$

The query score returns the threads sorted by search score, and any ties sorted by date of last communication. Future testing will provide an answer as to which method is more effective.

(c) Organizing the discussion threads into a hierarchy, based on the 135 UMLS semantic types, for users to browse the threads.

(d) Retrieving a set of citations for a given thread, along with direct links to each of the referenced papers.

The three different navigation methods provide the users with different approaches to finding their desired thread, and once there they can browse the content of the conversation and retrieve the pertinent medical literature with a single click.

Results

We give below an example discussion thread to demonstrate the linkage of PPML discussions with research articles. This thread, the first thread ever on the PPML, is from 1993, on the subject of music therapy.

```
Sender: 1
Subject: Music Therapy
Date: Mon Jun 28 21:19:36 ADT 1993
The last several days, the local NBC station
aired a "medical report" about the use of
music therapy.  The report was from Miami and
included a short report on the use of music
therapy in a NICU.  The report stated that
when music therapy was used, the babies
required less pain medication.  Does anyone
know of any published reports of empirical
research demonstrating this effect?
..........
Sender: 2
Subject: Music Therapy
Date: Tue Jun 29 08:25:12 ADT 1993
I would suggest that you might contact [name
removed]  in  Pediatrics  at  Washington
University Medical School.  Her research is on
neonatal pain and she might know where the
local station picked up the report. I haven't
seen any data on the topic.
..........
Sender: 3
Subject: Music Therapy
Date: Tue Jun 29 10:20:41 ADT 1993
I'm not aware of specific studies conducted
using music therapy to reduce the need for
pain medication (i.e., music therapy to manage
pain).  However,  several  cognitive
interventions have been used quite effectively
to manage pain.  Donald Meichenbaum developed
a technique in the early 1970s called stress
inoculation training which combines aspects of
self-instruction  training  and  relaxation
training.
```

The example has been parsed and threaded correctly, and is ready to be converted to MeSH terms. Table 2 lists a sample of the MeSH terms that have been for retrieved after parsing the thread using Metamap.

Table 2- A sample of the mappings for a thread in PubMed. (The thread has 18 total MeSH terms)

MESH	SCORE	# OF PAPERS
Music Therapy	4802	1621
Pain	4215	237890
Pharmaceutical Preparations	1688	254813
Infant, Newborn	1660	438290
Education	1654	422011
Teaching	1320	429705

The returned set of MeSH terms for the thread seem to be appropriate, with the exception of the terms *education* and *teaching,* which are examples of terms added to the stop list. Table 3 contains a sample of the citations for the papers linked to the thread by our literature search strategy.

This example demonstrates the efficacy of our knowledge linkages framework. We took a thread containing the experiential knowledge of practitioners and retrieved corresponding published literature to supplement that experiential knowledge.

Table 3- The first three papers connected to the thread with MeSH terms, cumulative score and citation, and link to the paper, or the PubMed entry

MeSH: Music Therapy;Pain;Infant, Newborn;Behavior: *12609 Bo LK, Callaghan P.* **Soothing pain-elicited distress in Chinese neonates.** Pediatrics:2000,105(4).
MeSH: Music Therapy;Pain;Infant, Newborn;Behavior: *12609 Kemper KJ, Danhauer SC.* **Music as therapy.** Southern medical journal:2005,98(3).
MeSH: Music Therapy;Pain;Infant, Newborn;Behavior: *12609 Tagore T.* **Why music matters in childbirth.** Midwifery today with international midwife:2009,(89).

Pilot Study

A pilot study was conducted on a sample of the archives, using all messages on the PPML in 2007 and 2008. The threads were reviewed by the project authors to determine (a) the accuracy of the message parsing, (b) the accuracy of the thread assignment, and (c) the accuracy of the papers returned.

The results of the pilot study were promising. The message parsing was successful on 76% of the messages, with problems arising only from MIME and HTML formatted messages. These problems can be rectified using more sophisticated message parsing algorithms, and we plan to fix them in the next version. The organization of messages into threads was achieved accurately over 90% of the time, which is very promising. The problems arose when users changed the subject line of a message when replying to a previous problem, or replied on a thread about a new topic. Some of these problems can be dealt with more sophisticated parsing algorithms, but when there is no obvious connection between the original and the modified version of the subject lines it is impossible to connect the two automatically. Future work will incorporate an override of the threading function to allow messages to be connected manually if a mistake is found in the thread reviews.

The correct linkages of the discussion threads with corresponding articles was achieved with an overall success rate of 65%. The linkage success rate can be improved by better filtering the content of the threads. Many of the messages on the PPML, such as job postings or advertisements for conferences, are not proper candidates for knowledge linkage and hence their presence compromised the retrieval rate of corresponding articles.

The results revealed some potential problems in the literature search strategy due to the functionality of Metamap, as it tends to miss key terms. The most common example was a lack of an age group indicator to represent children (ages 0-18). This age group is represented by the MeSH terms *Infant*, *Child* or *Adolescent*. Several of the threads that had problems with knowledge linkage were discussions about complex material, but within the thread Metamap did not recognize any MeSH term related to children, which resulted in papers that were not restricted to the proper age group. Following the lead of Abidi et al. [8] the next step in the project will apply an age group filter to restrict all the queries to include the MeSH term C*hild*, restricting the searches to papers about pediatric medicine.

The pilot study was successful enough to warrant future research. Once the changes recommended from the pilot study are completed a formal study using clinical experts will be conducted to evaluate both the conversion to MeSH, the linkage to publications, and the online presentation format.

Conclusion

This project has demonstrated the potential of a system to supplement the experiential knowledge contained in a medical mailing list with explicit, evidence-based research from published journals. It has also demonstrated the potential of a system to leverage archived medical text to provide a novel knowledge-based tool. Using the Metamap system and a novel information retrieval algorithm, the conversations have been processed and linked to pertinent medical literature, presenting the results in an online forum. The forum provides an arena through which clinicians can browse the archives of the PPML and reaffirm the experiences they shared with evidence-based literature.

Abstract

An increasing number of clinicians, researchers, educators and patients routinely search for relevant medical images using search engines on the internet as well as in image archives and PACS systems. However, image retrieval is far less understood and developed compared to text-based searching. The ImageCLEF medical image retrieval task is an international challenge evaluation that enables researchers to assess and compare techniques for medical image retrieval using test collections. In this paper, we describe the development of the ImageCLEF medical image test collection, consisting of a database of images and their associated annotations, as well as a set of realistic search topics and relevance judgments obtained using a set of experts. 2009 was the sixth year for the ImageCLEF medical retrieval task and had strong participation from research groups across the globe. We will provide results from this year's evaluation and discuss the successes that we have had as well as challenges going forward.

Image retrieval, Information storage and retrieval, Content analysis and indexing, Systems and software

Introduction

Image retrieval is a burgeoning area of research in medical informatics [1, 2]. With the increasing utilization of digital imaging in all aspects of health care and medical research, there has been a substantial growth in the number of images being created every day in healthcare settings. Consequently, there is a critical need to manage the storage and retrieval of these image collections, whether they are stored in Picture Archival and Communication Systems (PACS), in patient health records, or on the web. Effective image annotation and retrieval can be useful in the clinical care of patients, education and research [2, 3]. Image retrieval can be used by clinicians to generate differential diagnoses, monitor patient response to therapy, and for quality control. Medical students and residents have also indicated that effective image retrieval can be useful for self-education [4], and other practitioners report using image retrieval systems for patient education, as well. Data-mining of large image collections can provide useful information for researchers. Examples include prevalence of certain findings including polyps during routine screening [5], visual characteristics associated with malignancy in mammography [6, 7], and prediction of response to radiation therapy based on FDG-PET [8].

Many areas of medicine, such as radiology, dermatology, and pathology are visually oriented, yet surprisingly little research has been done investigating how clinicians use and find images. In particular, medical image retrieval techniques and systems are under-developed in medicine when compared with their textual cousins. In particular, the field has suffered from a lack of evaluation opportunities and avenues for researchers to use to compare and measure their systems' performance. The lack of standardized test collections is an especially large problem facing medical image retrieval researchers.

Text retrieval, on the other hand, has a long history of evaluation campaigns, in which different groups use a common test collection to compare the performance of their different methods. The best-known such campaign is the Text REtrevial Conference (TREC), which has been running continuously since 1992. There have been several offshoots from TREC, including the Cross-Language Evaluation Forum (CLEF). CLEF operates on an annual cycle, and has produced numerous test collections since its inception in 2000. While CLEF's focus was originally on cross-language text retrieval, it has grown to include multimedia retrieval tracks of several varieties. The largest of these, ImageCLEF, first began in 2003 as a response to the aforementioned need for standardized test collections and evaluation forums and has grown to become today's pre-eminent venue for image retrieval evaluation.

ImageCLEF itself also includes several sub-tracks concerned with various aspects of image retrieval; one of these tracks is the subject of the present paper: the medical retrieval task. This medical retrieval task was first run in 2004, and has been repeated each year since.

The medical image retrieval track's test collection began with a teaching database of 8,000 images. Since then, it has grown to a collection of over 66,000 images from several teaching collections, as well as a set of topics that are known to be well-suited for textual, visual or mixed retrieval methods. In 2008, images from the medical literature were used for the first time, moving the task one step closer towards applications that can be of interest in clinical scenarios. Several user

studies have been performed to study the image searching behavior of clinicians. These studies have been used to inform the development of the task over the years, particularly to help identify realistic search topics. In 2009 we introduced a case-based retrieval task as we continue to strive for scenarios that more closely resemble actual clinical work-flows.

A major goal of ImageCLEF has been to foster development and growth of multimodal retrieval techniques: i.e., retrieval techniques that combine visual, textual, and other methods to improve retrieval performance. Traditionally, image retrieval systems have been text-based, relying on the textual annotations or captions associated with images [9]. Several commercial systems, such as Google Images (images.google.com) and Yahoo! images (http://images.yahoo.com), employ this approach.

Although text-based information retrieval methods are mature and well-researched, they are limited by the quality of the annotations applied to the images. There are other important limitations facing traditional text retrieval techniques when applied to image annotations: 1) image annotations are subjective and context sensitive, and can be quite limited in scope or even completely absent; 2) manually annotating images is labor and time intensive, and can be very error prone; 3) image annotations are very "noisy" if they are automatically extracted from the surrounding text; and 4) there is far more information in an image than can be abstracted using a limited number of words.

Advances in techniques in computer vision have led to a second family of methods for image retrieval: content-based image retrieval (CBIR). In a CBIR system, the visual contents of the image itself are mathematically abstracted and compared to similar abstractions of all images in the database. These features could include the color, shape or texture of images. Typically, such systems present the user with an ordered list of images that are visually most similar to the sample (or "query") image.

Materials and Methods

The traditional system-oriented IR evaluation process depends on a test collection made up of three parts: a "collection" of content items (articles, images, videos, etc.) that are to be retrieved; a set of "topics" representing potential queries or information needs that are to be answered by searching over the collection's content items; and a set of "gold standard" relevance judgments describing an expert's (or several experts') opinion as to which content items are relevant for each of the search topics.

ImageCLEF Medical Image Retrieval Test Collection

For the first several years, the ImageCLEF medical retrieval test collection was an amalgamation of several teaching case files in English, French, and German [9, 10]. In both 2008 and 2009, the Radiological Society of North America (RSNA) made a subset of its journals' image collections available for use by participants in the ImageCLEF campaign. The 2009 database contained a total of 74,902 images, the largest collection yet.

All images were taken from the journals *Radiology* and *RadioGraphics*, both published by the RSNA. The ImageCLEF collection is similar in composition to that powering the "ARRS GoldMiner"[1] search system [11]. This collection constitutes an important body of medical knowledge from the peer-reviewed scientific literature, and includes high quality images with annotations. Images are associated with specific published journal articles, and as such may represent either an entire figure or a component of a larger figure. In either event, the image's annotations in the collection will contain the appropriate caption text. These high-quality annotations enable textual searching in addition to content-based retrieval using the image's visual features. Furthermore, as the PubMed IDs of each image's article are also part of the collection, participants may access bibliographic metadata such as the MeSH (Medical Subject Headings) terms created by the National Library of Medicine for PubMed.

Creation of Realistic Search Topics

Our goal in creating search topics for the ImageCLEF medical retrieval task has been to identify typical information needs for a variety of users. In the past, we have used search logs from a different medical websites to identify topics. This year again search topics were identified by surveying actual user needs. The starting point for this year's topics was a user study conducted at Oregon Health & Science University (OHSU) during early 2009. This study was conducted with 37 medical practitioners in order to understand their needs, both met and unmet, regarding medical image retrieval. During the study, participants were given the opportunity to use a variety of medical and general-purpose image retrieval systems, and were asked to report their search queries.

In total, the 37 participants used the demonstrated systems to perform a total of 95 searches using textual queries in English. We randomly selected 25 candidate queries from the 95 searches to create the topics for ImageCLEFmed 2009. We added to each candidate query 2 to 4 sample images from the previous collections of ImageCLEFmed, which represented visual "queries" for content-based retrieval. Additionally, we provided French and German translations of the original textual description for each topic. Finally, the resulting set of topics was categorized into three groups: 10 visual topics, 10 mixed topics, and 5 semantic topics. This classification was performed by the organizers based on their knowledge of the capabilities of visual and textual search techniques, prior experience with the performance of textual and visual systems at ImageCLEF medical retrieval task, and their familiarity with the test collection. The entire set of topics was finally approved by a physician. An example of a "visual" topic can be seen in Figure 1 while that of a "textual" topic is shown in Figure 2.

[1] http://goldminer.arrs.org/

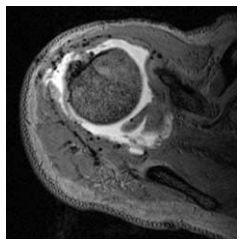

Figure 1-A "visual" topic: "MR Images of rotator cuff"

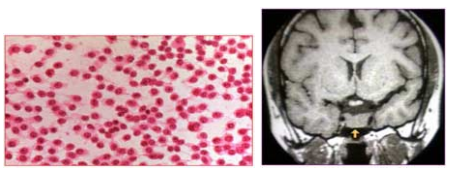

Figure 2-A "semantic" topic: "Pituitary adenoma"

In 2009, we also introduced "case-based" topics as part of an exploratory task whose goal was to create search topics that are potentially more aligned with the information needs of an actual clinician in practice. These topics were meant to simulate the use case of a clinician who is diagnosing a difficult case, and has information about the patient's demographics, list of presenting symptoms, and imaging studies, but not the patient's final diagnosis. Providing this clinician with articles from the literature that deal with cases similar to the case (s)he is working on ("similar" based on images and other clinical data on the patient) could be a valuable aide to creating differential diagnosis or identifying treatment options.

These case-based search topics were created based on cases from the French teaching file Casimage, which contains cases (including images) from radiological practice. Ten cases were pre-selected, and a search with the final diagnosis was performed against the 2009 ImageCLEF data set to make sure that there were at least a few matching articles. Five topics were finally chosen. The diagnoses and all information about the chosen treatment were removed from the cases to simulate the aforementioned situation of a clinician dealing with a difficult diagnosis. However, in order to make the judging more consistent, the relevance judges were provided with the original diagnosis for each case.

Relevance Judgments

During 2008 and 2009, relevance judgments were made by a panel of clinicians using a web-based interface. Due to the infeasibility of manually reviewing 74,900 images for 30 topics, the organizers used a TREC-style "pooling" system to reduce the number of candidate images for each topic to approximately 1,000 by combining the top 40 images from each of the participants' runs. Each judge was responsible for between three to five topics, and sixteen of the thirty topics were judged multiple times (in order to allow evaluation of inter-rater agreement).

For the image-based topics, each judge was presented with the topic as well as several sample images as shown in Figure 3. For the case-based topics, the judge was shown the original case description and several images appearing in the original article's text. Besides a short description for the judgments, a full document was prepared to describe the judging process, including what should be regarded as relevant versus non--relevant. A ternary judgment scheme was used, wherein each image in each pool was judged to be ``relevant'', ``partly relevant'', or ``non-relevant''. Images clearly corresponding to all criteria were judged as ``relevant'', images whose relevance could not be safely confirmed but could still be possible were marked as ``partly relevant'', and images for which one or more criteria of the topic were not met were marked as ``non-relevant''. Judges were instructed in these criteria and results were manually verified during the judgment process.

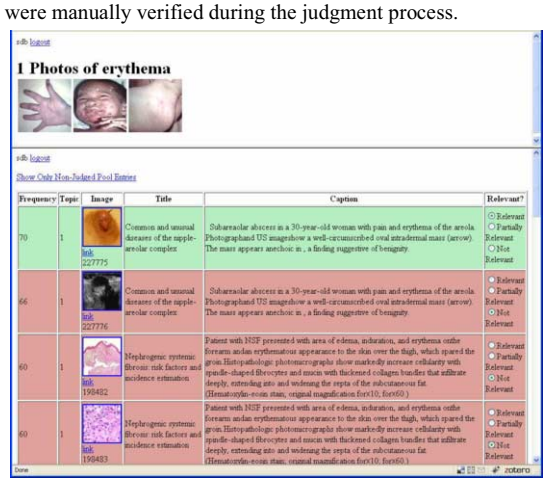

Figure 3-Web interface used for creating relevance judgments

As mentioned, we had sufficient judges to perform multiple judgements on many topics, both image-based and case-based. Inter-rater agreement was assessed using the kappa metric, given as:

$$\kappa = \frac{P(A) - P(E)}{1 - P(E)} \quad (1)$$

where $P(A)$ is the observed agreement between judges, and $P(E)$ is the expected (random) agreement. It is generally accepted that a $\kappa < 0.7$ is good and sufficient for an evaluation. The score is calculated using a 2x2 table for the relevances of images or articles. These were calculated using both "lenient" and "strict" judgment rules. Under the lenient rules, "partly relevant" judgment was counted as "relevant"; under strict rules, "partly relevant" judgments were considered to be "not-relevant".

In general the agreement between the judges was fairly high (with a few exceptions), and our 2009 overall average κ is similar to that found during other evaluation campaigns.

Participation

For the medical retrieval task, the participation remained similar to the previous year with 37 registrations. 17 of the participants submitted results to the tasks. We had six first-time participants in 2009, which we consider to be a very positive development.

A total of 124 valid runs were submitted, 106 of which were submitted for the image-based topics, while 18 were submitted for the case-based topics. The number of runs per group was limited to ten per subtask and case-based and image-based topics were seen as separate subtasks in this view. Participants were requested to provide information about each run that they submitted. Runs could be classified as "textual", "visual" or "mixed" depending on the type of search engine used. They could also be classified as automatic, manual or feedback depending on the level of user interaction. The number of runs by run type can be seen in Table 1 below.

Table 1 – Number of runs by run type

Number of Runs		Run Type		
		automatic	feedback	manual
Retrieval Type	Textual	52	7	
	Visual	15	1	
	Mixed	25	3	2
	N/A	1		

Results

The metrics used to evaluate the runs include the mean averge precision (MAP), early precision (e.g. P@5, p@10) and bpref), measures that have historically been used for TREC and other challenge evaluations [12]. As was the case in the recent past, the focus of many participants in this year's ImageCLEF was primarily on text-based retrieval methods (as opposed to visual techniques). Almost half the runs submitted were automatic and textual. The increasingly semantic topics, combined with a database containing high-quality annotations, produced an evaluation environment better-suited for text-based image retrieval, and this fact was not lost on the participants. Only a few participants submitted visual runs, and those runs that were submitted were small in number and generally performed poorly, as can be seen from the average of the MAPs of the runs in Table 2.

Table 2 – Mean average precision by run type

Average MAP		Run Type		
		automatic	feedback	manual
Retrieval Type	Textual	0.27	0.26	
	Visual	0.01	0.01	
	Mixed	0.20	0.26	0.19

Mixed-media runs performed similarly to textual runs in terms of mean average precision. That said, mixed runs that effectively combined visual and textual retrieval approaches typically outperformed the corresponding purely textual runs when considering metrics such as early precision, as can be seen in Table 3 where some mixed automatics runs demonstrated high early precision.

Case-based topics were introduced for the first time, and only a few groups participated. Runs submitted for case-based topics performed slightly worse than those submitted for image-based topics.

Table 3 – Maximum precision@5 by run type

Maximum P@5		Run Type		
		automatic	feedback	manual
Retrieval Type	Textual	0.73	0.61	
	Visual	0.09	0.06	
	Mixed	0.71	0.74	0.62

A kappa analysis between several relevance judgments for the same topics showed that there were differences between judges but that agreement was generally high. There were, however, a few judges that had significant disagreements with other judges. Additionally, feedback that we received from the judges indicated that the level of expertise of the judge in the specific area being searched affects their leniency with the relevance judgment process. The relevance judgments from judges with markedly different opinions were not used for calculating the final results. Interestingly, as has been found in the text retrieval domain, the overall rankings of the systems remain relatively stable even with using relevance judgments from different judges. However, the topic of relevance judging and the role of the judge (student, resident, general practitioner, expert radiologist, etc.) while evaluating the relevance of an image is of significant interest to us and one that we are investigating further.

Very few participants submitted interactive and manual runs as most participants seem to prefer batch processing with automatic text-based approaches, leading to primarily system-based evaluation. However, the role of the user in the retrieval process is important and we continue to encourage participants to introduce interactivity into their search systems and runs.

Conclusion

The ImageCLEF medical image retrieval campaign have been quite successful in attracting international researchers by providing a test collection that can be used to evaluate the performance of both text-based and content-based image retrieval systems. The test collection has grown from 8,000 images in 2004 to over 74,900 images in 2009. The participants in ImageCLEF have had interesting but diverse approaches to the addressing the problem of effective image retrieval in the medical domain. However, the collaborative nature of the forum and the annual workshops have fostered a community of participants that have willingly shared their techniques and

even resources to the common goal of improving access to clinical images.

This work has some limitations. First, like all test collections, the topics were artificial. However, since they grew out of the results of a user study, we feel that they are reasonable and valid examples of clinician information needs and language use. Another limitation is the pools uses for relevance judgments reflect the runs submitted by the participants. Images that may have been retrieved by other techniques or were not the top hits would not be evaluated.

Going forward, we plan to expand the case-based topics as we believe that they more closely simulate the experiences of real user. We will continue to encourage participants to improve their multimodal techniques by making available the best visual and textual runs from past years in an effort to identify optimal ways of combining them. We are also continuing our user studies to better understand the needs of real users and to assess the validity of the performance measures used in these evaluation campaigns. The role of the user in assessing relevance continues to be of interest to us.

Abstract

Preanesthetic evaluation purpose is to reduce morbidity and mortality through the review of the patient's medical history, clinical examination, and targeted clinical studies, providing referrals for medical consultations when appropriated. Changes in patient care, standards of health information management and patterns of perioperative care, have resulted in a re-conceptualization of this process where the documentation of patient medical information, the efforts in training and maintaining the integrity of the medical-legal evaluation are areas of concern. The aim of this paper is to describe the design, development, training, and implementation of a computerized preanesthetic evaluation form associated to the evaluation of the user satisfaction with the system. Since the system went live in September 2008 there were 15121 closed structured forms, 60% for ambulatory procedures and 40 % for procedures that required hospital admission. 82% of total closed structured forms had recorded a risk of the procedures of 1-2, according to the American Society of Anesthesiologists classification. The survey indicates a positive general satisfaction of the users with the system.

Keywords:

Preoperative care, Computerized medical records systems, Perioperative procedures, User satisfaction

Introduction

Preanesthetic evaluation is a clinical assessment process that precedes the accomplishment of surgical and non surgical procedures, which will be carried out under general or local anesthesia or sedation. This process includes review of the medical records of the patient, current medical history, clinical examination, test results and referrals to other specialists when appropriate[1]. The purpose of the evaluation is to reduce preoperative morbidity and mortality [2]. The detection of risk factors influences the choice of the anesthetic technique, the complexity of required actions and the need of specific anesthetic postoperative care [3].

Changes in patient care, standards of health information management and patterns of perioperative care, have resulted in a re-conceptualization of every aspect of preoperative preparation, where the documentation of patient medical information, the efforts in training and maintaining the integrity of the medical-legal evaluation in preanesthetic are areas of concern and research [4, 5]. The registration of this assessment is often done on paper.

A study compared the efficiency of a new computerized preoperative evaluation system against one paper based and the waiting and examination periods were analyzed. The computerized system required less examination time than the manual system and the authors presumed that time is saved at other points of patient care by the legible, instantly retrievable preoperative evaluations that the computerized system produces. The computerization of clinical records improves the quality of patient care by transforming this information into data which is easily readable and accessible [6, 7].

The implementation of a computerized version of a structured Preanesthetic evaluation questionnaire in obstetric patients reduced time-consuming tasks, captured far more detail and provided immediately available data for quality assurance activities[8].

The purposes of this study are 1) to describe the design, development, training and implementation of a Preanesthetic Evaluation Electronic Form (PEEF) included in an Electronic Health Record (EHR), 2) results of system use since implementation and 3) to assess the user satisfaction with the new system. This is done within the framework of a new Center for Preanesthetic Evaluation (PEC) in the Hospital Italiano of Buenos Aires.

Materials and Methods

Design

This is a descriptive study of a Preanesthetic Evaluation Electronic Form implementation.

Setting

The Hospital Italiano of Buenos Aires (HIBA) is a non-profit health care academic center founded in 1853. HIBA has a network of two hospitals with 750 beds, 500 home care pa-

tients under care, and 23 outpatients care centers. There are more than 2,400,000 outpatient visits annually, each year over 38,000 inpatients are admitted to its hospitals and 23,000 surgeries in the last year.

In 1998 HIBA began the implementation of a Healthcare Information System (HIS) to manage clinical information with preexisting administrative applications. It is an in-house project that currently handles all the information related to health care both clinical and administrative from capture to analysis.

The EHR is a full-implemented web based, problem oriented, patient centered record with customized functionalities depending on the level of care (outpatient, inpatient, emergency care and home care) This EHR system includes a computerized provider order entry (CPOE), available throughout the HIBA network. The terminology server [9, 10] has allowed the mapping of local vocabulary (thesaurus) to reference vocabulary SNOMED CT, allowing the auto-codification of 80 % of diagnosis.

Computerization of the preoperative process

The computerization of the preoperative process was planned and included the following stages: the computerization of the Preanesthetic Evaluation Form, the appointment for surgery, and the Surgery & Anesthesia Form. In addition to this, and in the context of the proposed creation of the PEC, a multidisciplinary working team was established enabling the development of the PEEF (Figure 1).

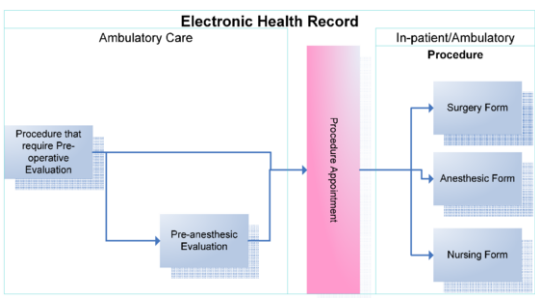

Figure 1- Computerization of the preoperative process

Multi-disciplinary working team

An anesthesiologist, a pediatrician, a clinician, a cardiologist, norms and procedures area specialist and two medical informatics residents integrated the working team. The medical informaticians were in charge of preparing the functional requirements, the implementation and user satisfaction survey using QUIS ™.

Evaluation Process pre go live

The Preanesthetic Evaluation (PE) for adults and pediatric populations was carried out in HIBA in a decentralized manner in several locations, with different methods of coordination and evaluation. An average of 1500 patients per month was evaluated.

The PE began with the ordering of a surgical procedure or any other that is carried out under anesthesia. To record the steps during the evaluation, a paper form was used. This form was given to the patient, in the majority of cases by clerks during scheduled visits or by the surgeon´s secretaries that was going to execute the procedure.

The paper form had specific data fields, depending on the circumstances. It was completed by the patient, the clerk or the secretary, the clinician, the cardiologist, the anesthesiologist and the nurse.

Finally, the form consisted of a summary generated through the participation of multiple key users involved. Sometimes, the records were illegible. Anesthesiologists highlighted the most important data evaluated in the paper so that the anesthesiologist at the operating room could quickly visualize it. At that time a copy was given to the patient with the fasting schedule, the preparation for surgery, the procedure explanation and an informed consent.

Preanesthetic Evaluation Electronic Form (PEEF)

The PEEF was included in the ambulatory EHR (AEHR) and was developed entirely in Java.

Every PEEF starts with the input of the problem or a procedure coded by the terminology server [10, 11]. While the PEEF is opened the user can navigate between modules and add or modify information, when the PEEF is closed the final print version of the structured form could be given to the patient with the highlighted data chosen by the physician.

This new structured form was divided into the following sections or modules:

- Relevant Diseases: there is a predefined list of diseases and pathologies, as shown in Figure 2. If any of these were already in the problem list of the AEHR, it automatically appears highlighted (underlined) in this module. This helps to avoid duplication of information and enabled integration of a structured data into a longitudinal patient record. Also contains the vital signs and tetanus immunization data.

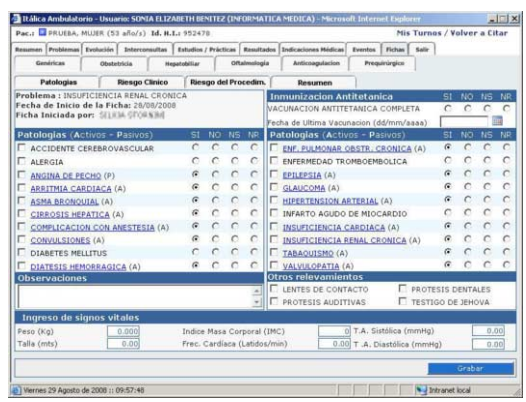

Figure 2- Snapshot of the EHR: pre-defined relevant diseases list in the Preanesthetic Evaluation Electronic Form.

- Clinical risk: in this section clinical, respiratory and renal risk is evaluated; laboratory test can be ordered; referral can be made as well as to order the medication suspension. If respiratory risk is marked an alert suggesting ordering a test is triggered (Figure 3)

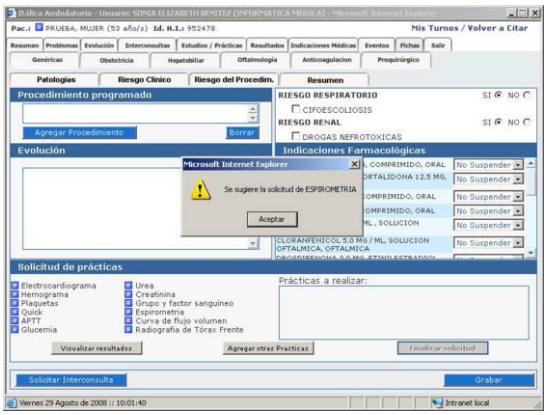

Figure 3- Snapshot of the EHR: Section for Clinical Risk evaluation in the Preanesthetic Evaluation Electronic Form.

- Risks of the procedure: the risk of bleeding and the difficulty on intubation is evaluated by the anesthesiologist. The result of this is expressed using the ASA (American Society of Anesthesiologists) score.
- Summary: In this module all the records made are visible in a summarized form.

Training in the use of the PEEF

During the pre go live stage a virtual training space was created and online reading material was made available to the users. The training course had interactive material and assessment activities. The implementation process was accompanied by a face to face support made by medical informatics residents.

Databases analysis

Secondary databases were analyzed to evaluate the amount of PEEF created and closed, the most frequent diagnosis and procedure and the prevailing ASA classification.

The ASA Score is a five category physical status classification system for evaluating a patient before surgery. The categories are: 1)The healthy patient, 2)The patient with mild systemic disease, 3) The patient with severe systemic disease, 4) The patient with severe systemic disease that is a constant threat to life 5) The patient who is not expected to survive without the operation.

QUIS: Evaluation of User Satisfaction

The Questionnaire for User Interaction Satisfaction (QUIS ™)[12] is a standardized usability testing instrument for interactive computer systems. An adapted Spanish edition of the short version was used supplemented by free-text comments.

The survey contains a demographic questionnaire with the identification of the physician specialty, a measure of general satisfaction and an organized evaluation of four specific interface factors: screen, terminology and system feedback, learning, and system capabilities. The global satisfaction with the interface are measured, as well as the factors that are part of that aspect, on a 9-point scale, where 1 (one) correspond to the worst and 9 (nine) characterize the best evaluation.

When the survey was completed, each area was analyzed separately and grouped by medical specialties. Central tendency of data was summarized by the median and the dispersion by range.

Results

Databases analysis

Since the system went live in September 2008 there were 15121 closed structured forms, 60% for ambulatory procedures and 40 % for procedures that will require hospital admittance. The prevailing ASA was 1-2 with 82% of total closed structured forms.

Currently 20 general practitioners (GP), 5 anesthesiologists and a variable number of cardiologists are working in the Center.

Evaluation of User Satisfaction

Between 29/09/09 and 10/10/09, 18 users completed the survey. 66 % of them have been working with the system between 6 month up to a year and 53 % worked between 4 hs. to 10 hs. 61% of users who completed the survey were general practitioner with a response rate of 55% and the 16 % corresponding to anesthesiologists with a response rate of 60%.

QUIS categories were compared between the user's specialties as shown in Table 1.

Table 1 - Results of Category[1]

Categories	GP	Anesthesiologist	Global Median
General Satisfaction	7 (5-8)	7 (3-8)	7
Learning	8 (7-9)	8 (8-9)	8
Screen design	8 (7-9)	8 (7-9)	8
Use of terminology	7,5 (6-8)	7,5 (7-9)	7,5
Capacity of system	7 (6-7,5)	8 (8)	7,5
Users manuals & Help desk	7 (6-8)	7 (6,5-8)	7

Due to the variability number of the cardiologist that used the form, they were not included.

The majority of items were scored up to 7, except two items of General satisfaction (Flexibility and Adequacy of power) and

[1] The results of Table 2 related to GP and Anesthesiologist are expressed in median (range).

one item of Help desk & user manual (Clarity of User Manual) as is shown in Figure 4.

Learning to use PEEF was appraised as easy by the anesthesiologists.

Characters on the screen were easy to read and sequence of screen was considered very clear. Anesthesiologists rated more positively the system's capabilities in contrast with GPs. The help desk service was helpful and the support more appreciated for both GP and Anesthesiologists.

Free-Text Opinion Space

In addition to the above mentioned 71% (10/14) of the physicians who completed the questionnaire also contributed with narrative responses about different problems or features of the PEEF. The problems mentioned were the downtime of the system, problems and procedures correction, rigidity of tetanus vaccination data entry and medication suspension. Alerts and more amount of free text were solicited, among others.

Three of the cardiologists wrote their opinion. Only one of them asked about a specific section for cardiologists' record.

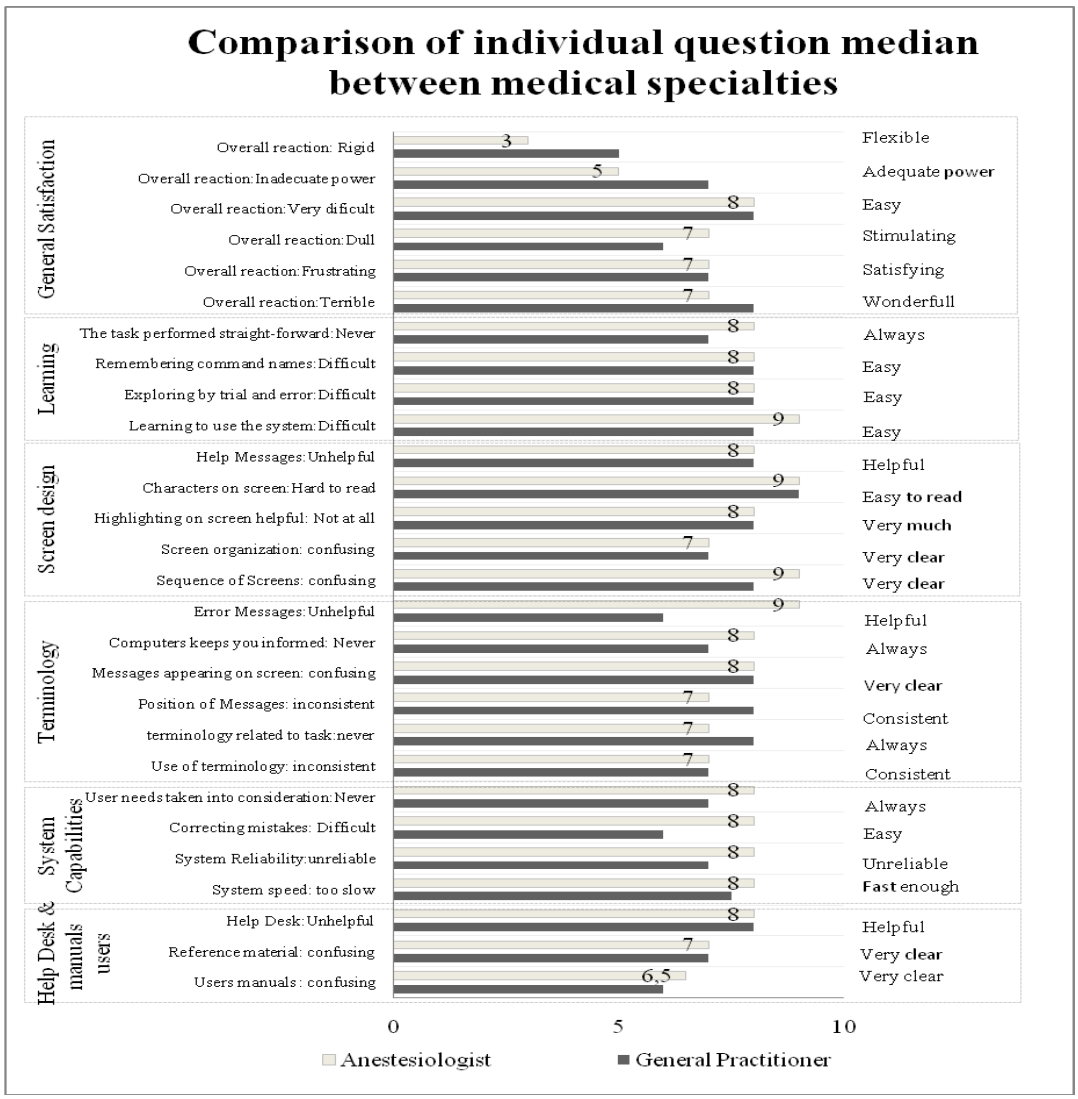

Figure 4 – Comparison of individual question median between medical specialties

Discussion

In this study we described the experience of the implementation of an integrated computerized preanesthetic evaluation form in an academic center and the evaluation of user satisfaction of the new form.

User interface of systems has been evaluated by QUIS™ in other opportunities. Using QUIS™, 75 primary care physicians where surveyed about the Brigham and Women's Integrated Computing System (BICS). The system scored highest in the area of screen design and lowest in the area of system capability. General satisfaction was most highly correlated with screen design and layout [13]. Also was the instrument used for comparing the physician satisfaction with two order entry systems. User satisfaction differed significantly between the two systems, the Veterans Affairs CPRS had a mean of 7,06 in General Satisfaction against the Commercial System evaluated [14].

The survey results indicated a positive general satisfaction on the PEEF. It scored highest particularly in the area of screen design. The system was globally considered as stimulating, with adequate capacity and ease of use.

The lack of flexibility expressed in the results is associated to a pre-defined list of problem and rigidity of tetanus vaccination data entry and medication suspension

The limitation of this user survey can be summarized in the following points: the overall response rate was low and the cardiologists were not included due to the variability of number of them.

Conclusion

A PEEF was successfully implemented, used and accepted by the end user.

Acknowledgments

The authors would like to extend their gratitude to the personnel who participated in the surveys, especially Cecilia Acosta, Eduardo de los Rios, Andrea Venica and Paula Otero.

Usability of Clinician Order Entry Systems in Singapore: An Assessment of End-User Satisfaction

Yung Ming Tan[a], JVPG Flores[b], Mee Lee Tay[b]

[a] *Department of Clinical Informatics, Integrated Health Information Systems (IHIS) Ltd., Singapore*
[b] *Department for Chronic Disease Management, Integrated Health Information Systems (IHIS) Ltd., Singapore*

Abstract

Objectives: To gather end-user feedback and evaluate factors that influence end-user satisfaction of order entry systems used in the hospitals under National Healthcare Group, Singapore. Design: Questionnaires were sent to a randomly selected group of 100 doctors and nurses. Results & Conclusions: 52 doctors and nurses responded to the survey. The users' satisfaction with the clinical systems was average. (Mean satisfaction score is 3.85 on a scale of 1 to 7). Users generally agree that the systems could help reduce patient care errors and improve delivery of quality care to patients. System reliability, intuitive navigational capabilities and ease of use are strongly and positively correlated with user satisfaction. System response time however, is found to be strongly but negatively correlated with user satisfaction with a correlation coefficient of -0.717 ($p<0.001$). These findings suggest that more efforts should be made to improve these aspects in order to improve user satisfaction. These elements should also form important considerations in all future clinical systems development.

Introduction

Computerized physician order entry (CPOE) systems have been shown to significantly reduce medication errors and improve quality of care in many studies [1, 2]. However despite the benefits of CPOE systems, many implementations have failed or met with high levels of user resistance [3, 4]. Studies have shown that it is vital to understand the needs of clinical users, the various system and human factors that can impact user satisfaction [5- 7]. A study by Bailey [8] found that user satisfaction is an important predictor of a system's success.

In Singapore, despite the increasing number of implementations over the years in public tertiary hospitals, there is a paucity of studies covering user satisfaction and perceptions of CPOE. One recent study in Singapore reported generally high user satisfaction levels with an electronic prescription system used by a group of general practice clinics [9].

In National Healthcare Group (NHG), Singapore, a CPOE user feedback survey was planned in early 2009 as part of a post-implementation review. The CPOE system for laboratory, radiology and medication orders was designed, custom-built and implemented over four years in several of its tertiary hospitals. To date, there are more than a thousand doctors and nurses using them daily.

The aim of this study is to: (a) determine the overall satisfaction level of NHG users (doctors and nurses) with respect to their order entry systems; and (b) identify the constructs that are associated with user satisfaction

This study will contribute an Asian perspective into the current body of knowledge around CPOE implementation, and the findings should help hospitals learn about the factors that influence clinician user satisfaction. The results may also provide further insights into how order entry systems should be designed to improve adoption and reduce user resistance.

Methods

Fifty doctors and fifty nurses from various institutions under the National Health Care Group (NHG) were randomly selected and requested to complete a pretested questionnaire based on the study of Lee et al [10]. The doctors and nurses were from both medical and surgical departments. The only inclusion criterion was that the users (doctors and nurses) must have worked for at least six months in the group. This was to ensure that the user surveyed has sufficient experience with the systems to give effective feedback.

The questionnaire is composed of 16 questions respectively attached to a seven-point Likert scale, where '1' corresponds to 'never'; '4' corresponds to 'it varies'; while '7' corresponds to "always' . There was also an inclusion of 6 open ended questions in the questionnaire to ensure that the exercise can capture important user feedback that may not be reflected by the 16 standardized questions.

The initial draft questionnaire was tested with 2 doctors and 2 nurses from both medical and surgical disciplines for face validity. The final questionnaire was then derived subsequently for use.

The survey tool is designed to measure the users' perception of reliability, speed of the systems, ease of use of the applications, adequacy of training to use the system, impact on productivity, impact on patient care and overall satisfaction with the clinician order entry systems. The questionnaire is made available in hard copy which is hand-delivered to those selected participant. At the same time, the selected participants are sent emails to introduce them to the study as well as to instruct them on how they can participate either through the hard-copied questionnaire or through a web-based survey tool.

The questionnaire contains a simple introduction and instructions. The survey responses were anonymous and participants were told that no individuals will be identified in the study. All doctors and nurses selected in our random sample had the right to refuse to participate without prejudice. This study was further reviewed and endorsed by the NHG Electronic Medical Records committee as a form of post-implementation user feedback.

Once the questionnaire was completed, the data was validated, edited for consistency and encoded into a spreadsheet for analysis.

Results

A total of fifty-two users handed in their questionnaires. About 98% of these responders were doctors and nurses with a ratio of 1:1. These health care professionals come from Alexandra Hospital, NHG Polyclinics, The National University Hospital and Tan Tock Seng Hospital representing both the Inpatient and the Outpatient sectors of the medical group.

Cronbach alpha of the data collection tool is measured to assess internal consistency of the questionnaire, i.e. 0.656. Factor analysis of the data collection tool suggests four statistically significant components present in the questionnaire. These components pertain to the following user satisfaction constructs: ease of use; facilitating efficiency of work; promotion of quality of care and patient safety; and availability of prompt assistance whenever the users need it.

Further assessment of the tool likewise reveals that the consistency of responses are much more homogenous among nurses than among physicians ($p<0.001$). There is no sufficient evidence to say however that internal consistency of the questionnaire varies across gender, across institutions and whether the user is either in the in-patient or outpatient setting.

The mean overall satisfaction score of the study population is estimated to be 3.85 ± 1.39. Figure 1 illustrates the distribution of satisfaction levels among users.

It can readily be seen in Figure 1 that about 33% of the respondents (those who answered "Frequently" or "Almost Always") find the clinical systems to be consistently satisfactory. There is no evidence that the satisfaction levels are different between doctors and nurses. There is likewise no evidence to suggest that satisfaction levels vary across institutions from where the samples are selected.

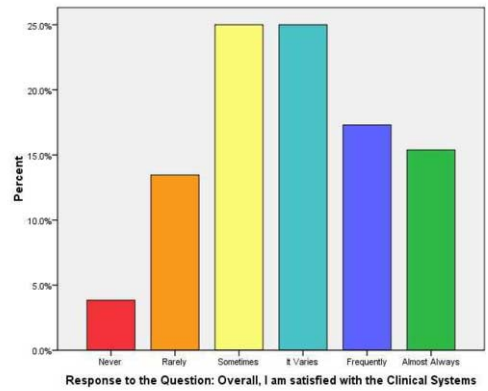

Figure 1- Distribution of Overall Satisfaction of Users on the Clinician Order Entry Systems, NHG Singapore, 2009.

Looking into some of the details, the study population has provided a good contrasting feedback, i.e. from good comments to areas of improvement. On one hand, the data suggest that the order entry systems are perceived not only to reduce patient care errors but also to improve delivery of quality of care to patients. As such, responders feel that the systems provide the necessary information for the health care providers to do their respective jobs better. Qualitatively, doctors like the fact that they can access clinical information remotely and that they can find information in "one place." Nurses likewise highlighted that with the clinical systems in place; they can readily access old laboratory results as well as monitor laboratory requests with pending results

On the other hand, the responders feel that the opening of multiple windows while using the applications can be quite annoying. They also said that the system response time has a lot of room for improvement. As the doctors are very adept in their habits in ordering, they are of the opinion that computerized order entry for tests and medications slow down their respective processes. Nurses, however, love the fact that they can readily and legibly read instructions from doctors. They also like the fact that they are being prompted by their respective systems when medications are due to be administered.

Correlation analysis is done to determine which facets of the order entry systems are strongly associated with user satisfaction. Table 1 shows the four factors with the strongest correlation found. System reliability, intuitive navigational capabilities and ease of use are strongly and positively correlated with user satisfaction. Correlation coefficient are estimated to be 0.736, 0.741 and 0.731, respectively ($p<0.001$). System response time however, is found to be strongly but negatively correlated with user satisfaction with a correlation coefficient of -0.717 ($p<0.001$). Test of heterogeneity suggest that inasmuch as the direction of correlation is the same for doctors and nurses, responses solicited from nurses are more homogenous than responses elicited from the physicians ($p<0.05$).

Table 1- showing the facets of the order entry systems that are strongly associated with user satisfaction (p <0.001)

Facets of the systems	Correlation coefficient
System reliability	0.736
Intuitive navigational capabilities	0.741
Ease of use	0.731
System response times	-0.717

Interestingly, there is no sufficient evidence suggesting that training of users for the systems of interest is associated with user satisfaction.

The summary scores of the responders are presented in Table 2 below.

Table 2 - Summary Table of Responses of Clinical System Users, NHG Institutions, 2009. (based on the 7 point Likert scale)

Question	Mean	SD
Q1 The systems are reliable - it does its job consistently.	4.35	1.14
Q2 The systems improve my productivity.	4.35	1.27
Q3 Navigating through the systems is intuitive and easy	4.13	1.44
Q4 The systems have a negative impact on patient care.	3.17	1.48
Q5 The systems reduce patient care errors.	4.71	1.27
Q6 The systems are easy to use.	4.25	1.40
Q7 Compared to paper ordering, computerized order entry for tests and medications slow me down	5.18	1.68
Q8 The systems give me information I need to do my job better.	4.87	1.34
Q9 I feel that I had adequate training on the systems	4.50	1.50
Q10 The systems improve the quality of patient care.	4.60	1.27
Q11 System response time is slow.	5.75	1.36
Q12 Opening multiple windows to access different applications can be annoying.	5.88	1.32
Q13 When I have a problem with the systems, I just ask someone for help.	4.81	1.34
Q14 I feel that I can benefit from refresher classes on the clinical systems.	3.79	1.63
Q15 When I need help on the system, I can find it.	3.96	1.30
Q16 Overall, I am satisfied with the systems.	3.85	1.39

Discussion & Conclusions

The relatively low response rate of this study can lead to some selection bias and thus be considered as one of its significant limitations. A number of non-responders told their department secretaries that they could not spare the time to answer the questionnaire. The implication of this response is that if the lack of time to answer the questionnaire is associated with non-satisfaction of the users, then the estimated overall satisfaction rate of the users will be significantly diminished. The converse is also true. If the lack of time to answer the questionnaire is associated with satisfaction of users, then the estimated overall satisfaction rate of the users will be significantly increased. Considering that the slowness of the system has been cited as one of the pain points and is associated with adequacy of time, it can be reasonable to assume that the study results can swing towards more user dissatisfaction. Future studies should consider the use of incentives eg. vouchers to improve response rates.

Moreover, the fact the Cronbach alpha of the questionnaire varies between doctor (0.514) and nurse (0.757) responders suggest that either the doctors have a different concept of user satisfaction compared to nurses or the data collection tool with its contents are more effective in measuring nursing constructs than doctor mindsets --- at least as far as assessing user satisfaction of the clinician order entry systems. Doctors and nurses have different job scopes which lead to different needs and expectations of the clinical systems. Therefore in healthcare IT development, it is imperative to involve both physicians and non-physicians.

Based on our correlation analysis, end-user satisfaction is strongly associated to four key system elements – reliability, intuitive navigation, ease of use, and system response time. These findings suggest that more efforts should be made to improve these aspects in order to improve user satisfaction. These elements should also form important considerations in all future clinical systems development.

Beyond optimizing clinical software design, hospitals need also to improve and maintain good IT infrastructure like hardware and network to improve the overall system performance.

While there are numerous studies [11-13] showing that proper user training can improve the success and acceptance of electronic medical records, our results do not show any correlation between training and user satisfaction. The is likely due to the fact that the last CPOE training session was conducted more than six months ago, and the impact of training on user satisfaction have waned with time.

In light of the study's findings, recommendations have been made to the software team for future enhancements, particularly the need to optimize system performance and usability. A further study on clinical users may be warranted to explore in-depth the issues uncovered here.

Abstract

Background: To improve the quality of reports of health informatics evaluations we recently devised and published a guideline named STARE-HI, now formally endorsed by IMIA. Objective: To develop a prioritization framework of ranked items (a mini-STARE-HI) to assist authors when reporting health informatics evaluation studies in a restricted space conference paper. Method: We invited 111 editors of health informatics conference proceedings and reviewers and authors of health informatics evaluation studies to score 106 reporting items on a scale ranging from "0 - not necessary" through to "10 - essential" by a web-based survey. Results: The response rate for the survey was 63% (70 out of 111). The most important items (score >9) were "Interpret the data and give an answer to the study question", "Whether it is a laboratory, simulation or field study" and "Description of the outcome measure/evaluation criteria". Four items had a mean score <6. Conclusion: It has been possible to produce a ranking of reporting items from STARE-HI according to their prioritized relevance for inclusion in space-limited conference papers. We believe that this prioritization framework can improve quality and utility of conference papers on health informatics evaluation studies.

Standards, Reporting, Evaluation studies, Conference papers, Evidence

Introduction

Modern healthcare tends increasingly to depend on health informatics applications such as electronic patient records, order entry and image processing systems. Within the last two decades, the viewpoint that interventions in healthcare should be evidence-based has become the accepted norm. In this context it is more than ever imperative to also assess the impact of health informatics investments, as concluded in [1,2]. Until now this has seldom been the case, and in those cases where health informatics applications have been assessed reports on these evaluations are often of limited value because essential information is not properly communicated – possibly because reporting standards were missing. High quality reporting is essential as it serves the target audience better and assists in the build-up of a robust evidence base. To improve reports of health informatics evaluations we recently devised and published a Statement on Reporting of Evaluation Studies in Health Informatics - STARE-HI [3]. This is now endorsed by IMIA, and listed by the EQUATOR initiative [4].

About half of all health informatics evaluation studies are published in health informatics journals and conference proceedings as shown by [5]. Too many studies report their results in a conference paper without a full journal report, as noted by [6]. Therefore, conference papers provide valuable information for systematic reviews about studies that are not otherwise published, the exclusion of which from the review would seriously weaken the evidence base as well as possibly introduce publication bias. For these reasons, conference papers should contain sufficient information about the evaluation study to serve as an accurate record of its conduct and findings, providing optimal information about the study within the space constraints of the conference paper format so that they are of sufficient quality and utility to contribute to the evidence base. However, they are inevitably constrained by prescribed limits on length, providing authors with a severe challenge in meeting the STARE-HI guidelines. This paper describes the development of a prioritization framework, called Mini STARE-HI, to assist authors in considering which items to include, and which to exclude on space grounds, when reporting health informatics evaluation studies in a conference paper.

Materials and Methods

The scope and purpose of the full STARE-HI is to provide guidelines for reporting evaluations in Health Informatics, independent of the evaluation method used. Therefore, these guidelines have a general character, with a main focus on the description of the context in which the study took place including a description of the system being evaluated, the description of the methodology, the systematic reporting of results, and the structuring of the discussion [3]. STARE-HI formed the basis for the development of this Mini STARE-HI, which had two steps.

First, all members of the core editorial team of STARE-HI independently identified in STARE-HI all items in the various reporting (sub) areas that they believed authors should consider when reporting an health informatics evaluation study. For example, the sub area "system details" contains items such as "type of system", "aim of the system", "profession and number of users", etc. We included in the next step all items identified by one or more editorial team members.

Next, a total of 111 participants, consisting of authors of health informatics evaluation studies, reviewers with an interest in health informatics evaluation and editors of Medical Informatics conference proceedings, were invited by email to participate in a web-based survey and rate the importance of each of the checklist items. Respondents were asked to score the items with the common limitation of a 5-6 pages conference paper such as MIE, Medinfo and AMIA in mind. The scoring system was a scale ranging from "0 - not necessary" to "10 - essential" to include the item in a report of a health informatics evaluation study in a conference paper. Furthermore, respondents were invited to provide any items per reporting (sub) area they felt important but were missing in the checklist.

Results

One-hundred-and-six items were identified in the STARE-HI guideline in step one and included in the survey. After the original invitation and two reminders the response rate for the survey was 63% (70/111).

Table 1 shows the items per reporting area ordered on their mean score. The most important items (score >9) were "Interpret the data and give an answer to the study question" (in the discussion section), "Whether it is a laboratory, simulation or field study" (in the methods/study design section) and "Description of the outcome measure/evaluation criteria" (in the methods/study design section). In contrast, the items "Name of the health care organization" (in the methods/study context section), "Authors' contribution", "Formal permission and ethical concerns" (in the introduction) and "study limitations" (in the abstract) were considered the first candidates to ignore in case of lack of reporting space (score <6). The overall mean score per reporting area was highest for the discussion (8.3).

In total 19 different comments were given for adding new or "how to" items, rephrasing items, or for rearrangement of order. The latter group counts for more than half (11/19) of the comments.

Table 1- Survey results on the prioritization score of health informatics evaluation items derived from the STARE-HI guideline when applied to a conference paper.

Reporting area (mean score)	**Reporting items (generated from STARE-HI, [3], re-ordered per reporting area based on the mean score)**	**Mean score (SD)**
Content of Title (7.1)	Study question	7.5 (2.8)
	Type of information system	7.5 (2.9)
	Study design	6.6 (2.9)
	The term "evaluation" or "assessment"	6.6 (3.1)
Abstract (8.0)	Describe the major results	9.0 (1.1)
	Include the objective	8.9 (1.4)
	Include a conclusion	8.7 (1.7)
	Describe/define the outcome measures	8.5 (1.6)
	Describe the methods - study design	8.5 (1.6)
	Describe the setting	7.7 (2.1)
	Describe the participants	7.6 (1.9)
	Be structured	7.6 (2.4)
	Describe study limitations	5.2 (2.8)
Keywords (7.1)	Refer to the type of system being evaluated	7.8 (2.3)
	Include "evaluation" or "assessment"	7.3 (2.8)
	Refer to the outcome measure	7.1 (2.4)
	Based on MeSH terms	6.9 (2.4)
	Refer to the study design	6.9 (2.5)
	Refer to the setting	6.5 (2.6)

Table 1 (continued)

Introduction (6.9)	Study questions and hypotheses	8.7 (1.8)
	Motivation for the study	8.1 (2.1)
	What is already known about the type of system	7.4 (2.0)
	A description of the system (e.g. function)	7.0 (2.4)
	Position of this study in a larger study/project	6.5 (2.4)
	Which stakeholders viewpoint(s) is/are used	6.3 (2.4)
	Potential influence of the study	6.1 (2.3)
	Formal permissions and ethical concern (e.g. ethical board)	5.0 (3.0)
Methods – study context (7.1)	Kind of facility (e.g. outpatient clinic, hospital)	8.2 (1.4)
	Aim of the system	8.0 (1.9)
	Type of system	7.8 (1.9)
	Type of information managed	7.6 (1.7)
	Clinical or other tasks of the system	7.4 (1.9)
	How long the system is used	7.4 (1.9)
	How wide spread the system is used	7.4 (2.0)
	Description of how the system works	7.3 (2.2)
	Which facilities/department(s)	7.1 (2.1)
	Professions and number of users	7.0 (2.3)
	Reference to a full technical description of the system	6.7 (2.4)
	Geographical location of the health organization	6.4 (2.6)
	Name of the health organization	4.3 (2.9)
Methods-study design (7.9)	Whether it is a laboratory, simulation or field study	9.1 (1.1)
	Description of the outcome measure/evaluation criteria	9.1 (1.5)
	Study type (e.g. case study, (quasi) experimental etc)	9.0 (1.5)
	Methods to select participants	8.5 (1.6)
	Allocation strategy in controlled trials	8.3 (1.8)
	Definition of the key concepts e.g. Medical error, Adverse Drug Event	8.2 (2.1)
	Focus of the researchers in case of qualitative concepts	8.0 (1.8)
	Entry criteria	8.0 (1.9)
	Description of the study flow	7.7 (2.0)
	Sample size calculation in controlled trials	7.6 (2.3)
	Start and end dates of the study	7.6 (2.2)
	Date of intervention(s)	7.3 (2.5)
	Theory on which the study is based (e.g. the user acceptance model that guided a quantitative survey)	6.9 (2.5)
	Biases following from the chosen study design	6.8 (2.6)
	Motivation for the study design	6.3 (3.0)
Methods-data collection (7.8)	Methods used per outcome measure	8.8 (1.4)
	Retrospective or prospective data collection	8.6 (1.6)
	Validity of the measurement (e.g. use of a validated questionnaire)	8.3 (1.5)
	Blinding of observer and participants	8.1 (1.9)
	Number and type of interviews	8.0 (1.8)
	Type and duration of observations	8.0 (1.8)
	Details about new measurement tools	7.7 (2.2)
	Location and setting where data is collected	7.7 (2.3)
	Full disclosure of new measurement tools in appendix	6.8 (2.8)
	Professional background of the interviewer	6.2 (2.7)
Methods-data analyses (7.7)	Analysis methods for qualitative data	8.7 (1.3)
	Statistical techniques for quantitative data	8.7 (1.5)
	Kind of triangulation used	7.4 (2.0)
	Awareness of any analysis bias	7.2 (2.6)
	Analysis software used	6.5 (2.7)

Table 1 (continued)

Results (8.1)	Basic numbers of the study (e.g. no. of observations, response rate etc)	8.9 (1.5)
	Quantitative data in tables and figures	8.6 (1.2)
	Most important results in the text	8.6 (1.6)
	Sufficient data for all outcome measures	8.6 (1.6)
	Baseline demographic data / characteristics of participants	8.3 (1.7)
	Special notice to any unexpected striking result	8.3 (1.6)
	Any unintended side effect (positive or negative) of the system	8.1 (1.8)
	Absolute numbers and not just relative numbers	7.9 (2.1)
	Characteristics and qualities of the participants in qualitative studies	7.8 (2.0)
	Influence of unexpected events on the study findings	7.8 (2.0)
	Number and type of drop outs	7.7 (2.0)
	Quotes to illustrate any major qualitative points	7.6 (1.9)
Discussion (8.3)	Interpret the data and an answer to the study question	9.5 (0.9)
	Strong and weak points of the study	9.0 (1.2)
	Meaning/implications of the study	8.8 (1.4)
	New insight from this study	8.7 (1.3)
	Generalizability/ applicability of the study results	8.5 (1.7)
	Discuss any biases	8.4 (1.7)
	What is novel compared to other studies	8.3 (1.6)
	Reasons for disagreement with other studies	8.0 (1.8)
	Critically discuss the methods used	8.0 (2.1)
	Agreement of findings with other studies	7.8 (1.9)
	Comparability of the setting of other studies	7.3 (2.2)
	New future research questions	7.3 (2.3)
Conclusion (7.7)	Impact of the findings	8.4 (2.1)
	Summarize the findings	8.3 (2.6)
	Relation of the findings to the big picture	7.7 (2.1)
	Recommendations of the authors	7.4 (2.4)
	Future research to be done	6.8 (2.6)
References should be included according to the conference guidelines		8.9 (1.5)
Acknowledge any financial or other support		8.0 (2.2)
Financial or other interests which may influence the design or interpretation of the results		7.6 (2.3)
An appendix can be used to describe any supporting material		6.6 (2.7)
Authors' contributions		5.1 (3.1)

Discussion

In this study we used opinions from key stakeholders to develop a ranked list of reporting items for health informatics evaluation studies. Rather than presenting a rigid list of items to report in a conference paper, the prioritization framework of "Mini STARE-HI" assists authors in meeting the principles of the STARE-HI guideline within the constraints of a conference paper, and related to their study topic.

We were somewhat surprised by the low mean score (5.0) for "Formal permission and ethical concern" in the introduction section of a paper. In medical research formal approval of a study by an ethics committee or Internal Review Board is mandatory. Based on the premise that evaluation of health informatics interventions is ethically imperative (as stated in [1]), we should be careful that all participants in such studies are properly protected. This is clearly an issue that requires a wider discussion in the health informatics community, in particular since about an equal number of our respondents found this item either unnecessary (6 scored 0) or essential (8 scored 10).

We asked the respondents to score the items with the common limitation of a 5-6 pages conference paper such as MIE, Medinfo and AMIA in mind. Conference papers and abstracts for medical conferences are often even more restrictive in space (250 to 300 words). As the basic principle of Mini-STARE-HI is to prioritize items to report instead of urging what should be or should not be reported we believe these guidelines are also applicable to health informatics evaluation studies presented as the more restrictive short medical conference abstracts. Similar methods as applied in our study were used to develop comparable guidelines for RCT abstracts based on CONSORT [7]

and for observational study conference abstracts [8]. Our response rate of 63% was comparable to [7].

A weakness of our study is that we only sent out the questionnaire once. We did not give feedback to the participants and did not ask for a potential revision of their position as is commonly done in Delphi studies.

For our ranking purpose, we computed the mean of the scores of the respondents. In principle our measurement scale is of ordinal type and medians and percentiles are the most appropriate way to represent the characteristics of the underlying distribution. Ranking on medians, however is more problematic, since the median can only take the integer values assigned to the response categories. Since we have 11 response categories, the response categories approach an interval scale. Hence we considered taking means as a good alternative for ranking purposes.

We plan to measure the quality of health informatics evaluation conference papers published in the past. Authors, reviewers and editors of health informatics evaluation papers are encouraged to use the results of this study to improve the quality of conference papers. In the future, we will monitor the effect of (Mini) STARE-HI on the publications as some studies (i.e. [9]) show an increase of publication quality after the publication of similar reporting guidelines.

Conclusion

It has been possible to produce a ranking of reporting items from STARE-HI according to their prioritized relevance for inclusion in space-limited conference papers. Only a few items were considered to be (nearly) essential for inclusion in a conference paper, some of the items from STARE-HI that add credibility to full paper publications were considered of less relevance to be included in a conference paper on a health informatics evaluation study and can be left out. Which of the other items to select to be included in a report is the responsibility of the authors, but the ranking that resulted from our study will help them to make an informed decision.

We believe that by guiding authors in prioritizing what information is important to report within the given constraints of a conference paper, quality and utility of such publications can be improved.

Acknowledgments

We thank all respondents to our survey for their opinions on the reporting items.

Formatively evaluating the importance of different aspects of an electronic blood transfusion system from the end users' point of view: a questionnaire study

Kate Goddard[a], Omid Shabestari[a], Jonathan D S Kay[a], Abdul Roudsari[a,b]

Abstract

Blood transfusion is a process in which potential errors may result in serious adverse events to patients. To help improve the safety and efficiency of the blood transfusion process an electronic clinical transfusion management system is being piloted by NHS Connecting for Health. Evaluation of the implementation is being carried out in parallel. One component of the evaluation project aims to assess the importance placed in the various potential benefits of this new system by patients and healthcare workers. A questionnaire was generated and completed by healthcare workers and patients. Results indicate respondents viewing all factors as at least "important". "System" factors were deemed most important. Overall, clinical workers expressed the lowest importance to new process factors. Ultimately these results will be measured against final satisfaction with the system to assess 'fit' between perceived importance and satisfaction to guide areas for attention and resource allocation.

Keywords:

Blood transfusion, Value theory, Evaluation.

Introduction

Blood transfusion is the transference of blood or any blood products from one person to another. In many instances such as major trauma of post surgical operations this process can be life saving. It is also essential in treating certain chronic diseases which cause anemia.

A fundamental factor in safe blood transfusions is the compatibility between the transfused blood and that of the recipient. This compatibility is based on blood groupings. There are 30 major blood groups, among which the ABO and Rh systems are most significant. If incompatible blood is transfused to a patient the reactions may vary from a simple allergic reaction to severe hemolysis.

Cross match testing is used to ensure the compatibility of blood products to the recipient. In this test red blood cells of the donated blood are tested against the plasma of the recipient; if no agglutination occurs, it means that the product and the patient are compatible. Although rigorous regulations exist and cross match testing is performed prior to each transfusion, any mistakes during the transfer of the blood unit from the blood bank to bedside and then transfusion may result in fatal errors. Although this process appears deceptively simple it is composed of 11 stages and 66 steps. To tackle this potential problem a detailed procedure utilizing electronic technology – the Electronic Clinical Transfusion Management System (ECTMS) - has been defined by the National Patient Safety Agency (NPSA) in conjunction with the National Blood Transfusion Committee (NBTC) and the Serious Hazards of Transfusion (SHOT) to ensure the transfusion of right blood to right patient at bedside.

Traditionally this process was performed manually by two nurses. As blood transfusion is mostly required for more critical patients in high traffic wards, a new system would prove highly beneficial by reducing the number of staff required for this process, increasing the accuracy of this procedure and reducing the overall time spent carrying out the steps.

The ECTMS has been designed to improve this process by tracking the blood product through from arrival to blood lab to transfusion of the right blood to the right patient. After the pioneering implementation of this system at the Oxford Radcliffe Hospital, the Mayday Healthcare NHS Trust, South London, is the second site of implementation of this system and is the first site to integrate Radio Frequency Identification (RFID) technology into this process. One of the biggest problems in health care is the failure of uptake of new technologies which have been successfully implemented in other industries. To help document and prevent such problems in the Mayday project, the Centre for Health Informatics at City University, London, has been commissioned to perform a formative and summative evaluation of the implementation.

As the evaluation commenced before the "go live" of this system, the evaluation team had the opportunity to measure the perceived importance of factors in the new process before undertaking evaluation of opinions influenced by the bias of experience with the live system.

Based on definitions from Rokeach, Feather and Brown [1-3], values can be described as enduring principles with which people use to guide object evaluation and attitude formation.

Values are the main independent variables in the study of human attitude and behavior. User attitude and behavior are key factors in the acceptability of a new system which will lead to increased uptake and effectiveness. Rokeach classifies values into two groups, terminal and instrumental. Terminal values are those which are the end-state that one can strive for and in most cases are inaccessible to achieve. Instrumental values are single preferable modes of conduct, or means of achieving terminal values. The Johonson definition [4] includes a usability factor. According to this definition we attempted to include only instrumental values in this survey as both achievability and usability were the key factors for this evaluation.

As this evaluation was carried out within a formative framework, the goal of researchers in this phase of study was to ensure that the future users of system had the most realistic view of it. Pre-existing low expectations will result in unacceptability of the system. On the other hand extreme high expectations for the system will result in risk of future dissatisfaction.

Methods

Initially a literature review was performed to identify various values of electronic blood transfusion system or similar electronic management systems in health care [5].

In a brain storming session the obtained list of variables was discussed and related terminologies were merged. Finally, agreed variables were classified into four main categories: System, implementation, technical support and outcome. Detailed list of questions are presented in Table 1. Questions were adapted from the expected benefits outlined by the Mayday Project Initiation Document (PID), the updated DeLone and McLean model of Information System success [6].

A list of job roles related to blood transfusion was prepared. This list consisted of clinical staff (doctors and nurses), paraclinical staff (laboratory technicians and phlebotomists), IT technicians, porters and patients. A matrix of relativity between the values for blood transfusion management systems and the above roles was generated. The respondents were gathered via pseudo-proportionate opportunistic sampling.

According to King and Epstein a rating scale can be as reliable as a ranking scale [7]; to measure perceived importance of generated values a questionnaire was created using Likert-type scaling.

Table 1 – List of questions in value measurement questionnaire

Question Group	Question
System Specifications	The ability to track products across the hospital in real time
	Improving product information due to electronic storage and delivery of information
	The system is easy to use
	The system is fast
	The system is responsive
	The equipment is durable and hard wearing
	The system is flexible and is able to absorb any changes in processes
	The system is secure from unauthorized access
	Compliance with standards and legislation
	Data recovery from error e.g. if there is a problem with the power supply
Implementation	Involving patients in the ordering process
	Involving patients in the checking process
	The requirement for adequate training
	Terminals and equipment are readily available to use
Technical Support	The implementation of a formalized change management plan including training on the new system
	Improved system auditing and control
	If there's a problem with the system, there is immediate support
	Availability of online help
	Availability of back up devices in case of device failure
Outcome	Reducing the number of blood samples rejected by the lab
	Time savings for staff involved in blood transfusions via the automation of processes
	Decreasing the number of manual labor intensive systems

Table 1 (continued)

Question Group	Question
Outcome (Continued)	Having guided steps in any given process involved with blood transfusion
	Improving access to patient transfusion history and any special requirements
	Patient information is accurate and complete at the time of enquiry due to quick and easy information updating
	Providing early alerts to blood labs for product requests and special product requirements
	The system is reliable and does not experience substantial "down time"
	Removing paper-based processes and providing information electronically
	Improving the wristband technology to assist the checking process

Based on the recommendation from Kahle and Kennedy [8], a zero to positive rating model was chosen for this value survey. To prevent the middle point effect being interpreted as a neutral point, we chose a six item scale according to recommendation from Fowler as shown in Table 2.

Table 2 – Classification of Likert-type response used in this questionnaire

Importance level	Description
1	Not important
2	Not so important
3	Slightly important
4	Important
5	Very important
6	Extremely important

Demographic questions concerning and age and gender were included for further classification of responders.

Regarding the internal validity of this questionnaire, a review of the literature was performed to ensure that all proposed elements about importance of such a system were covered. A semi-structured questionnaire was also carried out to give the responders the opportunity to express other values which were not included in the questionnaire. To verify external validity the same study should be performed in other sites to check if similar results will be obtained.

A paper-based questionnaire was designed and completed during individual interview sessions with respondents.

For checking the reliability of information obtained, a random sample of 10% of responses was checked by another member of team before data analysis.

All recruitment was carried out at the Mayday Healthcare NHS Trust.

Results

SPSS 16 was used to analyze data obtained in this study. A pre-analysis data preparation process was performed for further validation of data.

Outlier Control

This study included 29 variables. Two methods of multivariate outlier control were used; if any response failed in both methods it was excluded from final analysis. The first method used was Mahalanobis Distance which evaluates the distance of each case from centroid of the remaining cases. Mahalanobis Distance Test was performed on the 29 questionnaire items. The maximum residual statistic was 35.673. The related value in table of Chi Square (degrees of freedom = 28) and P value of 0.05 is 41.34. The second method used was Cook's Distance. In this test one of the records had the value of 3.7 and as this value was more than 1 it was considered to be an outlier and excluded from final analysis (see Figure 1).

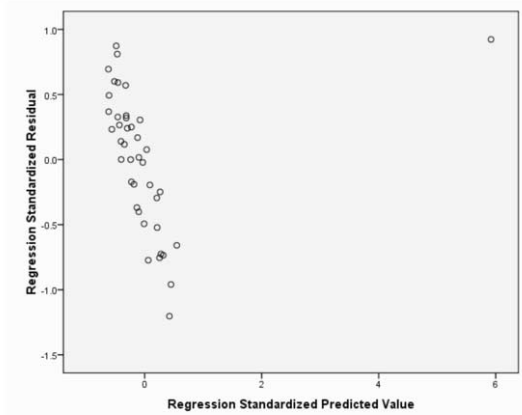

Figure 1– Distribution of responses based on residual and predicted values

After deleting the single outlier record, the distribution of respondents based on their role was presented in Table 3.

Table 3 – Frequency of participants according t role-based classification

Respondent Group	Frequency of respondents
Clinical Staff	45 (54.22%)
Para-clinical Staff	9 (10.84%)
Porters	9 (10.84%)
Patients	20 (24.10%)

Reliability

This is the first time that a value questionnaire has been implemented in this field. To validate this questionnaire the reliability of the items were evaluated using Cronbach's alpha test shown in Table 4.

In the next step, the mean value of responses for each category of questions was calculated. A Kolmogorov-Smirnov test showed normal distribution of these calculated mean values. Also there was a high internal consistency between these grouped variables, with Cronbach's alpha equal to 0.864.

Table 4 – Reliability test results for value questionnaire

Values	Cronbach's alpha
System	0.906
Implementation	0.714
Support	0.846
Outcome	0.816

The overall results obtained for level of importance in each aspect of the system is presented in Table 5.

Table 5 – Descriptive analysis of mean of value in each aspect of system

Mean of Values	Minimum	Maximum	Mean	Std. Dev
System	2.90	6.00	4.95	0.91
Implementation	2.50	6.00	4.73	0.84
Support	1.20	6.00	4.56	1.03
Outcome	3.00	6.00	4.55	0.72

Comparing the results between the respondent role groupings by using ANOVA analysis showed significant difference among the mentioned groups as presented in Table 6.

Table 6 – Comparison of results between the respondent groups

Values	F	P Value	Eta Squared
System	13.18	0.000	0.34
Implementation	2.54	0.062	0.09
Support	3.61	0.033	0.11
Outcome	3.28	0.044	0.10

Post hoc tests showed significant difference in clinical staff responses compared to answers from porters and patients in importance of the system. Clinical staff gave overall lower scores for importance in the survey items. The effect size test showed this was a large effect for "system" values and medium effect for the rest of the items according to the Cohen classification.

Most of the people involved in blood transfusion process at the Mayday Hospital were female. In our survey 8 of participants did not respond to the question about gender but a similar pattern was found in the respondents presented in Figure 2 which demonstrates proportionate sampling based on gender.

There was a significant difference between the responses from two gender groups on "system" values with t (73) = 3.702 and P = 0.000, with lower average by females.

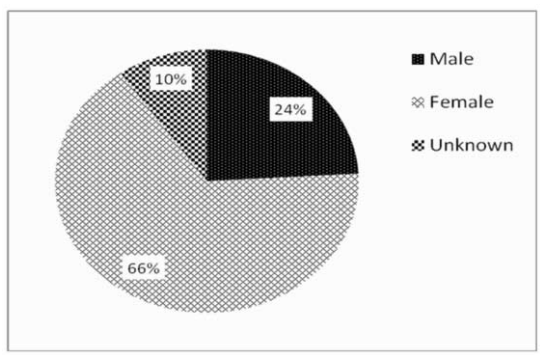

Figure 2– Distribution of responses based on gender

The other demographic factor that was used to classify the participants was age. We discretized the participants by age based on quartiles in four buckets as shown in Figure 3.

A one way ANOVA test showed a significant difference among the mentioned groups in the "outcome" category as presented in Table 7.

Post hoc analysis was not possible because of limitations in sample size.

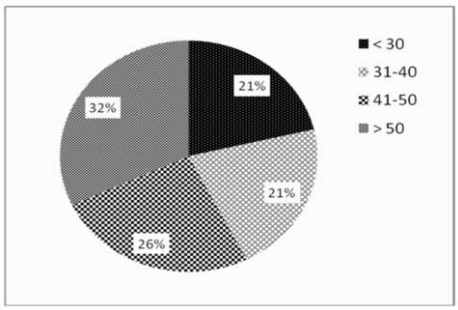

Figure 3– Distribution of responses based on age groups

The effect size test showed a large effect in "support" and "outcome" values and a medium effect in the rest of the items according to the Cohen classification.

Table 7 – Comparison of results between the age groups

Values	F	P Value	Eta Squared
System	2.13	0.110	0.13
Implementation	2.15	0.107	0.13
Support	1.81	0.170	0.17
Outcome	2.98	0.049	0.26

Discussion

The results presented appear to express a relatively high level of importance placed in all aspects of a potential blood transfusion management system by end users. The highest importance was given to "system" values and the lowest to "outcome". This implies that the end users it is important for this system to be more of a process facilitating tool rather than something to produce effective final outcomes in blood transfusion.

There was a significant difference in importance placed in different factors between the clinical staff compared to porters and patients. Clinical staff expressed lower importance in all aspects of the system. Some of these differences might be explained by the type and amount of involvement in the process of blood transfusion. For example, clinical staff are more directly involved at the point of transfusion and may rate their own self-efficacy in the process comparatively highly, thus additional technology as superfluous. It may be a factor that clinical staff see additional technology as an unnecessary complication in a job they consider as fairly routine.

For most factors, males and females have similar views, but males placed higher importance in the system itself. Different age groups have generally no significantly different views but outcomes were considered more important in respondents over 50 years of age.

Conclusion

Although this was the first time that value-based model was applied to a blood transfusion management system, the designed questionnaire appears valid and provided statistically reliable results. All four categories relating to the new system were rated as at least "important" on average, with "system" variables rated most important overall.

According to value theory, the outcomes of this importance survey are related to perceived effectiveness of the system. Disproportionately high expectations may result in dissatisfaction with the system. This is a subject for the next phase of evaluation, to be investigated at the end of the project.

Acknowledgements

This research was commissioned by NHS Connecting for Health Evaluation Program (CfHEP). Also the researchers acknowledge the continuous support by Shanaz Sohal (project manager at Mayday Hospital) and Dr. Tony Newman-Sanders (chairman of the project board).

Abstract

Most EU Member States have a documented policy on eHealth. Documented follow-up and evaluation strategies for assessing whether national level systems have reached their set aims and outcomes are, however, rare. Methodologies for large scale information system assessment and evaluation are poorly established. This article describes the approach used to generate the Finnish National Health Information System (NHIS) evaluation plan. The core elements of the plan are illustrated, discussing also challenges and solutions in implementation. The article is based on NHIS evaluation planning project [15] and its presentation in the MIE workshop in Sarajevo in 2009 [16], where core issues and challenges of large-scale evaluations were discussed using the Finnish NHIS evaluation plan as a frame of reference.The Finnish plan offers other countries tools with which to assess their own plans and generate national methodologies for NHIS evaluation.

Keywords:

Medical informatics, eHealth policy, Program evaluation, Evaluation methodology

Introduction

By the end of 2006, 25 out of 27 EU member states and the four other countries active in the i2010 initiative of the EC, were identified as having a documented government level policy on eHealth [1]. In Finland, a decade of implementation activities of the eHealth strategy culminated in the publication of the Finnish eHealth Roadmap in 2007 [3]. Permanent legislations introduced in 2007 on electronic processing of health and social care client data and on ePrescribing, were a major step in the implementation of the Roadmap.

The most common aims for EU eHealth policies are reforming the health care system, improving its performance for more efficiency and quality of care, promoting quality of life and citizen centeredness in care, better data for management of the system and better communication among stakeholders. [1].

In contrast to the vigorous development of national health-IT programs, surprisingly few national level plans and actions were found in a rapid literature review that documented the steps taken for follow up and evaluation of these programs. [2]. Among EU Member States, only the UK was found to have launched national level evaluation [2].

In Finland, the legislation of 2007 stipulated that a National electronic Health Information System (KanTa) [20] is to be built in Finland. The Social Affairs and Health Committee of the Parliament required an action to *monitor and assess the implementation of national eHealth services with a view to providing timely support to the different actors involved.* The project described in this paper is premised on the given requirement. An evaluation planning project (KaTRI) was launched in November 2008 as a joint venture between the Ministry of Social Affairs and Health (MoH) and the National Institute for Health and Welfare (THL). The KaTRI-project set out to draft a plan on how to monitor and assess the implementation of the NHIS (KanTa) taking into account the Committee's requirement. Rather than producing a detailed evaluation plan, the idea was to lay the groundwork for research collaboration to generate knowledge that is mutually beneficial to the government and all parties and that could support success of the construction work of the NHIS.

Evaluation Materials and Methods

In order to define the objects, objectives, questions and methodologies for the NHIS evaluation, three preparatory strands of work were undertaken by the core KaTRI-project team consisting of the authors:

1. A selective literature review of international experiences on evaluation of large scale systems
2. Content analysis of documents describing the NHIS to be implemented in Finland.
3. Content analysis of the bills of ePrescription and eArchiving legislation, which set official objectives, intended outcomes and requirements for the system.

Results of the eHealth ERA project (Towards the Establishement of an eHealth European Research Area) [1] together with a more globally oriented review of the adoption of health in-

formation technology [21] confirmed the leading role of a handful of countries. Due to this fact and our limited project resources, the literature review focused on the experiences of the UK [4], Canada and Australia [5-7] using materials available through official web sites. The analysis focused on objects and objectives of evaluation, methodologies and organisation of evaluation.

Content analysis of documents describing the NHIS and its elements focused on questions depicted in Table 1. Content analysis of the documents stating objectives and intended outcomes of the NHIS was conducted using a qualitative data analysis programme AtlasTI. Open coding of the data was grounded on the data, axial coding was done by using elements from the ICT-enhanced service change model [10] and elements of the IS success model [13] as a conceptual framework to group the codes. This approach provided 10 dimensions for evaluation. These are depicted in Table 2.

The results were fed to eight working groups (WGs), formed by extending an open invitation to end user organizations, research and industry, as well as organizations representing patients and lay people. Leading scientists on Health IT from Universities of Oulu, Tampere and Turku were appointed to lead each group: Prof. Pirkko Nykänen from University of Tampere led the NHIS development and requirements assessment teams, Dr. Eija Karsten from Åbo Akademi led the implementation team, Prof. Reima Suomi from Turku School of Economics led the process change and cost-benefits -teams, Dr. Persephone Doupi from the National Institute for Health and Welfare led the quality evaluation team, and Dr. Ilkka Winblad from University of Oulu led the health benefits assessment team. Dr Hannele Hyppönen from the National Institute for Health and Welfare coordinated and collated the work.

The task of each WG was to refine the evaluation outlines, the core evaluation questions and methodologies identified in the three preliminary studies listed above, taking into account the Committee requirement. The reports of the WGs were then collated into the NHIS evaluation methodology. The Steering Group for the work was led by the Ministry of Social Affairs and Health, and consisted of representatives of all key stakeholders.

Results

Review of evaluation methodologies for large-scale health information systems

The elements included in NHIS systems vary, but all are build around an Electronic Health Record. Evaluations have focussed on benefits to healthcare access, quality and productivity; patient safety; user satisfaction, usability and acceptability and organisational aspects. The use of multiple methods is emphasised, focusing on combining formative and summative evaluation, and covering the whole roll-out life-cycle (pre-implementation, implementation and post-implementation phase). A useful tool (Delone and McLeans model [13]) for structuring the required pre-post-implementation data was identified through the Canadian documentation. Organizational, cultural and business process elements are out of the tool's scope, and needed to be added. The model also does not cover the planning and implementation phases of an IS. A suitable conceptual model and evaluation methodology was, thus, not found, and had to be generated. National level evaluation also raises challenges for and demands development of large scale methods for data collection [2, 10].

Analysis of the object of evaluation - the NHIS and its functionalities

The National Health Information System in Finland consists of a national EHR (Electronic Health Record) archive and ePrescription centre, with ePrescribing, eArchiving and citizens' eViewing as the main functionalities. The architecture (planned to be functional by 2011) is depicted in Figure 1.

The national EHR archive and ePrescription centre will be maintained by Kela (Social Insurance Institute) and used via different legacy systems in public and private health care organisations and pharmacies over public networks. In order to be operational, the core services require interoperable EHR-systems, various national terminologies and classifications, consent management, certification and registering as well as security services.

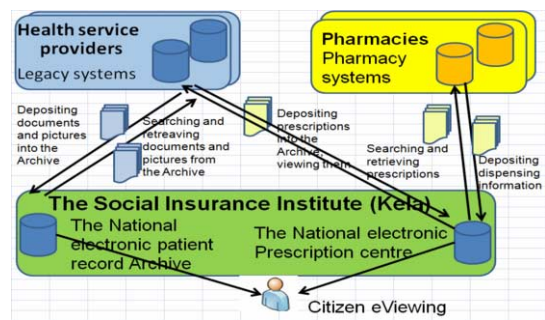

Figure 1- The Finnish NHIS architecture with key actors and their roles

For the purposes of evaluation, a more detailed description of the NHIS system and services was needed. To generate a structured overview of the NHIS and its characteristics, a classification of questions generated in the field of Health Technology Assessment (HTA) [11] was found useful.

The key questions for NHIS are depicted in Table 1. Most elements of the NHIS are "manufactured" by different actors for specific purposes. Together they form the NHIS. Some elements (e.g. legacy systems, variously structured records) exist, but need updates in order to be operational with NHIS. Other elements (e.g. ePrescription centre, national archive, citizens' access) are new, replacing existing ways of transferring and dispensing prescriptions, archiving patient records and accessing the EHR data NHIS evaluation is not a question of comparing a paper-based system to a fully electronic NHIS. The setting is much more complicated, consisting of comparison of combination of local and regional IS systems and services in different phases of transition towards the NHIS.

Table 1- HTA-drawn questions [11] for defining the NHIS as an object of evaluation

Nr	Question (EUnetHTA question ID nr in brackets)
1	Who manufactures technology (A0019)?
2	What are the technical and functional characteristics of technology (B0001)?
3	Are there any special features relevant to this technology (B0006)?
4	For what purpose (Why) is technology used (B0002)?
5	What are the current "tools" used for this purpose (A0011)?
6	Do other evidence-based alternatives exist? If so, what (A0014)?
7	Who are the users of the technology and where is it utilized (context of use) (B0004-5)?
8	How much is the technology being used, are there any restrictions on the use of technology (A0009, C0004-5)?
9	Are there variations in use across countries/ regions /settings (A0010)?
10	How many people belong to the specific target group (A0007)?
11	What is the phase of technology (design, testing, pilot/experimental, diffusion, routine use), is it a new use for an existing technology (B0003, A0015, C0003?
12	What material investments, equipment and special premises are needed to use the technology (B0007-9)?
13	What kind of records/registers are needed to monitor the use of technology? (B0010-11)?
14	What kind of training is needed for the personnel using or maintaining the technology (B0012-13)?
15	What kind of training is needed for the patients, their families and for the general public (B0014-15)?
16	Are there published guidelines how the condition should be managed (A0012)?
17	Has the technology been included/ excluded in the benefit basket of any country? Are there differences in coverage across countries (A0017-18)?
18	Does the technology need a license or certification (C0001)?

Analysis of the objectives of the NHIS/ domains of evaluation based on the text of the Finnish bills

The bills on eArchive and ePrescription stated the official objectives and anticipated impacts of the NHIS architecture and related services. The relative importance of the generated dimensions was estimated by calculating frequencies of dimension-specific key words in the bills. Several important observations can be made from Table 2. The relative importance of meeting of the requirements set for the eArchive, followed by improvements of the service processes due to ePrescribing became evident. There was a strikingly low frequency of statements related to health impacts of ePrescribing and eArchive. This may be due to health impacts being quite far in the impacts-hierarchy (many of category 1-5 impacts need to be realised before health impacts become visible). Health impacts also need time to mature and are dependent on a multitude of other factors. The seemingly low expectations of cost-benefits of ePrescribing may be due to overlapping with category 4 objectives.

Table 2 - Dimensions of evaluation and frequency of dimension specific statements in the Finnish ePrescribing and eArchive bills

NHIS Objectives => dimensions of evaluation (keywords in brackets)	ePresc.	eArchive
1. Quality of development process (process requirements, actor roles)	14	35
2. Meeting the set requirements (requirement, interoperability, secuirty, usability, reliability etc.)	42	124
3. Successful implementation (training, procurement, change management, implementation, support system)	12	11
4. Improvements in service processes (activity, processes, practices etc.)	57	31
5. Quality improvements (information quality, service quality)	24	25
6. Positive health impacts (health, welfare)	3	3
7. Cost-benefits (economy, costs, savings, productivity, efficiency)	8	31
8. Secondary impacts (secondary beneficiaries e.g. state authorities, supervisors, researchers)	18	11
9. NSIS-development boost (National Social Information System development, Social services)	0	48
10. Future service models (future)	4	3

The analysis showed the importance of constructive or formative data from the key stakeholders' viewpoints to be used to inform the development of the systems (dimension 1), especially for eArchiving, where development started later than that of the ePrescribing system. However, the relative importance of objectives related to implementation and diffusion for both the eArchive and ePrescription was strikingly low. This is in contrast to the requirement of the Social Affairs and Health Committee of the Parliament to monitor and assess the implementation of national eHealth services with a view to providing timely support to the different actors involved.

Generating a comprehensive evaluation plan

Figure 2 illustrates the proposed evaluation activities versus the evaluation studies that have actually been launched thus far. The evaluation planning project KaTRI suggested the evaluation to be organised into three main projects, targeting different phases of the NHIS system life cycle: The development support project (Project 1) should focus on providing information through formative assessment of NHIS project activities during the NHIS construction phase, and through assessing the system against set requirements in the testing phase. The implementation support project (Project 2) would use formative assessment methods and focus on support for the service provides' during implementation. The diffusion and impacts follow-up project (Project 3) would focus on providing information

mainly for the national decision makers on diffusion of the system and meeting of its objectives using primarily questionnaires and register data. For each phase a list of key evaluation questions and suggestions for data collection methods were drafted.

A coordinated programme funding to cover the key projects was seen as an ideal way of organizing the evaluation. However, this type of funding mechanism was not available in Finland. Three consortia (for formative assessment, assessment of implementation and impact assessment) have been collaborating and seeking separate funding. Projects 1 and 2 have not received funding so far in spite of the rhetoric and evidence [10; 14] on importance of this work. Two studies in project 3 have started (study 1 and study 2).

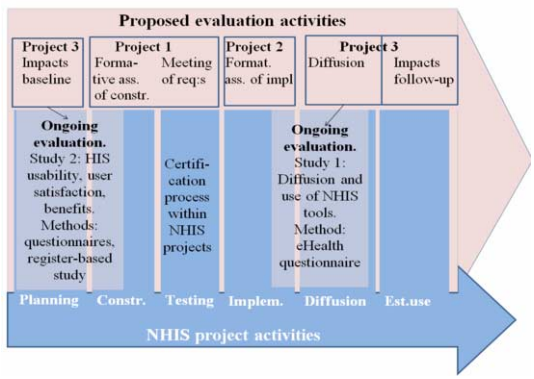

Figure 2- Evaluation framework and ongoing projects in different phases of NHIS implementation.

The diffusion study (Study 1 in Figure 2) focuses on questions in Table 1 (specific focus on questions 4, 5, 7, 8, 9, 11, 12, 13, 14) and is funded by the Ministry of Health and Social Affairs. It is a questionnaire-based study; aiming to map the state of the art of Information Systems used in health care at regular intervals to see a change from old IS tools and services to the new. The questionnaire is targeted at the health care information officers, and results are targeted for the national decision makers [18].

Study 2 in Figure 2 focuses on collecting baseline information on questions 4-7 in Table 2. Two sub-studies have started as stakeholder collaboration without external funding. The first is a questionnaire-based study for doctors (sample = 12 000), collecting baseline information on usability of current HIS and their impacts on service processes, quality, efficiency and health. The Canadian NHIS evaluation tool based on the Delone and McLean's IS success model [13] together with conceptual tools from a co-construction framework [10] was used to construct an information model for the study. The results are targeted to benefit NHIS project participants and decision makers. The ex-ante study offers concrete information on state-of-the art and user needs related to IS usability, user satisfaction and experienced benefits on service processes, quality, productivity and health. The ex-post study will inform on changes in these. For decision makers the results can be used to clarify short and long term objectives and steer the activities of the NHIS project.

The second sub-study aims at defining register-based indicators for process, quality, productivity and health related change, which can be used to indicate NHIS impacts. The sub-study has performed a small-scale pilot structuring EHR data manually with selected national EHR classifications, which will be implemented in Finland by 2011. The pilot aimed to test the utility of the selected classifications for evaluation purposes. Classifications are part of NHIS semantic interoperability development, and exploited as part of a national register reform which aims to implement an on-line nation-wide register on primary care patient visits directly from EHR data with unified data structures [19].

Discussion and conclusion

The planning project KaTRI was set out to draft a preliminary plan on how to evaluate construction and impacts of NHIS. Work done by other national evaluation efforts was elaborated by combining elements of HTA [11], IS success model [13] and ICT-enhanced change model [10]. The work to operationalize the elements and to develop an information model of the individual measures has been started in the diffusion and indicator -studies. The work generates a solid basis for implementing the recent EU Council conclusions (to follow-up and evaluate the health benefits and cost-effectiveness of different eHealth services, building on accumulated knowledge at EU and national levels) [17]. With the results of this work Finland joins the still small number of EU countries with a documented follow-up and evaluation plan of their national level eHealth programs. The plan offers also other EU countries tools with which to develop their plans and methodologies for NHIS evaluation. The work done offers basic building blocks for a solid conceptual framework and methodology, which covers the entire life cycle of a NHIS development from planning to implementation and impacts evaluation.

There are several risks for realizing the plan produced by the planning project KaTRI, which need to be tackled, starting from the availability of resources for committing the evaluation studies. Currently the Finnish NHIS is under construction and the first ePrescriptions are to be launched soon. Delay of evaluation in relation to NHIS development and implementation increases the risk of being too late for effective feedback. Availability of the required data especially for financial and register-based evaluation, limited possibility for controlled studies and challenges inherent in multidisciplinary work required form yet other challenges. The will to invest in this work can determine the future of the NHIS. In the end, the NHIS will not be defined by its current problems and challenges, but by the way they will be solved.

Mapping stakeholders for system evaluation - the case of the Electronic Prescription Service in England

Lichtner V[a], Petrakaki D[a], Hibberd R[b] , Venters W[a] , Cornford A[a], Barber N[b]

Abstract

This paper discusses the process of identifying stakeholders for the evaluation of health information systems through a map. Defining the multiplicity of stakeholders associated with a new system as well as the nature of their relationships is an important aspect of evaluating any intervention. We report a study of the Electronic Prescription Service (EPS) in primary care in England. We describe the complexity associated with the process of identifying stakeholders and illustrating their dynamic relationships. Reflecting upon our experience of map-making *and* map-using*, we discuss the role of a stakeholder map to generate and communicate knowledge. The EPS stakeholder map – in its variety of possible alternative representations – reveals the complexity of the electronic prescribing scenario and the challenge of its evaluation. Recognising the drawbacks of a static two dimensional representation, we argue that a dynamic use of a stakeholder map and a reflective map-making practice is useful and important for the evaluation of IT programmes in healthcare.*

Keywords:

Information systems, Electronic prescribing, Community pharmacy services, Method, Evaluation studies as topic

Introduction

Health information systems are expected to improve the delivery of healthcare, raise patient satisfaction and support excellent work practices by healthcare professionals. The adoption of any health information system will be dependent upon a number of different stakeholders including the people who are directly or indirectly associated with and affected by it (patients, nurses, doctors, software developers, IT managers, product specialists) and a number of organisations and institutions that frame its adoption and functionality (government departments, regulators, health care institutions, professional bodies, technical service providers) [1-3]. Identifying the multiplicity of stakeholders associated with a new system as well as the nature of their interests and relationships one to another, constitutes an important prerequisite for evaluating any intervention. A powerful means to do this is through the drawing of a map, a visual representation of entities and relationships.

This paper discusses drawing a stakeholder map as part of an evaluation study of the Electronic Prescription Service (EPS) in primary care in England. EPS is the National Health Services (NHS) new system for the electronic transmission of prescriptions. EPS is part of the UK National Programme for IT (NPfIT), which is delivered by the Department of Health agency, Connecting for Health (CfH). One of the main objectives of the EPS is to provide a more efficient and accurate NHS prescription service, able to cope with the issuing, dispensing and reimbursement of "around 1.5 million paper prescriptions" per working day [4]. This service is being delivered over two main releases of software and functionality, and our paper draws upon work investigating the introduction of the Electronic Prescription Service Release 2 (EPS2).

Stakeholders are often identified in accordance with their position relative to a focal system and/or an organisational position. In that way stakeholders may be distinguished, for example, as being either 'internal' or 'external' stakeholders relative to the owner organization [5]. Stakeholder importance may be identified by their power to influence, their legitimacy to make decisions, or their right to make claims (perhaps urgent or arbitrary) that have an immediate impact on the focal system or on other stakeholders [6]. In conventional maps, stakeholders are often depicted as revolving around an organization or system, and to have unidirectional and simple relations with it [5] but not with each other. Pouloudi and Whitley [3], however, argue that identification of stakeholders is a complex and dynamic procedure that requires taking into consideration that stakeholder inter-relationships are important, temporally and spatially bound, interdependent, dynamic and often conflicting. We contribute to this critical approach by discussing the complex nature of stakeholder mapping during the identification of stakeholders in EPS2.

The paper has two aims. First, we explore the complexity associated with the process of identifying different stakeholders and illustrating their dynamic relationships - *map making.* To do so we reflect upon our experience in drawing a stakeholder map as a methodological question. Second, we aim to discuss the benefits and drawbacks that emanate from using the map as an analytical tool - *map using*.

An Introduction to EPS2

At the core of EPS is the electronic transmission of prescription messages from prescribing systems, to a secure server - the 'Spine' - from which the prescription message can be sent to, or called by a dispensing contractor of the patient's choice. The service is being introduced into England over two releases. EPS Release 1 (EPS1) introduced and tested the technical infrastructure, with electronic messages holding copies of prescription content supplementing the traditional paper prescriptions. In EPS2, launched in 2009, the prescription switches to a digitally signed electronic message, offering a potentially paperless prescribing and transmission process. The prescription is transmitted from the prescriber through the Spine enabling the unique identification of patients, and service providers (prescriber and dispenser in this case). Access to the Spine for digital signing of prescriptions is allowed by use of a person specific smartcard, with chip and pin code. Software suppliers for prescribers and dispensers are expected to independently implement EPS2 compliant functionalities. Their systems are then subject to a CfH certification process before they can connect to the Spine. Prior to deployment of EPS2 prescriber systems in different Primary Care Trusts (the purchasers of healthcare for a geographic area), the Secretary of State must authorise the issuing of electronic (paperless) prescriptions and electronic signatures. This is done area by area, making electronic prescriptions legal in England for the first time.

A detailed description of the functioning of EPS compliant systems is outside of the scope of this paper. Information can be found on the CfH website[1].

Methodology

The stakeholder mapping for EPS2 was part of a wider project aimed at the evaluation of the Electronic Prescription Service. The evaluation began while software testing for EPS2 compliant systems was still in progress and EPS1 compliant systems were in use. The technology for EPS2 was not available for use at the start, but key stakeholders were preparing for initial pilots and successive deployments across PCTs in England. The data reported here was therefore based on stakeholders' initial experiences with EPS1 (e.g. feedback from pharmacists) and *expectations* for EPS2, *plans*, *prospected* problems and solutions. The study is based on interviews with a number of different groups and organisations including software suppliers for dispensing and prescribing systems, PCTs, community pharmacies and the Department of Health. Interviews were recorded when possible with participants' consent, and transcripts were used for the analysis. Written field notes were used when recording was not possible.

The map – in its successive cyclical revisions - was used during these interviews as a starting point for discussing roles and relationships of different parties and organisations in the pre-EPS business model, and in the development, adoption and use of EPS. The stakeholder map was (and at the time of writing still is) constantly modified and further refined in order to reflect participants' viewpoints.

Results – Map-Making

Connecting for Health presents the expected benefits of EPS2 in terms of benefits for prescribing staff, dispensing staff, patients and their representatives[2]. Initially these appear as the three primary stakeholders of EPS2 as direct users of the system functionality (Fig 1). Prescribers (Pr) (typically General Practitioners - GPs) use EPS2 compliant systems for issuing prescriptions; patients (or their representatives) (P) use EPS2 systems to nominate the pharmacies where they wish to collect the prescribed medications; dispensers (D) (typically Community Pharmacists) use EPS2 compliant systems to receive the e-prescriptions, and then dispense and label products, record the dispensed medication and transmit the e-prescriptions onward to the reimbursement agency (NHS Prescription Services).

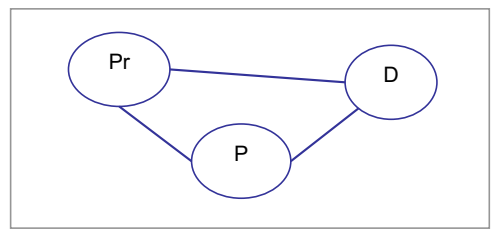

Figure 1- Three stakeholders - direct users of EPS systems

Reading the official documentation of EPS2 [eg. 4], the reimbursement agency could be interpreted as (at least) a secondary stakeholder. Yet, some interviewees thought of the reimbursement agency as one of the main beneficiary of a paperless system on the grounds that EPS2 would reduce manual paper handling and eliminate data entry duplication. Our initial map with the three main users would need to expand and include another perhaps less visible beneficiary in the Prescription Services (PS).

Further analysis of prescribers and dispensers revealed a multiplicity of different parties under these broad headings. For example, among the receivers of prescriptions, are Care Homes, requesting and collecting prescriptions on behalf of their residents. Among the dispensers, together with local small community pharmacies are larger organisations of pharmacy chains under the control of a multinational company, supermarket pharmacies, internet pharmacies, and dispensing appliance contractors. There are also the interesting hybrids – dispensing doctors and prescribing pharmacists. All these stakeholders may adopt EPS2 compliant systems, but differently - depending on their prospects, hopes and fears - and with more or less choice in terms of software or autonomy in organising their work practices around EPS2.

[1] http://www.connectingforhealth.nhs.uk/systemsandservices/eps

[2] http://www.connectingforhealth.nhs.uk/systemsandservices/eps/staff/benefits

Moving from a perspective of system users to the stakeholders involved in the implementation of EPS2, the map extends to the software suppliers (SW) that develop and provide prescribing and dispensing solutions to prescribers (SWpr) and dispensers (SWd) respectively (Fig 2). Developers offer system compliant solutions responding to requirements presented by users, Connecting for Health, professional bodies and Royal Colleges. Prescribing and dispensing software solutions are different markets (and, usually, companies) in England and therefore we chose to present them in the map separately. The relatively simple map in figure 2 is rapidly revealed too restricted to illustrate the number of stakeholders associated with EPS2 and who might be incorporated in an evaluation.

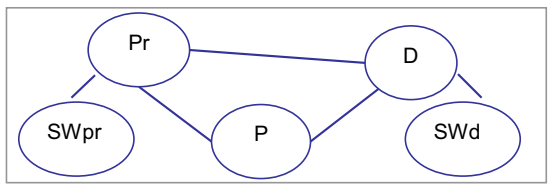

Figure 2- Five stakeholders - implementers and users of EPS systems

The delivery of EPS is a complex partnership between the Department of Health (DH), its agency Connecting for Health (CfH), the regional Strategic Health Authorities, the PCTs and dispensing and prescribing system suppliers. The role of CfH is to define standards, ensure these are adhered to, and to provide the infrastructure in order to support this service. The DH provides funding for community pharmacy to purchase EPS compliant systems (via PCTs) and also an ongoing allowance to pay for the maintenance of the required secure broadband connection. General practices also gain support for purchasing CfH accredited prescribing systems as part of their IT systems. Pharmacies and GP practices as independent contractors, however still make, at least in theory, the ultimate choice of which software to purchase and use.

If we follow financial exchanges, more stakeholders enter the map. Financial exchanges in connection with EPS relate not only to the payment and reimbursement of prescribed medications and appliances, but also to payment and reimbursement for software and services, connection to secure network, possible financial incentives to use the service, potential sale and purchase of prescribing/dispensing data and marketing opportunities for pharmaceutical products/medical services. This indicates the potential of EPS2 to condition important changes in the business of community pharmacies. For instance, the rise of internet pharmacies, or the capture and use of prescribing and dispensing data for research purposes. Indeed, patient data and information governance is a sensitive aspect of EPS2. The design of this system will potentially allow a comprehensive database of drug use (prescribing and dispensing) linkable to patient medical history. This could be incredibly valuable for research purposes and for medicine management, but also potentially subject to abuses and infringement of patient confidentiality. An important stakeholder here may be the Information Commissioner.

Table 1- List of stakeholders (not comprehensive, in alphabetical order)

AG	Aggregators
CP	Community Pharmacies (independent and chain headquarters)
CPst	Community Pharmacy stores (dependent from chain management/headquarters)
CP.pr	Prescribing community pharmacists
DAC	Dispensing Appliances Contractors
D	Dispensers (including CP, DAC, IP, etc.)
DH	Department of Health
DW	Drug and Medication Wholesalers
GP	General practitioners (family doctors)
GPd	Dispensing GP
IMS	IMS Health Pharmaceutical
IP	Internet Pharmacies
IC	Information Commissioner
NPA	The National Pharmacy Association
NPSA	National Patient Safety Agency
NP	Nurse prescribers
P	Patients (and carers)
PCT	Primary Care Trusts
Pr	Prescribers (including GP, NP, etc.)
PSNC	Pharmaceutical Services Negotiating Committee
PS	NHS Prescription Services
RS	Royal Societies
SHA	Strategic Health Authorities
SUS	Secondary Use Service
SW.gp	Software supplier for GP
SW.cp	Software supplier for CP

The above brief description of our attempt in map-making indicates the complexity found in the unfolding of interests that occur in the process of identifying stakeholders and representing their inter-relationships. Table 1 lists some (but not all, given space restrictions) of the stakeholders found to have a role or interest in EPS2 and Figure 3 illustrates examples of their interdependent relationships. The map can support further investigation of transactional, financial, regulatory, or professional relationships. Of course the map is never complete and never an exact illustration of all stakeholders and all their relationships. The drawbacks and the benefits of a map as a tool for analysis in evaluations are discussed below.

Discussion – Map-Using

The stakeholder map is intended to serve multiple purposes. It serves as an effective *communication tool*, used to elicit views and insights from interviewees by visualising presences and relationships. Over time and as it developed the map became a

means to *generate knowledge*. By developing an object which could be shared and discussed between the various stakeholders (and which each would recognise and be able to contribute to), we were making use of the map as 'a boundary object' [7]. Boundary objects are objects which allow the tacit difficult to express knowledge of one community to be expressed and shared by another community [8]. Through readers' different interpretation of the map and through constant discussions, the map's perceived gaps and 'errors' came to the fore, leading to further refinements and expansions, and allowing the interests and perspectives of stakeholders to be captured. This iterative process broadened our understanding of the meaning of EPS to different people and organisations. But to the extent that people differed on who was a stakeholder and how they fitted into the map, the challenge remained as to how to capture these multiple versions of reality.

The strength of a map as a means to *produce* knowledge derives from its three main features: *mobility*, *stability* and *combinability* [9]. The map is a mobile tool in the sense that it can be transferred between different people and organisations crossing boundaries. Using the map's mobility we could communicate our understanding of stakeholders and their relationships among researchers as well as between researchers and participants/stakeholders. The map also embeds information that is perceived as stable (relatively) when the map is transferred between people. In this way, information the map holds can resist distortions and misunderstandings that may emerge in any one place. Finally, the map is combinable because it enables further refinements and developments, inclusion of new stakeholders and new relationships, or a drilling down into stakeholders in more detail, for example into the complex structure of a PCT. Mobility, stability and combinability is what has allowed the map to develop from a simple three-stakeholder version (Figure 1) to the complex 28 stakeholder version (Figure 3).

The map reveals the complexity that surrounds EPS2 and the ways in which different stakeholders interrelate and contribute to it. However, the process of map-making is inevitably a process of selection and omission of stakeholders or relationships. For instance, figure 1 represents the typical flow of a prescription going from prescriber to patient and then to dispenser; however, some pharmacies provide a collection service which means that prescriptions go direct from prescriber to pharmacy, bypassing the patient. This could be considered an exception to the usual scenario – whether (and how) exceptions are represented in the map is an open question. Exceptions, being on the one hand by definition unusual, but on the other, as boundary conditions, are key areas of interest to any analysis. Map making is in other words both an intended and unintended mode of simplification as complexity is synthesised into a comprehensible and sharable picture [10].

A stakeholder map can only illustrate part of the 'whole' picture or one possible picture among many potentially to be drawn. This implies that a map is fundamentally *political* as it prioritises, accentuates and excludes stakeholders and their relationships, and embodies the worldviews of those who take part in its construction. As illustrated, our map started with three basic stakeholders who constituted our initial understanding of the 'pragmatic' view of EPS2. Through research we expanded the map in such a way so as to include additional stakeholders, who remained in the earlier version hidden. And there are many other potential stakeholders and relationships still to be discovered and presented. For that reason we would rather accept, in the spirit of Heisenberg and Schrödinger, that "*Every new attempt to represent the world in a scientific formulation, no matter how detailed and cumulative, will be swallowed up by the world expanding to contain it*" [11]. In that way, a map is not only a means to generate knowledge but it is also a means to hinder and hide it. Furthermore, a static 2 dimensional map in itself does not provide a rich account of

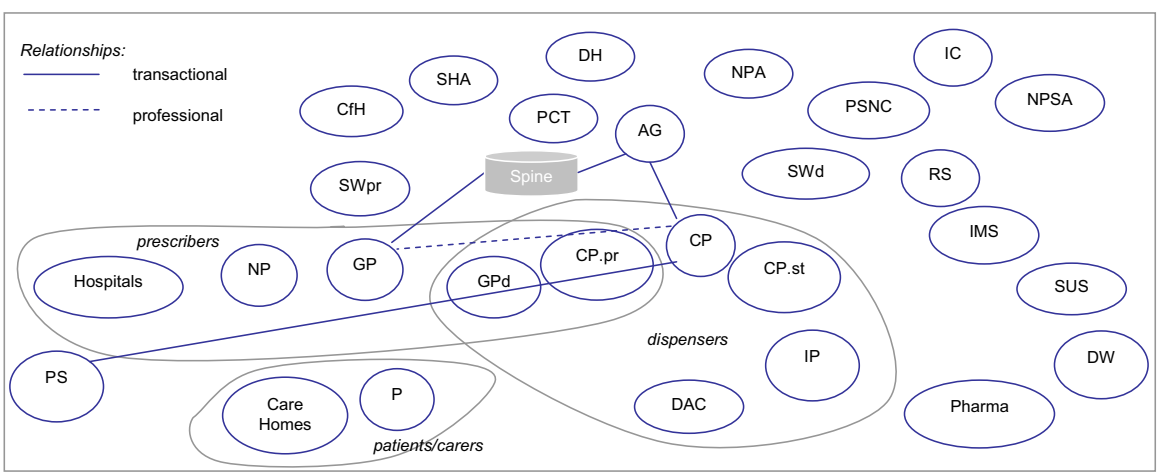

Figure 3- A more complex stakeholder map of EPS2 (a transaction flow of a patient's e-prescription and a professional relationship between general practitioner/prescriber and community pharmacist/dispenser shown as examples.)

the dynamic changing of relationships between stakeholders. Though, through layering of versions or digital animation a map may present or account for the historical development of stakeholder relationships, even if it cannot predict their future dynamics.

Conclusion

This paper discusses the strengths of map-making as a tool as well as the complexities and challenges surrounding a stakeholder map in terms of *map-making* and *map-using*. We present the iterative process of identifying stakeholders in the Electronic Prescription Service and some of the benefits and drawbacks of using a map as a methodological tool for data collection and analysis.

The map shows strongly how implementation and adoption of systems in healthcare takes place in a distributed landscape. In relation to our research topic this implies that electronic transmission of prescriptions does not start with a prescribing authority and end with a dispensing authority. Rather the EPS draws in a great number of stakeholders who mediate between prescribing and dispensing, each of whom has distinctive interests and a role in making this initiative work (or not). Understanding stakeholders and their interests as part of evaluating the adoption of EPS2, ultimately means capturing this distributed network of interests and relations.

Our research has also illustrated the limitations of a map in analysing stakeholders. The map is not an exact representation of the prescribing and the dispensing scenario in all its detail (although when it is taken out of the context of the identification process - it may be interpreted and judged as such). Our map, as a tool to identify stakeholders and their interests, constitutes one among many possible representations of the world of prescribing and dispensing. Cartographers are well aware that maps are an outcome of a reductionist activity that abstracts complexity from reality: "*...mapping allows for an understanding of terrain as only the surface expression of a complex and dynamic imbroglio of social and natural processes*" [12].

As our map-making and map-using research processes continue, we will investigate different variations of the stakeholder map; we will depict, explore, compare and superimpose: stakeholders, boundaries, transactions, flows, movements, and transformations of business models, connected with the introduction of electronic prescribing in primary care in England. We argue that a dynamic use of a stakeholder map, and a reflective map-making practice, has great potential to inform the analysis and evaluation of IT programmes in healthcare and beyond.

Acknowledgments

We are grateful to the interviewees who shared views and experiences, and gave their time to the project. We thank the research team for their comments and suggestions in the writing of this paper.

The Evaluation of the Electronic Prescription Service in Primary Care is a collaboration between The School of Pharmacy – University of London, The London School of Economics and Political Science and The University of Nottingham, under the leadership of Prof. N. Barber, Prof. A. Avery, Prof. R. Elliott and Dr. T. Cornford. It is funded by the Connecting for Health Evaluation Programme.

Abstract

The introduction of computerized information systems into health care practices may cause changes to the way health-care workers conduct their routine work activities, such as work flow and the time spend on each activity. To date the available work measurement tools are confined to activities in hospitals and do not cover residential aged care facilities (RACFs). There is little evidence about the effects of technology on caregivers' work practices, including the distribution of time on activities in a RACF. This requires the measurement of caregivers' activities using a valid and reliable measurement tool. The contribution of this research is to develop and test such a tool. The tool was developed based on literature research and validation in two RACFs. The final instrument contains 48 activities that are grouped into seven categories. They include direct care, indirect care, communication, documentation, personal activities, in-transit and others. This measurement tool can be used to measure the changes in caregivers' work activities associated with the introduction of computerized information systems in RACFs, including the efficiency gains of such systems.

Caregiver, Computerized information system, Residential aged care, Work measurement, Work sampling, Work activity.

Introduction

Computerized information systems are increasingly being introduced in Residential Aged Care Facilities (RACFs) with the expectation of improving the efficiency, quality and safety of care to the elderly. These systems range from stand-alone, hand-held technologies to Web-based applications, with some RACFs using a combination of several systems. However, there is limited evidence about the effects of these systems on caregivers' work performance, because the majority of research in this area has been confined to hospital settings [1, 2, 3, 4]. A clear understanding about the effects of health information systems on caregivers' work is necessary in justifying the need for technology in nursing practice [5]. This requires the availability of a measurement tool that can provide valid and reliable assessment results. Such instruments have been developed for assessing health care workers' activities in hospitals [1, 2, 6, 7]. However, many caregivers' activities in RACFs are significantly different from those in hospitals [8] and appropriate measurement tools are not available. The aim of this project is to develop and test a work measurement tool for use in RACFs.

Methods

The work measurement instrument was developed through a three-stage research process;

1. Literature review to understand the research methods of previous authors with similar aims and to identify activities that may be relevant to a RACF.
2. Development of specific categories of activities in a RACF.
3. Validation of the measurement instrument. The following sections describe the research processes.

Developing the categories of caregivers' activities

The first step of this investigation was to identify and classify caregivers' activities in a RACF. Potential activities were identified from the previously published instruments [1, 2, 9]. Nursing activities can be grouped into six categories. They include direct care, documentation, unit related, personal, personal education and faculty/research time. The following definitions of these categories were suggested by Bosman et al.[1].

- 'Direct care' includes all nursing activities directed at the patient and in the vicinity of the patient, such as administration of drugs, endotracheal suctioning, admission/assessment, hygiene, medication, patient mobility, patient/family interaction and transporting a patient.
- 'Documentation' includes all activities that are related to paper-based or electronic documentation, such as registration of fluids and writing hand over reports.
- 'Unit related activities' are those activities related to general maintenance of the unit such as cleaning the room and ordering supplies.

- 'Personal activities' include those activities that are not related to patient care or unit activities, such as meals breaks and personal phone calls.
- 'Personal education' includes activities that are designed to increase the knowledge and skills in nursing practice.
- 'Faculty/research time' is time spent on activities of research and/or the preparation for and supervision of students.

We believe that the first four categories of work activities reflect caregivers' routine tasks in Australian RACFs based on our research experience in these settings. Existing work measurement tools [1, 2, 9] have three main gaps hindering their immediate application in RACFs. These are:

- The naming of the categories of activities does not conform to the convention used in Australia.
- Some terms in the instrument are not relevant to the activities in RACFs.
- Incomplete coverage of caregivers' activities in a RACF. In our experience, oral communication between caregivers, with allied health workers and with the elderly and their relatives, is a common activity undertaken to meet care requirements of the elderly in a RACF. It is also evidently caregivers' preferred means of communication in aged care facilities [10].

Development of specific categories of work activities in a RACF

Two steps were undertaken in the development of specific categories of work activities in a RACF.

Step 1. The categories of work activities in the previous measurement instruments were screened and those considered relevant to a RACF were adapted into our measurement tool.

Step 2. Amendments were made to the adapted categories of nursing activities: some were re-named to comply with the common vocabulary in RACFs in Australia. For example the term 'unit–related activities' was re-named 'non-nursing activities' and 'patient' was re-placed by 'resident'. The resulting work measurement tool contained 25 activities that were grouped in five categories. Nine activities were grouped under the category of direct care, seven activities under oral communication, five under documentation, three under non-nursing and one activity under the category of personal (See Table 1).

Table 1- Caregivers' categories of activities

Category	Work activities
Direct care	Admission/assessment, hygiene/oral care/toileting/shaving, medication preparation/administration, nutrition/feeding
Oral communication	Information about a resident, staff orientation, resident/family interaction
Documentation	Taking records from the storage place, flipping through to identify the correct page
Non-nursing activities/miscellaneous	Supplies check/re-stock, room cleaning/bed-making
Personal	Personal errands/off unit chores/meal breaks

Validating the content of the measurement instrument in a RACF

A three-step approach was undertaken to test the preliminary five classifications of work activities with the aim to determine their validity and accuracy for measuring work activities in RACFs.

Step 1. The face value of the measurement instrument was validated with the Residential Service Manager (RSM) of a RACF. The RSM agreed with the classification of activities. She suggested minor changes in the nursing activities, for example, the addition of 'entero-feeding system' under the activity of 'nutrition' in the category of direct care activities.

Step 2. A further refinement of the tool was carried out with two Registered Nurses (RNs), one Endorsed Enrolled Nurse (EEN) and five Personal Carers (PCs).

Step 3. The measurement tool was further validated in a pilot study at a RACF through a work sampling study using the tool to record caregivers' activities. The observation lasted 3.5 hours per day for three days in a week. A tabular data collection tool was used to collect caregivers' observed activities for three weeks (See Table 2).

Table 2 - Data collection tool for the observed activities

Date_____Day_____Time_____Section of the house_____

Observed work activities					
Participants / **Round of observation**					
1					
2					
Comments					

The instrument contained information about the day and date of observation, the time period and the section of the house under observation. A section for comments allowed the observer to record any significant events that could assist during interpretation of data, for example staff shortages.

Procedures for data collection using the work measurement instrument

Using the developed data collection tool, an observer started each round of observation from a specific point in the facility. Following the same route within the facility, the observer recorded all the observed tasks for each caregiver on every round of observation using a code number allocated to each task. A unique code number was also used to identify each caregiver on the data collection tool. This was necessary for ensuring anonymity of participants and to facilitate longitudinal comparison of caregivers' task time and pattern of work. Caregivers were observed at an interval of 20 minutes. This gave the observer time to rest before starting the next round of observation, thus avoiding errors introduced due to observer fatigue. A caregiver who was missing at the time of observation was denoted by a dash (-). This pilot study led to the clarification and validation of caregivers' activities in a RACF.

Validation of the measurement tool in a second RACF

Validation of the work measurement tool was conducted in another RACF with the aim of further testing the generalisability of the instrument. A focus group discussion was conducted with the RSM, four senior RNs and two EENs. This was followed by a direct observational work sampling study using the modified instrument. Besides agreeing with the five categories of activities in the original work measurement tool, the group recommended the addition of two new categories of activities, 'in-transit' and 'others'. 'In-transit' includes the time caregivers spend between tasks, for example time spent walking to access medication in the store. 'Others' covers all activities that are not included in the identified categories of activities, for example, faxing medication orders.

Inter-rater reliability of observations was tested by two observers who independently observed the same activities. A training session was given by the first author (EM) to an RN with residential aged care work experience. Following the same procedures for work sampling, EM and the RN independently recorded activities of four caregivers for a period of two hours. Comparison of recordings suggest that a minimum agreement of more than 90% was achieved, which was adequate according to Pelletier et al. [9].

Results

Work categories and activities

Inter-rater reliability achieved 93% agreement. The remaining 7% was for the activities initially grouped together, which include 'recreational' and 'active' exercises. Observers agreed that these activities should be recorded separately to achieve accurate recordings.

The structure and content of the work measurement instrument

The initial testing of classifications and activities in the first RACF resulted in the development of a work measurement tool that includes 30 activities that were grouped into five categories. There were eight activities in the category of direct care, seven activities in communication, nine in documentation, five in indirect care and one in personal activities.

The following are the amendments to activities specified in the previous work measurement instruments [1, 2, 9]. The activity of 'palliative care/care for the deceased' was added to the category of direct care activities. 'Family interaction' and 'resident interaction' were recorded as separate activities in the category of communication, as the RSM was interested in the separate time spent on these activities. Four computer related activities were added to the category of documentation. They include; locating the correct window/resident's name, inputting a username and password, typing progress notes/care plans and closing the system. 'Room cleaning' was omitted from indirect care as the activity was not undertaken by caregivers in a RACF.

The results of further validation in the second RACF

Validation of the tool in the second RACF resulted in a measurement instrument with 48 directly observable activities that can be grouped in seven main categories (nine in direct care, 13 in communication, 12 in documentation, 11 in indirect care and the remaining three activities in separate categories of personal, in-transit and others) (See Table 3).

The following amendments were made to the work measurement tool developed in the first RACF. The activity of 'transporting a resident' under the category of direct care was replaced by 'preparing a resident for transfer'. Several activities were added to the category of oral communication, including 'discussion with allied health workers', class training and 'receiving a phone call'. Medication-related documentation was recorded under documentation. Additional activities under indirect care included 'answering to buzzers', 'personal hygiene set-up', 'cleaning up spills' and 'transporting waste/clinical waste'.

Discussion

The purpose of this project was to develop a work measurement tool that can be used in work measurement studies in RACFs. To our knowledge, this work measurement tool is the first of its kind in the setting of a RACF. Our research achieved a higher score of inter-rater reliability (93%) than the recommended level of 90% [9]. This implies that the work measurement tool is implementable in measuring caregivers' activities in a RACF.

Inadequate coverage of caregivers' activities appears to be one of the factors hindering the application of work measurement tools designed for hospitals into RACFs. Through developing and validating the work measurement tool in RACFs, our approach has potential to alleviate this problem and provide a more comprehensive instrument that is applicable in different aged care settings such as nursing homes and aged care facilities in hospitals. The major challenge is getting caregivers to participate in this process of developing a work measurement tool as their time is often limited because of staff shortages in these settings [11].

Table 3 – Caregivers' activities included in the validated instrument

Categories	Work activities
Direct care	All nursing care activities performed in the presence of the resident and/or relative, for example assessments/ sub-sequent assessments, hygiene/oral care/toileting, resident mobility, medication preparation/ administration, assisting with procedures/wound care, specimen collection/urine collection, nutrition/entero-feeding system, preparing a resident for transfer and palliative care/care for the deceased.
Communication	All activities related to oral communication such as sharing information about a resident/de-briefing, discussing with allied health workers, receiving a phone call/making a phone call, staff orientation, on-job training/induction, class training, co-ordination of care/care planning, staff meeting, resident interaction, family interaction.
Documentation	All activities related to paper-based or electronic documentation including taking records from the storage place, flipping through to identify the correct page, reviewing resident information, writing progress notes/charts/forms/care plans, putting records back to filing area, medication documentation, admission documentation, locating the correct window/resident's name , inputting a user name and password.
Indirect care	All activities that are not resident specific for example identifying correct supplies, packing supplies to a trolley, restocking supplies in a residents cupboard, equipment set up, bed making and de-bulking.
Personal	All personal activities unrelated to residents' care such as meal breaks, making telephone calls.
In-transit	Time between tasks
Others	Tasks not included above

In our development of the instrument from those previously formulated for use in hospitals, the categories of work activities increased from five to seven and directly observable work activities increased from 25 to 30 and then to 48. These increases in the classifications and activities are partly due to the differences in caregiver activities in different health care settings including hospitals and RACFs, as described earlier. The increases may also have been caused by the increased attention by caregivers in the second validation group to the rigor of the instrument, motivated by their strong interest in having accurate results about time on their activities. A further reason may be that care practices in different aged care facilities are different. The second RACF that participated in this project is vast in its layout and caregivers found it necessary to measure their time in-transit between tasks, in contrast to their counterparts in the first RACF.

These points suggest the need for the current work measurement instrument to undergo revision before its application in any other long term care facility. Based on our experience with this process, the following suggestions may be useful in modifying the tool.

- Have a clear research objective. The objective is important in determining the activities and classifications to be included in the measurement tool, for the purpose of answering the research questions.
- Understand caregivers' work flow. Aged care facilities may have different work flows including those that are run by the same management group, as was the case in our project. The work flow may have significant implications on activities to be included in the measurement tool. An understanding of the work flow may be achieved through discussion with the facility' managers and the caregivers in different job roles. Their views are necessary in obtaining a deeper understanding of work practices, including the layout of the facility and what may be termed as 'normal' activities in a shift, including their definitions. To confirm the completeness of these activities, it may be necessary to conduct a pilot study using the modified instrument.

Conclusion

To date, there is a lack of reliable and valid work measurement tool that can be used to measure caregivers' activities in a RACF. This project has led to the development of such an instrument. It can be used by researchers to measure how care staff members work and their proportion of time spent on each task in the settings of aged care facilities. This measurement is important in contributing to our understanding about the effects of electronic information systems on nursing practice. As demonstrated in our research, work activities in different RACFs may vary by layout of the facility and also the terms used for various activities in different countries or regions. Therefore, further validation of the work measurement tool is required in any future application of our measurement instrument.

Acknowledgements

This project was funded by Australian Research Council Industry Linkage Grant Scheme, Project No. LP0882430. It is part of

a larger investigation of the introduction of computer-based documentation to residential aged care. The authors would like to thank all the caregivers (RNs, EENs, RAOs and PCs) at Warrigal Care Warilla and Albion Park Rail aged care facilities for their participation.

The managers in Warrigal Care, (the CEO Mark Sewell, Care Systems Officer Dylan Hepworth, and the Residential Service Managers Karen Herbert and Helen Pavlik) are acknowledged for providing the necessary management support for the field survey.

A Multi-method Approach to Evaluate Health Information Systems

Ping Yu

Health Informatics Research Laboratory, School of Information Systems and Technology
University of Wollongong, Wollongong 2522 Australia

Abstract

Systematic evaluation of the introduction and impact of health information systems (HIS) is a challenging task. As the implementation is a dynamic process, with diverse issues emerge at various stages of system introduction, it is challenge to weigh the contribution of various factors and differentiate the critical ones. A conceptual framework will be helpful in guiding the evaluation effort; otherwise data collection may not be comprehensive and accurate. This may again lead to inadequate interpretation of the phenomena under study. Based on comprehensive literature research and own practice of evaluating health information systems, the author proposes a multi-method approach that incorporates both quantitative and qualitative measurement and centered around DeLone and McLean Information System Success Model. This approach aims to quantify the performance of HIS and its impact, and provide comprehensive and accurate explanations about the casual relationships of the different factors. This approach will provide decision makers with accurate and actionable information for improving the performance of the introduced HIS.

Keywords:

Evaluation, Health information system, Implementation, DeLone and McLean IS success model, Multiple methods

Introduction

Many healthcare organizations around the world are introducing health information systems (HIS) to improve health care quality and efficiency. To ensure that their HIS will be accepted and used by the intended users and bring in the expected outcomes, the decision makers would wish to fully understand the extent to which the HIS fulfilling its objectives, the strategies, processes and final outcomes of introducing the system, particularly its impact on health care quality and efficiency. Therefore, an important area of health informatics research is to evaluate the processes and outcomes of introducing HIS in health care organizations. Evaluating HIS is a complex issue that has long plagued HIS researchers [1-5]. As different stakeholders have different interest in the evaluation study; the nature and types of questions to be asked can be quite different; health care organizations vary in size, organizational culture, power structure and management; there is no one-size-fits-all solution. Also different issues may emerge at different stages of system introduction; therefore, the evaluation methods and approaches vary significantly. The previous researchers have discussed the challenges in evaluating HIS and raised the problem of lacking a uniform conceptual framework to guide the evaluation research [1,2]. In an effort to conceptualize and conduct a comprehensive investigation to produce thorough and accurate answers about the best strategies, practices and outcomes of HIS introduction, this paper discusses a multi-method approach to evaluating HIS. This is followed by a case study to illustrate how various evaluation methods are integrated in a comprehensive evaluation project that has been undertaking in long-term care facilities in Australia.

End user HIS perspectives

In 1992, the DeLone and McLean Information System Success Model (abbreviated as the D&M IS success model) was developed [6]. This model consists of six interrelated dimensions of success: system quality, information quality, system use, user satisfaction, individual impact and organizational impact. In response to the increasing importance of information services, DeLone and McLone added another dimension - service quality to the quality constructs [7]. To increase the genealizability of the model, they collapsed the two constructs about individual impact and organizational impact into one construct: net benefits. Therefore, the reformulated D&M IS success model is composed of six constructs: (1) system quality, (2) information quality, (3) service quality, (4) user satisfaction, (5) use and (6) net benefits. They believe that use and user satisfaction are determined by information quality, system quality and service quality, besides their mutual influences. Use and user satisfaction determine the final outcome of system introduction – net benefits (see Figure 1).

The D&M IS success model has been widely adopted by many researchers in measuring success of introducing various information systems into organizations. It was used by van der Meijden *et al.* [8] as a conceptual framework to summarize the critical factors that contribute to the success of inpatient clinical information system introductions from 31 empirical studies during the period of 1991 to 2001. This study shows that the majority of variables or attributes the previous researchers used to measure the success of HIS introduction can be successfully assigned to the six dimensions in the D&M IS suc-

cess model. Lehmann et al. adapted the model to qualitatively interpret the critical success factors of a mobile bed management system in a regional hospital in New Zealand [9]. Jen et al. used it to measure a mobile patient safety information system success in Taiwan quantitatively [10].

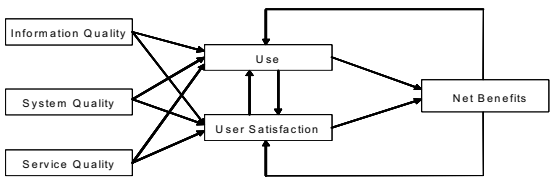

Figure 1- The reformulated DeLone and McLean Information System Success Model

Qualitative requirements

It is recognized that the introduction of HIS involves not only technological systems but also a significant change in culture, politics and power that tie professional groups together in organizations [11]. Organizational change and the implementation of information and communication technology are closely intertwined. It is an innovation and learning process. Therefore, Seddon [11] and DeLone and McLean [7] all recognize that the application of the D&M IS success model to empirical research requires a contextual variance specification of the model. Friedman and Wyatt [12] also emphasize the importance of context for the empirical investigation of the practice of introducing HIS into health care settings. However, the context issue is not addressed in the D&M IS success model. This leads to an inability of the D&M model to interpret the failure cases in the systematic review of the published literature about inpatient clinical information system implementation by van der Meijden *et al.* [8]. To remedy this deficiency, Yusof et al. [5] proposed a new model of human, organization and technology-fit evaluation framework (HOT-fit), which is a combination of D&M IS success model and the IT-Organization Fit Model adapted from Morton [13].

The D&M IS success model describes the relationships between different inputs, process variables and outputs. According to Lee and Lings [14], a model by itself can only describe what happens, but not explain how phenomena relate to each other and why this may be so. Although the proposed HOT-fit model was used successfully to explain what happened, how and why in the implementation of a Fundus Imaging System in a health care setting through qualitative case study approach [5], this mixed model appears to have lost significant potential of each of the original ones as psychometric measurement models. In order to understand this perspective, it is essential for us to understand the basics of psychometric measurement theory.

Psychometric measurement theory

"Measurement is the process of mapping the magnitude of an attribute to a numerical value – to transferring the amount of a quality to a quantity" [14]. As the science of psychological measurement [15], psychometrics is based on the assumption that latent constructs actually exist, although unobservable, they influence some things that we can actually observe [14]. Structural equation modeling is the conventional statistical method used to conduct psychometric analysis to test the causal relationships between the constructs. There are two models in a structural equation model: a structural model and a measurement model [16]. A structural model consists of the unobservable, latent constructs and the theoretical relationships among them, such as the six latent constructs in the D&M IS success model (see Figure 1). For each construct in a structural model, there is a related measurement model, which links the latent construct with a set of observed items. The measurement model consists of the relationships between the observed variables (questionnaire items) and the latent constructs which they measure [16]. For example, questionnaire items can be built to measure each construct, such as 'system quality' in the D&M IS success model. The relationships between the questionnaire items and the latent construct 'system quality' are the interests of the measurement model. Together, the structural and measurement models form a network of constructs and measures.

Psychometrics is widely used to measure knowledge, abilities, attitudes and personality traits. The D&M IS success model is derived from empirical data analysis and has been proved to be a validated psychometric measurement model. Petter and McLean [17] included 52 empirical studies that examined relationships within the IS success model at the individual level of analysis in their meta-analytic assessment of the D&M IS success model. The recent empirical psychometric examination of the D&M IS success model includes Wu and Wang [18], Wang and Liao [19].

The limitation of the HOT-fit model

Come back to the limitations of the HOT-fit model. This model was proposed as a conceptual framework for researchers to incorporate comprehensive dimensions and measures of HIS [5]. The case study of the Fundus Imaging System provides a good example on how to use the HOT-fit model to interpret the complex, interweaved relationships amongst people, organization, processes and technology. However, by this extension of the original D&M IS success model, the causal relationships among the constructs in the D&M model is mixed with the concept of 'fit', which is not a term in psychometrics.

Quantifying the weight of each construct is important, because without rigorous quantification, the magnitude of the impact of each contributing factor to the success of HIS can not be decided. As most healthcare organizations are resource stressed, without adequate information about the weight of each construct, the decision makers would find it challenge to make informed decisions on how to effectively allocate

resources to the much needed area to support HIS implementation.

Lee and Lings [14] suggest that the function of model is to describe, whereas the function of theory is to explain. Ortigueira believes that it is a utopia to think that it is possible to build models with all attributes, properties and characteristics of a specific system [cited by 20]. Roldå and Leal [20] also suggest that it is impossible to obtain a total correspondence between the attributes of the real-world system and the model. Thus the ambitious HOT-fit model is yet to prove its capacity to accurately and thoroughly explain the complex phenomena associated with the introduction of HIS and be validated quantitatively.

Having discussed various evaluation frameworks, their contributions and limitations in guiding HIS evaluation effort, we propose a multi-method approach combining the strength of quantitative evaluation guided by D&M IS success model and supported by other quantitative and qualitative methods.

A multi-method evaluation of HIS

To accurately identify and classify the issues that are critical for the introduction of HIS and explain the observed phenomena thoroughly and accurately, both quantitative and qualitative research methods need to be adopted in HIS evaluation research.

In order to implement the evaluation framework of the D&M IS success model, appropriate measurement items need to be adopted in a self-administered questionnaire to measure each construct. This questionnaire survey can then be implemented to gather end users' responses to each measurement statement.

This strategy of evaluating IS through structured questionnaire survey has a long established tradition in IS research. It is supported by Goodhue, who believes that users are capable of performing the evaluation of the task-technology fit of a particular technology that they have been using [21]. The modified technology acceptance model developed by Venkatesh and Davis [22] has been applied in more than 1000 empirical investigations through questionnaire survey to predict end user acceptance of information technology. In addition, questionnaire surveys also have a number of distinct advantages, including the ease of distributing questionnaires to a large number of users and the automated analysis of the results with statistical packages [23].

Therefore, the approach and rational for the undertaking of each type of research is summarized below:

Approach 1. Both cross sectional and longitudinal questionnaire survey of HIS end users to ascertain their changing perceptions about the HIS to be evaluated. The questionnaire is structured to measure the six theoretical constructs of the D&M IS success model (see Figure 1).

Rational. Self-administered questionnaire is the proven best method for measuring personal belief, perception and attitude. It has been employed broadly in information system and health research. Cross sectional questionnaire survey can quantify the performance of each construct in different sites; longitudinal survey can quantify the change of end users' perceptions about each measurement items.

Approach 2. Conduct Interview or focus group discussion with a convenient sample of HIS end users at different levels of participating organizations. This activity should be conducted at the same period of time when questionnaire data was collected.

Rational. In-depth interview and focus group discussion is effective for understanding how and why things have happened and would happen, and end users' perceptions on what can be done better. This will provide relevant explanations to the results of the questionnaire survey.

Approach 3. Work sampling with direct observational study to objectively measure any changes in work activities undertaking by each member of the care team and validate whether there is any objective evidence that the introduction of the HIS has improved the efficiency of work tasks that the system supports or vise versa.

Rational. End users' perceptions and opinions can be biased; therefore, objective measurement is required to validate the changes in work practices associated with the introduction of the HIS under evaluation. Work sampling is also effective in providing objective, relatively accurate measurement of the proportions of time end users spend on different work activities.

Approach 4. Auditing records that have been recorded both before and after the introduction of the HIS if the system is a health record system. Both quantitative and qualitative auditing needs to be conducted.

Rational. Direct auditing of health records can provide objective evidence about the changes in quality of records associated with the introduction of the HIS, if the HIS is a health record system. The results of cross-sectional auditing will be sound evidence for benchmarking across sites. Regular, longitudinal auditing will provide valid evidence about the longitudinal changes in quality of records.

The information collected from the above four sources, once triangulated, will provide a comprehensive and accurate picture of what has happened, why and how and what is the direction for the further evolution of the HIS. It is useful for the decision makers to implement effective interventions to ensure adequate return on investment from the HIS at different stages of system introduction and infusion.

A case study

The health information systems evaluated in this case are commercial electronic nursing documentation systems introduced by two aged care management groups in two states in Australia. Our research settings are residential aged care facilities belonging to these two aged care management groups. The project started in June 2008 and the planned completion date is May 2011.

For elderly people living in residential aged care facilities in Australia, nursing documentation includes functional assessment, care planning and daily progress reporting. Such documentation is essential for providing care that reflects the needs of the elderly [24, 25]. The functions of the two electronic nursing documentation systems were similar; both include resident details, assessment forms, progress notes, care plans, charts and printing out reports. The system was used by all levels of care staff members and management to record and review nursing records.

This particular evaluation study aimed to develop and validate the D&M IS success model and instruments to measure the model and identify factors that affect IT implementation in residential aged care using the above mentioned multi-method evaluation framework.

Approach

A multiple case study with both cross sectional and longitudinal research design has been undertaken. The above mentioned research methods were adopted. The implementation of each research component is described below:

Questionnaire survey. The questionnaire survey instrument was further developed from that used by Yu et al. [26]. Face validity of the instrument was validated through a consultation process with 16 personnel, including three focus group discussions with nursing managers (11 people in total), interviewing managers in aged care organisations (3 people), two vendors of HIS and health IT managers (6 people). The questionnaire survey was conduct 1-3 months before the introduction of an electronic documentation system, repeated 3 months, 6 months and 12 months after the electronic documentation system was introduced.

Interview. Interview guide was designed to elicit care staff members' perceptions about 'why' and 'how' things have happened and what can be done better. After acquiring consent, each interview was audio-recorded and transcribed. The interview transcripts are analysed in NVivo software.

Work sampling study. After a systematic literature review and detailed observation of care staff members' work practices in residential aged care facilities, a staff work activity classification system was developed. It included six major categories of care staff activities in a residential aged care facility: direct care, indirect care, nursing documentation, communication, personal and transit (such as walking between residents' rooms). There are many sub-categories of activities under each of the above six categories of the activities. The work sampling instrument was validated through two focus group consultations with care staff members in two aged care facilities.

Pilot study was conducted before the start of the formal measurement. The data quantified how different categories of care staff members spend time and how many proportions of their time is spent on each activity.

Auditing nursing records. A registered nurse was recruited to undertake this research component. The person developed nursing documentation audit tool based on extensive literature review and residential aged care accreditation standards in Australia. As most of the previous studies in this field were conducted in Europe in hospital setting, whereas Australian residential aged care setting has specific documentation requirements and protocols, significant development has been conducted to reflect Australian aged care documentation standards and practice.

Results

Currently 351 questionnaire responses were collected from eleven residential aged care facilities. Preliminary data analysis suggests that the instrument is adequate in detecting the performance difference of each measurement item between facilities; as well as different measurement points in one facility. This allows the research team to confidently inform the management group about the performance of the HIS as perceived by the participating care staff members in each aged care facility, between different facilities, and the longitudinal changes of their perceptions over time. Through triangulating questionnaire survey data with interview and work sampling data, a comprehensive picture about what happened, why and how were drawn.

For example, longitudinal questionnaire survey results in one facility suggest that the care staff members' perceptions about HIS quality and information quality were less positive than those measured in the previous survey. The interview data suggested that new staff members were not trained properly, also the support services could be more accessible. Based on the feedback, the facility management implemented more effective training and support strategies, such as peer-support, HIS training for any new member joining the team. After the enhancement of education and training programs, the survey conducted one year later found that the care staff members' perceptions about the performance of the system was improved in all aspects. The cross-sectional survey results also suggested that the electronic documentation out-weighed the paper-based documentation system in another facility. This re-enforced the management that investment in electronic documentation was correct.

Future work

The author is in the process of building structural equation model to validate the HIS success model in residential aged care settings in Australia. The members of the research team are in the process of analysing data collected from interview and work sampling study.

The nursing documentation audit instrument has been developed. It has been validated through two focus group discussions with RNs in two aged care management groups and consultation with nursing experts. The next step is to recruit two RNs to conduct nursing documentation audit, together with our RN researcher to test inter-radar reliability, then start nursing documentation audit in each participating site.

Conclusion

After explaining the importance of HIS evaluation, this paper introduced the D&M IS success model for evaluating HIS.

The limitations of the D&M IS success model are discussed. This led to the introduction of a recently developed HIS evaluation framework HOT-IT fit model. The weakness of this model is addressed through the introduction of the basic concept of psychometric measurement theory and the importance of quantitative measurement for both cross sectional and longitudinal benchmarking of HIS performance and impacts. Then a new model of HIS evaluation was introduced. This model is based on a multi-method approach that incorporates both quantitative and qualitative methods and centered on the D&M IS success model. A case study was presented to show an approach to implement the multiple methods to a large scope, both cross sectional and longitudinal HIS evolution project.

Abstract

Clinical decision support systems (CDSSs) have the potential to increase guideline adherence, but factors of success are not well understood. ASTI-GM is an on demand guideline-based CDSS where the user interactively characterizes her patient by browsing the system knowledge base to obtain the recommended treatment. We conducted a web-based evaluation of ASTI-GM as a before-after study to assess whether the system improves general practitioners' (GPs) performance and how they would use it. Five clinical cases had to be solved, as usual in the before phase, and using ASTI-GM in the after phase. On a 2-month period, 266 GPs participated and 1,981 prescription orders were collected. The overall guideline adherence rate increased from 27.2% to 64.3%. Only 56.4% *of ASTI-GM uses corresponded to a "good use" of the system. Adherence increased from 28.5% to 86.1% in the sub-group of "good uses", whereas it only increased from 28.1% to 36.6% in the complementary sub-group. Reasons for non "good uses" of CDSSs should be investigated since they impede their potential impact.*

Keywords:

Clinical decision support system, Intervention study, Guideline adherence, Primary health care.

Introduction

Clinical practice guidelines (CPGs) are commonly being developed to provide up-to-date knowledge of evidence-based best clinical practices. They are intended to improve the quality of clinical care by promoting effective care procedures and avoiding ineffective interventions. However, despite the development and the wide dissemination of CPGs, there is still a considerable variation in the effectiveness of guidelines to change the behavior of clinicians. Clinical decisions support systems (CDSSs) are defined as any software in which characteristics of individual patients are matched to a knowledge base (KB), built from the computerized version of original textual guidelines, to generate patient-specific assessments or recommendations. Numerous studies have established that CDSSs have the potential to increase physician compliance with recommendations. However, delivering patient-specific recommendations appears to be *"neither necessary nor sufficient"* to ensure adherence [1]. Failure to improve adherence using computer-based strategies has been often reported [2, 3] addressing the issue of identifying factors responsible for the success or failure of CDSS intervention strategies. Researches have been carried out to elicit successful design factors although many reports failed to describe the systems in sufficient details to precisely ascertain users interfaces or operating modalities. "Unintended consequences" [4] and the potential for CDSSs to harm patients have also generated much debate.

ASTI [5] is a guideline-based CDSS applied to therapeutic prescribing in primary care. ASTI can be used according to two modalities: *(i)* the "critiquing mode" which operates as a background process and automatically provides critics in the format of alerts when the physician's order does not follow guideline recommendations; *(ii)* the "guiding mode" which operates on demand when the general practitioner (GP) needs support to assess the best drug prescription of a complex case. Both operating modules have been integrated in the workflow of the GP and implemented using the commercial "éO"[1] electronic medical record (EMR). While the critiquing mode exclusively relies on coded patient data to operate, the guiding mode can be used as a stand alone tool. In this case, the infomation necessary to characterize a patient's clinical condition has to be documented by the user while browsing the KB.

[1] The "éO" software is a product of Silk Informatique, Angers, France.

Prior to a large scale appraisal of ASTI on physician adherence with CPG recommendations and the organization of a cluster randomized clinical trial, we have conducted a web-based preliminary evaluation of ASTI guiding mode (ASTI-GM), carried out as a before-after study. The aim was to check that using ASTI-GM does improve adherence for a series of clinical cases, apart from any connection with an EMR. Another objective was to analyze the situations where ASTI-GM propositions were not followed by GPs, to identify the explaining factors of such situations, and assess GPs' acceptance to using such a system.

Background

Reviews of computer-based guideline intervention strategies have reported mixed conclusions about the effectiveness of CDSSs to improve physician compliance with CPGs [1, 3]. The type of medical support provided by guidelines seem to influence the success or failure of guideline implementation systems. For instance, CDSSs have often demonstrated to improve preventive practice for vaccination, cancer screening, and cardiovascular risk reduction [6] whereas numerous studies evaluating CDSSs in the management of chronic diseases have found that the intervention had little or no effect. In addition, CDSSs vary greatly in design and modalities of output presentation, ranging from brief prompts and calculation services through complex decision-support systems providing explanations and the rationale that supported specific recommendations. Four features have been identified as independent predictors of improved clinical practice by Kawamoto *et al* [7]: *(i)* automatic provision of decision support as part of clinician workflow, *(ii)* provision of recommendations rather than just assessments, *(iii)* provision of decision support at the time and location of decision making, and *(iv)* computer-based decision support.

However, this is only a statistical statement based on the identification of a significant correlation, no causality or logic implication has been established, and there are CDSSs with no impact on physician behavior that possess the four features. In fact, no design factor is consistently associated with significant improvement. Even the success of reminder-based approaches is subject to variability: Garg *et al* [3] reported that CDSSs that automatically prompt users improve practitioner performance, whereas other authors were unable to influence guideline adherence with concurrent reminders. More recently Shojania *et al* [8] showed that computer reminders achieve small to modest improvements in physician decisions, even when they make the difference between point of care computer reminders, e-mail alerts, computer-generated paper reminders and any other way of delivering "computer reminders". Thus the question of understanding why and when a given guideline-based CDSS could improve physician compliance with CPGs is still open. ASTI-GM is a CDSS that holds the four features of success identified by Kawamoto *et al*. The web-based evaluation has been handled to check whether using ASTI-GM would improve physician compliance with CPGs and to help understand why and when physicians don't follow the system propositions.

Material

ASTI guiding mode

ASTI-GM is a guideline-based CDSS elaborated with a knowledge-modeling approach in the document-based paradigm first developed with OncoDoc [9], keeping the advantages of CDSSs that deliver optimized patient-centered information and the advantages of text reading that allows for contextual interpretation. Decision knowledge is encoded as a tree where nodes represent the patient parameters that drive the decision process. As a consequence, a path in the tree represents a patient-specific situation as a list, or conjunction, of statements *parameter* = *value*, *e.g.* coronary disease = no.

Borrowing from Shiffman's multi-step process to translate textual CPGs into the KBs of CDSSs [10], the verification of completeness ensures that all medically relevant combinations of state parameters are anticipated. Thus, the total expansion of the tree is the exhaustive nosological catalog of all the possible clinical situations that can be encountered in practice, and the search through the tree can be considered as a discrimination process to select the path that best fits a given patient clinical condition. The discrimination process can be driven either automatically from patient data or under the control of the user while dynamically browsing the KB. At each depth level of the tree, a patient parameter is displayed as a closed-ended question along with its definition, and the user has to answer by a simple mouse click. When this hypertextual navigation is completed, *i.e.*, when the leaf level of the tree is reached, a page is displayed with the summary of the selected "scenario" along with recommended therapeutic propositions. All leaf pages are numbered to characterize the corresponding paths of the tree (Figure 1).

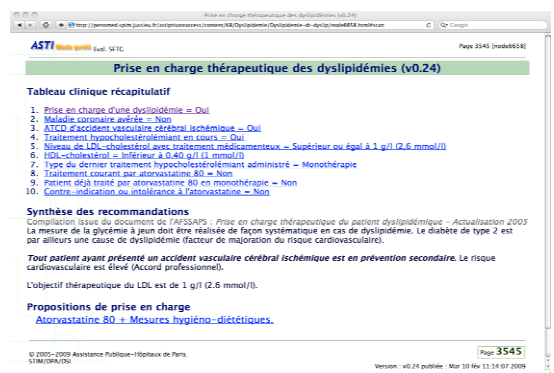

Figure 1- Recommendations issued by ASTI-GM for a patient profile with the page number (bottom right)

ASTI-GM propositions are guideline-based recommendations except for clinical situations, or profiles, that result from the verification of completeness, which are by construction not explicitly covered by CPGs. In these "gaps" of CPGs, therapeutic options proposed by ASTI-GM are expert-based.

ASTI-GM is currently applied to the management of hypertension (HT), lipid disorders, smoking cessation, and auricular fibrillation (AF). Knowledge bases have been built from national French CPGs published by HAS and AFSSAPS. ASTI is not yet used in routine care.

Patient case set

The web-based study consisted in the resolution of 5 clinical cases. The 5 clinical cases are not hypothetical simplified cases but *actual* clinical cases extracted from the EMR database of a general practice (Paris, France). All cases are presented as a textual description of the patient clinical situation, including disease history, comorbidities, and relevant biological data. Cases have been selected to cover different levels of patient complexity. Three cases are moderately difficult and describe patients under monotherapy: case 1 concerns a patient with cholesterol disorder, the current treatment is tolerated and active, but suboptimal because of the patient's personal history of stroke; case 2 concerns an hypertensive patient who coughs under ACE inhibitors, the current treatment is thus non tolerated although active; case 5 concerns a patient with familial hypercholesterolemia, the current treatment is neither tolerated nor active. Case 4 is more complicated and concerns a diabetic hypertensive patient (two comorbidities) under a non-active bitherapy. Finally, case 3 is really complex and concerns a patient with a documented history of auricular fibrillation. The difficulty here comes from the double management of rhythm troubles and thromboembolic risk.

Method

Protocol and data collection

This study has been handled as a web-based questionnaire following a before-after design. The questionnaire has been implemented using the dedicated "It's Quizz" platform[2]. GPs in relation with the SFTG (Société de Formation à la Thérapeutique du Généraliste, the French national association of GPs involved in the ASTI project) were invited to participate by email. Participation was on a voluntary basis. There was no financial incentive although CME credits were offered to GPs that completed the questionnaire. No training on how to use ASTI-GM was provided. Only a one-page textual user's guide was attached to the call for participation.

In the "before" phase, GPs had to solve the 5 clinical cases. Each case was displayed on a page. The textual description of the case was followed by 10 input fields for the GP to enter her order in plain text, one drug by input field. In this first phase, the user had no access to ASTI-GM so that case resolution was performed without the support of ASTI. As long as the before phase was not completed, it was possible to switch from one case to another and modify previous prescriptions. Once orders were validated, they were definitely recorded and the before phase was completed.

In the "after" phase, the GP had to solve the same clinical cases and enter her prescriptions but after having used ASTI-GM. A link to the CDSS had been inserted after the case description so that it was easy to access ASTI-GM once the case reviewed. For each case, GPs could use at their convenience, one, two, or the three KBs (HT, lipid disorders, or AF) to get the therapeutic propositions related to each disease. They had to report in the questionnaire the page number that characterized their navigation in ASTI-GM (see Fig. 1). Similarly to the before phase, the user could get back to any of the 5 cases resolved with ASTI-GM. Once orders of the after phase were validated, the questionnaire was completed.

Gold standards

Each case was reviewed with a domain expert to establish the gold standards to which collected data should be compared.

The gold standard order considered as the "solution" of the case, was determined according to CPGs completed by the state of the art[3]. As it is the case in CPGs, this order has been expressed at the abstraction level of therapeutic classes. For instance, for the first dyslipemia case (#1), the specific correct order was "atorvastatin 80", but the gold standard has been set as "atorvastatin". As a result, any order of atorvastatin, whatever the dosage or the commercial name used, was considered as compliant with CPGs.

Then, we determined the gold standard navigation as the navigation that best matched the case description, characterized by its page number. For instance, for the first case, the "good" page is 3545 (see Fig 1). Any user that reported this page number was considered to have performed a good use of ASTI-GM[4]. Any other situation was considered as a "non-good use". This category includes *(i)* a missing page number (although the user might have used the system or not, used it correctly or not), and *(ii)* the report of a page number that doesn't correspond to the gold standard navigation.

Data analysis

The analysis unit is the prescription order. Each line of prescription was first abstracted to its therapeutic class to reach the level of abstraction of CPG recommendations. Then the abstracted order was compared to the gold standard order of the case to assess the adherence of the prescription with CPGs. This comparison is independent of the use of ASTI-GM.

Overall adherence rates were computed for all prescriptions in the before and after phases. To eliminate orders only done in the before phase, with no corresponding order in the after phase, we selected matched pairs of orders proposed for the same case by the same GP in the two phases. In this subpopulation, adherence rate of the before phase is considered as the baseline rate to which the adherence rate of the after phase can be adequately compared. Then we have identified two subpopulations according to the "good use", or not, of ASTI-GM in the after phase. Intra- and inter-group comparisons of adherence rates have been performed (Fisher's exact test or χ^2, and McNemars's test in the case of paired data).

[2] "It's Quizz" is a product of "It's Sauquet.com", Paris, France.

[3] In some cases, several order patterns were possibly used.

[4] Interpretation of some clinical cases could lead to more than one good navigation.

Results

The study started on February 11th, 2009 when the mailing was performed. It was closed and data collected on April 1st. A total of 2,040 GPs were solicited, among which 266 registered on the web site, 143 completed the questionnaire and solved the 2×5 cases. A total of 1,981 orders have been collected, 1,193 in the before phase and 788 in the after phase.

Overall adherence rates

For each of the 1,981 orders, adherence to the gold standard has been computed. Table 1 reports this data by case and by phase. The baseline adherence rate, measured in the before phase, increased from 27.2% to 64.3% in the after phase. It should be noticed that the number of reported prescriptions decreased as the number of solved cases increased, showing a progressive loss of user commitment.

Table 1 - Adherence rates by case in both before and after phases.

	Before phase		*After phase*	
Case (theme)	*n*	*Adherence*	*n*	*Adherence*
1 (lipids)	256	25.8%	177	66.7%
2 (AHT)	252	68.7%	160	78.8%
3 (AF)	233	1.7%	155	63.9%
4 (AHT)	237	5.9%	153	50.3%
5 (lipids)	215	31.1%	143	60.8%
Total	1,193	27.2%	788	64.3%

Adherence rates in paired orders

Matched pairs of orders are the orders proposed in both before and after phases for the same case by the same GP. There are 752 pairs of matching orders, 441 orders of the before phase has no correspondent in the after phase, and 36 orders of the after phase has no correspondent in the before phase. Table 2 gives the distribution by pair patterns, with the number of occurrences and corresponding adherence rates in both phases.

Table 2 - Paired orders according to pattern and adherence rates in both phases.

Pair pattern	*n*	*Adherence before*	*Adherence after*
$(O_1,\varnothing)$	441	25.17%	—
(O_1,O_2)	752	28.32%	64.49%
$(\varnothing,O_2)$	36	—	61.11%

The difference of adherence rates between before and after phases in matched pairs of orders (28.32% vs 64.49%, n = 752) is highly significant ($p < 10^{-15}$, McNemar's test). This suggests that the intervention might have an impact.

However, the difference of adherence rates in the before phase between orders with a matching order in the after phase (28.32%) and those without (25.17%) is not significant (Fisher's exact test). This suggests that the GPs that gave up after the before phase (n = 441) would not be different in performance level than those who carried on in the after phase.

Good vs non-good system uses

For each of the 752 matched pairs of orders, we considered whether the second order was prescribed after a "good" use of ASTI-GM. This splits our sample into 2 subgroups. Table 3 reports the overall proportion of good and non-good uses of ASTI-GM and the adherence rates in the two phases.

Table 3 - Good and non-good uses of ASTI-MG and corresponding adherence rates in both phases.

Category	*n*	*%*	*Adh. before*	*Adh. after*
Non-good	328	43.6%	28.05%	36.59%
Good	424	56.4%	28.54%	86.08%
Total	752	100.0 %	28.32%	64.49%

Orders associated with good system uses represent about one half of the GPs (56.4%). In the after phase, the comparison between adherence rates of the two sub-groups, i.e. when ASTI is correctly used (86.08%) and when it is not (36.59%), is highly significant ($p < 10^{-15}$, χ^2), illustrating that a "good" use of the system does considerably increase adherence.

However, the adherence rate in the "non-good use" sub-group significantly increased between the 2 phases (28.05% vs 36.59%, p = 0.0015, McNemar's test). This suggests that, despite a "non-good use", something in the intervention might have impacted GPs' prescriptions.

As the difference of the baseline adherence rate (before phase) in both groups is not significant (Fisher's exact test), it can be assumed there is no difference of initial performance level in GPs who used the system correctly (or at least reported it) and the others.

Discussion and conclusion

ASTI-GM has been designed to be a computer-based *thinking support* on how to decide. Indeed the interactive characterization of a patient clinical condition is intended to play the role of a check list of guideline-based relevant parameters to structure the understanding of the patient by the GP and thus help her improve her therapeutic decision.

In this study, 5 clinical cases were proposed to GPs for which they had to give their prescription as usual, without using ASTI-GM, and after using ASTI-GM. Guideline adherence of GPs' orders was computed with respect to a gold standard, established for each clinical case by a domain expert on the basis of the currently used French national CPGs improved by last results from the state of the art, but not to ASTI-GM propositions while included in the gold standard. ASTI-GM was only (part of) the intervention, but not the reference.

In this experiment, as reported by many studies of CDSS-based interventions, the adherence rate of GPs to CPGs was significantly increased from 27.2% to 64.3% after using ASTI-

GM. When analyzing the results by clinical case, we observed in the before phase a variability of adherence rates, which seems to depend on the a priori difficulty of the case, with higher rates on cases 1, 2, and 5 that describe less complex patients, and lower rates on cases 3 (atrial fibrillation involving 2 types of therapeutic management) and 4 (patient under bitherapy). It must also be noticed that even simple cases on high blood cholesterol management (lipids) are not well handled by GPs in the before phase suggesting the weak penetration of cholesterol management CPGs and illustrating their poor quality (that we experimented when formalizing the textual document to built ASTI-GM's KB). However, after using ASTI-GM, variability of adherence rate by case is decreased which suggests a normative effect of the intervention and the resulting harmonization of practices that could be expected after using the system.

The good use of ASTI-GM seems to be a determinant factor of the system impact. Indeed, considering the sub-population of good users, the increase of the adherence rate is considerable from 28.54% to 86.08%, suggesting that GPs are more disposed to follow therapeutic propositions when they correctly interpret a clinical case. They probably found the system advices consistent with their case perception. On the contrary for non-good users, adherence rates before and after remain low although there is a significant increase. This may be attributable to the help-to-think effect of using the system, or simply because of thinking twice about the case. For those who reported a "wrong" page number, the question is thus why did they do a "wrong" navigation? We have little information to answer. We can only assume hypotheses such as *(i)* misinterpretation of clinical cases explained by the fact that there is no actual patient and that it is difficult to reason on textual description (some GPs for instance interpreted the appearance of side effects with simvastatin as a contraindication to all statins), *(ii)* careless mistakes in the navigation explained by the fact that GPs are busy people, the study took them at least one hour and they wanted to go fast (error on the categorization of the age, HDL-cholesterol, personal vs familial history of a pathology, etc.), *(iii)* incoherent navigations beyond ASTI-GM misuse (technical difficulties related to the poor computerized environment of some GPs, old versions of browsers, wrong report of the page in the questionnaire...).

The limitations of this study concern the potential recruitment bias of GPs since there was no randomization and participation was on a voluntary basis. In addition, because of variable computerization of medical practice, some GPs experimented technical difficulties even without knowing it (they could not navigate through the KB, they did not find the page number, etc.) leading them to withdraw. Moreover, results have been obtained for only 5 cases (2 with AHT, 2 with dyslipemia, and 1 with AF) and could be generalized neither to this 3 domains nor to other domains. We have evaluated ASTI-GM apart from its actual use in general practice.

However, it seems that usability features of CDSSs and how CDDSs are used could impact adherence rates of GPs with CPGs. Therefore, a better understanding of the reason why CDDSs are not used or misused is required. This has to be further investigated.

Acknowledgments

We would like to thank all GPs who participated in this study, the SFTG staff, especially Marie-Claude Cassard for her assistance. ASTI has been partially supported by the French National Health Authority (HAS) and the C.N.A.M.T.S.

Abstract

Follow- up of abnormal test results for discharged Emergency Department (ED) patients is a critical safety issue. This study aimed to explore ED physicians' perceptions, practices, and suggestions for improvements of test result follow-up when using an electronic provider order entry system to order all laboratory and radiology tests and view results. Interviews were conducted with seven ED physicians and one clinical information system support person. Interviews were analyzed to elicit key concepts relating to physicians' perceptions of test result follow-up and how the process could be improved. Results described the current electronic test result follow-up system with two paper-based manual back-up systems for microbiology and radiology results. The key issues for physicians were: responsibility for test follow-up; the unique ED environment and time pressures, and the role of the family physician in test result follow-up. The key suggestion for improvement was a complete integrated electronic information system with on-line result endorsement. The study highlighted the complexity of the test result follow-up process and the importance of engaging clinicians in devising solutions for improvements.

Keywords:

Test result follow-up, Computerised provider order entry systems, Electronic medical records, Patient safety, Laboratory test results, Emergency department, Family physician.

Introduction

Problems with follow-up of test results have been identified in a number of studies [1, 2]. Physicians acknowledge that they need safe and efficient processes to manage test result follow-up [1, 3]. Emergency Departments (EDs) have been shown to be complex, interrupt driven environments with rapid throughput of patients and team-based care delivery [4]. It is understandable that in this environment, particularly for discharged ED patients, follow-up of results presents challenges for physicians and safety concerns for patients. The test follow-up process, therefore, needs to be systematic to ensure diagnoses are not delayed or missed and patients receive appropriate treatment in a timely fashion [5-7].

A number of studies have explored the extent of failure to follow-up test results in the ED [5, 7-12]. The extent of the problem varies depending on the study methods used and test type examined. However rates of failure to follow-up laboratory tests for ED patients have been found to range from 3% for microbiology tests [9] to 75% for pregnancy tests [7]. Radiology lost to follow-up is also an area of concern with one study finding that for 6% of ED patients who had a missed diagnosis of cervical spine injury, the error was due to the treating surgeon not seeing the radiographs [10].

The systems used to manage test results in EDs vary with studies reporting physicians using completely manual systems [7], completely electronic systems [11] or more commonly a mix of electronic and manual systems [8, 9]. Suggestions for improvements to the test result management process have suggested further utilization of electronic test management systems [13, 14]. However, studies have shown that electronic systems can create their own problems and hinder rather than assist clinical processes [15, 16]. Given that lack of follow-up of test results is a critical problem for ED clinicians, there needs to be an exploration of physicians' perceptions of the test management process and how technology might assist. We could find no published studies which investigated the practices of result follow-up and opinions of ED physicians already using an electronic test management system. This study aims to fill that gap by exploring in-depth, physicians' perceptions, practices and suggestions for improvements of follow-up of test results in an ED which used a computerised provider order entry system to order and view all laboratory and radiology test results.

Methods

Design and setting

A qualitative study design using interviews to explore ED physicians' current test management work practices was undertaken. The ED was situated in a 400 bed metropolitan teaching hospital which had 25,000 attendances per annum of which 17,000 were discharged (68%). Physicians in the ED used a commercial computerised provider order entry (CPOE) system, which had been in place since 1992, to order laboratory and

radiology tests and view test results for all in-patients and ED patients.

Sample

Five consultant physicians, one ED resident physician and the ED clinical director (n=7) were interviewed. An Information Systems Department clinical support person (n=1) was also interviewed to describe features of the CPOE system.

Data collection

Semi-structured interviews were conducted with the eight participants over a one week period in August 2007. The lead questions included: How do you manage your test results currently? What factors impact on your current management of viewing test results, for example, handover, team-based care etc? Can you suggest ways in which the follow-up of test results might be improved? Which features of the current system hinder you in tracking test results? How could the computerised test management system be used to improve tracking of test results? Each interview took approximately 25 minutes and was undertaken during work hours in an administrative area of the ED. The study was approved by the Human Research Ethics Committee of the study site.

Data analysis

Interviews were taped and transcribed to allow for qualitative analysis using a thematic grounded theory approach. Two researchers (JC & MP) independently analysed the interview text to elicit key concepts. These two researchers then discussed their independently derived concepts and agreed on a final set to accurately reflect perceptions and practices of the respondents in relation to test-result follow-up.

Results

The results are presented in four sections: demographics of study participants; description and perceptions of current test result follow-up processes; key concepts in relation to what impacts on the result follow-up process, and physicians' perceptions of how follow-up could be improved using the electronic test management system.

Demographics of participants

Six of the physicians interviewed were emergency specialist physicians and this represents the population of specialist physicians for the ED. One physician interviewed was a registrar. Five of the staff specialists, including the ED Director, were male with ages ranging from 30 to 52 years with one female 30-35 years of age. The registrar was a 25-29 year old male.

How do ED clinicians follow-up test results?

Description of current process

ED physicians use a computerised provider order test management system (*Cerner Powerchart*) to order and view all diagnostic laboratory and radiology tests. Clinicians almost always accessed test result electronically, except sometimes for urgent results they would phone the laboratory.

"I would wait for results to come up on Powerchart unless it was a particularly urgent result, for example, raised potassium which I would let the lab know the urgency of the result and get them to either ring it back down or ring them up directly" (Doctor 5)

Some physicians built their own personal *patient list* in the *Powerchart* test management system (by ward or specialty) to assist them manage their results, however only two of the seven clinicians described doing this. At the time of the study there was no operational function to allow physicians to endorse test results on-line. There was a *bookmarking* function which enabled the user to indicate they have seen all the results of one patient on the screen; however this was used intermittently by only one ED clinician.

In the ED there is an additional manual back-up practice specifically for radiology and microbiology test results as these may arrive after the patient is discharged home.

"So particularly with micro results and things like that by the time you actually grow something…by the time a result's back it's maybe four days so the patients gone home" (Doctor 7)

Radiology and microbiology results for discharged ED patients were reported electronically and also sent to a dedicated printer in the ED. Staff specialists in the ED department are rostered to administrative duty for one shift per week and it is their responsibility during this shift to check all manual radiology and microbiology results to ensure they have been seen and acted upon, that is, appropriately followed up. To do this the ED staff specialist on administrative duty checks all printed radiology and microbiology results and any abnormal results are checked against the electronic discharge summary or the manual medical record to ensure the patient's family physician or general practitioner (GP) has been alerted to the outstanding result. In some cases the ED specialist will contact the patient or the family physician to ensure follow-up of the abnormal result has occurred. To further ensure that there is no duplication of follow-up for microbiology results which may have a number of interim reports printed with the final report coming through days after the initial interim report, the physician who sees the abnormal result and follows-up with appropriate action, will document this in an 'Abnormal result log book'.

ED physicians' perceptions of the current process

All clinicians liked the electronic process of ordering and viewing test results using the current computerised system. Two clinicians mentioned that they were not very good at typing with one stating, *"Well I'm just slow at typing" (Doctor 2)* and one admitting that he *"still liked pen and paper"* and typing was *"like a two finger job, very slow" (Doctor 1).* One of these clinicians (Doctor 1) suggested that a voice recognition system would be useful to improve the tracking of test results.

"If you had a little mike system and you could talk into it and it automatically typed for you.." (Doctor 1)

Key concepts in relation to what impacts on ED clinicians' follow-up of test results

The three key concepts derived from the data were: responsibility for test result follow-up; busy ED environment and time pressures, and the role of the family physician in test result follow-up.

Concept 1: Responsibility for test result follow-up

There were mixed opinions regarding the extent of the physicians' responsibilities in following up discharged ED patient's test results. Most ED staff specialists agreed that they had final responsibility for following up their patients results.

"If you order a test you should be checking the results." (Doctor 2)

In response to how a result is followed-up if it is abnormal and the patient has been discharged, most physicians said they would contact the patient or the GP.

"So generally we will contact the patient. …I see it as our job to try and organize what's going to happen and not just fob it off on the general practitioner." (Doctor 3)

Some however thought that if the result was written as 'outstanding – GP to follow-up' in the discharge summary, then it was the patients and GPs responsibility to follow-up the result.

"… the letter says for the GP to follow that up. Now I don't go and ring the GP because I think patients should have some responsibility for their own health." (Doctor 1)

"..it's clearly impractical for us to verify that they have gone and seen their general practitioner. And on the other side you know people do have to assume some responsibility for their health" (Doctor 3)

"So with us the delineation of who is going to follow-up the result is much clearer – it's not us because we are an isolated emergency visit. So for patients it's very clear. That's it, you're out. We won't be seeing you again. Whereas they have an ongoing relationship with the GP…" (Doctor 7)

The complexity of the decision of whether to contact the patient or not post-discharge regarding an abnormal result was highlighted by one clinician who reported in relation to an elbow x-ray which might state 'cannot exclude fracture':

"…if it's reasonable that the thing does exist rather than it's just 'it might be' because obviously you don't want to create unnecessary distress or panic amongst people when it's not a conclusive finding….These judgments are not easy…myself and other clinicians do them slightly differently…" (Doctor 3)

"…this is why we have senior clinical people doing this job [in reference to the administrative staff specialist checking all hard copy microbiology and radiology results of discharged ED patients]*...because there's a lot of subjectivity around well which ones do you follow- up and which ones don't you follow-up and what advice do you give and do you always ring the GP, you know there are a lot of 'ifs' in there and that's why ..it does need a senior clinician to make those sort of judgement decisions and assume the responsibility." (Doctor 3)*

Concept 2: ED environment and time pressures in test result follow-up

The clinicians highlighted their time pressures, unique ED work environment and the large number of test results which come through.

"…it takes a lot of time going through all the results and then checking the letter [discharge summary] to see if they've [the GP] been asked to follow-up." (Doctor 1)

"…you know it's well known that no matter what the error rate is the more volume you've got the higher your absolute number of errors are going to be….you're never going to be able to eradicate errors even putting in whatever sense of follow-up you want to do there's still so many subjective steps in there that it's never going to be possible to have an error rate of zero" (Doctor 3)

Two clinicians raised the issue of the absence of an on-going relationship between ED physicians and ED patients:

"..as an inpatient consultant you have accepted responsibility for an inpatient admission … there is absolutely no doubt that everything that happens to that person is your responsibility. The situation in emergency is much less clear and different departments do it in different ways. I mean here everything is done under the name of the director…that's just the way we do it here." (Doctor 3)

"… it's very clear that we have no ongoing relationship with the patient when they leave us." (Doctor 7)

Concept 3: The role of the family physician in test result follow-up

A key issue raised by most respondents was the problem of the electronically created discharge summary at the study site which was not transmitted to the patient's family physician either electronically by email or by facsimile. The hospital had a system whereby an electronic discharge summary was created on-line and then printed and the hard-copy was given to the patient to give to their family doctor or GP. Most ED specialists thought that the family physician should play a key role in following up test results which were outstanding at the time of the patient's discharge from the ED.

"We have looked at the issue of faxing or emailing to GPs. There's still a lot of security issues around that….I mean the system has the capability…it's a security issue." (Doctor 3)

"The main difficulty as an ED specialist in following up results is actually tracking down the local doctor." (Doctor 5)

Another issue raised in relation to the discharge summary was the difficulty of completing summaries for all ED patients due to time constraints.

"I must admit that I don't do them all…It takes time." (Doctor 2)

How could test result follow-up be improved using the electronic test management system?

When asked how the current test result follow-up system could be improved most clinicians responded that they would like "all the information in one place." They acknowledged that

there were currently electronic and manual test management information systems and this created problems.

"I think a lot of the way it could be improved is actually just to have all the information in one place…I think that we've done a pretty good job of centralizing the information, although obviously the reliance on it still being a piece of paper that can be lost, destroyed not printed…" (Doctor 3)

Verifying on-line that a test result was seen and what action was taken was also seen as a positive advance with a reduction in reliance on the manual medical record.

"I think that if you could arrange for it to be transmitted electronically, reviewed electronically…that would be ideal" (Doctor 3)

Refining on-line endorsement for just critical results and only for senior clinicians to verify was suggested by one clinician.

"If it has a functionality that anything that you order comes to your in-box and then you have to sign off…now that could be made to work, that would make sense but only at a senior level. There's no point having RMOs and interns having every single electrolyte coming back to their in box, that's just useless….I mean for the bulk of tests there's no point and there'd be hundreds of them and you'd just get overwhelmed. You could have criticals coming back to the staff specialist that was on." (Doctor 7)

One staff specialist also emphasised that if the electronic system was used to assist with verifying results on-line it would have to be reliable and fast.

"..it would have to work all the time because if it doesn't work reliably we just stop doing it and go back to old ways that we know work all the time down here …if it works sometimes or it's too slow or when you've got downtime then that's a big problem." (Doctor 7)

Discussion

This study showed that the ED physicians at the study site, who work in an environment which uses a computerised provider order entry system to order and view all test results, would generally be comfortable moving to some form of integrated clinical information system with a complete electronic test result follow-up system. On-line electronic endorsement of test results presents as the logical next step to these ED physicians in assisting them track the large volume of test results they receive and particularly to assist them in tracking late arriving results of discharged ED patients. Some specific functionality requirements were requested, such as on-line endorsement of critical results only and endorsement by senior clinicians only, which reinforce the importance of involving physicians in any plans for developing and implementing such a system. A number of other studies support the importance of engaging clinicians to ensure an appropriate fit between the technology, the clinical environment and clinicians' work practices [17-21].

A combination of manual and electronic information systems presents challenges in terms of safety, with some items possibly being missed, and duplication of information, with wasting of resources and time [22, 23]. The printing of manual microbiology and radiology results for all discharged ED patients at the study site was seen to be an essential back-up system to the CPOE system as these results, particularly for microbiology, were likely to arrive several days post-discharge. The ED physicians however, acknowledged that the combination of manual and electronic test management systems was not ideal. When asked for suggestions for improvements to the current system a number stated that a completely centralized electronic medical record with on-line endorsement of results was preferred. The problem of a mix of electronic and manual information systems is shown in another study by Casalino et al. [24] who quantified the extent of failure to inform patients of abnormal results in 23 medical centres in the United Sates. They found that where there was a partial electronic medical record (electronic progress notes or test results but not both) it was associated with higher rates of failure to inform patients of clinically significant outpatient test results compared to not having an electronic medical record (OR 1.92, p=0.03) or with having an electronic medical record that included both progress notes and test results (OR 2.37, p=0.007) [24].

The results from our study show that the test result follow-up procedure is a complex and often subjective process for ED physicians. Decisions are made about whether to contact discharged ED patients or family physicians when results are abnormal depending on the context and level of abnormality of the result. There are subtle differences between clinicians' practices in relation to follow-up of test results for discharged ED patients. Differences between clinicians in the integration of information systems into their work practices have previously been reported [25]. Other studies have also reported that the test result follow up process is complex and multifaceted [26, 27]. It is important to recognize this complexity when designing and implementing clinical information systems.

Limitations:

This study was qualitative and undertaken in one Emergency Department so results may not be generalisable to other settings. The study did not explore physicians' perceptions of direct reporting of test results to patients through secure web-based portals however this has been reported in other studies as an option [26, 27] and future studies should investigate physicians' attitudes towards this.

Conclusion

Our study has highlighted the complexity of the test management process and the importance of engaging the users in any design and implementation of new systems. On-line test endorsement is perceived by ED physicians as a way to improve the efficiency of the test result follow-up process for clinicians.

Evaluation Methodology for Automatic Radiology Reporting Transcription Systems

Valéria Farinazzo Martins Salvador[a], Lincoln de Assis Moura Jr.[b]

[a] *Escola Politécnica da USP and Universidade Presbiteriana Mackenzie*
[b] *Escola Politécnica da USP and Zilics eHealth*

Abstract

This article describes a usability evaluation methodology for automatic transcription system used for radiology reporting. In order to assess this class of system's limitations and strengths, a review of the concepts involved in this kind of system is done in a critical way. Specific requirements, for this category of application, that are forgotten when a product is launched in the market, are listed and a methodology for their evaluation is presented.

Keywords:

Voice user interface, Usability evaluation, Automatic transcription system for reports

Introduction

Voice User Interface (VUI) uses technology of recognition and voice synthesis to provide access to information to its users, allowing them to perform transactions and offering communication support. Even though dialogue speech systems have appeared in the 1950's, during the onset of Artificial Intelligence research [1, 2, 3], a significant growth in the production of systems with users interface based on voice took place in the past decade, especially for commercial use, via telephone, such as airplane ticket reservations, hotel reservations, flight schedule queries, accessing bank accounts and others. The state of the art in voice technology (recognition and synthesis) allows for the development of automatic systems that work in real conditions, even though the systems are quite simple, meaning they have a limited vocabulary and therefore a high rate of recognition – close to 95%. Companies such as Philips [4], IBM [5] and Nuance [6] have invested in the development of voice recognition technologies for restricted domain [7-10].

According to [8], this uncontrolled growth is due to a series of factors: clients dissatisfaction when using touch tones systems, information access through mobile devices growth, the company's need to provide clients with a more efficient way and with lower costs for their clients demands. Although the authors state that this growth is due to the development of voice recognition and synthesis technology that have become stronger and more capable of sustaining effective interactions, one must realize that the present systems have a restricted capacity for voice recognition, a limited vocabulary and grammar coverage, and a limited ability of tolerating and correcting mistakes. Voice recognition systems, based on tasks that have a high level of variability, with a large vocabulary and that have to work with an open grammar, similar to man-to-man communication, make real voice recognition more difficult.

In Health Care, the use of voice recognition in general-purpose systems, in emergencies for instance, does not work efficiently because of the large domain's vocabulary (it is known that a Health Worker uses more than 100 thousand vocabulary words in their daily routine) In addition, there are over 60 million diagnostic possibilities in SNOMED [11]. The information available in Health Care is quite diverse.

Nevertheless, VUI has been used in voice recognition systems for more specific purposes, such as the Automatic Transcription of Reports in Radiology. That means the vocabulary is considerably smaller and gives a higher precision of recognition of specific denominations.

Regarding the usability of Voice Recognition Systems as a whole, there is yet much to determine as an evaluation methodology. In his research, Nielsen [12] proposed rules and determined heuristics to allow the interfaces to be analyzed in regard of usability. The authors got his inspiration from the user's graphic interfaces that were (and still are) in widespread use. But VUIs system evaluation is different from GUIs, mainly when it comes to voice transience that affects major usability factors such as transparency, learning, cognitive overload, error handling and user's control.

The research for usability evaluation of voice recognition systems is still quite new. The Methodology and suggested methods to evaluate VUIs come from the present knowledge of UI evaluation, related to the work of some researchers that developed methods to investigate their specific projects, and that tried to generalize and proposed reference models for such applications. That is the case of PARADISE [13], EAGLES [14] and DISC [15].

An even more incipient case is the usability evaluation of automatic transcription system. There are many specific usability issues that have not being analyzed as part of more concrete evaluation methodologies. There are two main reasons for that. First of all, owing to the fact that the classic usability evaluation methodologies cannot cope with voice systems, significant changes must be done for these methodologies to become efficient for that purpose. Secondly, the evaluators of such systems are still focused on evaluating only the accuracy or detecting mistakes in these systems [16-19]. In other words, there

are many other usability issues that are being neglected. The evaluation of automatic report transcription systems is a relatively different task because:

- Health Care vocabularies are more extensive than commercial vocabularies, and also contain specific terms, increasing the likelihood of a lower rate of recognition.
- The dialogue between the user and the system is much simpler, since the system must only generate a text from the user's speech, with no questions to be made (through speech) to the user.
- The handling and prevention of mistakes are quite different. The system must be able to show, somehow, the words in the text that are misunderstood, but must not interrupt the user or ask for confirmation. The radiologist does not wish to be interrupted by an error message while they are dictating a report.
- The quality of the messages and the adequacy of the outcoming speech should be replaced by the text's accuracy.

There are some other important considerations applicable to the automatic report transcription system.

- Flaws in the report that were caused by a wrong recognition of words can be catastrophic to the patient, for it can lead to an inaccurate diagnosis.
- It is necessary to think of how to create a methodology that takes into consideration the main requirements for this kind of system.

The challenges found when assessing automatic report transcription systems are:

- Define the VUI requirements that have to be considered to evaluate this system;
- Determine which, among the many requirements presented, are said to be essential and viable of evaluation;
- Determine how to measure each requirement pointed out as essential for these systems;
- Define how to evaluate these systems in a viable way, with acceptable costs and time for the Health Care organizations and/or systems supplier;

Thus, any suitable evaluation methodology for these systems must take into account the issues mentioned above in order to decide if a product is appropriate in matters of use efficiency, user's satisfaction and functionality, or if the product has only a good rate of voice recognition.

The objective of this article is, therefore, to organize concepts of voice recognition, voice recognition systems evaluation aiming at proposing a useful set of methods that are feasible, practical and suitable. So, a specific methodology to evaluate this category of applications will be suggested.

This article is organized as follows: The following part points out the material and methods used in the research. After that, a critical review of the concepts involved in this work will be made: Voice recognition and synthesis, technology evaluation, automatic transcription system for report and its specific demands. Then, a methodology for the evaluation of these systems is described. In the end, the limitations and advantages of the proposed methodology are discussed.

Materials and Methods

This article is enclosed in a wider context of a doctorate's research for the evaluation of user interface based on voice with the purpose of accomplishment of the following activities:

- Bibliographic review of the themes in use in the Project, including: VUI, radiology information systems with VUI and traditional methods of usability evaluation;
- Identification of generic demands for the users interfaces based on voice and the users interface requirements for voice-based system in Health Care, especially for radiological information systems.
- Proposition of a methodology that is able to provide usability evaluation focused on automatic transcription system for radiology reports.

Conceptual Foundations

Voice Recognition

The main characteristic of the VUI applications is the interaction, through voice, of a user with a system. This kind of interface includes elements such as: *prompts* or system messages, grammar and logical dialogue or call flow. Prompts are all the pre-recorded or synthesized voice messages that must be executed during the dialogue with the user. Grammar defines all the words, sentences or phrases that can be said by the user in answer to a prompt. The logical dialogue defines all the actions that should be taken by the sys-tem in a specific moment of the interaction, such as the access to the database [8, 20, 21].

According to [22], when an application with a users interface based on voice is developed, there are some issues that shouldn't be neglected for the application to be successful.

- The vocabulary affects the voice recognition through its size and subject field coverage. So, an extensive vocabulary with good subject field coverage is appealing, for it is capable of recognizing more words. Nevertheless, smaller vocabularies provide an enlargement in recognition accuracy.
- The users influence the voice recognition through clarity and consistency in the pronunciation of words. User- dependent systems have a higher rate of voice recognition than the systems that are user independent, but the formers need training sessions and can be more sensitive to noise, microphone and voice variations.
- A noisy environment affects the voice recognition in two ways: a) voice signal distortions cause difficulty to distinguish the pronounced words; b) when in a noisy environment, users tend to alter their voices and doing so, cause distortion in or alter the voice signal.
- All voice recognition systems are based on the statistical standards principles. However, in spite of its similarities, systems differ in their voice signal parameterization, the acoustic model of each phoneme and the language pat-

tern used in the choice of words accord with the words spoken and stored previously. Thus, many systems bring about differences in relation to the recognition errors, even when they have similar rates of recognition.

Voice Synthesis

Voice synthesis is the process that converts text into voice. The synthesizer receives a piece of text in digital form and vocalizes it. A Voice Synthesis program is useful to vocalize information that comes from data base queries and when the user cannot divert his attention to read something or does not have access to the written text; a system with the users interface based on voice can use a module for voice synthesis or use pre-recorded messages when there is no variation in the information given to the user [8].

It is worth noting that until now, the voice synthesizers cannot represent intonation and are still quite poor when compared to voice dialogue among humans.

Usability in Voice Recognition Systems

Usability is a system quality requirement that contains aspects related to the efficiency when using the system, ease of learning, subjective satisfaction from the user and adequacy to specific patterns; it is the process of assuring interface usability and guarantee that the user's demands be met [12, 23- 25]. Although the aspects for usability mentioned above are conceptually clear, it is difficult to use these definitions in practice. When the evaluation is made through empirical studies, the researchers need to decide about metrics for each factor [26].

If the companies in general have not been preoccupied about following usability patterns in its websites, established many years ago, these issues are even more serious in VUIs, for it is an even newer and less settled form of interaction with the user.

General Usability Requirements for Voice Recognition Systems

One way of evaluating voice recognition systems usability is through general heuristics proposed by Nielsen [12] such as: simple and natural dialogue, use of feedbacks and handling and preventing errors. Nevertheless, more specific criteria are necessary to evaluate VUI specific issues, such as the ones proposed by [27- 31]. Those criteria include:

- Output phrasing adequacy: The output content of the system must be correct, relevant and informative enough, without providing information overload to the user. The system's way of communicating with the users must be clear and unambiguous and the language must provide an appropriate and familiar terminology to the user.
- Output voice quality: this quality is connected to issues of clearness and intelligibility (right intonation, emotion, appropriate speech pace and pleasure when heard).
- Input recognition adequacy: appropriate voice recognition means that the system rarely misunderstands the user's entry. But this is associated to many factors in the environment (as level of noise) and also to user's factors: gender, age, accent, depth or shrillness of voice and the voice quality as received by the system.
- Adequacy of dialogue initiative: it is necessary for the system to choose, in a reasonable way, the dialogue initiative established between it and the user. This is related to the user's level of knowledge of the system.

Voice Recognition Systems in Radiology

One of the main problems shown in the literature [16, 17, 32-35, 37] is the delay in radiology reports due to the time spent from the moment of entry of a recorded reports to its return in textual form for the radiologist to assess.

The automatic report transcription systems (that use VUI) have been thought of as a solution to decrease this time (Turn Around Time) and also to decrease the running costs of the radiology department. To verify the efficiency of the use of automatic report systems, not only the VUI general requirements must be evaluated but also the specific demands in the area, to see if the available commercial products have been used correctly by the users.

Specific Usability Requirements for the Automatic Transcription System for Radiology Reports

In addition to the general requirements for interfaces and to the general requirements found in voice recognition systems, there are specific requirements for automatic transcription system for radiology reports. We propose that the following set of requirement should be formally assessed when evaluating VUI-based report transcription systems

1. Accuracy: It is one of the most important requirements, because the wrong information can compromise report quality, alter a diagnosis and compromise a treatment.

2. Vocabulary Extent: It is a very important requirement, as the vocabulary can neither be too big in order to lower the rate of word recognition nor too small for it not to consider the words in the application's dominion.

3. Specific Dictionary for RIS: The system must consider the words used daily in radiology reporting

4. Hospital environment: depending on the area, hospitals can be very noisy, but that should not interfere with the efficiency of recognition.

5. Continuous Recognition: the user must be able to dictate the report naturally, without having to worry about pauses between words, i.e., the user must be able to speak in a natural and continuous way.

6. Desirable separation between the keyboard and the dictation system: The user should be able to dictate through a specific voice capture device, through a cellular or regular phone, allowing the application to be ubiquitous;

7. Use of client-server or browser-server architectures: For the radiologists to be free to move from one station to another in a hospital or clinic, or even across hospital units in a network of health care providers:

8. Integration with exiting systems: PACS, HIS e RIS;

9. Time for the report to be ready: must be at least shorter than the human transcription systems;

10. User's naturalness of speech: The user must be able to speak in a natural and continuous way, as if the user were recording an audio tape;

11. Resolution of ambiguity for homonyms: Words that have the same pronunciation but different spelling should not affect the application.

Proposed Methodology

The proposed evaluation methodology should be able to:

- Use additional usability and inspection tests to provide a lower cost and shorter assessment time.
- Be applied to previously implemented systems;
- Function as a guide to evaluating the usability in this class of systems;
- Investigate the difficulties in evaluating specific requirements;
- Group the proposed requirements according to their characteristics;
- Propose metrics for evaluating each of those requirements.

This methodology proposes that the interface evaluation should be done by inspection[1] whenever possible, without involving the user in order to decrease the usability tests session prices. Use the usability tests when it is verified that the inspection is not enough.

To assess automatic report systems, the following classes were here defined in a modified way from what Möller [31] proposed in his work about general purpose voice recognition system evaluation:

- Class 1 – Achievement Requirements associated to the correct operation of the application without degrading its achievement. Accuracy, vocabulary size, specific dictionary for RIS, noisy environment, user's naturalness of speech (continuous recognition)
- Class 2 - Usability Efficiency and efficient requirements, decreasing the user's cognitive load: Minimization of memory overloads, adequate modality, time for the report to be ready;
- Class 3 – Hardware and Integration: Requirements connected to physical achievement: Separateness between keyboard and dictation, use of proper architecture (client-server or browser-server), integration with existing systems, quality of audio system, and quality of database entries.
- Class 4 – Human Factors Requirements connected to the user's pleasure in using the system and the will to continue to use it;
- Class 5 – Feedback: System's feedback time, system's visibility, feedback's adequacy, message exit quality;
- Class 6 – Handling Error and Help: Requirements that are related to the capacity of the system in correcting not only errors found but also correcting a dictation, may it be in real or posterior time.

[1] Usability inspection is a set of methods where an evaluator inspects a user interface. It can generally be used early in the development process by evaluating prototypes or specifications for the system that can't be tested on users. It generally considered to be cheaper to implement than testing on users [35].

The requirements were classified according to the level of assessment difficulty (Level 1 – low complexity, Level 2 – medium complexity and Level 3 - high complexity) as an example: accuracy; vocabulary size; noisy environment; continuous recognition fall in complexity Level 1.

A method for analyzing each requirement was developed. A template was created for each requirement in order to facilitate the assessment, as illustrated in Table 1, for Client's Satisfaction.

Table 1 – Template of Client's Satisfaction

CLIENT'S SATISFACTION	
Kind of Evaluation	Subjective
Evaluation Methods	Questionnaire
Importance	High
Difficulty in Evaluation	Level 3
Evidence to look for / Metrics to use	Ease of use, aggregated value, success of the task

The corresponding questionnaire was based on SUMI (Software Usability Measurement) of University College Cork.

Conclusion

This article focuses on the evaluation of automatic transcription system for radiology reports. Various specific requirements in this class of systems that are not taken into consideration either by the classic evaluation methodologies of usability or by the new VUI evaluation methods were identified. These requirements have been neglected when these applications are evaluated.

A methodology to provide these peculiar requirements based on usability inspection and usability tests was proposed, in order to assure a lower cost and a higher efficiency.

As future work, this methodology should be applied to several case studies in order to be perfected and validated for real cases.

Abstract

The development of efficient e-services for patient-centered healthcare requires insight into concrete problems in administrative and clinical work processes as well as an understanding of the strategic goals that should guide these healthcare processes. However, considering both concrete process-related problems and high-level strategic goals during process analysis and solution design can be problematic. To address this, we propose a structured approach for analyzing both high- and low-level goals in a healthcare process and relating these to identified problems. Thereby proposed solutions for each problem in form of, e.g. e-services can be connected to strategic goals. The approach consists of five steps; process modeling; process-based problem identification and classification; process goal identification; mapping to strategic goals; and solution proposal. The approach is illustrated by examples from a case study of Swedish stroke care. In conclusion, the approach enables analysis of high- and low-level goals in a healthcare process by relating these to identified problems. The results thereof form a basis for redefinition of current care processes, as well as for design of supporting e-health solutions.

Keywords:

Medical informatics, Systems analysis, Process assessment (Health Care)

Introduction

Healthcare is facing a number of challenges, due to demographic, economic and societal developments. This has brought a movement away from episodic treatment of acute health issues to provision of coordinated services that will provide continuity of care for those with chronic conditions and enhance the health status of defined populations [1-3]. Yet, current care provision processes remain to a large extent organisation focused, which leads to fragmented care and a lack of continuity. This is particularly problematic in the care of patients with chronic, sometimes multiple, conditions who require care from many care provider organisations.

One example of increased focus on a holistic, high-level view, of healthcare processes is the recent interest in *patient-centered* care. The concept is used to describe a shift from organization- to patient-centric provision of healthcare, in order to strengthen the role of patients and family carers [2]. This change poses new challenges for existing healthcare processes; new solutions that create concrete value for patients while meeting general high-level goals set by the healthcare community need to be provided. In order to be able to redesign healthcare to meet the described challenges, new instruments to represent and visualise the complexities of healthcare are required.

The objective of this paper is to describe an approach for analyzing high- and low-level goals in a healthcare process by relating these to identified problems in the process, and to apply this approach in form of a case study.

Related work

The approach presented in this paper combines the use of processes and goals. Generally a process describes a set of linked activities that produce a certain output [4]. In the health care sector the use of processes is crucial to understand problems and improve performance [5]. While we in this paper use processes as a mean to identify process related problems in a health care organization, more detailed process models can also be used for verification purposes [6]. Together with processes we employ the notion of goals to relate high-level strategic goals with the low-level goals needed to be attained in order to solve the identified problems. The way we use goals in this paper is similar to the well-known approach of goal decomposition [7]. However, rather than performing a top-down decomposition, such as in [8] and [9] we relate identified low-level process problems to a fixed set of high-level goals.

Material and Methods

Data for this study is collected: (1) from documents, (2) through focus groups with different stakeholders, (3) through interviews with single experts, and (4) by using the Business Process Modeling Notation (BPMN) [10] for process model-

ing. These methods are iteratively applied during the approach described below, using document analysis, focus groups and BPMN for initial process modeling and applying focus groups and expert interviews in each successive step of the approach for further modeling and verification. The entire approach is then applied in form of a case study using stroke care.

Overview of the proposed approach

The purpose of the approach presented in this paper is to improve healthcare processes by aligning them with well-accepted, high-level goals, starting from concrete problems that exist in the processes and continuing to propose solutions to those problems. The suggested approach consists of five steps:

Step 1 - Process modeling: the healthcare process at hand is modeled (if such a model is not already available). This is done in collaboration between all the stakeholders relevant for the given healthcare process and process modeling experts.

Step 2 - Process-based problem identification and classification: concrete problems in the process are identified by using a *problem classification* based on process aspects. Here, we address four process aspects (functional, behavioral, organizational and informational [11, 12]), but other aspects can be taken into account. For each process activity, every process aspect is considered and related problems are identified.

Step 3 - Process goal identification: all identified process problems are transformed into low-level goals, by rewriting the problem as a desired state that alleviates the problem.

Step 4 - Mapping to strategic goals: after defining a process goal, this low-level goal is mapped against one (or more) strategic, high-level goals. The high-level goals can either be set-up on a process basis, or more likely, a well-established set of goals such as the organization's strategy can be used. In this paper, we apply the major aims for healthcare improvement set up by the Institute of Medicine (http://www.iom.edu/); safety, effectiveness, efficiency, patient-centeredness, timeliness, and equity [13].

Step 5 - Solution proposal: the final step is to propose possible solutions in order to solve the problems and achieve the goals. In this step the problem classification and each problem's related goal can aide in the design of the solution.

In contrary to previous work, we chose these steps because a bottom-up analysis was considered best to relate existing problems to strategic goals. This way we aim to both find suitable solutions for the problems and to elucidate the entire process between the operational and the strategic level.

Application of the approach to Swedish stroke care

In the following sections details of our approach will be further explored by describing how each of the five steps in the proposed approach was performed in the VIPPA (the Swedish acronym stands for visualization of patient-centered process models in healthcare) research project.

Step 1: Process modeling

In the VIPPA project a combination of process-modeling, interviews, and structured problem analysis was used to gather information about the stroke care process and its inherent problems. Modeling of the stroke care process was based on documentation of previous work done in Sweden [14] as well as interviews with key stakeholders. Swedish national guidelines and national performance measures [15] for stroke care was also a valuable source of information. The modeling was done according to the Business Process Modeling Notation (BPMN) [10]. Both process modeling and analysis were done in collaboration between experts on process modeling, stakeholders from healthcare and health informatics researchers. The results were also presented to different stakeholders who had not been actively involved in the modeling process to receive feedback and validation.

An extract from the process model, showing discharge of a patient from hospital care to homecare, including examples of identified problems, is presented in Figure 1.

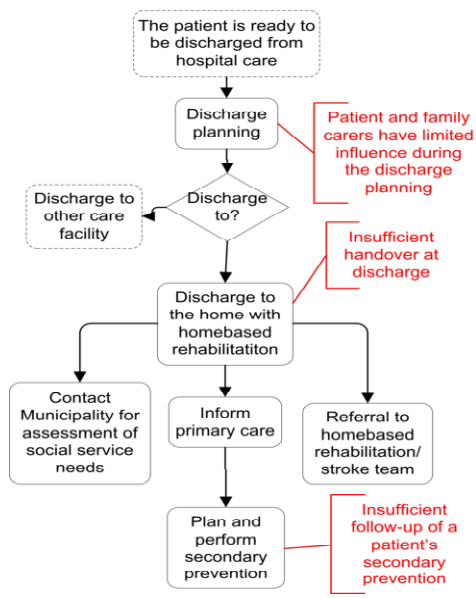

Figure 1 – Extract from the Stroke care process model indicating identified problems

Step 2: Process-based problem identification and classification

The process modeling revealed a number of problems in the stroke process. To structure, document and analyze the problems they were classified into four problem classes. Each problem class conforms to a specific process aspect, as presented by Jablonski [11] and Raush-Scott [12]:

Information: problems related to availability of process information. It is for instance problematic if the hospital doing the

acute treatment does not pass on information to the primary care and the patient's municipality.

Functions/Activity: Problems related to the outcome and execution of process activities; for instance limited follow-up activities regarding secondary prevention is considered a functional problem.

Behavior/Time: These problems refer to the timing, ordering and selection of activities; for instance, in the stroke process it is important that the time between the first symptoms (the first activity) and diagnosis is less than three hours in order for certain effective treatments, such as thrombolysis ("clot busting"), to be possible.

Organization: Problems referring to the actors that participate in the process and their available resources, such as skilled nurses and physicians, and equipment. It is for example considered as an organizational problem that patients and family carers have limited influence on discharge planning.

Each elicited problem in the process was assigned to one of the above described problem classes. When an initial problem was difficult to classify it was further decomposed into more concrete problems by the use of the four problem classes.

Figure 2 illustrates how the problem "Insufficient handover at discharge" is broken down into three more concrete problems in this manner.

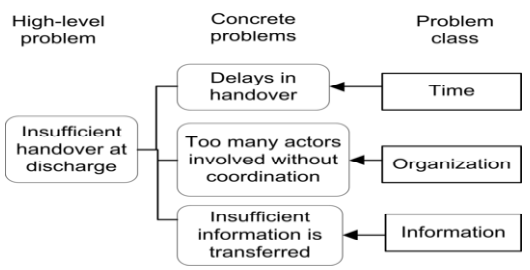

Figure 2 – Problem break-down and classification

Step 3: Process goal identification

Once the problems identified in step two are addressed the health care process under study can be improved. However, in addition to addressing classified process problems it is of interest to examine how a solution of the problems contributes to high-level goals, such as increased patient safety.

In order to relate the problems to high-level goals we transform each problem into a low-level goal by rewriting the problem as a desired state that alleviates the problem. Since each problem is related to a problem class (information, behavior/time, functions/activity, organization) we can express the desired state in terms of the desired condition for that class. For example the information related problem "Delays in handover from hospital care to other care providers" (figure 1), can be expressed as a desired state of the *behavior/timing* of the process, "Reduce delays in handover from hospital care to other care providers".

In Table 1, we provide a number of low-level goals defined based on the problems illustrated in Figures 1 and 2.

Table 1 – Classified problems related to lw-level and high-level goals

Problem class	Problem (concrete)	Low-level goal	High-level goal
Behavior/Time	Delays in handover from hospital care to other care providers	Reduce delays in handover from hospital care to other care providers	Timely care (continuity of care)
Organization	Too many actors involved in the care of a patient without coordination	Appoint a coordinator that is responsible for the overall care process	Patient-centered care
Information	Insufficient information is transferred from hospital care to other care providers	Improve the quality of the information being transferred	Safe care
Functions/Activity	Insufficient follow-up of a patient's secondary prevention	Create routines for continuous follow-up of stroke patients	Effective care
Organization	Patients and family carers have limited influence during the discharge planning	Invite patients and family carers to take a more active part in the discharge planning	Patient-centered care

Step 4: Mapping of low-level goals to strategic, high-level goals

After defining a low-level goal, the goal needs to be mapped to one of the high-level goals. In doing so, the goals of the process become justified from a strategic perspective. The approach presented here can be applied when using any high-level goal framework; it is up to the healthcare management to set up overall high-level goals. In order to illustrate our approach, we apply a framework of six goals proposed by the Institute of Medicine [13]. These goals state that healthcare should be

1. *Safe* - avoiding injuries to patients from the care that is intended to help them,
2. *Effective* - providing services based on scientific knowledge to all who could benefit and refraining from providing services to those not likely to benefit (avoiding underuse and overuse, respectively),

3. *Patient-centered* - providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decision,
4. *Timely* - reducing waits and sometimes harmful delays for both those who receive and those who give care,
5. *Efficient* - avoiding waste, including waste of equipment, supplies, ideas, and energy, and
6. *Equitable* - providing care that does not vary in quality due to personal characteristics such as gender, ethnicity, geographic location, and socioeconomic status.

In order to map an elicited low-level goal to a high-level goal it is examined *why* a certain low-level goal should be fulfilled. For example, why is it important to "Improve the quality of information transferred"? Is it (primarily) because safety will be improved (the first high-level goal), or is it because of effectiveness reasons (the second high-level goal)? In this case we indicated that improved information quality is primarily motivated by the desire to improve patient safety (Table 1).

Step 5: Solution proposal

Proposing solutions is a creative process, involving initial brain storming techniques to propose alternative solutions to each problem. Often a few solutions appear obvious, such as directly fulfilling each individual low-level goal. However, it is important to take this process further by considering how different solutions could contribute to several high and low-level goals.

As an example, Figure 3 depicts how a solution in form of an e-service for discharge care planning is suggested as a potential solution to achieve the different low-level goals. The solution analysis can be detailed to different levels, either remaining on high level suggestions, or being further detailed into different models depending on the type of problem analyzed. Further analysis of an informational problem may e.g. result in e-service specifications including information models.

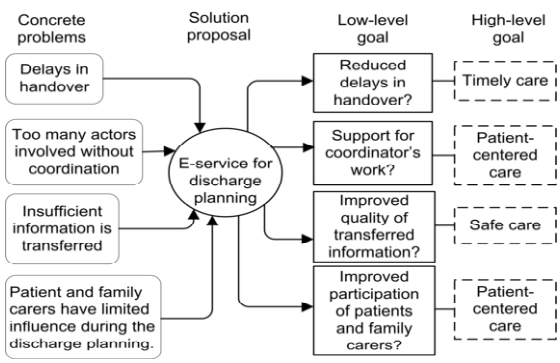

Figure 3 – Solution proposal

Results

We consider the application of this five step approach as useful for analyzing complex processes in multi-actor environments and specifically for elucidating the entire process between the operational, tactical and strategic level.

More specifically, we found the following advantages. Although some problems were previously known, others were first discovered and made explicit during the process modeling and analysis. Use of the process aspects was very useful to classify the problems and also when concretizing the problems further. As the low-level goals are defined based on the classified problems, they are process-related and concrete enough to be defined in a measurable form, In turn, high-level goals are difficult to measure but as they are connected to low-level goals, their impact on specific problems can be shown and it is possible to evaluate the impact on a strategic level. The mapping from low-level goals into high-level goals is not always a straight-forward process. However, the mapping is made simpler if the high-level goals are well defined, or even broken down into sub-goals. Likewise, the mapping is made easier if the low-level goals are not too wide; in the approach presented here this is ensured by using the four process aspect framework to break down the problems. In addition, the defined low-level goals will be further useful when evaluating the impact of the e-service. Considering several different concrete problems, low-level and high-level goals can improve the design of the e-service such that it gets the ability to tackle several problems in the complex care process. Moreover, during the detailed solution design, design decisions can be made and, sometimes more importantly, motivated based on the desire to reach the high-level goals associated with the solution.

Discussion and future work

Implementation of health information systems (HIS) will only be successful if decision-making processes at strategic, tactical and operational levels can be matched [16]. This is especially true for HIS that should support patient-centered care as they usually need to support both multiple actors and multiple organizations. The approach presented in this paper is a first step towards matching different levels by connecting problems in existing processes with high- and low-level goals as well as supporting e-services.

In the VIPPA-project, the entire stroke care process was modeled; from primary prevention, acute and continued hospital care, rehabilitation, discharge to primary care/homecare and finally secondary prevention activities. A holistic view of the process enabled us to identify problems relating to for example continuity of care and patient-centeredness that could otherwise have been overseen. The process involves a large number of different stakeholders, and we also aimed at analyzing the process from their different perspectives in order to capture all potential problems and their respective goals.

The goals described here need to be broken down further and be related to each other in order to evaluate potentially conflicting goals. Similarly, problems and possible solutions need

to be fine-grained and mapped to each other. In addition, their impact on the redesign of existing processes has to be analyzed. In order to be able to better understand all these relationships, we aim for visualizing selected scenarios out of the whole process. As a next step we will visualize a scenario as is in current care processes, then discuss possible sub-solutions for each identified problem, relate these to identified goals and visualize how implementation of these solutions would meet these goals and change current care processes.

Conclusion

In this paper, focus was on analyzing problems in existing healthcare processes, in order to solve them in alignment with strategic goals, as established in a certain healthcare community. Using a process modeling approach, we classified problems into four categories: behavioral/time, functional/activity, informational and organizational. This approach is used to aid domain experts when identifying problems in current processes. Once identified and classified problems are transformed to process-related goals, which aim to improve the functional, organizational aspects of processes. Those process goals are further examined for a relation with a set of well-established, high-level goals to justify requests for their realizations. A way to realize the goals implies the design of adequate solutions, for example in the form of e-services.

In conclusion, the approach presented in this paper enables analysis of high- and low-level goals in a healthcare process by relating these to identified problems in the process. The results thereof can be used as a basis for decision making and redefinition of current care processes, as well as for design of e-health solutions to support the re-designed processes.

Acknowledgments

The project VIPPA is supported by VINNOVA – Swedish Agency for Innovation Systems. We also thank all stakeholders involved in the stroke care case.

Abstract

This paper describes a combined evaluation approach for an information system on intensive care units. Staff self assessment of time needed for documentation activities during admission, daily treatment and discharge/transfer has been compared to a workflow analysis which demonstrated that the system eliminated process steps mainly in daily documentation activities. Interestingly, nursing staff reported major time savings rather during discharge/transfer than in daily documentation, whereas physicians noticed no time savings at all. We conclude that combining workflow analysis with either self assessment of time needed or alternatively appropriate time measurements or both increases insight into organizational changes and their implications after system implementation.

Keywords:

Evaluation, Workflow, Patient data management system.

Introduction

Implementation of a clinical information system does not only concern technical issues but is driven by operational, strategic, cultural or even political changes in the respective organization where the system is introduced. System failures can often be blamed on insufficient change management [1,2]. Berg even stated that implementation of a patient care information system can never be fully planned and controlled due to ongoing organizational changes in a process of mutual transformation [3].

Numerous evaluation studies found improvements after implementation of an information system but others couldn't confirm these findings (see e.g. [4,5,6,7,8] with focus on intensive care environments). Some studies demonstrated an impairment of communication and organization issues, with the potential of system failure or even endangering of patients [9,10].

With regard to Patient Data Management Systems (PDMS) for Intensive Care Units (ICU) there are few studies comparing modifications e.g. in organization and workflows before and after implementation of an information system. We found several studies [11,12,13] dealing with the development of new types of role- and activity-dependent respectively cognitive workflow models. Only Cheng et al [14] compare workflows before and after implementation of a CPOE system on ICU.

With the implementation of a PDMS in one ICU of Erlangen University Hospital we expected improvements in all areas where data could be reused, e.g. reuse of ADT data and automated data transfer from patient monitoring and respirators. We expected more work in all areas where previous paper documentation had now to be done tediously on computer.

The objective of this study was to analyze how our expectations would be met, which activities in the documentation workflow did change and how these workflow alterations correspond to time needed for clinical documentation.

Materials and Methods

The study took place between October 2006 and October 2007 in the Interdisciplinary Operative ICU (IOI) of Erlangen University Hospital, Germany. The IOI has 25 beds and cares for approximately 2000 patients respectively 6800 patient-days per year. In October and November 2006 a commercial PDMS (Dräger ICM) was stepwise introduced. It was fully operational for all 25 beds in December 2006.

A multifocus evaluation study consisting of time measurements, questionnaires and documentation workflow analysis was performed before and after system introduction. The questionnaire was distributed 3 times, namely before (t1), 3 months after (t2) and 12 months after implementation of the PDMS (t3). Among others it included a self assessment of time needed for different documentation activities. The questionnaire described decisively which activities should be assessed (e.g. all documentation activities around admission of a patient) giving explicit examples for physicians, nurses and clerks respectively. We asked to quote the total time needed to perform those activities for one single patient during one shift within the interval options less than 10 minutes, 10-19 minutes, 20 to 29 minutes, 30 to 39 minutes, 40 to 49 minutes and more (with the option to enter a precise number). From the returned questionnaires we calculated a mean value of time spent.

We analyzed documentation workflows before and after implementation of the PDMS and documented them using the software Aris® from ids Scheer. Workflow analysis was performed in two steps. In the first phase one person observed the activities and documented them over several weeks. The same person collected information on all kind of paperwork done on the ICU and the computer systems which were employed before PDMS implementation. This resulted in a first set of pre-PDMS workflow models. In the second phase those models have been reviewed and rectified together with staff members (physicians, nurses, medical clerks) of the ICU. A second similar analysis was performed 3 months after PDMS implementation.

For workflow analysis we used the method described by Pomberger/Gerken [15,16] which usually comprises seven steps:

1. *Analysis of structure.* Comprises organizational structures / hierarchies, number and qualification of staff and relationships to other divisions of the corporation.
2. *Analysis of forms and paperwork.* Systematic collection and analysis of all forms and paperwork with a formal description for each form and its workflow.
3. *Analysis of data items.* Systematic collection and analysis of all data items and information systems in which those data are applied or produced.
4. *Analysis of atomic actions.* Systematic collection and analysis of all process steps which are not further decomposed. For each process step responsible person, forms used and data required are recorded.
5. *Analysis of workflows.* Systematic collection of all complex action sequences based on the process steps analyzed in the previous stage.
6. *Analysis of communication structures.* Systematic definition of a communication matrix, illustrating all communication processes and information flows between different partners based on the first 5 analysis steps
7. *Analysis of weak points.* The identification of weak points aims at providing the basis for future optimization.

For the current project we restricted this analysis to Step 1 to 5 focusing on documentation workflows. Activities of nursing or medical care were omitted.

Workflow diagrams were arranged according to the Aris model [17] with a four level depth of hyperlinked workflows. We used value-added-chain models on level one and two, process-matrix models on level three and event-driven-process-chain models on level four. From these resources we synthesized parallel workflow diagrams in order to compare the status before and after PDMS implementation.

Results

Self assessment of documentation time

Nurses returned 42 of 92 (t1), 29 of 96 (t2) and 23 of 97 (t3) questionnaires. Physicians returned 11 of 15 (t1), 9 of 16 (t2) and 12 of 18 (t3) questionnaires. The average response rate was relatively low with 33% for nurses and 65% for physicians.

Figures 1 and 2 demonstrate the results of time estimations. While physicians did not estimate any relevant time savings for any of the activities such as admission, daily activities and patient transfer/discharge, nurses reported a continuously decreasing time spent for daily documentation activities (down from a mean of 41 at t1 to 31 minutes at t3) and a quickly decreasing time spent for documentation activities around patient discharge (down from 37 minutes to 11 respectively 13 minutes at t2 and t3).

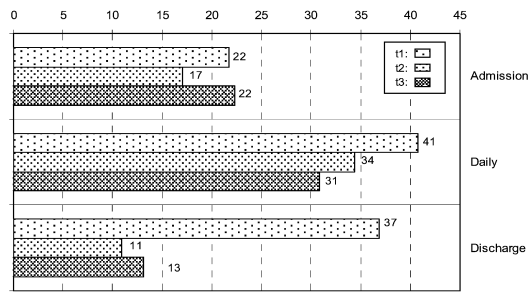

Figure 1- Nurses: estimated time needed in one shift for documenting one patient at t1, t2 and t3 (minutes)

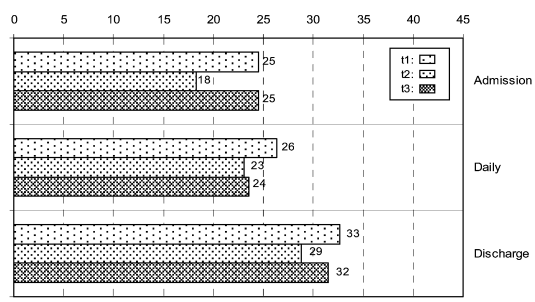

Figure 2-Physicians: estimated time needed in one shift for documenting one patient at t1, t2 and t3 (minutes)

Workflow analysis before and after PDMS implementation

We obtained a total of 29 workflow models for administrative activities of ICU staff before and 25 after PDMS implementation. We grouped them under the high level process-chain steps “admission”, “daily activities” and “discharge”. Together

with organizational view and data view models we ended up with a total of 61 diagrams before and after PDMS implementation. From these resources we synthesized 27 parallel workflow diagrams in order to compare the status before and after PDMS implementation. Figures 3 and 4 demonstrate two examples of such parallel workflow diagrams.

As shown in figure 3 nursing documentation activities for a blood gas analysis (a frequent process in an ICU) have been simplified with the implementation of the PDMS. Previous process steps such as printout of results from the BGA machine and sticking those paper results into the patient paper record have been eliminated after PDMS implementation due to automated data transfer, thus simplifying this workflow.

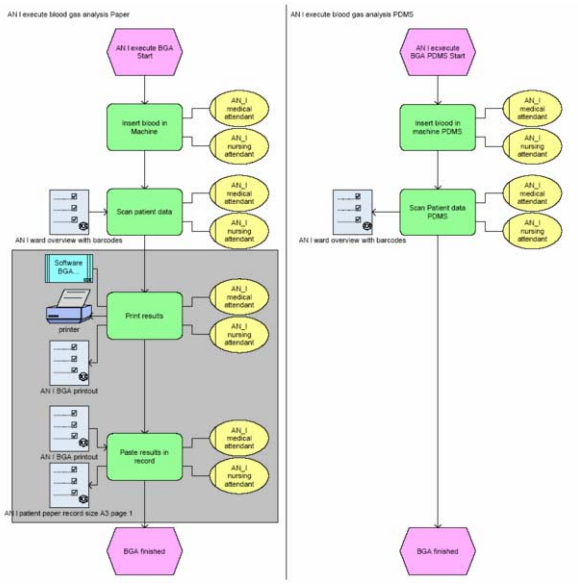

Figure 3- event-driven-process-chain "execute blood gas analysis" and related documentation steps. Left before, right after PDMS implementation

We also found workflows which have been extended. Figure 4 may serve as an example illustrating administrative process steps for admission of a new patient to the ICU.

In the former paper-based workflow the patient arrives on the ward with an empty paper record or the latest available paper record in case of previous admission. No further process steps were required. After PDMS implementation however a new electronic record had to be created for each patient upon arrival in order to start the clinical documentation. Creation of this electronic record comprises working in two software applications. In the generic hospital information system a short electronic admission procedure for the patient and the creation of a new follow-up case is necessary. In the PDMS the new patient case information must be imported and a bed must be assigned. In addition a third specialized ICU software application was used to collect essential reimbursement data. Later this last process step could be performed using new enhanced functionalities of the PDMS thus substituting this activity.

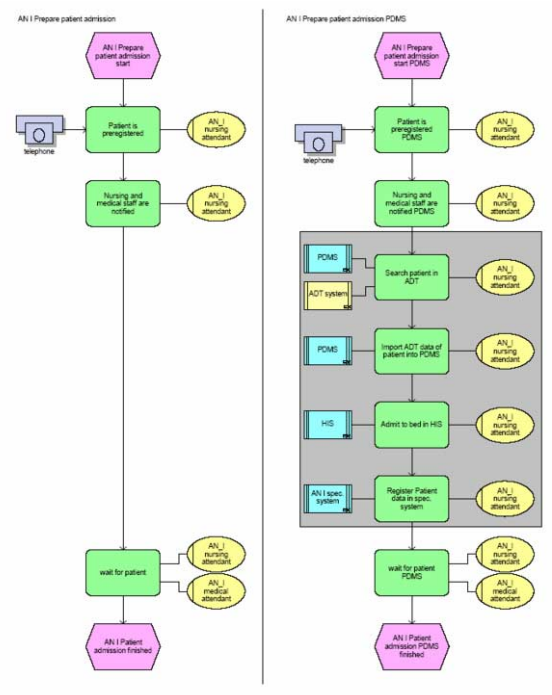

Figure 4 - event-driven-process-chain" prepare patient admission". Left before, right after PDMS implementation

The 27 parallel workflows can be divided into 5 workflows concerning "patient admission", 16 workflows for "daily activities" and 5 workflows concerning patient "discharge or transfer". A top level workflow links these three groups together. Summarizing we detected a multitude of workflow alterations within the 27 parallel workflows.

Eighteen workflows were found to be at least one process step shorter after PDMS implementation, six were of equal length and three workflows had grown considerably (table 1). We noticed shorter workflows in fields such as automated data import from medical equipment (see figure 3), but also in areas where documents could be composed semi-automatically with the help of the PDMS, e.g. during patient discharge and preparation of the discharge documentation. An increased number of process steps was found in the workflows "closing patient record" and "synchronizing PDMS data with HIS".

It is interesting to note that the largest reduction of process steps was found in the group "daily activities" (with three level 3 process steps eliminated). We saw a small respectively non existent reduction of process steps in the groups "admission" and "discharge/transfer".

Table 1 – rows 1-4: No. of workflows in the groups "patient admission"," daily activities" and "patient discharge / transfer" before and after PDMS implementation. Rows 5-6: Number of eliminated process steps in these workflows. Note that the total No. of workflows mentioned in the text (27) includes a top level linkage workflow which remained unaltered and is not considered here.

	Admission	Daily Activities	Discharge
1. Total No. of workflows	5	16	5
2. Workflows shorter with PDMS	2	13	3
3. No change in workflow length	2	2	1
4. Workflows longer with PDMS	1	1	1
5. Total No. of eliminated process steps	-1	16	0
6. No. of eliminated process steps level 3	1	3	0

This is in sharp contrast to the self estimation of nurses and physicians. Physicians reported no time savings at all whereas nurses reported considerable time savings during discharge activities which is not reflected in the actual workflows. Only the time savings in daily nursing documentation fit to a reduction of process steps in the respective workflows.

Discussion

Methods

Self assessment of time spent for documentation has been reported in other studies (see e.g. [18]). Compared to other available methods such as time motion studies, or workflow sampling its results are prone to subjective opinion, may reflect individual convenience and could be influenced by effects such as Hawthorne effect. In addition, predefined answering options may influence the results. Therefore we used intervals of equal length up to 50 minutes plus an option for precise numbers to minimize this effect.

Other time measurement methods require appropriate consent of the observed staff and enough observers to perform them. Another problem for exact time measurements is that we didn't know exactly what to measure before the second workflow analysis was finished. Thereafter a "before" measurement was no longer possible. Within the study we took some objective time measurements before and after system implementation, but the measured activities did not correspond well to the workflows. There are methodical limitations to measure e.g. the time spent for documenting for one patient one day or shift, because these are disruptive activities and clinical staff tends to combine documentation activities for several patients at a time.

We found only four studies dealing with workflow analysis in intensive care environment [11-14]. Just one study had a comparative approach [14]. Workflow analysis has gained impact in the area of hospital information systems and more specifically to improve workflows in radiology departments (see e.g. [18]). We are not aware of any study in ICU where workflow changes have been contrasted with time measurements or self assessment of time spent for activities. A potential problem of workflow modelling is the method used and the depth of process decomposition. We used a well described method for business workflow modelling [17] but nevertheless considerable degrees of freedom e.g. regarding depth of decomposition remain. Therefore it can be difficult to compare workflow models between institutions.

Results

Self estimations showed a reduction in nursing documentation time for daily activities and discharge whereas physicians did not report relevant time savings after PDMS implementation. This seems strange because the PDMS supports automated scoring of ICU patients and automated compiling of discharge summaries which otherwise consumes much time [20]. As a potential reason (apart from possible Hawthorne effect which should affect nurses and physicians likewise) we assume that fluctuation of medical staff, which was much higher than of nursing staff may have led to a situation where physicians at t2 and t3 had not been in contact with the previous paper based documentation. Altogether only 2 physicians completed all three questionnaires compared to 9 nurses. The majority of nurses had worked more than 4 years on this ICU, the majority of physicians less than 1 year. Both findings support this assumption. An objective time measurement should not be influenced by fluctuation, but self assessment of time spent for activities may well be dependent of the fact that the person noticed an improvement after PDMS implementation. Alternatively, the disjunct time intervals of self assessment (10 minutes) may have been longer than the potential time savings noticed by physicians.

We found a reduction of process steps in the "daily activities" workflows. Workflows during "admission" and "discharge" showed nearly the same total number of process steps before and after PDMS implementation. As mentioned previously, we expected improvements in those areas where data could be recorded once and then be reused. Typically, this would be the case e.g. in "daily" documentation of vital signs (automated data transfer from patient monitor), but also in activities around "discharge/transfer", where the PDMS helps to compile all previously recorded relevant information into one or several discharge documents. Obviously this is not reflected in a reduction of the total number of process steps. There, an analysis of time spent for "identical" process steps before and after system implementation would be conclusive. Again, the granularity of process steps (see methods discussion) may have influence not only on the total number of process steps but also on the differential count before and after PDMS implementation. Future work (the PDMS is in rollout to other ICUs as well) will concentrate on those findings and implement specific time measurements for such process steps.

Self assessment of time reduction reported by nurses did only partially correspond to a reduced number of process steps ("daily activities" group), but not in the "discharge" group. At this point a look into [14] is interesting. In this study dealing with a CPOE system the authors conclude that workflows in reality do not reflect workflow assumptions made during CPOE system design.

Methods such as direct time measurements or extensive work sampling studies to evaluate time savings after implementation of an information system have not always been conclusive [7,8]. In some cases time spent for indirect patient care tasks such as charting has been decreased, in others no change was found or even more time was required. Therefore we recommend to add the method of workflow analysis in order to pinpoint changes in workflow which can then be measured and validated much more specifically than before.

Conclusion

Considering our knowledge about change management and its influence upon success or failure of introduction of information systems it seems worthwhile to include pre/post workflow analysis into the toolbox for system evaluation in order to gain insight into the nature of inflicted changes. Results of this method can be used directly but will be even more valuable in conjunction with other evaluation methods such as time measurements, time estimates, subjectivist interview techniques, user satisfaction surveys etc. In addition, workflow analysis can play a formative role in system development and help to find weak spots in workflow. Its results may generate the base for an objectivist study which strives to deliver summative results. For comparison between different institutions it will be desirable to standardize the methods of workflow analysis and workflow modelling to achieve comparable workflow models.

Abstract

In this paper an evaluation of methods determining the bolus arrival time (BAT) using a four-dimensional flow phantom to simulate 4D MR angiography is presented. Spatiotemporal 4D MRA images were acquired for analyzing the hemodynamic characteristics of cerebral vessel anomalies. Model-independent and model-dependent methods for BAT extraction are published. Generally, for the evaluation no gold standard exists and datasets with known BAT values are required. Here, a 4D flow phantom is generated based on a synthetic 3D MRA dataset with BAT values defining the time point of blood inflow for each voxel. Then, voxel-by-voxel concentration-time curves based on the gamma-variate function were computed leading to a simulated 4D MRA dataset. Additionally, partial volume effects and Gaussian noise were integrated. The simulated 4D MRA was visually inspected and regarded as similar to clinical data. Finally, phantom datasets with different vessel diameter and signal-to-noise ratio are computed. Three state-of-the-art methods were used to extract BAT values. Computed and known values were compared. The results suggest that model-dependent approaches perform better than the model-independent method.

Hemodynamics, Blood flow, Vascular desease, Phantoms, Imaging

Introduction

Cerebral vascular diseases like aneurysms or arteriovenous malformations are one of the major causes of death worldwide [1]. For an improved rating of the disease and therapy planning detailed knowledge about the individual vessel anatomy and hemodynamic situation is needed [2].

Generally, imaging techniques like 3D computer tomography (CT) or digital subtraction angiography (DSA) are clinical standard for the analysis of the hemodynamics. Unfortunately, those techniques are based on ionizing radiation. Furthermore Warnock et al. [3] reported that the DSA as an invasive procedure has a complication rate of approx. 3.8% and supplies only 2D projections of the vessel system. Recently, new parallel MR image acquisition techniques enables the time resolved 4D MRA imaging of the blood flow. In clinical practice these spatiotemporal 4D MRA images were acquired for the qualitative and quantitative analysis of hemodynamic characteristics of cerebral vessel anomalies like arteriovenous malformations (AVMs) or aneurism. Figure 1 shows an image sequence of a 4D TREAT MRA dataset from a patient with AVM.

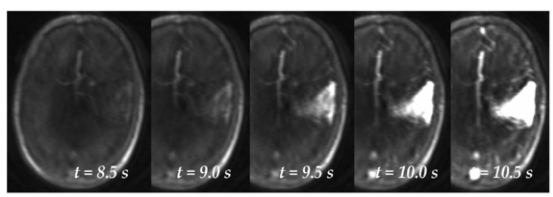

Figure 1- Temporal image sequence of a 4D TREAT MRA

Detailed evaluation of the arterial inflow and venous drainage of AVMs is important for clinical evaluation and management [4,16]. A lot of research has been done on simulation and determination of the cerebral blood flow. In 3D datasets often computational fluid dynamics (CFD) [5] were used to simulate the blood flow. Unfortunately, these approaches are computational expensive and due to acquisition time requirements the vascular system is often not completely covered by the resulting images [8].

In 4D image sequences BAT values can be determined by analyzing the concentration time curves after bolus-injection [6,7]. Here, the tracking of the signal changes provided by an injected bolus of contrast agent travelling through the vessels is used for further analysis. The focus of this work is the evaluation of methods that extract hemodynamic characteristics based on the concentration-time curves of 4D MRA.

State-of-the-art Methods for Determination of Bolus Arrival Time in 4D MRA Image Sequences

The number of publications dealing with determination of the bolus arrival time in 4D MRA is high [8]. Commonly used

approaches for analysis of concentration-time curves can be classified as model-independent or model-dependent.

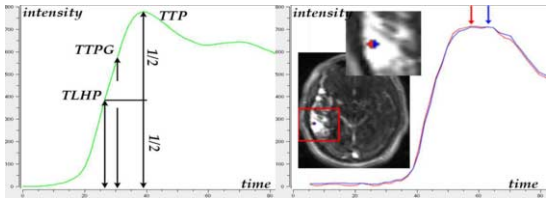

Figure 2- Concentration-time curve with criteria TTP, TTPG and TLHP (left) and the unexpected time difference of two neighbouring vessel voxels using TTP as BAT (right)

Model-independent approaches estimate the BAT directly based on the concentration-time curve. Therefore several criteria have been proposed e.g. time to peak (TTP), time to peak gradient (TTPG) or time of leading half-peak (TLHP) [9]. The major drawback of the model independent criteria is the fixed discrete BAT estimation which depends on the temporal resolution of the used data. Furthermore, it has been reported that due to noise and artefacts e.g. interpolation during the image acquisition these parameters lead to insufficient results, in terms of strong temporal differences between the bolus arrival times of neighbouring voxels [10]. Figure 2 shows the proposed criteria TTP, TTPG and TLHP (left) and the concentration-time curves of two vessel voxels and their temporal difference using TTP as BAT (right).

One *model-dependent* approach is the BAT estimation based on the fit of a gamma variate function

$$C(t) = K(t - AT)^{\alpha} e^{-(t-AT)/\beta} \qquad (1)$$

to the concentration-time curve [10,11]. Eq. 1 is valid for t > AT where t is the independent variable, AT the appearance time, K the constant scale factor and α and β are arbitrary parameters describing the shape. After fitting the gamma variate function to the concentration-time curve the BAT value is determined by extracting one criterion e.g. TTP, TTPG or TLHP of the fitted gamma variate function. Due to the mathematical properties of this function the extracted BAT value is not constrained by the temporal resolution of the given 4D MRA dataset. Unfortunately, the gamma variate fitting can lead to unsatisfying results when applied to concentration-time curves resulting from a rapid injection of a small bolus like in 4D TREAT MRA [12]. Additionally, due to the blood recirculation the realistic concentration-time curves do usually not only consist of the first pass bolus but do also show following bolus passages. So, the concentration-time curve is not as steep as the assumed hypothetical exponential decay [13].

Another *model-dependent* approach was published by Forkert et al. [8]. Here, a patient-individual reverence curve $r(t)$ is generated based on a collection of present concentration-time curves $s_i(t)$. Based on $r(t)$ one criterion is e.g. TTP, TTPG or TLHP is used to define the BAT. Estimating a linear transformation $f(x) = Ax + B$ the concentration-time curves of all vessel voxels were fitted to the reference curve such as $r(t) \approx s_j(f(t))$. The estimated fitting parameter A and B can be used to adapt the extracted criterion to determine the BAT value for the signal curve.

In order to assess the accuracy and precision of the presented methods different approaches were used. In general a qualitative evaluation was done by obtaining clinical datasets from normal volunteers. The results were compared with predicted values based on physiological and anatomical findings [6]. Additionally, series of Monte Carlo simulations were performed using realistic synthetic concentration-time curves with known parameters and covering a range of signal-to-noise ratios (SNR) [14]. As a drawback most studies focused only on the determination of the cerebral blood volume. Also the impact of selecting the optimal criteria, e.g. TTP, TTPG or TLHP for BAT estimation was not investigated.

Aim of this Work

In this paper we evaluate the aforementioned three state-of-the-art approaches with three different BAT criteria and three different pre-processing approaches for determining BAT values in 4D MRA concerning quality and robustness. Therefore, we generate a four-dimensional flow phantom to simulate 4D MRA using an extended version of the established gamma variate function. The quality is assessed by calculating and analyzing the differences between synthetic and extracted BAT values. For the robustness the chosen methods are applied to phantom datasets with different vessel diameter and varying signal-to-noise ratio (SNR). Additionally, we evaluate the optimum criteria for BAT determination.

Materials and Methods

Generation of a 4D MRA Flow Phantom

For generation of a synthetic 4D MRA flow phantom the following steps are applied.

- Extraction of realistic geometric vessel structures based on clinical three-dimensional time-of-flight MRA (3D TOF MRA).
- Generation of a synthetic 3D MRA dataset and definition of bolus-arrival-time for each vessel voxel.
- Simulation of 4D MRA datasets based on the gamma variate function considering the partial volume effects (PVE) and the signal-to-noise ratio (SNR)

These steps are described in detail in the following.

Extraction of Realistic Geometric Vessel Structures

Providing realistic geometric vessel structures a vessel system was segmented based on clinical 3D TOF MRA and a 3D model of a part of the system was generated. Then, a centerline was computed and the vessel bifurcations as well as the endpoints of the branches were detected and organized in a network. The geometrical characteristics of the bifurcations of the 3D vessel model are represented in this network by a parameter set including the position and the diameter. Based on

this information tube structures are used to build a synthetic representation of the original vessel structure. The parameter set e.g. the diameter value for each bifurcation can be adjusted for further evaluation.

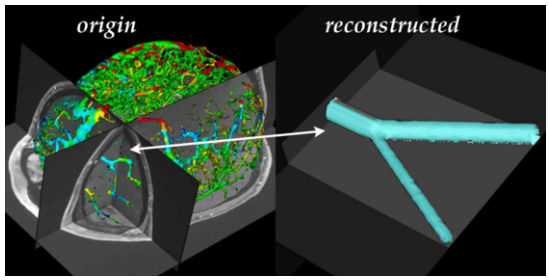

Figure 3- 3D surface model of the original (left) and the reconstructed geometric structure of the vessels (right)

Generation of the 3D MRA and BAT

The generation of a 4D MRA flow phantom dataset requires the definition of bolus arrival times. Therefore, the parameter set was extended by a new BAT entry. Then, the synthetic 3D vessel representation was transferred to a 3D image dataset with high spatial resolution. The image extents and voxels size as well as the intensity values for the vessels, brain structures and background were chosen based on clinical 3D TOF MRA. Additionally, a BAT value was computed for each vessel voxel. Here, a linear interpolation of the BAT of the neighboring bifurcation or end points is used. Figure 3 shows the 3D surface model of the original (left) and the reconstructed geometric structure of the vessels with different diameter (right).

Simulation of 4D MRA

The simulation of spatiotemporal 4D MRA image sequences based on a synthetic 3D MRA dataset requires the simulation of concentration-time curves for each vessel voxel. Therefore, the established gamma variate function (1) is used with $\alpha = 3.0$ and $\beta = 1.5$ regarding to the values published by Chen et al. [15]. In order to address the effect of recirculation of the contrast agent bolus the final concentration-time curve is computed by adding two gamma variate functions with different scaling factors $K_1 = 400$ and $K_2 = 80$ as well as different appearance time points $AT_1 = BAT$ and $AT_2 = BAT + \partial t$ with $\partial t = 8$ frames. Figure 4 shows a clinical concentration-time curve with a fitted gamma variate function (left) as well as a generated signal curve $C(t)$ (right).

Then, a temporal sequence of 3D MRA images is generated where the intensity of each vessel voxel V at time point t_i with $i = 0 \ldots n$ are defined by its concentration-time curve $C_V(t_i)$ leading to a 4D MRA with high spatial resolution.

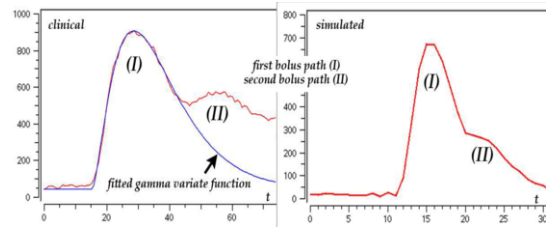

Figure 4- A clinical concentration-time curve with a fitted gamma variate function (left) as well as a generated concentration-time curve (right).

The acquisition of clinical 4D MRA datasets has a tradeoff between temporal and spatial resolution. To improve the temporal resolution the spatial resolution is decreased leading to a partial volume effect (PVE) that can have a significant impact on the accuracy of blood flow measurement [15]. To get realistic synthetic datasets the PVE is simulated be reducing the spatial resolution of the generated 4D MRA as described in [15]. Finally, Gaussian noise with different standard derivation σ is added to simulate the variance of SNR in clinical datasets.

Evaluation Procedure

4D MRA Phantom Datasets

Firstly, the quality of the generated 4D MRA was rated. Therefore, the synthetic image data was visually inspected and compared to clinical image data by two medical experts with experience in 4D MRA image analysis. Related to the clinical datasets the voxel size of the phantom was computed using a spatial resolution of 0.47×0.47×0.5 mm^3 for 3D MRA and 1.88×1.88×4.0 mm^3 with 50 time frames for 4D MRA.

Secondly, different 4D MRA datasets for the evaluation of the BAT determination were generated, one dataset representing four vessels without bifurcation but different diameters (d = 0.5, 1.0, 2.0 mm) to evaluate the robustness concerning vessel thickness and image artifacts e.g. noise. Another dataset was generated representing a part of a vessel system with one bifurcation and different BAT values for each draining vessel to evaluate the quality concerning different flow characteristics.

Also, each dataset is generated with different signal-to-noise ratio (SNR = 5, 10, 20) to evaluate the quality concerning different noise levels. This leads to 20 synthetic 4D MRA datasets for the evaluation process.

Image Pre-Processing

The model-independent and the model-dependent methods were used to compute the BAT values based on the raw concentration-time curves derived from the generated 4D MRA phantom datasets. Furthermore, since concentration time curves are usually affected by noise and other artifacts, the BAT values were also extracted based on B-Spline approximated (degree of 4) and binomial smoothed (1-4-6-4-1) signal curves in order to investigate whether smoothing is useful to improve robustness.

Similarity Measurement

For quantitative evaluation a regression analysis of the extracted and the defined BAT values of all vessel voxels is computed. Here, the correlation coefficient R^2 is used to quantify goodness of the fit. Whereas, a R^2 value near to one indicates a good fit.

For qualitative evaluation the 3D visualization was used. Here, the extracted BAT values are mapped color-coded on the 3D surface model of the vessel system. Due to the fact that the BAT values in between the bifurcations and endpoints are linear interpolated the color gradient should be homogeneous in case of optimal BAT determination.

Results

Quality of 4D MRA Flow Phantom

The generated 4D MRA image sequences were visually inspected by two medical experts. Therefore, 4D TREAT MRA datasets acquired on a 1.5T MR scanner with SNR between 10 and 25 of 20 patients with known AVM are used to compare. Figure 5 shows the comparison of clinical and simulated 3D and 4D MRA images (left) and the color-coded BAT values (right). The images with SNR = 10 were rated as most similar to the clinical one.

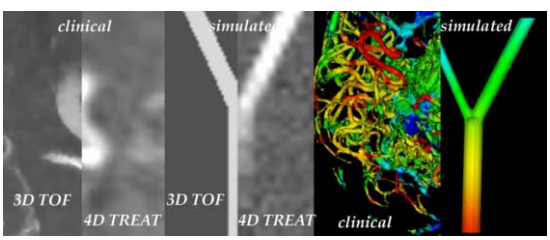

Figure 5- Comparison of clinical and simulated MRA images (left) and its color- coded BAT values (right).

Comparison of the Methods

For comparison of the model-independent (MI), gamma variate fit (GV) and reference based curve fitting (RCF) approaches with three different BAT criteria and three different pre-processing approaches were used to extract BAT values based on the simulated datasets with bifurcation. Table 1 shows the results of the regression analysis (R^2) using different criteria based on the phantom dataset with SNR = 10.

Table 1 – R^2 values for the BAT determination using different criteria (TTP = 1, TTPG = 2, TLHP = 3) computed based on a phantom dataset with SNR = 10.

	MI			GV			RCF		
	1	2	3	1	2	3	1	2	3
RAW	.985	.960	.967	.932	.971	.986	.991	.981	.987
BIN	.970	.970	.977	.975	.968	.978	.977	.980	.979
SPL	.986	.962	.966	.949	.970	.969	.987	.970	.987

Figure 6 shows the regression analysis of MI, GV and RCF using the THLP criteria and the RAW pre-processing (left). The model-independent approach depends on the discrete time points which leads to a step function line representation of the BAT times (R^2 = 0.967). The results in Figure 6 (right) show that the model-dependent methods have the best fit. Generally, the combination of reference-based curve-fitting, RAW pre-processing and the TLHP or TTP criterion leads to the highest accuracy.

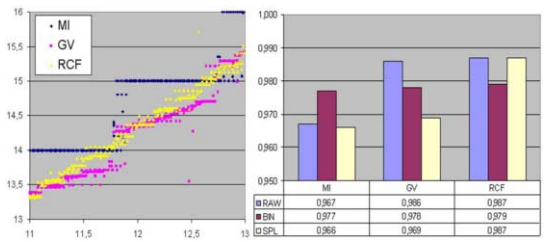

Figure 6- Regression analysis of MI, GV and RCF using the THLP criteria based on the RAW signal curves (left) and the calculated R^2 values for the approaches using THLP (right).

Influence of SNR

For evaluation of the influence of SNR the simulated datasets with tubes generated with different diameters and disturbed by Gaussian noise were used. Figure 7 shows the R^2 values of the regression analysis for MI, GV and RCF using THLP based on a tube structure with d = 1mm. The results show the quality and the robustness of the RCF approach concerning image artifacts in comparison to the other approaches. For SNR = 5 and d > 2 mm the R^2 values of all methods get similar. But, with vessel structures of d = 0.5 mm the value for the MI approach decreased to 0.929 (GV = 0.996 and RCF = 0.998).

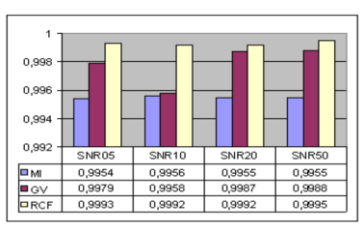

Figure 7- R^2 values of the regression analysis for MI, GV and RCF using THLP based on a tube structure with d = 1mm.

Discussion

We have evaluated three methods for BAT determination based on a 4D MRA flow phantom. Based on the gamma variate function for each vessel voxel a realistic concentration-time curve including the recirculation effect was generated. In a post-process these curves were disturbed by Gaussian noise

and partial volume simulation. The synthetic 4D MRA datasets were rated as similar to clinical 4D MRA by two medical experts.

For the evaluation process a number of 4D MRA datasets were generated with varying parameters like SNR or vessel diameter. The voxel-by-voxel definition of the BAT values enables the validation of BAT determination methods concerning robustness and accuracy. Three state-of-the-art approaches with different BAT criteria and different pre-processing were evaluated based on the 4D flow phantom. The results show that the model-dependent methods have the best potential for extraction of hemodynamic characteristics. In particular the reference-based curve-fitting obtains the most accurate results.

Due to the fact that the gamma variate function is used to generate the concentration time curves the best result was expected to be based on the GV approach. Nevertheless, the simulation of the second bolus and the image artifacts leads to a realistic modified signal curve enabling the evaluation of different methods for BAT determination.

In future the accuracy of the 4D flow phantom concerning physiological aspects should be improved by integrating e.g. poiseuille flow conditions to simulate the dispersion of a bolus during a flow down a tube. Furthermore, the recirculation process should be extended by varying the peak of first and second bolus regarding to the vessel diameter. For the evaluation process more parameters describing hemodynamic characteristics like cerebral blood volume, cerebral blood flow and mean transit time should be integrated.

Automatic Analysis of the Anatomy of Arteriovenous Malformations using 3D and 4D MRA Image Sequences

Nils Daniel Forkert, Dennis Säring, Heinz Handels

Department of Medical Informatics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Abstract

The cerebral arteriovenous malformation (AVM) is an abnormal connection between arteries and veins without capillaries in between, leading to increased blood pressure which might result in a rupture and acute bleeding. Exact knowledge about the patient's individual anatomy of the AVM is needed for improved therapy planning. This paper describes a method for automatic extraction of the AVM and automatic recognition of its feeders and draining veins and en passage vessels based on 3D and 4D MRA image sequences. After registration of the MRA datasets, the AVM is segmented using a support vector machine based on blood velocity information, a vesselness measure and the bolus arrival time. The extracted hemodynamic information is then used to detect feeders and draining veins of the AVM. The segmentation of the AVM was validated based on manual segmentations for five patient datasets, whereas a mean Dice value of 0.74 was achieved. The presented hemodynamic characterization was able to detect feeders and draining veins with an accuracy of 100%. In summary the presented approach can improve presurgical planning of AVM surgeries.

Keywords:

Intracranial arteriovenous malformations, Magnetic resonance angiography, Computer-assisted image analysis, Anatomy, Blood flow

Introduction

The cerebral arteriovenous malformation (AVM) is a disorder of cerebral vessels, represented by locally missing capillaries between the arterial and venous system [1]. The missing capillaries often lead to changes of the hemodynamic situation and especially increased blood pressure in the draining veins causing dilation, which in approx. 50% of all cases leads to a rupture and following acute bleeding [2].

The aim of AVM therapy is the disconnection of the AVM from the cerebral blood circulation coincided with rupture prevention. The therapy possibilities available include endovascular embolisation, neurosurgical resection, radiosurgery and a combination of these [2]. In any case the detection of the feeding arteries is of major interest. For risk estimation of surgical resections the Spetzler-Martin scale [3] is often used. Here the morphological parameters size and location of the AVM and its drainage patterns are used to classify the patient risk for persistent neurological deficits from neurosurgery according to five grades. Additionally the detection of en passage vessels, which are vascular structures close to the AVM but not directly connected, are important for therapy planning since impairment should be avoided during therapy.

In most cases high resolution CTA or MRA image sequences are acquired to obtain morphological information about the AVM whereas the digital subtraction angiography (DSA) remains the gold standard for evaluation of hemodynamics. Unfortunately DSA is based on ionizing radiation. Furthermore an overall complication rate of 3.89% has been reported by Warnock et al. [4]. The fact that only 2D projections of the vessel system are supplied is another drawback of this technique. Recent development of new MR image acquisition techniques, especially parallel MR and echo sharing, enables the time resolved MRA (4D) imaging of the blood flow with a high temporal resolution close to the DSA but a rather low spatial resolution. The acquisition of 4D imaging might considerably reduce the risk for the patient but due to the high number of acquired images and the complex AVM anatomy the slice wise manual visual inspection for therapy planning is very time consuming and might lead to suboptimal results. A computer based preparation and visualization of image sequences can help the clinicians to obtain improved therapy plans while at the same time reducing the temporal expenses.

Although the arteriovenous malformation is of high interest in neurosurgery and neuroradiology research the number of publications dealing with the computer based analysis is low. For visualization of the AVM Bullitt et al. [5] proposed a combined visualization of surface models of healthy vessels and a representation of the AVM using volume-rendering techniques to enable the visualization of the complicated structure of the AVM. Temporal (dynamic) information of the blood flow is not included. For the estimation of the size and location of the AVM an exact segmentation is needed. For this an approach based on dynamic CT images using factor analysis was proposed by Nyui et al. [6], as a drawback the results have not been quantitative evaluated and also previous knowledge about arterial, venous and noise signals are required.

Materials and Methods

MRA measurements

For development and evaluation of the method proposed 18 datasets of patients with an AVM were available. The MRI measurements were carried out on a 3T Trio scanner (Siemens, Erlangen, Germany) using an 8-channel phased array-head-coil.

New parallel MRA and echo sharing techniques enable the acquisition of 4D TREAT image sequences (time resolved echo-shared MR-angiography technique) after application of contrast agent and is described in detail by Fink et al [7]. These spatio-temporal image datasets serve as the basis for the analysis of the patient individual hemodynamics. The spatial quality of 4D TREAT images with a time resolution of 0.5 s and a voxel size of 1.875 × 1.875 × 5.0 mm^3 is rather low (see Figure 1 b-c).

For this reason the 3D TOF MRA (time-of-ight) image sequence with high spatial resolution (0.469 × 0.469 × 0.5 mm^3) was also acquired. Three-dimensional TOF MR angiography is one of the most commonly used non invasive method for evaluating the intracranial vasculature and offers a superior blood-to-background contrast (see Figure 1a). Therefore a detailed segmentation of the vessel system is possible.

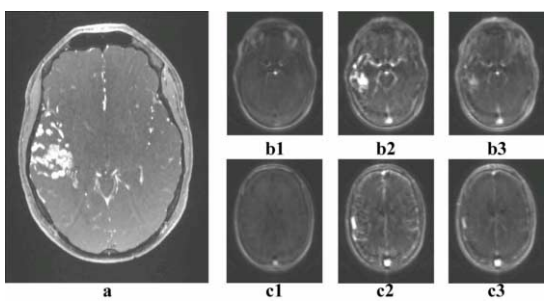

Figure 1 – Slice from TOF image sequence (a), and two slices from TREAT image sequence (b,c) at three different time-points (1-3)

Feature Generation

For segmentation of the AVM nidus several features used for the support vector machine (SVM) classification have to be extracted, which are described in the following.

Computation of the Vesselness Image

Based on the high resolution 3D TOF MRA the multi-scale vesselness filter as proposed by Sato et al. [8] is used to assign every voxel a value based on a vesselness measure based on eigenvalues of the Hessian matrix. This leads to an enhanced display of the vascular structures. Since implicitly the gray value variation of healthy vessels is used in this approach, often malformed vessels are not detected correctly (see Figure 2b).

Segmentation of the Vascular System

The cerebrovascular systems, which serve as the basis for the automatic analysis of the AVM, were automatically segmented for every dataset using an in-house developed fuzzy based method [9]. In this approach vesselness and maximum parameter images are computed first based on the TOF image. These parameter images are then combined with the TOF sequence using a fuzzy inference system. The resulting fuzzy image offers an improved enhancement of small as well as malformed vessels against the remaining brain tissues. Finally, the fuzzy-connectedness approach is used to extract the vascular system (see Figure 2c). Using the Marching Cubes algorithm a surface model of the vascular system can be generated and visualized 3D (see Figure 2d).

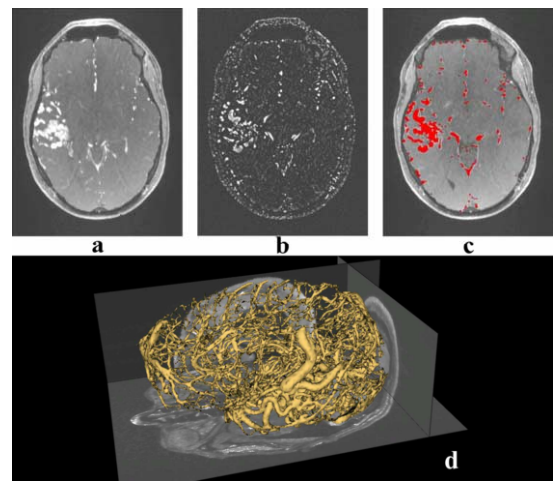

Figure 2 – Slice from TOF image sequence (a), corresponding vesselness image(b), extracted vessel segmentation (c), 3D surface model of the vascular system (d)

Bolus Arrival Time Estimation

The 4D MRA image sequences serve as the basis for the hemodynamic analysis. For every voxel a temporal signal curve representing the concentration of contrast agent at each acquired time point can be extracted from the 4D dataset.

Based on the signal curves several hemodynamic characteristics can be extracted. Whereas the bolus arrival time (BAT) of the concentration time curve is a parameter most important for the assessment of cerebral malformations. For BAT estimation the reference based linear curve fitting as proposed by Forkert et al. [10] was used.

In this approach a patient individual hemodynamic reference curve is extracted from the 4D MRA dataset by fitting and averaging a defined number of signal curves with a standard deviation higher than a given threshold σ. The threshold ensures that only signal curves which exhibit a typical signal process are used for reference curve generation. After computation of the reference curve its reference BAT (rBAT) is es-

timated using the time-to-peak criterion. Then in a following step the reference curve is linearly fitted to each signal curve of the 4D dataset such that the sum of squared differences (SSD) is minimized. Using the parameters obtained by the linear curve fit the reference BAT can be transferred to a target BAT (tBAT) (see Figure 3a).

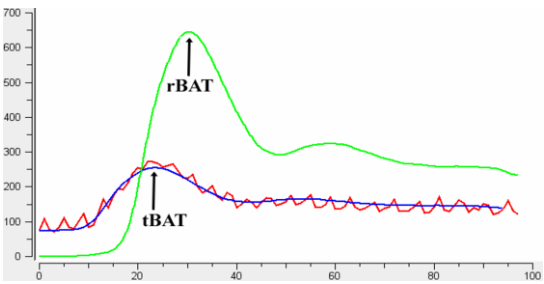

Figure 3 – Example for BAT estimation using reference based linear curve fitting: reference curve (green) signal curve (red) and fitted reference curve (blue)

Registration of 3D and 4D MRA datasets

The combined analysis of information of hemodynamics based on the voxel-wise analysis of the signal curves in the 4D TREAT dataset and anatomical vessel structures in 3D TOF dataset requires the registration of both datasets. For this purpose the method as proposed by Säring et al. [11] was used. In this approach a 3D maximum intensity projection over time (MIPt) is computed based on the 4D TREAT dataset. This projection leads to an advanced representation of the vessel system (see Figure 4a) which is helpful to improve the registration result. In a following step the resolution of the 3D MIPt is adapted to the 3D TOF MRA using a linear resampling. Finally, the transformation field between TOF MRA and MIPt is calculated using a B-spline based 3D-3D registration method with mutual information as similarity measure. The computed transformation field can then be used to transfer the BAT and MIPt datasets into the coordinate system of the 3D TOF image sequence. The transferred BAT values can then also be mapped to the surface model and visulized color coded (see Figure 4b) and dynamically over time using the method described in [12].

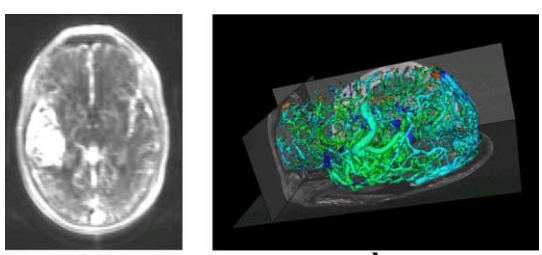

Figure 4 – Slice from the MIPt dataset (a), color coded visualization of the BAT values on the 3D surface model (b)

Support Vector Machine Based Segmentation of the AVM

Assumptions for the Method

The exact segmentation of the AVM is necessary to extract the important parameters size and location of the AVM. Furthermore it is needed for the detection of feeding arteries and draining veins. The method presented in this paper for the segmentation of the AVM is based on three assumptions:

1. The AVM does not exhibit typical vessel morphology. Therefore it can be assumed that the computed vesselness parameter image should exhibit low values for AVM structures while healthy vessels are represented by high values.
2. The missing capillaries of the AVM result in a reduced resistance in the vascular system leading to an increased blood flow velocity and early relative bolus arrival times. Since the intensities of Time-of-Flight image sequences represent the blood flow velocities it is assumed that the AVM is represented by high values in the TOF image. Due to artefacts caused by the TOF image acquisition turbulent or high flow might lead to low output values. Since the MIPt does not suffer from this problem it will be taken into account in the following step too.
3. The AVM is represented by the biggest local cluster of voxels fulfilling the previous assumptions.

These assumptions are used in the method described in the following to extract the AVM from the image sequences available.

Voxel wise Classification using Support Vector Machine

The BAT datasets are not directly comparable due to different injection and acquisition starting times. Therefore normalization of the datasets is required. For this reason the BAT dataset is masked with the vessel segmentation and the mean BAT is computed. Then in a following step the BAT dataset is normalized in terms of calculating relative differences to this mean BAT.

In the last years support vector machines (SVM) increasingly moved into the focus of supervised classification research. The aim of SVMs is to find an optimal separating hyperplane between classes based on training cases which can be used for classification. The optimal hyperplane is defined by the property of leaving the maximum margin between the classes. SVMs have been found to be a powerful recognition method. More detailed descriptions of support vector machines are for example given in [13]. In this study a linear kernel was used for training.

A total of 13 MRA datasets of patients with an arteriovenous malformation have been employed for the training of the SVM. The AVM have been manually defined based on the vessel segmentation by a neuroradiologist. The SVM was then trained voxel-wise using the four features described above, whereas only voxels, part of the vascular system, were considered for this purpose.

After training of the SVM the generated model can be used for voxel-wise classification, whereas the problem of detecting the AVM was formulated as a two-class problem. The output of the classification is a value describing the distance to the optimal hyperplane, whereas positive values represent voxels classified as belonging to the AVM. The SVM is then used to generate a distance map by classifying each voxel based on its exiting features.

After the classification dataset has been generated thresholding at distance zero is performed. Finally largest connected component analysis is used to extract the final AVM volume (see Figure 5).

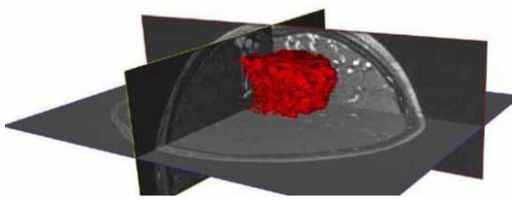

Figure 5 – Example for an automatically extracted AVM

Hemodynamic Characterization

In order to automatically detect feeders and draining veins of the AVM the mean bolus arrival time is computed based on the AVM segmentation. Then for the analysis of the vessels surrounding the AVM the segmentation is dilated. In a first step a connected component analysis is performed, whereas vessels not connected to the AVM are defined as en passage vessels. Then, the AVM segmentation is subtracted from the remaining components and a second connected component analysis is performed. For every extracted component the mean BAT is estimated. If the mean BAT is earlier than the mean BAT of the AVM segmentation the component is defined as a feeder else it is defined as a draining vein. After automatic characterization the different vascular structures can be visualized color coded (see Figure 6) based on the 3D surface model of the vascular system.

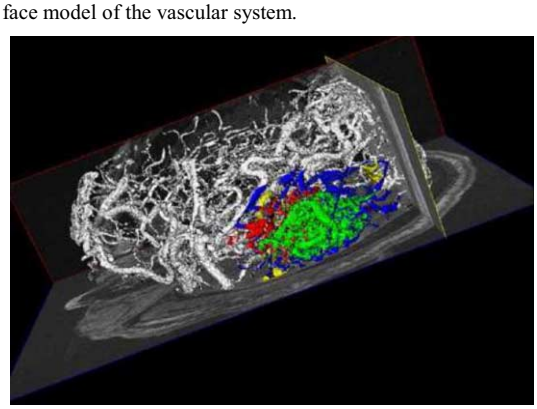

Figure 6 – Example for hemodynamic characterization

Experiments

For evaluation of the method proposed the AVM was defined for all 18 datasets by a neuroradiologist based on the vessel segmentation. 13 datasets (AVM sizes: 0.7 ml – 39.5 ml, Ø 14.1 ml) were used for the training of the support vector machine (approx. 9 mill. samples). The remaining five datasets (AVM sizes: 2 – 32 ml, Ø 13.4 ml) for quantitative evaluation of the results yielded by the AVM segmentation method. For quantitative evaluation of the segmentation results the Dice coefficient D(A,M) was used:

$$D(A,M) = (2|A \cap M|) / (|A| + |M|)$$

whereas A denotes the automatic segmentation and M the manual segmentation. Dice coefficients close to 1.0 denote a good consensus.

For evaluation of the automatic hemodynamic vessel characterization feeder and draining veins were manually defined by a neuroradiologist and compared to the results yielded by the method proposed

Results

Table 1 shows the results from the quantitative evaluation of the AVM segmentation method. A mean Dice coefficient of 0.74 and a projected volume match of 83.6% were achieved. The average time needed for the automatic segmentation procedure took approximately 5 minutes whereas the manual segmentation took between 5 – 35 minutes, depending on the size and complexity of the AVM.

Table 1 - Quantitative results of the AVM segmentation

Dataset	AVM size (in ml)	Segmented AVM size (in ml)	D(A,M)
1	32.83	25.43	0.75
2	16.95	18.99	0.74
3	9.5	11.05	0.85
4	5.71	4.66	0.71
5	3.75	4.48	0.65
Ø	13.39	13.75	0.74

The evaluation of the automatic vessel characterization revealed that feeding arteries and draining veins were detected with an accuracy of 100% for the five datasets analyzed.

Discussion and Conclusion

In this paper an automatic method for the segmentation of the AVM was presented. First quantitative results show that the AVM can be sufficiently extracted from the image data available. Ignoring dataset #3 the results suggest that bigger AVMs are easier to detect than the smaller ones. In order to achieve more significant quantitative results leave-one-out test have to

be performed. More manual segmentations from more observers are necessary in order to be able to make a statement about the inter-observer variability. Additionally it has to be evaluated how the results differ when using other kernels for the SVM, such as polynomial or radial basis function kernels.

The automatic detection and 3D visualization of the feeding arteries, draining veins and en passage vessels was rated to be very helpful for diagnosis therapy planning and can improve the therapy planning in future. Performing the mentioned leaving-one-out tests will lead to more significant results of the vessel characterization. Furthermore it has to be emphasized that the results of the hemodynamic classification rely to a great extent on the extracted vessel segmentation.

The dynamic 3D visualization of the cerebral blood flow can help the clinicians to explore the patient individual blood flow situation (see Figure 7).

A future combination with a functional atlas of the brain might enable an image guided therapy of AVM patients.

Abstract

Content–based visual image access is in the process from a research domain towards real applications. So far, most image retrieval applications have been in one specialized domain such as lung CTs as diagnosis aid or for classification of general images based on anatomic region, modality, and view. This article describes the use of a content–based image retrieval system in connection with the medical image sharing platform MEDTING, so a data set with a very large variety. Similarity retrieval is possible for all cases of the social image sharing platform, so cases can be linked by either visual similarity or similarity in keywords. The visual retrieval search is based on the GIFT (GNU Image Finding Tool). The technology for updating the index with new images added by users employs RSS (Really Simple Syndication) feeds. The ARC (Advanced Resource Connector) middleware is used for the implementation of a web service for similarity retrieval, simplifying the integration of this service. Novelty of this article is the application/integration and image updating strategy. Retrieval methods themselves employ existing techniques that are all open source and can easily be reproduced.

Keywords:
Image retrieval, Medical social web, Visual information retrieval.

Introduction

Images are produced in enormous quantities in all modern hospitals, and they are an essential part of diagnosis and treatment planning [1]. They are also increasingly accessible to non–imaging specialists in hospitals directly through the electronic patient record creating a need for a diagnosis aid based on the images. To better manage the information and extract knowledge from existing cases, new tools are required. Content–based image retrieval (CBIR, [2]) has been proposed in the medical domain several times [3,4]. Still, real use of medical CBIR has been limited to a few examples [5] and most often purely academic tasks such as image classification have been performed [6]. In general, CBIR extracts visual features from the images and then allows for searching visually similar images to one or several examples given, sometimes relevant and irrelevant examples can be given. One of the current problems of image retrieval is the integration of research tools into existing applications such as viewing stations or directly into the patient record. In such an integrated case image retrieval can give access to anonymous and annotated cases from the past (so from the patient record or the literature) to solve a current case. There are of course several hurdles regarding secondary data use to overcome such as legal and ethical questions [7].

The GNU Image Finding Tool used as a visual retrieval engine has an interface for querying and receiving results. The interface language of GIFT is called MRML[1] (Multimedia Retrieval Markup Language) and allows for connecting to a server, choosing databases, parameters for algorithms, and receiving similarity results including identifiers and scores for images. The current implementation has several drawbacks:

• GIFT uses socket–based communication, typically on a port blocked by firewalls.

• MRML is based on XML but its handling is cumbersome and does not follow current standards as it was developed over ten years ago.

In this paper, we present a solution for adding a web service for similarity–based image retrieval with example images that is easy to integrate. The solution follows standards and communicates through port 80, often open in networks for WWW access. A medical Web 2.0 application for sharing case reports (often from radiology) including images integrated this web service to allow for finding similar cases not only based on key words but also on similar images regarding visual similarity. The web portal of MEDTING[2] is commonly used by clinicians and particularly radiologists. For our application, two tasks were implemented:

(1) cumulative indexing of newly added images, and
(2) a web service for finding similar images based on visual similarity.

Cumulative indexing is needed since new images are added daily and need to be integrated into the collection in a simple way. For updating our database MEDTING generates an RSS (Really Simple Syndication) feed containing image URLs (Uniform Resource Locators). A small program reads the feed

[1] http://www.mrml.org/
[2] http://www.medting.com/

daily and indexes any new images. The motivation for a web service is the provision of a simple but flexible interface with WSDL (Web Service Description Language) that is absolutely standard and can be integrated easily in all programming languages.

Materials and Methods

Tools reused

All tools reused for the described implementation are open source and available free of charge, so results can be reproduced easily. The GIFT[3] [8] is an open source tool for visual retrieval in large photo collections. Color plays an important role but GIFT has also been applied for medical image retrieval from collections containing grey–scale images. GIFT employs four groups of visual features for retrieval. Texture features based on Gabor filter responses exist as local features of small blocks and as global features in the form of a global histogram. Color or grey level features in the HSV (Hue, Saturation, Value) color space equally exist as local blocks at various scales and as a global histogram. GIFT uses many techniques from text retrieval such as frequency–based feature weightings and relevance feedback techniques. This creates a fast retrieval of under 0.5 seconds for databases of over 100'000 images on standard desktop computers. MRML is an XML–based query language that allows connecting to a GIFT server.

MEDTING is a social Web 2.0 service allowing clinicians and lecturers to share medical cases including images. Cases can easily be added and annotated via an ontology. Similar cases are proposed to the user when browsing and also comments on particular cases made by other users. The web side allows for a fast navigation including simple image viewing. Started only in 2008, the portal has reached in spring 2009 over 1'800 registered users. Currently, 2'400 clinical cases are stored on the portal with over 20'000 images and over 10'000 accesses per week. Such a scenario requires a stable and fully automatic solution to limit integration work, leaving mainly the possibility to place a button "Show me similar images" next to the images in the interface.

KnowARC[4] (Knowhow sharing with the Advanced Resource Connector) is a project developing a Grid middleware used for computationally expensive tasks in the physics domain but also in medical imaging. One goal of the project is to integrate existing medical applications into clinical real–world applications showing the potential of Grid technologies to make existing research tools faster and more effective. The Grid technologies are mainly used for the offline feature extraction in our case and not for the online querying that is already fast. The ARC [9] middleware of the project offers several tools that are useful, for example to ease the creation of web services.

Database used

The database used in the work described in this article includes all images currently stored on the MEDTING web pages. By summer 2009, well over 20'000 images from more than 2'000 cases are indexed and thus taken into account for similarity retrieval. The images are extremely varied and include almost all medical imaging modalities, drawings, and photographs. The number of images is continually rising. There is no ground truth available to evaluate the performance of retrieval on this database. All employed tools have been evaluated on standard databases for their quality, though.

Results

Main result of this article is not a new retrieval technique but the integration of an existing system (GIFT) into a new application and the creation of a framework for this integration. The same techniques have been used for integrating the same image retrieval application into the viewing stations of the Geneva University Hospital in the past. More on the retrieval quality using GIFT on a standard database can be found on the ImageCLEF[5] web pages.

To limit the amount of integration work we decided to use web services. Web services [10] provide a language independent interface. A useful feature of web services is the use of the WSDL (Web Service Description Language) that simplifies client development. As a web service container (a server that provides the services), we used a component of ARC, a recent development. The web service 'FMEDTING' is invoked by MEDTING when the user views an image of interest and clicks the "Find similar" button. The button calls a client module. fname is the name of the source image file, for instance v_tmp_22042009_14121159.jpg:

```
\$client=newSoapClient(''FMEDTING.wsdl'')
\$res=\$client->image(array('imagefile'=>\$fname));
```

The functionality of the web service can be described as follows:

- The service is invoked with a file name (parameter "imagefile"). Optional parameters indicate the number of results and a similarity threshold.
- The service initiates a connection with GIFT. The IP address of the server and the port number are configured in the configuration file.
- The service sends a query to GIFT, receives result and forwards them to the caller.

[3] http://www.gnu.org/software/gift/
[4] http://www.knowarc.eu/
[5] http://www.imageclef.org/

Figure 1 - Screenshot of MEDTING including the button to search for similar images.

Since the web service itself is straightforward, it adds no overhead compared to a situation where GIFT is called directly via socket–based communication. The client's overhead consists of generating the service call from the WSDL file and interpreting the result. On a modern desktop computer, these add 0.2 seconds. Calling the service with a client and receiving the image URLs of the 10 most similar images takes 1.5–2.5 seconds. Image identifiers in GIFT are URLs, and thus the integration is easy using the URLs of images on the MEDTING web site. A screenshot of the functionality integrated into MEDTING can be seen in Figure 1 with the "Show me similar images" button. Figure 2 shows the result of similar images shown to the user and allowing to navigate to other cases with visually similar images.

After an integration of the image retrieval functionality into MEDTING it became clear that besides the retrieval a mechanism was needed to keep the database up to date every day. RSS (Really Simple Syndication) is an XML–based format that allows developers to describe and syndicate content [11]. The syndicated content, called feed, can consist the content itself, or its metadata. MEDTING started to provide an RSS feed containing the images added to its web side towards the end of 2008. The RSS feed contains URLs pointing to two versions (full size and thumbnail) of the images:

```
<rss version="2.0"
xmlns:media="http://search.yahoo.com/mrss"
xmlns:atom=''http://www.w3.org/2005/Atom''>
<channel>
<atom:link rel="next"
href=''http://medting.com/rss/resources.php?
page=2&amp;orderby=lastaddedresources''/>
<item>
<title>v_tmp_22042009_14121159.jpg</title
>
<link>http://medting.com/atlas/view.php?id=2
8428</link>
<media:thumbnail url=''http://media.medting.
com/28/28428_3VGn5Ih7IcoFYo_t.jpg''/>
<media:content url=''http://media.medting.
com/28/28428_3VGn5Ih7IcoFYo_e.jpg''/>
</item>
```

The RSS feed is read daily. If new images are discovered, they are added to the collection to always keep the files up to date. An average of 30 images have been added daily since February 2009. An overview of the entire system is shown in Figure 3.

Conclusion

The work described in this article details the integration challenges when using a research prototype for medical visual information retrieval in the context of a social medical image sharing site. The use of a web service for this simplifies the inclusion of finding similar images. The application is located at a University server and only the similarity search service is provided to the MEDTING web site. An important part of the integration was the automatic addition of new images, and using RSS provides a lightweight solution. For the integration of research prototypes into real applications it is particularly important to provide simple interfaces low in maintenance. This is surely more important than pure retrieval quality. For applications such as a permanently accessible social web site it is also important that the application is available all the time. We sometimes had maintenance stops or changes in the University server room resulting in a downtime and causing errors. In a next step we plan to analyze the usage logs of the system, finding out in which scenarios users search for visually similar images and which key word searches were performed with the system ahead of visual search. Having data of real, routine use can help understand situations in which users prefer to search visually and where key words are preferred. The created prototype allows obtaining direct feedback on visual search, important for a domain going from research to routine applications.

Figure 2 – Visually similar images to an example are shown under the image.

Indexing the medical open access literature for textual and content-based visual retrieval

Ivan Eggel[a], Henning Müller[ab]

[a] *Business Information Systems, University of Applied Sciences Western Switzerland (HES–SO), Sierre, Switzerland*
[b] *Service of Medical Informatics, Geneva University Hospitals and University of Geneva, Switzerland*

Abstract

Over the past few years an increasing amount of scientific journals have been created in an open access format. Particularly in the medical field the number of openly accessible journals is enormous making a wide body of knowledge available for analysis and retrieval. Part of the trend towards open access publications can be linked to funding bodies such as the NIH[1] (National Institutes of Health) and the Swiss National Science Foundation (SNF[2]) requiring funded projects to make all articles of funded research available publicly.

This article describes an approach to make part of the knowledge of open access journals available for retrieval including the textual information but also the images contained in the articles. For this goal all articles of 24 journals related to medical informatics and medical imaging were crawled from the web pages of BioMed Central. Text and images of the PDF (Portable Document Format) files were indexed separately and a web-based retrieval interface allows for searching via keyword queries or by visual similarity queries. Starting point for a visual similarity query can be an image on the local hard disk that is uploaded or any image found via the textual search. Search for similar documents is also possible.

Keywords:
Visual information retrieval, Open access literature, Medical information analysis, Information retrieval

Introduction

Images play an increasingly important role in medical practice. They are used in a large variety of contexts such as screening, diagnosis or treatment planning and also with an increasing variety of modalities and radiology protocols. Through the electronic patient record images are not only accessible to radiologists but for all clinicians, and so new tools providing aid particularly for less experienced clinicians in interpreting images seem necessary [1].

Many open access publishers have become available on the Internet, also through initiatives by the NIH (National Institute of Health) and the SNF (Swiss National Science Foundation) to oblige researchers to make articles of publicly funded research available. BioMed Central[3] is surely the most well known publisher but others such as BenthamOpen[4] or Hindawi[5] also provide open access publishing possibilities. Most (medical) articles containing text and images are provided in the form of a complex format such as PDF (Portable Document Format), although some are also accessible in HTML (Hyper Text Markup Language) format. Large journals often provide several thousand articles in a linked hierarchy on their web pages with bibliographic information and abstracts very often being available directly on the HTML pages. Web pages of journals allow for text search in the articles but a particular image search, or search for articles containing similar images is very often not possible. Textual search for images is also provided by ImageFinder[6] and Biosearch[7] but currently no visual search is possible. Such a visual data access has shown to well complement textual search [2].

To obtain all articles of a particular journal, simple web crawlers can be developed to parse the HTML web pages and then follow the links to the full PDF versions of the articles that can then be analyzed further. To obtain articles from BioMed Central's journals it was necessary to crawl their website to obtain meta information on articles, download the corresponding PDF files and extract their texts and images separately for indexing. In a next step all obtained information was indexed using the Lucene[8] text retrieval engine and the GIFT[9] (GNU Image Finding Tool) visual retrieval system [3].

Information retrieval (IR) has traditionally rather concentrated on textual information and a large number of text retrieval systems exist [4]. Image retrieval started much later and then concentrated on text close to the images searched or manual annotation of images themselves [5]. The next step was (visual) content-based image retrieval that relied solely on visual characteristics in the images for retrieval [6], leading to other problems such as the gap between the simple visual features used and the high-level semantics a user is normally searching for. In the medical domain, visual retrieval was proposed several times [7,8] but real clinical applications are scarce [9]. Access to the medical literature was also proposed in [10]. It

[1] http://www.nih.gov/
[2] http://www.snf.ch/

[3] http://www.biomedcentral.com/
[4] http://www.bentham.org/open/
[5] http://www.hindawi.com/
[6] http://krauthammerlab.med.yale.edu/imagefinder/
[7] http://biosearch.berkeley.edu/
[8] http://lucene.apache.org/
[9] http://www.gnu.org/software/gift/

has become increasingly clear that neither visual nor textual retrieval can solve all the problems alone. Rather, a combination of media is required to optimize performance of IR systems [2,11] in the medical field.

This paper describes an approach for multimodal (text and images) medical IR using open source tools limiting the time required for development and also the costs. For the parsing of web pages, the extraction of images and text from the PDFs, as well as for indexing textual and visual information, existing tools were reused. A web interface using JavaServer Faces (JSF), Javascript, and AJAX (Asychronous Javascript and XML) allows for an easy use for the final interface.

The next section describes the materials and methods used for this project. Then, the results of the web crawling as well as the indexation step are given with a description of the user interface. The article finishes with a critical discussion.

Materials and Methods

Data used

The data used for the system described in this article consists of articles from 24 journals (217 are available in total) from the online open access publisher BioMed Central. The chosen journals were in the fields of medical informatics and medical imaging. Each journal contains between 16 and 2500 scientific articles in PDF format, as BioMed Central is still a very young publisher. All PDF documents were publicly accessible and are free of charge. Information taken from the articles was of textual and visual (images) nature. The mentioned journals were crawled on August 20-21, 2009.

Table 1- Overview of the amount of data indexed.

Measure	Value
Number of journals	24
Number of articles	9403
Min. number of articles per journal	16
Max. number of articles per journal	2495
AVG number of articles per journal	392
Total number of images (after a cleaning step)	37940
Min. number of images per journal	28
Max. number of images per journal	13618
Average number of images per journal	567
Min. number of images per article	0
Max. number of images per article	1659
Average number of images per article	4
Size of all images total	2.81 GB
Average image size	77 KB

Textual information was parsed in HTML format from the description of each article on BioMed Central's webpage consisting of the title, abstract, journal name, publication date, author names and the URL of PDF documents. Extracted information of the PDF documents consists of the entire text in the document and the contained images. The average number of extracted images per article was around 4 (with a total of 9403 indexed articles and 37940 extracted images). The minimum number of images per journal was 28 with a maximum of 13618 and an average of 567. The total size of all extracted images was about 2.8 GB. An overview of the data is given in Table 1.

Technologies used

Goal of the project presented in this article was to reuse well-established existing tools to limit the development time. For text retrieval, the open source Java library Lucene was used, which is easy to integrate and adapt to a variety of scenarios. With Lucene providing the possibility to index more than one field per document it allowed searching in several data fields such as text content, author name, and article title. Several other options Lucene offers were not used in the first prototype described in this paper.

For visual retrieval, the GIFT was chosen that has equally been in use for almost ten years and that has shown to deliver stable visual research results.

The separation of images and text from PDF documents was performed using Apache PDFBox[10]. To parse basic meta information (on the web page) of each article NekoHTML[11] was used. NekoHTML is an open source Java HTML scanner and tag balancer library that enables developers to parse HTML documents and access the information using standard XML (Extensible Markup Language) interfaces. As application server Glassfish v2.1 was used. We relied on Java and JSF for the integration. Other Technologies used on the client side were pure Javascript and AJAX.

For the work described in this article it was not necessary to start from scratch since a previous system for the separation of text and images had already been developed [3]. The current system is an extended version of the previous system with an additional web crawler and changes in the user interface.

The server was a rack server with two Intel Xeon Dual Core 1.6 GHz processors with 2 GB of RAM and total disk space of 244 GB in a RAID array.

Results

This section describes the main results concerning mainly the implementation of our prototype with its search interfaces.

System setup

The work described had six main goals and for all of them existing tools could be combined with an ergonomic web interface that was developed in this project (Figure 1):

[10] http://incubator.apache.org/pdfbox/
[11] http://sourceforge.net/projects/nekohtml/

(1) crawling and parsing HTML pages on BioMed Central and writing the collected information into XML files (one file per journal with information on each article in a journal),

(2) downloading all PDF documents (web addresses of each article's PDF document saved in the XML files),

(3) extracting images and free text from the PDF documents,

(4) indexing the meta information of the articles (saved in the XML file) and of information directly extracted from the PDF documents with Lucene,

(5) indexing the extracted images with GIFT, and

(6) combining the extraction and the retrieval systems in a single interface based on JSF.

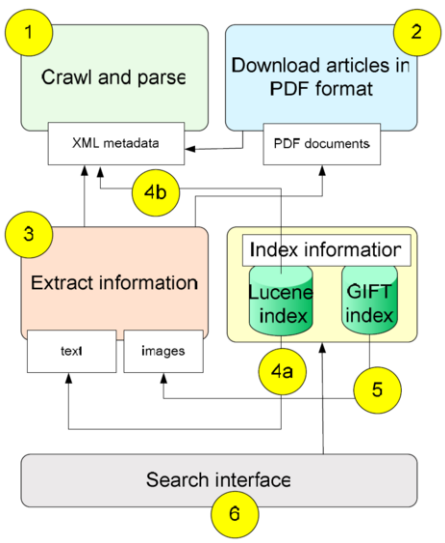

Figure 1 – The six main goals of work in a diagram with the basic system architecture.

Crawling and indexing the dataset

To crawl and parse the pages of BioMed Central, a trivial crawler was developed as a Java console application. The application takes the journal's starting URL and the directory to save the generated XML files as arguments. Starting the application results in the crawler finding all articles of the journal following well-defined links, parse the necessary information and save it to an XML file.

A simple download tool was also developed in Java being able to download all corresponding PDF files of a journal's articles from the URLs stored in the XML file. With all PDF documents downloaded, the extraction and indexation can take place. For this task we use a web interface that lists all XML files in the server's directory of journals. By choosing one of the listed files the application parses the content of a single XML file and each article's information is processed. First, the article's PDF document is located and subsequently the extraction of text and images takes place. Images are stored directly on the hard disk also generating thumbnails at the same time. The next step adds all textual information of the article to the Lucene index. One single step indexes/stores the following information on an article:

- auto generated id,
- title,
- abstract background,
- abstract methods,
- abstract results,
- abstract conclusions,
- online Article URL (if available),
- PDF document URL,
- authors,
- journal name,
- publication date,
- text content,
- image names,
- homepage URL.

The average duration of extracting and indexing one article was about 1 second. After indexing one article, the next article's information is extracted and indexed. This step is repeated until all the XML files are processed. Subsequently, images are indexed with GIFT, taking about 6 hours (around 0.5 seconds per image) with a total of 38'000 images.

One problem regarding the images was the existence of TIFF (Tagged Image File Format) images inside the PDF documents since TIFF is not supported directly by web browsers. We solved this problem by converting each TIFF image automatically to a PNG (Portable Network Graphics) image with the aid of Java Advanced Imaging (JAI). This task is performed directly after extracting a TIFF so before saving the picture and before adding information to the index.

After indexing several journals it was obvious that many articles contained the same or similar BioMed Central logos, which can be considered as irrelevant. To avoid storing the logos, the system discarded all images that were equal to a small set of example images selected manually (comparison of binary data). Another problem in our first extraction phase was a large number of small logos and graphical elements in the articles resulting in over 200'000 images to index. To avoid this problem, only images higher and larger than 32 pixels were considered for indexation, which reduced massively the amount of data to index visually.

It was also found that it was not always possible to extract all images from a PDF automatically. The reasons for this have not been totally investigated but it can be due to the production of the PDF that can be formed in a way not understood by our extraction module PDFBox. A very small number of mirror-inverted images also occurred during the extraction phase due to PDFBox, and we have not found a way to avoid this. However, these problems are expected to be fixed since PDFBox is improved and extended regularly.

Another challenge was parsing the HTML documents on BioMed Central. Although each page had a uniform design and layout we found several differences concerning the position of certain HTML tags, which forced us to take all possible

positions of an HTML element into account and not to rely on the initial structure.

Figure 2 - Screenshot of a purely visual search

Query options

The query interface can be found for testing at MedSearch[12]. A query start is typically a keyword or a new image that can be uploaded to start a visual query. It is possible to switch between a visual and textual query interface and it is always possible to show all images of a particular article (if any images were extracted) together on a single page or to show a link to the full text PDF of this article. After displaying images contained in an article it is possible to launch a visual search by clicking the button "Similar images" below an image. After this start, positive and negative relevance feedback can be used to refine the visual query further. All found images are marked neutral at the start and can be selected as relevant (green) or irrelevant (red) as shown in Figure 2. Another way to start a visual search is to obtain random images of the image database and perform queries by relevance feedback afterwards. It is then possible for the user to select "Show dedicated article" below an image. This will cause the system to switch to the textual search interface and to automatically phrase a query searching for the article the image is contained in. In the same interface the user can phrase his own textual queries with the client afterwards performing a HTTP-GET-request to the server passing relevant query parameters. This can facilitate integration of the system into other web pages. The user may also specify the number of results to show. Once queried, the results screen shows details of the retrieved articles consisting of the following elements (see Figure 3):

- article title with link,
- publication date,
- journal name,
- the first 500 characters of the abstract,
- link to full abstract,
- download link for article in PDF format,
- link to view all images and possibly to launch a visual search,
- search for similar articles based on the text (article search based on similar images not implemented yet),
- link to author names, which causes the system to search for all articles by the same author,
- web address of original article homepage,
- thumbnails of first three images in article (if available); it can be configured to show more images.

The entire retrieval system was installed on a server of the University of Geneva, Switzerland. However it is possible to integrate both into a totally distributed system, as Lucene, the query interface, and GIFT are independent components.

Figure 3 – Screenshot of a single textual search result including images of the found article.

No evaluation of retrieval quality is given in this text as no ground truth of BioMed Central is available. Both GIFT and Lucene have been evaluated on retrieval of journal articles and images in the ImageCLEF competition [2].

Speed measurements

Lucene has been used in many large-scale projects and search times with single key words are in the order of a few milliseconds. In our case it averages 40 milliseconds with more than 9'000 indexed articles, leaving room for much larger databases. Visual similarity search using GIFT was around 0.5 seconds for single image queries using our database with about 38'000 images. This allows for fast querying and good usability. When using new images to query, the feature extraction takes another 0.5 seconds. In total, results are usually shown in a second.

Conclusion

This article presents a solution for visual and textual IR from the open access publisher BioMed Central's online journals. Meta information of articles was available in HTML format, and the articles themselves were crawled directly in PDF-Format. Crawling, parsing and extracting text and images separately were essential parts. For all implemented tasks open source components could be used. The goal of the system is to collect information on scientific medical articles and to make this search interface available publicly to medical students and clinicians. A combined visual and textual search interface should optimize the reuse of all existing knowledge including text and visual parts. Currently, only 24 of the over 200 available journals on BioMed Central were indexed. Considering this and also the several other publishers of open access arti-

[12] http://medgift.unige.ch:8080/MedSearch/faces/Search.jsp

cles, the system is extendable to include a much larger body of knowledge. The resulting system was achieved by developing a loosely coupled architecture that stores information in XML files after crawling and parsing. The component-based architecture allows the extension of the system simply by replacing the crawler or adapting it to a new structure of journal web pages. All web-components can be integrated into a distributed environment easily. Besides open access publishers there is also an increasingly large number of articles available in full text by traditional publishers, very often 6-12 months after the original publication data.

The current system only indexed some of BioMed Central's journals. A next step is to index all 217 journals with their images. With data collected of the current system we can estimate a total size of all images of ~25 GB and a total size of the Lucene index of 4.8 GB. The estimated time to index all journals would be ~18 hours, crawling and downloading time excluded. Including the crawling and downloading this should still remain less than two days.

Of course there is not only a single open access publisher on medical journals on the Internet. The next step is to consider other open access publishers such as Bentham Open or Hindawi into our index. Indexing all abstracts of PubMed[13] would be another step further. As the full-text articles are linked if available, a semi-automatic crawling could be developed for this. Still, particularities of single publishers would then need to be taken into account.

Another important aspect is to keep the system up to date as new articles are published very regularly. An automatic update function has so far not been included into our system. The system would have to crawl (e.g. every week) the publisher's sites detect new articles, then download and index them.

Regarding the query options it would be good to add mixed visual and textual into the system, so search based on visual and textual characteristics combined, for example to find similar documents. A visual search could also be limited to articles containing a particular keyword.

The current implementation does not use all functions of Lucene, yet. However, it allows for an easy expansion of the functionality. Language detection of the documents to be indexed can be integrated to allow for a multilingual indexing and retrieval. Currently, this is of little importance as the published open access articles are mainly in English. Still, when adding medical texts from clinical routine in a country like Switzerland, there are documents in several languages.

The implemented system responds to the needs of crawling, parsing and separating BioMed Central's articles into visual and textual components for an efficient visual, textual and combined search. The entire system is based on open source components and can easily be reproduced.

Abstract

Research at protein level is a useful practice in personalized medicine. More specifically, 2D gel images obtained after electrophoresis process can lead to an accurate diagnosis. Several computational approaches try to help the clinicians to establish the correspondence between pairs of proteins of multiple 2D gel images. Most of them perform the alignment of a patient image referred to a reference image. In this work, an approach based on block-matching techniques is developed. Its main characteristic is that it does not need to perform the whole alignment between two images considering each protein separately. A comparison with other published methods is presented. It can be concluded that this method works over broad range of proteomic images, although they have a high level of difficulty.

Keywords:

2-D gel electrophoresis, Block-matching, Proteomics, Computer-assisted image processing

Introduction

The images of 2D gels [1] resulting from electrophoresis are a powerful biomedical diagnosis mechanism. This process is based on the separation and analysis of proteins extracted from tissues, blood, cell, etc. This type of image is obtained by staining the proteins that have been separated in a polyacrylamide gel after applying electrical potential difference to it. The separation follows a bidimensional pattern according to their molecular weight and isoelectrical point.

When analyzing images from 2D gels, there is a reference image that represents the distribution of a sample of proteins in reference conditions (normal or healthy status). In such case, molecules are labelled and their spatial location is known. Test images are then presented. In this case, the spatial location of the proteins is unknown. Usually, the comparison between a test image and the reference image is performed in order to establish the correspondence between proteins. Subsequently, both images are compared in order to establish a diagnosis based on the differences in the pattern of the identified proteins.

Images, such as 2D gels, are increasingly used in the biomedical field. The analysis of such images is difficult due to the variability of the different electrophoresis processes. Consequently, images with an apparently complex correspondence may be obtained. Location, shape, size and intensity of a given protein may vary from one image to another, it may not even appear, so the correspondence can be difficult or it might not be established. Due to this reasons, computational techniques are essential for image analysis.

There are several current software packages which try to solve this problem (i.e.: Nonlinear Dynamics Samespots [2], Decodon Delta2D [3] and Genebio Melanie[4]). These approaches tend to perform the whole alignment between two images. This is done by using several image transformations. The user must correct manually possible misalignments in order to obtain reliable results in later stages of the analysis. The system marks each protein with the same edge over all the gels of the same experiment. In this way, the user can select the spots of interest and compare them over the different images and obtain several conclusions based on their differences.

Most of those software packages do not indicate the identifiers or the names of the proteins in the test images, so the user must identify visually the proteins from a labelled reference image.

Apart from the software packages, there are different image analysis methods to align 2D gel images. They can be divided in two groups: those which use landmarks and those which use intensity information.

Two key concepts should initially be defined. A landmark refers to a characteristic of the image from which information is intended to be obtained. In proteomic images, landmarks are identified as proteins (dark spots on a clear background) with an unknown spatial location which will then be obtained. Intensity relates to the function that describes the grey level values corresponding to each pixel in the image.

The approach based on landmarks is a research line applied by several previous works. In [5], the detection of coordinates for the protein centres is firstly performed using an approach based on gradient and Watershed transformation (which performs the image segmentation according to its grey levels). Typical protein characteristics are also considered for molecule detection, like circular or elliptic rim. A local matching process between the reference image and the test image based on the Delaunay triangulation is then performed. This technique consists of a network of triangles where the circumferences circumscribed to each triangle do not contain any vertex of other triangle. A system based on matching the spot centres is presented in [6]. In this case, the rim detection has been carried out, as in [5], by considering different characteristics of the proteins in order to separate protein overlapping. The matching based on the coordinates of the protein centres is also carried out in [7] by following the approach known as fuzzy matching. This approach calculates the nearest protein to every reference protein within a certain range.

Other approaches are focused on the image intensity distribution in order to perform the matching between two gels. With the present approach, the cost of the landmarks extraction process is avoided. The principal objective of [8] is to find the alignment using regional matching (rectangles containing several molecules) instead of spots matching. In [9] the matching is performed by calculating the crossed correlation between the intensity distributions of the test image and the reference image. The strategy followed for image registration is an iterative solution based on the gradual selection of images' resolution, obtaining at each step a more precise transformation. There are two more recent works [10, 11], which are based on Robust Automated Image Normalization (RAIN).

There are new techniques that merge the two previous groups, that is, hybrid approaches. Particular cases of the Iterative Closest Point algorithm [12] (used for solving the alignment between the spots of a test image and the reference image using the Euclidean distance) were presented in [13] and [14]. Both works propose new distance metrics that combine the Euclidean distance with information related to the shape and the intensity of the spots. The aim of [15] is to find a function that makes image alignment possible using a nonlinear deformation model (B-splines). The optimization is based on Levenberg-Marquardt (LM) [16]. This method performs an iterative parametric fitting taking into account a predetermined mathematical model. In [17], some pairs of corresponding spots of both images are selected. The information about the correspondence of the landmarks is introduced as part of the energy function, which is minimized to perform the transformation. The centres are detected by modelling the proteins as 2D inverted Gaussian functions using LM fitting (as in the previous case). A new version of this work [18] was presented in 2008. This work uses the Navier equation, which represents the regularization of the deformation field. It is used with the aim of considering the crossed effects of some gel deformations.

As a consequence of this analysis, the main objective of this work was to find a new method which allows the clinicians to identify automatically the spots, where the alignment of the images is not necessary.

Methods

Establishing a correspondence between molecules of two different gel images might be a difficult task. As has been previously mentioned, this difficulty is due to potential displacements or appearance changes between proteins in two different images.

Several techniques have been studied with the aim of finding a solution for this type of scenario. These techniques, used for movement estimation, consist of mathematical procedures that analyse the intensity changes of a sequence of images

Block-Matching

Among the optical flow estimation techniques, regional fitting (Block-Matching) has been chosen because it is suitable for measuring displacements due to nonlinear movements with a high degree of deformation. Due to their characteristics, these techniques are especially suitable for fluid analysis. A good performance in this context is expected as the proteomic images are obtained from viscous fluids (polyacrylamide gels).

The Block-Matching approach considers a reduced space of the correspondence problem in order to achieve a better approach rather than the global case. These techniques usually work as follows [19]: the image is divided into some regions; different criteria might be followed to perform this division. The simplest approach implies selecting non-overlapping regions of predetermined size, known as blocks. The aim of the next step is to calculate the displacement for each region between two images. This is done assuming that the local distortions caused by the displacement are almost negligible. Thus, considering a region small enough and a time lapse short enough, the characteristics of each region will not be affected by the movement. This is the only assumption made in relation to the movement which will be calculated. Every block of an image is then compared with several possible blocks of the following one, maximizing a similarity measure or minimizing a distance measure.

Modified Block-Matching

As the previous process is general, it does not fit closely to the 2D gel scenario. This is due to the assumption made by the generic Block-matching algorithms: despite the displacement, within an area small enough, the visual texture of a region remains unaffected. In the field of 2D gels this hypothesis is not fulfilled because the images are not part of a temporal sequence affected by movement. In those sequences there are few changes from an image to the next one. In proteomics, the images are independent. Besides, the variability is increased due to the previously mentioned changes experienced by the protein samples in different images. Due to this, the use of certain similarity measures presents some restrictions, because

the difference between a region and its corresponding region in the other image is very high in 2D gels. Although the result of the exploration might be correct, it might not meet the minimum difference criterion. Because of that, the system will assume that the displacement produced is not detected. A similarity measure based on the statistical distribution of the intensity levels is then required. This measure needs to be robust despite those factors that vary among samples.

Due to the reasons explained previously, a new Block-Matching-based method has been developed. This method proposes different specific strategies to adapt Block-Matching to proteomic images of 2D gels. The process, show in figure 1, is carried out as follows:

- Firstly, the method needs as input the list of coordinates of the spots in the reference image. This part can be done in different ways: getting the output of a spot picking robot, such as GelPix [20], or using several image analysis techniques. Present work does not focus on this phase, but on the modified block matching technique explained as follows.
- The system refines the coordinates in order to match exactly spots' centres. They are also the centres of the blocks into which the image is divided (the whole image is not divided into blocks, unlike in Block-Matching algorithms; only some blocks are marked: as many as the spots extracted). To perform this task LM fitting has been used. Therefore, it is necessary to define an area that might contain, with high probability, the centre of the protein. The coordinates of the centre of that area are also extracted and used as the initial estimation in LM fitting. That area is determined using wave search, which is carried out as follows: a minimum radius is established. The initial coordinates represent its centre. This radius is increased (to a maximum) until it reaches the rim (an intensity value up to a certain grey threshold) and contains the protein centre (an intensity value less than a certain grey threshold). The minimum intensity point in the delimited area is used as the provisional centre for each iteration.
- Once this area has been established, the centre of the protein is located using LM fitting. It was necessary to find a fitting function for the proteins' grey level. Then, an inverted bidimensional Gaussian function was chosen as it is a continuous function which is adequate to describe the distribution of the molecule intensity. This model determines the protein centre (the darkest value and therefore the lowest grey level) as the minimum in the inverted Gaussian curve. The fitting function undergoes a rotation geometrical transformation because the molecule can turn towards different directions.
- The protein centre adjusted in the previous phase is the central position of the search block for the modified Block-Matching algorithm. The size of the block is defined by specifying its dimensions using the Block Size parameter (in pixels). Using each block as a centre, a search region is defined. This region is demarcated by a maximum range of displacement (Search region).
- In the search region, a spiral exploration strategy has been followed. Thus, starting at the block coordinates of the first image, hops determined by the Search hop parameter are performed following a spiral. Each hop represents one pixel, in such a way that the whole space of states will be explored obtaining always the best possible value for the comparison criterion, the Pearson correlation coefficient which is a typical statistical coefficient used to calculate the linear relationship between two quantitative variables. It is immune to changes in the medium grey level and it is independent of the value scale used. It has also proved to be robust when there is noise.
- Once the correspondence with a block in the test image has been established, the position of the centre of this destiny block will be refined in order to match the protein centre, as was done at the beginning for the reference image. The output is showed in the Figure 2.

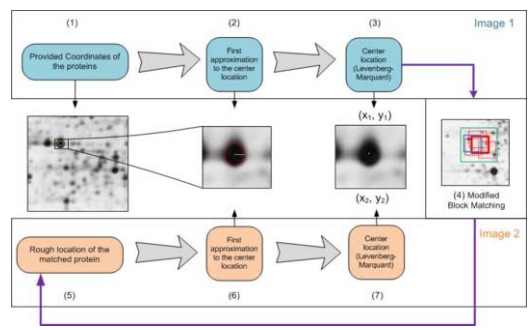

Figure 1 –Modified block-matching diagram

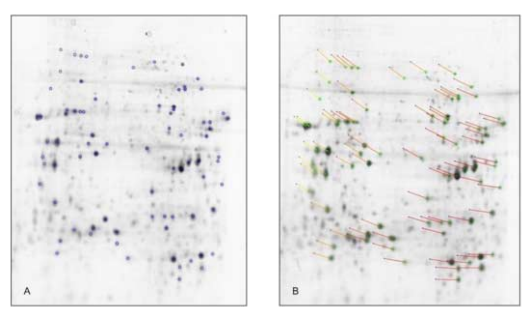

Figure 2 – System output. A) Marked molecules. B) market molecules in the test image, with a vector that indicates not only direction, but also the magnitude of the displacement in relation to the corresponding protein in the reference image

Results

The proposed system has been implemented using Open Source Computer Vision Library (OpenCV) [21] and has been tested in order to compare our results to those of other articles.

The Table 1 show the results, represented as success rates, of the comparison between the proteins in the reference and the test image. In order to understand better the results, it is necessary to define the following terms:

- It is considered a success when the centre calculated by the algorithm is included within the perimeter of a protein in the test image. In addition, this protein must match, according to the expert's criterion, its corresponding protein of the reference image, based on its spatial location and characteristics.
- It is considered failure when the calculated centre is out of the body of the protein which matches the reference one (according to the expert's criterion).

Test

In order to check the accuracy of the method presented in this paper, the results obtained were compared to those obtained in [18]. This work shows the success rates of a proposed hybrid method and those obtained with an approach based only on intensity. In [18], their results are compared to the results obtained in a previous work [17], which includes a hybrid approach and an intensity-based one.

The test bed was built by using the images of G.-Z. Yang (Royal Society/Wolfson MIC Laboratory, Department of Computing, Imperial College of Science, Technology and Medicine, London). This test bed consists of a group of images of 2D gels from different types of tissues and different experimental conditions.

The test bed used in the present work was built grouping these images in pairs in order to perform their alignment. Every couple was assigned a complexity level according to the criterion of an expert. As a result, the following groups were obtained:

- Five pairs of images where the visual correlation of the proteins between every reference image and test image is simple.
- Five pairs of images where most of the proteins can still be visually correlated, but, in this case, it is harder to establish the correlation.
- Five pairs of images of high complexity, where most of the proteins cannot be visually correlated

The comparison function, block size, search region and search method parameters were chosen according to previous tests on synthetic images. The values chosen for the parameters were Pearson Correlation as comparison function, wave search as search method, block size of 75x75 in easy and medium complexity images and 150x150 in complex images and search region of 75x75 in easy and medium complexity images and 125x125 in complex images.

We have selected [17] and [18] because their tests use images extracted from the Wolfson MIC Laboratory test bed. However, in both, only one pair of images was selected for each type of complexity (no results of high complexity images were published). In these works, 208 proteins were selected in order to test the results in low complexity images, and for the medium complexity pair 158 proteins were selected. After that, the number of proteins correctly and incorrectly identified was obtained. The success rate was then calculated. In order to fairly compare the results obtained in [17] and [18] to the results obtained in our work, the same pairs of images were used. As they do not show which proteins have been selected, it was carried out as follows: for the low complexity pair, 212 identifiable molecules were found. From these, 208 were selected. As a result, at the most, 2.4% of the molecules may vary. From the medium complexity pair, 158 proteins were selected from the 160 identifiable ones. In this case, at the most, 1.27% the proteins may vary. As these rates are minimal, the results can be considered comparable. The pair of high complexity images chosen in [17] was also selected, despite none of the papers having mentioned any related results. We have chosen 55 identifiable proteins for this pair. This number is not very high because most of the proteins have a high overlapping rate that prevents establishing a reliable correspondence.

Table 1 – Comparative with other methods

	Easy			Medium			Complex		
	n_{cor}	n_{inc}	%	n_{cor}	n_{inc}	%	n_{cor}	n_{inc}	%
[17] Intensity	187	21	89.9%	137	21	86.7%	-	-	-
[17] Hybrid	201	7	96.6%	149	9	94.3%	-	-	-
[18] Intensity	200	8	96.2%	150	8	94.9%	-	-	-
[18] Hybrid	203	5	97.6%	153	5	96.8%	-	-	-
Modified BM	207	1	99.5%	154	4	97.4%	47	8	85.4%

Test results

The number of correctly (n_{cor}) and incorrectly (n_{inc}) identified proteins are presented in Table 1 with the corresponding success rates.

The results obtained in the present work are slightly better than those obtained in the approaches published in [17] and [18]. Even more, these two works do not present results for high complexity images, as they do not consider them suitable due to their complexity. There are several differences between these methods and the one presented here: in [17] and [18], a manual selection process of certain proteins from the reference image and the corresponding ones in the test image is performed. This user-supplied matching information is used to refine the registration in regions where the information about intensity is not enough. Then, the alignment is performed on the whole gel. However, in this work, the process is fully automatic and the system performs the association between the proteins of interest, it does not carry out the whole gel alignment.

Conclusion

The aim of the present work has been to obtain an effective method in order to calculate the correspondence between the proteins of 2D gel images obtained using an electrophoresis process. An approach based on regional fitting techniques has been developed. The generic Block-Matching technique was modified in order to apply it to the 2D gel scenario. The success rates obtained after executing the required tests using real biomedical images were higher than the rates reached by previous works using the same test bed. This method performs the identification over each protein separately, and it does not perform the whole alignment. Thus, the identification could be performed over a subset of proteins because many times only some proteins are important for establishing a diagnosis. Since this method works at spot level, it could be easier to transfer protein labels between images, so the manual labelled process would be avoided. In this way, it could be very useful for protein information retrieval systems.

Abstract

Tumor excision is the primary treatment of aggressive or recurrent benign bone tumors and malignant bone sarcomas. This requires a surgical resection with the potential for large residual osseous defects that could be reconstructed using fresh frozen allografts. Virtual bone banks enable the creation of databases allowing a 3D pre-surgery evaluation of such allgorafts, based on segmentation of DICOM-CT images. This study demonstrates the usefulness of patient specific 3D models for an accurate host–donor allograft match. We describe one way to select the best match according to size and shape. The results suggest that a robust and realiable technique has been established. Since it is difficult to plan an allograft on a distal femur deformed by the tumor, we propose to plan the surgery on the contralateral side. Our results support this limb symmetry hypothesis. The use of this measurement protocol enables accurate selection of allografts from a contralateral healthy femur 3D CT model achieving the best match possible considering the geometry of available allograft candidate femur specimens.

Introduction

Tumor excision with wide surgical margins is the primary treatment of aggressive or recurrent benign bone tumors and malignant bone sarcomas [1]. This requires a surgical resection, with the potential for large residual osseous defects that could be reconstructed using fresh frozen allografts [2].

As diagnostic and therapeutic techniques improve, patients with musculoskeletal sarcomas should expect increased survivals, decreased complications and side effects, and an improved quality of life. That is why functional longevity of the reconstruction becomes a major concern, especially in young and physically active patients. Emphasis has been placed on biologic reconstructive alternatives due to concerns involving the durability of prosthetic materials, and the increasing survivorship of patients with sarcomas. Poor anatomical matching of both size and shape between the host and the donor can significantly alter joint kinematics and load distribution, leading to articular fractures or joint degeneration [1,2]. Determination of the distal femur size and shape is critical to obtain an appropriate allograft. In addition to this, it is difficult to plan an allograft on a distal femur deformed by the tumor.

The objective of this study was to develop a protocol to search and select of the best match (distal femoral allograft) from a virtual bone bank system, and to verify its intra- and inter-observer reliability. The feasibility of such protocol is based on our hypothesis, which states that the symmetry of the contralateral distal femur will provide the best match in preoperative planning allograft selection.

Materials and Methods

A total of thirty-three fresh-frozen whole femora were selected from the bone bank for this IRB-approved study, 15 right and 18 left (age range: 16-58 y.o., 35.9 ± 12.0 y.o.; 22 males and 11 females) were used in this study. 3D reconstructions of all specimens were created from CT images (Figure 1). The following distal femur morphometric parameters were measured with specialized 3D software (Mimics, Materialise, Belgium) on a plane perpendicular to the long axis of the bone: 1. Transepicondylar axis (A): the distance between the most medial point in the medial epicondyle and the most lateral point in the lateral epicondyle. 2. Medial condyle distance (B), determined as the distance between the most anterior and most posterior points, respectively, in the anterior-posterior direction. 3. Lastly, the length of the lateral condyle (C) determined with the same method used for the medial condyle (Figure 2).

Intra- and inter-observer reliability of this protocol was assessed measuring 33 and 20 femora, respectively, and was evaluated using an intra-class correlation coefficient.

Size symmetry was evaluated using R square coefficient between right and left A-B-C measures from the same donor in 10 cases (Figure 2).

Shape symmetry of the distal femur was evaluated also in the 10 cases by comparing a left femur model and a mirror image model of a right femur in each pair (Figure 3).

Point-cloud models were created from the surface polygon mesh model by using vertex points of the polygon (Figure 4). The 3D left femur model and the 3D right mirror femur model were registered by using a volume merge method [3].

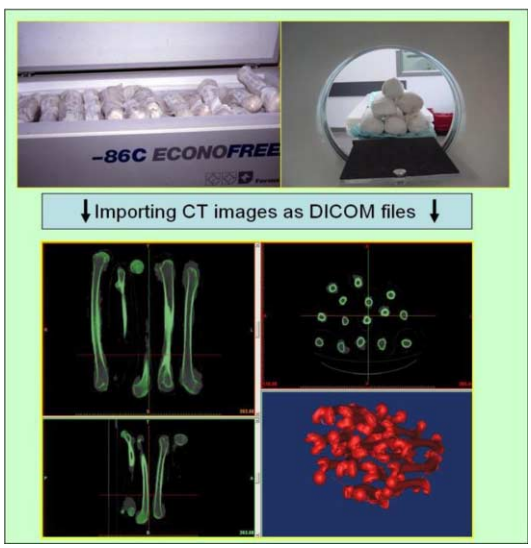

Figure 1 -Images from the CT scanner are imported and reconstructed as 3D objects with Mimics software

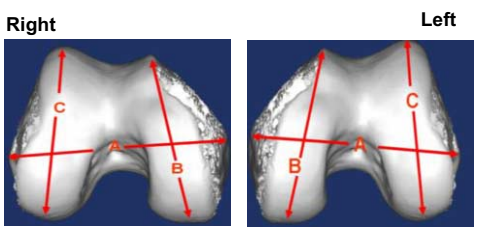

Figure 2 - Distal view: A-B-C size analysis parameters between right and left sides. A: Transepicondylar axis, B: Medial condyle distance and C: length of the lateral condyle.

The volume merge method was created with custom software program in Microsoft Visual C++.NET 2003 with Microsoft Foundation Class programming environment (Microsoft Corp, Redmond, WA). In the volume merge method, the right mirror femur (the moving femur) was virtually rotated and translated towards the left femur (the stationary target). These rotations and translations of the femur were conducted in 0.1° and 0.1 mm increments, respectively, until the moving femur merged with the stationary target. The degree of volume merging was maximized in real-time through rotation or translation of the moving femur using the following algorithm. A voxel with a dimension of 1.0 x 1.0 x 1.0 mm was created for each point of the stationary target. The number of points of the moving femur that fell within the voxel of the stationary target was determined and the percentage of volume merge was defined by a ratio of the number of the voxels including the moving femur points to the total number of the voxels on the stationary target [3]. The accuracy of the volume merge method was evaluated using a phantom with 8 precision ceramic balls (19 mm in diameter). The phantom was placed on a high precision 4-degree of freedom table. The phantom was scanned at 5 translated positions in x-direction with 0.1 mm increment up to 0.5 mm and at 10 translated positions in z-direction with 0.1 mm increment up to 1.0 mm. It was also scanned at 10 rotated positions about x-axis with 0.1° increment up to 1.0° and at 5 rotated positions about z-axis with 0.1° increment up to 5°. A total of 30 scans were analyzed using the volume merge method and system accuracy was determined using translations and rotations. The values were compared with the known translation and rotation values and errors in these calculations were evaluated. Mean absolute translation error was less than 0.1mm in x-direction and z-direction. Mean absolute rotation error was less than 0.2º about x-axis and z-axis. The translation in x-axis and rotation about z-axis correspond to transformation in axial-plane and the translation in z-axis and rotation about x-axis correspond to transformation in the sagittal plane [3].

Following the registration of the left and the right mirror distal femora, a closest distance algorithm was used to evaluate 3D shape matching between the left femur and the right mirror femur [4,5]. Distances between one point in the point-cloud model of the left femur and all points in the right mirror femur were calculated in 3D space. The closest distance at the point in the left femur was defined as the least distance among all distances. This procedure was repeated for all points in the left femur and mean closest distance from all measured closest distances of the closest distances was determined for each pair of the distal femur (Figure 5 and Figure 6).

Results

Protocol metrics: A single operator was tested for intraobserver repeatability while using the above-mentioned A-B-C protocol twice on thirty-three distal femoral allografts, obtaining an intraclass correlation coefficient of 0.99 in almost all measures (Table 1). Interobserver consistency of two separate observers was quantified when they measured the A-B-C parameters of twenty distal femoral allografts leading to an intraclass correlation coefficient of 0.99 in all measures (Table 2). R square coefficient between right and left side was 0.99 in the ten pairs evaluated (Figure 2).

Shape compliance: Evaluation of the overlapped original and mirror point-cloud models with the custom C++ program found that the average closest distance between points was 0.89±0.07 mm. (Figure 7). This result is within the CT slice thickness of 0.5 mm and CT resolution of 0.625 mm/pixel.

Discussion

The selection of the bank allografts has been closely related to the progress of the current visualization method. During the first decades traditional X-rays were used, assuming a transplantation selection error that reached the centimeter scale. Then donor-recipient two dimensional measurement protocols were established in CT scan images that narrowed down the bias to the millimeter scale.

More accurate data and a more precise donor-recipient selection can be achieved using various complementary techniques such as the multislice CT scan–digital representation of subject-specific models and CAD (computer aided design), software, moving a step closer to the creation of a virtual interactive musculoskeletal system (V.I.M.S.) [6].

The volume merge technique used in the current study for the registration of between the left and the right mirror femora has been used for kinematic analyses of lumbar spine, cervical spine, ankle joint, and and shoulder joint [3,7,8]. This technique also allows registration of the organ taken by different imaging modalities [7].

In the closest distance analysis, only the magnitude of the distance vector was evaluated and not its direction. Therefore, the distance was not evaluated in the normal direction to the surface of the femur and the distance may be overestimated. Especially, when the closest distance is small, overestimation is expected to be larger. However, this amount of overestimation does not exceed the spatial resolution. Calculation of the distance between a point to the polygon surfaces may improve shape matching evaluation. However, the random orientation of each individual polygon mesh element may vary significantly on the complex and irregular bone surface. Future studies will be required to establish better algorithms to evaluate bone surface geometry matching. Nonetheless, due to large macroscopic differences in size and geometry expected in a clinical setting, the magnitude of the error associated with the current method would be negligible for practical purposes and ready to be used with a virtual bone bank system (Fig. 8). Additionally, another limitation of this study is the small amount of samples.

Conclusion

This work demonstrates the usefulness of three-dimensional models when searching for the best similar host–donor allograft match and proves our symmetry hypothesis. The results suggest that a robust, reliable and most importantly, repeatable technique, has been established.

On the other hand, the results stemming from the use of this measurement protocol enable accurate selection of allografts from a contralateral healthy femur CT achieving the best match possible considering the geometry of available allograft candidate femur specimens (Figure 8). This newly developed method is a good example of translational research that can be readily applied to the patient with minimal effort.

Using Local Context Information to Improve Automatic Mammographic Mass Detection

Abstract

Despite their promising application, current Computer-Aided Detection (CAD) systems face difficulties, especially in the detection of malignant masses–a major mammographic sign for breast cancer. One of the main problems is the large number of false positives prompted, which is a critical issue in screening programs where the number of normal cases is considerably large. A crucial determinant for this problem is the dependence of the CAD output on the single pixel-based locations initially detected. To refine the initial detection step, in this paper, we propose a novel approach by considering the context information between the neighbouring pixel features and classes for every initially detected suspicious location. Our modelling scheme is based on the Conditional Random Field technique and the mammographic features extracted by image processing techniques. In experimental study, we demonstrated the practical application of the approach and we compared its performance to that of a previously developed CAD system. The results demonstrated the superiority of the context modelling in terms of significantly improved accuracy without increase in computation efforts.

Keywords:

Breast cancer, Computer-assisted decision making, Mammography.

Introduction

Breast cancer is a disease that no woman wants to be diagnosed with, but if it does occur, finding it as early as possible can save woman's life. Worldwide there have been developed screening programs where mammographic exams are performed in asymptomatic women. The enormous workload and the very low incidence rates of breast cancer (3-10 per 1000) in these programs, however, create various challenges for radiologists in the interpretation of mammograms.

The current advances in computer technology and screening digitalisation led to the rapid development of Computer-Aided Detection (CAD) systems. In screening programs these systems might be especially useful as a second reader for improving the mammographic analysis [1]. Essentially, the working principle of current CAD systems comprises a multi-stage process based on identification of regions of interest using image processing and pattern recognition techniques, extraction of a feature vector for each of these regions and classification of the regions as cancerous (abnormal) based on supervised learning techniques such as neural networks.

Computerized programs are currently employed for the detection and classification of masses and microcalcifications–the two major mammographic signs of breast cancer. Applications have shown that CAD tends to perform better in identifying malignant microcalcifications compared with masses [2]. Masses are more difficult to detect due to the great variability in their physical features and similarity to the breast tissue, especially at early stages of development. Hence, the prompt of the current CAD comprises not only the cancer but also a large number of false positive (FP) locations–undesired result in screening where the reading time is crucial.

In this paper, we focus on improving mass detection on mammograms by reducing the number of FPs while keeping the true detection rates high at the very first step of CAD–detection of suspicious pixel-based locations. In our previous work this selection is mostly based on the information provided by a single pixel [3], [4]. This contradicts, however, the basic decision-making principle of radiologists, accounting for context information in the region of interest. To incorporate this knowledge into a CAD system, we propose a novel approach for mass detection by explicitly modelling the dependencies of the neighbouring pixel features and classes. We use Conditional Random Fields (CRF), introduced in [5], as a powerful probabilistic tool to represent context dependencies using undirected graphs. CRFs model the class distribution given a set of observed features, which makes them especially suitable for sequential labelling and classification tasks such as mass detection. The main advantage of CRFs over generative models such as Markov Random Fields (MRF) is their conditional nature, relaxing the need for making a lot of independence assumptions among the observed features, required by MRFs to allow tractable inference.

A number of previous works considered context information for breast cancer detection. In [6] the authors propose an approach using MRF to segment breast masses achieving 90% sensitivity at 2 FP detections per image. In [7], a random field model is used to detect microcalcifications on mammograms. Alternative directed-graph approach based on Bayesian net-

works has been proposed in [8] to predict the type of breast cancer represented by microcalcifications, reaching prediction performance of a human expert.

In contrast to the previous studies where only the dependencies between the neighbouring labels are considered, in this work we also account for the dependencies between the observed features in the neighbourhood employing the CRF representation. In such a way we can better represent the mass characteristics and tackle the problem of noise in the labelling. Next we present our mammographic CRF model.

Materials and Methods

Mammographic Discriminative Model

In screening mammography, it is known that cancer develops mostly in one of the breasts and at one location. In the initial stage of development, malignant masses are often small and may have subtle characteristics, which hardly distinguish them from the surrounding tissue. This implies that scanning the whole breast for a mass would be a cumbersome task in terms of time and computation efforts. Therefore we propose to consider not the whole image but only those parts of it, which indicate certain cancer characteristics. Hence our method consists of two main steps: (1) Detection of suspicious pixel-based locations (PxL) and (2) Building a CRF model for each of the detected PxLs.

Initial pixel-based mass detection

In this step we use the pixel-based mass detection scheme from the CAD system presented in [3]. For all pixels in the segmented breast area, this algorithm calculates at each location i a set of 5 local mass features: 3 for stellate (star-like) lesions and 2 for focal masses. A 3-layer neural network classifier, supervised by the pixel labels $\in \{-1, 1\}$, combines these features into the so-called mass likelihood l_i – the likelihood that a mass is present at location i. The method is applied at a high sensitivity level to ensure that most masses are found. This implies that a large number of FPs would also be observed because the detection was based on 5 features only.

CRF modelling of the initially detected local masses

To further filter out the FP locations, for every selected pixel q we build a CRF model, which is defined with respect to a system of neighbourhood around q. The CRF modelling we propose in this paper is based on the approach in [9], which we extend to account for the specifics of the mammographic mass detection.

For every image we define a set $Q = \{q \mid q \in B,\ l_q > \theta\}$, where B is the set of all pixels in the breast area and θ is a threshold value. We then use every $q \in Q$ as a central point to construct a region (grid) R_q with a size of $M \times N$ pixels. Since the pixel information is very sensitive to small variations, we create non-overlapping groups of $m \times n$ pixels and we call these pixel groups *sites*. For every site s we compute the feature vector $\boldsymbol{y}_s$ as the mean of the feature values of the pixels in the site. We compute the site label x_s by assigning –1 (cancer) if sufficient cancer information is available in the site (e.g., 40% or more of the pixels are cancerous) and 1 otherwise.

Based on this construction we define a CRF over the labelling $\boldsymbol{x}$ given the observations $\boldsymbol{y}$ as an undirected graph with a set S of vertices corresponding to the random variables x_s, which satisfy the Markov property with respect to the graph stating that $p(x_s \mid \boldsymbol{y}, x_{S\setminus\{s\}}) = p(x_s \mid \boldsymbol{y}, x_{\mathbf{N}s})$ where $S\setminus\{s\}$ is the set of vertices excluding $\{s\}$ and $\mathbf{N}_s$ is the set of neighbours of s. In other words, the random variable x_s is conditionally independent of all other variables given the observations and its neighbours. We represent the neighbourhood (direct dependencies) of s in the graph by the set of edges between s and the 4 nearest neighbour sites. Then the conditional distribution of the labelling $\boldsymbol{x}$ given the observations $\boldsymbol{y}$ is factorised into a product of two potential functions, capturing the compatibility of a certain variable configuration: one local potential associating given site with a certain class ignoring the site neighbours and one interaction potential for the site dependencies. After log-transformation, the conditional distribution is defined as:

$$p(\boldsymbol{x} \mid \boldsymbol{y}) = \frac{1}{Z}\exp\left(\sum_{s\in S}\varphi(x_s, \boldsymbol{y}_s) + \sum_{s\in S}\sum_{r\in \mathrm{N}_s}\psi(x_s, x_r, \boldsymbol{y})\right). \tag{1}$$

where Z is a normalizing constant ensuring that p is a valid probability distribution, φ is the local potential and ψ is the interaction potential.

To account for the feature dependencies between the sites, for each site s we consider 2 scales at which $\boldsymbol{y}_s$ is computed–the original $m \times n$ scale and $2m \times 2n$ scale. This results in the doubled feature vector $\boldsymbol{Y}_s$. Next we define $\boldsymbol{t}_s = h(\boldsymbol{Y}_s)$, where h is a second-degree polynomial expansion, to explicitly model feature interdependencies. Given the computed features, the potentials are then defined by

$$\varphi(x_s, \boldsymbol{y}_s) = \exp(x_s \boldsymbol{w}_s \boldsymbol{t}_s) \tag{2}$$

$$\psi(x_s, x_q, \boldsymbol{y}) = \boldsymbol{\beta}\Phi(x_s x_q \boldsymbol{v}_{sq} \boldsymbol{t}_{sq}), \tag{3}$$

where Φ is the probit function, $\boldsymbol{t}_{sq}$ is the edge feature vector created by concatenation of $\boldsymbol{t}_s$ and $\boldsymbol{t}_q$, and the parameters $\boldsymbol{w}_s$ and $\boldsymbol{v}_{sq}$ are weight vectors. Note that we modify the standard definition of the edge potential as done in [9], by adding a parameter set $\boldsymbol{\beta}$ in order to account for different weights with respect to the label interaction. This set contains four values corresponding to the four label combinations. Since we aim at mass detection, the pairwise cliques for which $x_s = x_q = -1$ are expected to get larger potentials, facilitated by the larger value of $\beta_{-1,-1}$. Schematic presentation of the CRF modelling for mass detection is presented in Figure 1.

Parameter learning and inference

The parameters that need to be optimised in the learning process are $\Omega = \{\boldsymbol{w}, \boldsymbol{v}, \boldsymbol{\beta}\}$. Since in the construction of CRFs the observed features are dependent, the corresponding parameters need to be learned simultaneously. This implies that the

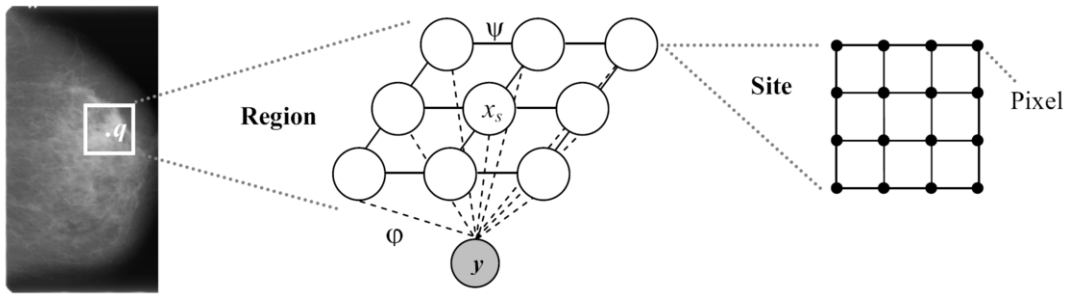

Figure 1- CRF modelling for automatic mass detection

evaluation of Z in Equation (1), which sums over all assignments, becomes intractable for exact inference. Various approximate techniques have been used to overcome this problem: mean-field, loopy belief propagation, stochastic gradient. Here we consider the stochastic gradient descent technique, which has shown fast converging properties. The true gradient is approximated by computing the gradient at an individual training sample. After each step, the new parameter set is adjusted using the approximated gradient based on the update rule of the form $\Omega_d = \Omega_{d-1} - \eta\nabla\Omega_i$, with d ranging over the number of training samples, ∇ being the gradient and η being the learning rate. As prior parameters we assumed that the values of $\boldsymbol{w}$ and $\boldsymbol{v}$ are drawn from the normal distribution with zero mean and variance σ^2.

The goal of inference in our modelling scheme is to find for a new test region the most likely output label sequence $\boldsymbol{x}^*$ over the region sites given the observed site features. We use as inference method belief propagation. To compute the single label probability of the whole region we take the mean over the label sequence on 16×16 window around the centre q. Only the pixels in the close proximity of q are considered as they are most likely to contribute to the correct classification.

Experiments and Results

Design

The proposed approach was evaluated using data collected in the Dutch breast cancer screening program. The dataset consists of mammograms for 164 cases from which 118 were with biopsy-proven cancer and 46 were normal. The total number of images was 220 from which 93 were normal. For every image, which has been digitized at 200 micron (0.2 mm) spatial resolution, the breast area was segmented by the CAD system and a likelihood image was created. The pixel-based locations with a mass likelihood ≥ 0.5 were selected as most suspicious. This resulted in 494 pixel mass locations from which 361 (73%) were normal. Each of these locations was then used as centre to construct a region of size 128×128 pixels (~2.5×2.5cm) for CRF mass detection modelling. Every region was partitioned into 32×32 non-overlapping sites and site features were computed as described above.

Given the classification problem at hand, we trained the CRFs using a random subset of 88 locations with cancer only. Our choice was motivated by the fact that the regions built on normal locations do not provide information about the difference in the labels and features of the sites. The remaining cancerous and all normal regions were used as a test set, accounting for 61% normal test cases. We note that *no* FPs from cancerous cases were used in training and testing, since in the evaluation procedure at a case level they are not included. The results presented next are based on the test data.

We compare the results of the CRF modelling scheme (CAD-CRF) with those obtained from CAD on the likelihood image (CAD-Lik) at two levels: region and case. We evaluated the performance at a region level by the Free-response Receiver Operating Characteristic (FROC) curve whereas at a case level we used the Receiver Operating Characteristic (ROC) [10]. The Area Under the Curve (AUC) is used as a standard evaluation technique. The CRF modelling was done using the freely available CRF toolbox for Matlab [9], where we applied necessary changes to implement the proposed model.

Results

Accuracy

Region level. Figure 2 shows test sample regions and the results on their detection obtained by CAD-CRF. In the test samples the black areas represent cancer whereas the white regions are FP regions detected by CAD-Lik. Clearly a large number of FPs are filtered-out by CAD-CRF, as indicated by the grey regions in the test results on Figure 2. Figure 3 presents the results from both CAD-CRF and CAD-Lik at a region level. We observe improvement in the mass detection rate for the proposed method, starting already at a FP rate of 0.023 per image. At a FP rate of 0.1 per image, for example, CAD-CRF detects 84.6% of the masses whereas for CAD-Lik the detection rate is 71.8%. Furthermore, the context modelling allowed the detection of all masses at a FP rate of 0.3 per image, whereas for the original likelihood image this was achieved at a FP rate of 0.58. The areas under the FROC curves for the FP range [0.01,1] are: AUC(CAD-CRF) = 0.782 and AUC(CAD-Lik) = 0.705, indicating considerable improvement in the detection of the cancer at a local level.

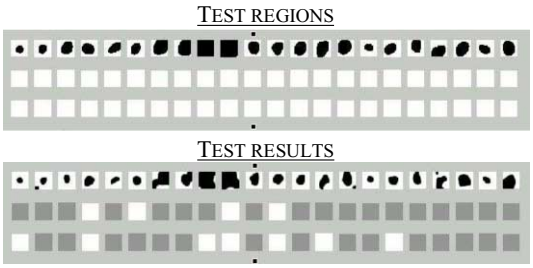

Figure 2- Test regions and corresponding results obtained from CAD-CRF. The black areas represent cancer, the white regions are FPs and the grey regions are true negatives

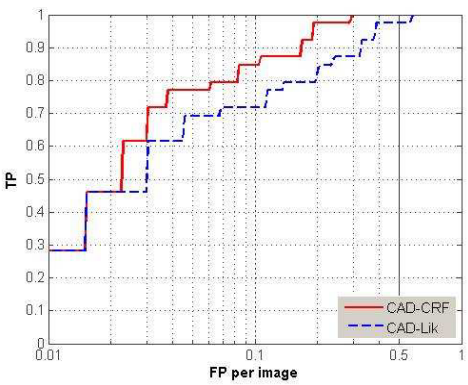

Figure 3- FROC curve for the performance of CAD-CRF and CAD-Lik at a region level

Case level. The probability for a case being cancerous is computed by taking the maximum probability for the regions in the case. Figure 4 presents the ROC curves with the respective AUCs for CAD-CRF and CAD-Lik at a case level. We performed a one-side statistical test for the difference between the AUCs using ROCKIT [11]. The obtained *p*-value is 0.6%, with 95% confidence interval of (0.01, 0.09) indicating the significant improvement in the cancer detection rate achieved by CAD-CRF. Figure 5 also demonstrates the improved performance of CAD-CRF based on filtering out the FP regions detected by CAD-Lik on two normal cases.

Next we examine the effect of the parameters $\boldsymbol{\beta}$ in Equation (3) on the performance of CAD-CRF. After training the model we obtained a vector $\boldsymbol{\beta}$ with values $\beta_{1,1} = 25.03$, $\beta_{1,-1} = 0.5$, $\beta_{-1,1} = 0.5$ and $\beta_{-1,-1} = 50.06$. These results confirm our expectation that the better classification of cancerous regions is facilitated by the large weight for cancerous neighbour pixels. Further evidence supporting this hypothesis is obtained by comparing the results obtained from CAD-CRF where all values of $\boldsymbol{\beta}$ are fixed to 1, as done in [9]. Then the case AUC drops to 0.786 because 17 cancerous test cases are missed.

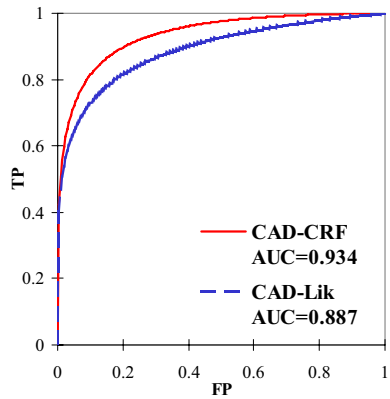

Figure 4- ROC curve for the performance of CAD-CRF and CAD-Lik at a case level

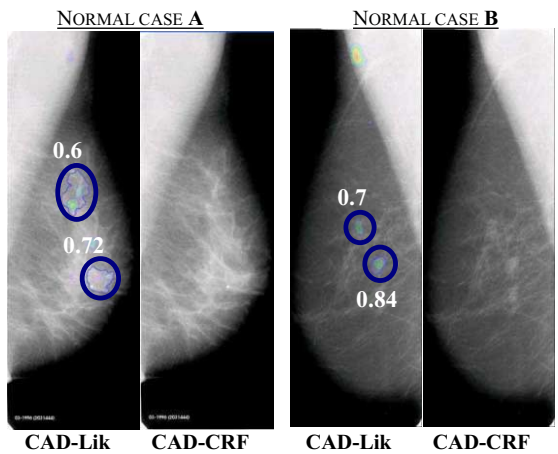

Figure 5- Performance of CAD-CRF and CAD-Lik on two normal cases. The numbers represent the pixel-based likelihoods computed by CAD-Lik for detected FP locations. For the same locations the likelihood computed by CAD-CRF is 0

Computational issues

The learning took 15 iterations in 4.8 minutes on a 2.33GHz Intel Core™2 Duo machine. The learning parameter η was set to 0.0009. The average time of processing a test region was 0.22 ± 0.04 seconds. This implies that for an image with an average number of 3 detected mass locations the testing takes around a second. Thus the improvement in accuracy achieved by using CRF modelling comes at *no* computational costs and can easily be applied in the screening setting.

Discussion

The motivation for the experimental study was to show that extending an existing CAD system by using context information (1) provides significantly better prediction decisions at a region and case level (2) without increasing the computational time. On the one hand, modelling context information leads to significantly better distinction between masses and FPs in comparison to the original CAD system, leading to considerable reduction of FPs while maintaining the high sensitivity rate reached by the CAD system. This improvement is crucial for screening programs where the number of normal cases is much larger than the number of cancerous cases and the sensitivity of human eye decreases with increasing the case disproportion. We also note that the proposed system obtained 100% sensitivity at a FP rate of 0.3 per image, which falls in the radiologists' operating FP range and it is considerably better than the result obtained in [6], for example. Next the current CAD-CRF makes better decisions based on a set of only 5 original pixel-based features. This might also explain the imperfect segmentation achieved by CAD-CRF as shown in Figure 2. However, region segmentation is performed in the subsequent stage of the CAD system once the suspicious pixel-based locations are detected. On the other hand, the extended system remains efficient since the added filtering step does not require additional computational time for providing the prediction decision. This makes the proposed context-based approach also attractive to apply in a screening program where time is an important factor.

Current problem in the original CAD system, which remains in its extended context version, is that a cancerous lesion can be detected by multiple regions. One solution is to perform the testing of the learned classifier for a new region on a larger area consisting of overlapping windows of fixed size. Additional advantage of this approach might be that cancers missed by the CAD-Lik system can eventually be detected.

Conclusion

We presented a novel approach for mass detection based on CRF modelling using local image-based context information. We tested the approach on screening data and compared the results with those obtained from the likelihood image built by a CAD system. The proposed method outperformed the benchmark by reducing significantly the number of FP regions and misclassified normal cases while maintaining high cancer detection rates. The additional filtering step added to the CAD system showed no increase in the computational effort. These results are encouraging for building reliable, fast and accurate CAD systems, which can be employed for assisting radiologists in mammographic screening programs. To make progress in this direction, future work aims to extend the proposed model by including temporal information on the mass development and conducting large-scale experiments with digital screening data.

The Clinical Research Data Repository of the US National Institutes of Health

James J. Cimino, Elaine J. Ayres

Laboratory for Informatics Development, National Institutes of Health Clinical Center, Bethesda, Maryland, USA

Abstract

The US National Institutes of Health (NIH) includes 27 institutes and centers, many of which conduct clinical research. Previously, data collected in research trials has existed in multiple, disparate databases. This paper describes the design, implementation and experience to date with the Biomedical Translational Research Information System (BTRIS), being developed at NIH to consolidate clinical research data. BTRIS is intended to simplify data access and analysis of data from active clinical trials and to facilitate reuse of existing data to answer new questions. Unique aspects of the system includes a Research Entities Dictionary that unifies all controlled terminologies used by source systems and a hybrid data model that unifies parts of the source data models and include other data in entity-attribute-value tables. BTRIS currently includes over 300 million rows of data, from three institutes, ranging from 1976 to present. Users are able to retrieve data on their own research subjects in identified form as well as deidentified data on all subjects.

Keywords:

Clinical research, Data repositories, Controlled terminologies and ontologies, Data reuse

Introduction

The United States National Institutes of Health (NIH) consists of 27 institutes and centers (ICs) dedicated to biomedical research for improving the health of the public. Most ICs are located wholly or in part at the main NIH campus in Bethesda, Maryland, just north of Washington, DC. All clinical research on the Bethesda campus is coordinated through the Clinical Center (CC), the 242-bed, 90-day-station hospital of the NIH.

Much of the information collected on human subjects at the CC exists in the Clinical Research Information System (CRIS). Many researchers also collect data in other locations, including IC systems, laboratory systems within the ICs, and even individual researchers' computers and notebooks. This data distribution causes two problems for researchers. First, CRIS is primarily an electronic medical record system, concerned with the tasks involved in patient care. Although it can support tasks related to research protocols, it is not designed to support research data analysis (e.g, queries for data across subjects in a clinical trial). Second, distribution of data across multiple sources complicates the ability of researchers to use the data to answer their research questions.

The clinical research data at NIH are also of interest to researchers besides those who are collecting them in the course of active trials. The US government mandates the sharing of clinical data that have been collected with federal funding, yet there is no mechanism at NIH to share the data that have been collected here for over half a century.

This paper describes the new NIH Biomedical Translational Research Information System (BTRIS), which has been providing investigators with access to clinical research data since July of 2009. Although still in evolution, BTRIS contains a substantial database and makes use of unique data models and terminology management techniques to merge data from multiple, disparate sources, to support active clinical trials and reuse of data.

Background

NIH Efforts to Consolidate and Reuse Research Data

NIH initiatives have recognized the need for a clinical research data repository to support reuse and sharing of data for clinical research, including the NIH Roadmap NECTAR project,[1] the CABIG project through the National Cancer Institute[2] and the current Clinical and Translational Science Awards (CTSA) program.[3] Based on researcher requirements as well as a business case, the NIH endorsed the concept of a clinical research data repository for aggregation and re-use of data collected at the NIH itself (as opposed to data collected by NIH-funded projects at other institutions). Initial funding for the project was received in 2007 and the development of BTRIS began in earnest in 2008.

The Columbia University Clinical Data Repository

The initial design of BTRIS has been based on experience with the creation of the Clinical Data Repository (CDR) at the Columbia University Medical Center in New York.[4] That system has accrued patient care data since 1988 from many different sources, including laboratories, pharmacies, radiology departments, order entry, and clinician documentation. Over the years, the repository has supported a number of systems for clinical care[5] and clinical research.[6]

All data in the Columbia CDR have been merged using a single, common relational data model that simplifies representation of disparate data while maintaining important distinctions and details.[7] The model makes extensive use of the "Entity-Attribute-Value" (EAV) approach, which allows specifications about the meanings of data to be stored with the data themselves, rather than being modeled as tables or columns in the data model. This method provides great flexibility for accommodating changes in data sources.[8]

The data in the Columbia CDR are represented with a single coding system, called the Medical Entities Dictionary (MED),[9] that unifies terminologies from all the sources providing data to the CDR. The MED provides a one-to-one mapping of individual concepts from each source and organizes them into a multiple-hierarchy ontology that provides definitional information about the concepts and supports data aggregation and inferencing functions.

Design Considerations

System Architecture

The first issue to be addressed in the BTRIS design was whether we should attempt to create a single, centralized repository (as was done at Columbia) or seek to create a federated system in which individual sources systems could be queried to provide data on demand. Although there are potential advantages to the federated model,[10] we quickly realized that most of the sources we would be dealing with (including archived repositories from defunct systems) would be incapable of participating in a federated design. We therefore proceeded to design a centralized repository.

Data Model

In designing the BTRIS data model, we considered the various advantages and disadvantages of traditional modeling approaches and the EAV modeling approach. We chose to take a hybrid approach in which data from disparate sources (for example laboratory test results from CRIS, from archives of the system that preceded CRIS, and from various IC systems) are analyzed and commonalities (such as the fact that all laboratory tests have primary times and results) are represented with columns in tables, while distinct source-specific differences are captured in EAV tables.

In addition to data collected from research subjects, we recognized that we would need a repository of information about the subjects themselves, including the protocols with which they are affiliated and the dates of those affiliations. While some of this information is available from CRIS, much is missing and some individual data may be "tagged" with protocol affiliations that do not match the CRIS database.

Data Acquisition, Extraction, Translation and Loading

The approach to adding data to the BTRIS database is a fairly typical *extraction, translation and loading* (ETL) process. Acquired data are dissected into their component elements and converted into a form compatible with the BTRIS database. They are then stored in the appropriate tables, rows and columns, according to a set of mapping rules. Sources include archived files, copies of active databases, and collections of transaction messages (typically in HL7 format). Sources may provide data on a one-time basis (from archives) or on a periodic basis (typically, daily or weekly). Mapping rules are created manually for each source, based on careful analysis of the source systems' documentation and the actual data provided (which do not always match the documentation).

Data Coding

Early in the project, we established a repository of controlled terminologies used by source systems to represent their data (for example, laboratory codes for tests and unique names for medications). This "Research Entities Dictionary" (RED) is based on the experience with Columbia's MED: each source term corresponds to a unique concept in the dictionary, with additional knowledge about the terms represented in hierarchical and non-hierarchical semantic relationships between concepts. The ETL process maps individual data elements to their corresponding entries in the RED so that the RED Codes can be stored along with the original data. Although the source systems do not use standard terminologies, concepts in the RED are being mapped to international standards to facilitate data sharing, including those contained in the US National Library of Medicine's Unified Medical Language System (UMLS).[11]

Data Reporting

Another key early decision in the system architecture was to determine that BTRIS users would perform retrievals themselves, using predetermined queries that could be tailored by the users for their specific needs. Given that a number of mature commercial "business intelligence" tools currently exist to support such capabilities, we evaluated several options and ultimate chose one to be our user interface to the database. System developers create query templates with general retrieval strategies (for example, to obtain demographic information or laboratory test results) and search filters (e.g., an age range, date range, type of laboratory test, or type of medication). Users provide values for the search filters when running the query to limit retrieval to specific subsets of data.

Queries were developed in response to a variety of perceived information needs. Some of these were identified in the original requirements gathering process for CRIS (see above), while others were developed through interactions with a BTRIS user group composed of interested NIH investigators.

Progress to Date

The BTRIS project officially began in January of 2008, with assembly of the development team in March, acquisition of sample data from several systems in May, and demonstration of a proof-of-concept prototype in July. The initial prototype used SQL Server (Microsoft, Redmond, WA) as the database management system, Terminology Development Editor (Apelon, Mountainview CA) for the RED, and Business Objects (SAP, Newton Square, PA) as the reporting tool.

Experience with the BTRIS prototype informed a number of changes in database design and user requirements, which led to the selection of Cognos (IBM, Armonk, NY) as the reporting tool. Based on the performance and user feedback with the prototype, approval for the project was secured in October. The first version of the actual BTRIS system was released on July 30, 2009 to PIs with active clinical protocols.

The Research Entities Dictionary

Each data source incorporated into BTRIS has one or more controlled terminologies that have been added to the RED. For example, the radiology system has a list of codes for procedures, while the laboratory has codes for tests, panels, organisms, antibiotics, specimens, and results. The RED currently contains 120,636 concepts with 155,321 hierarchical relationships (i.e., each concept has, on average, 1.3 parents).

Database Design

The BTRIS database contains five general sections, with information about investigators, protocols, subjects, the RED, and subject data. Investigator, protocol, and subject tables are related to each other in a typical manner.

Subject data are considered *measurable* (for data with normal ranges, such as laboratory tests), *substance* (for data with routes of administration, such as medications), and *general* (everything else). Data stored in *event* tables (for "things that happen", such as orders and procedures) and *observations* (for "things that report something", such as results and dosages given). Most events are associated with one or more observations. Each table has an associated EAV table (Figure 1); thus, there are a total of 12 tables for subject data (three event tables, three observation tables, and an EAV for each).

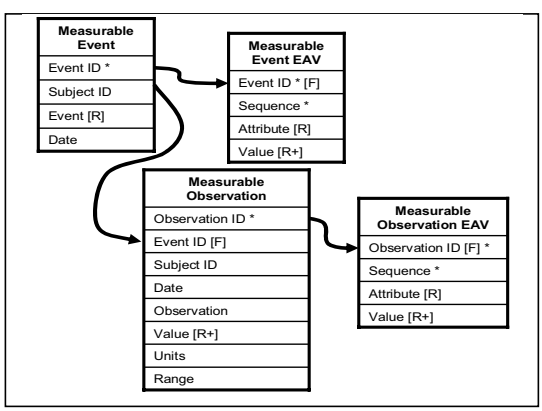

*Figure 1- Simplified view of part of the BTRIS data model. * = primary keys, [F]=foreign keys, [R]=elements coded in RED, [R+]=multiple column elements*

The six main tables include information common to all data from all the sources, such as subject ID, source, name, etc. These tables also include data elements that have been judged to be similar enough across sources that they form part of the merged data model. For example, each source provides one or more times (including date) for observations; for each source, we choose one of these to be the primary time. For radiology procedures, it is the time the procedures were performed. For laboratory tests, it may be the specimen collection time, or it might be specimen analysis time. Other times for each source are retained in the EAV tables.

Another example of the merged data model can be found in the way results of observations are treated. In the BTRIS model, results of observations that have normal ranges (such as laboratory test results and vital sign measurements) are all stored in the same table. Separate columns are used to store the result (or parts of the result) that are numeric, text, controlled terms, and comments. Controlled term results are stored as they appear in the data and as the corresponding RED Codes. Observations without normal ranges, whether nurse's notes, radiology reports, or discharge summaries, are all included as text results in the general observations table.

The RED is represented in two particularly interesting tables. One table relates every concept in the RED to one or more data sources, such that an identifier (such as a laboratory test code from the laboratory system or a medication name from the order entry system) can be uniquely mapped to a particular RED Code. This information is managed in the RED (see below) and exported to this table for use by the ETL process.

Another important RED table is the ancestor-descendant table. This table is derived from the RED hierarchy and supports class-based queries of the subject data. Figure 2 shows a simplified example of the use of the ancestor-descendant table for class-based queries. As of this writing, there are 1,214,646 ancestor-descendant relationships (that is, each concept subsumes, on average, ten concepts including itself).

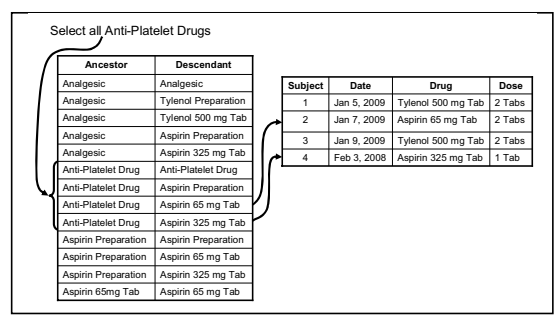

Figure 2- Class-based query for "Anti-Platelet Drugs" using ancestor-descendant table.

Figure 3- Example of text-based terminology searches in BTRIS. Note that each of the selected terms will be used to query against the Ancestor-Descendant table.

Database Content

As of this writing, data have been accrued from three ICs: the Clinical Center (including CRIS and archived tapes of CRIS's predecessor), the National Institute of Allergy and Infectious Diseases (NIAID), and the National Institute of Alcohol Abuse and Alcoholism (NIAAA). Data types include demographics, vital signs, laboratory test results, medication orders, medication administrations, medication lists, and problem lists. Additional data to be added in the near-term include clinical documents (e.g., progress notes and discharge summaries) and procedure notes (radiology, pathology, etc.). Next steps include obtaining radiology image data and gene sequence and expression data from the National Cancer Institute (NCI). Thus far, there are over 86 million rows in event tables, 180 million rows in observation tables, and 855 million rows in EAV tables. Data are derived from 436,422 subjects, 196,036 of whom have been affiliated with one or more of the 9,055 protocols involving 3180 investigators, for a total of 393,447 protocol-subject affiliations.

Reports

Thus far, we have created three types of reports for identifiable data: summary reports (enrollment inclusion report for the Institutional Review Boards (IRBs)), detailed data reports (demographics, vital signs, laboratory test results, and medication data) and "list" reports (which create lists of patients, tests and medications that can be used as filters for other reports). Summary reports and detailed reports for all of these data have been created for de-identified access as well. When running reports, users interact with the RED in one of two ways. A text-based search produces a list of terms from which users may select terms (Figure 3). The users may also browse the RED hierarchy to select terms (Figure 4).

User Experience

Currently, BTRIS has been providing access to identified data for 30 weeks; 111 users have logged on to date. Of the 4,349 reports run thus far, 3,015 have been to retrieve laboratory test results, 303 to retrieve medication information, 275 to retrieve vital signs, and 310 to create summary reports for IRBs. De-identified data have recently been made available. User feedback been extremely positive. Additional reports have been requested; the current BTRIS model appears to be capable of supporting these requests.

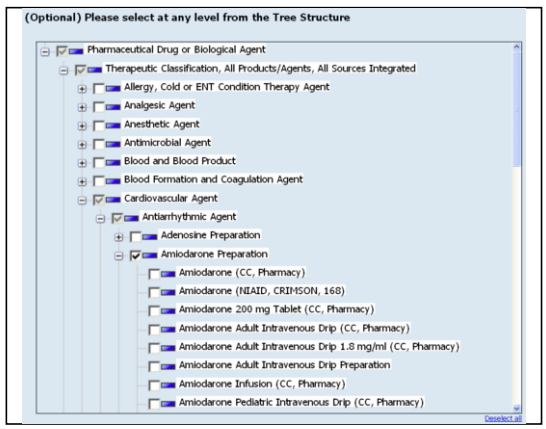

Figure 4- Example of tree-based terminology search in BTRIS. A subsequent query will use the ancestor-descendant table to select all data with any of the 12 amiodarone medications.

Discussion

BTRIS is intended to encompass all clinical research data collected on subjects at the NIH. We began with some initial assumptions about design requirements and desired functionality and have proceeded rapidly through design, construction, and deployment. Our hybridization between column-oriented and EAV data models has allowed us to accommodate diverse data from disparate source in a way that supports aggregation across multiple data sources. The use of the RED and the EAV tables allows us to maintain the distinct aspects of data that are unique to their sources. The combination of the hybrid data modeling and the rich terminology representation provides a novel approach to the creation of a multi-purpose clinical data repository.

Thus far, BTRIS appears to be meeting the needs for researchers to obtain identified data on active clinical protocols. BTRIS is poised to provide access to de-identified

NIH data, across protocols, to analyze old data in new ways and ask new questions. We do not yet know how our researchers will make use of such functionality, but we believe that it will be in creative, unforeseen ways. BTRIS is designed to be flexible enough to meet a wide variety of such needs.

In particular, coding data with the RED supports queries that can aggregate or distinguish data as needed for the users' purposes. For example, instances of the administration of a 325mg aspirin tablet will be retrieved when a user requests that specific information, or all instances of the administration of any aspirin, any analgesic, any antipyretic, any platelet inhibitor, or simply any drug of any kind.

Elements of different data sources that have been stored in common columns in our six main tables have been carefully chosen to support what we believe will be the kinds of data aggregation that researchers are likely to want. For example, a user interested in the use of aspirin in a set of research subjects can request all instances of aspirin administration from the CRIS system, all instances of aspirin orders from the CRIS system, all instances of aspirin on a subject's medication list from the NIAID system, or a combination of any of these. Together with the flexible class-based queries supported by the RED, users have a range of ways to retrieve desired data.

The commercial reporting tool we have chosen (Cognos), allows us to create a variety of reports that appear to meet many of the users' needs, while giving them the power to tailor their queries and immediately obtain results. However, we fully expect that there will be information needs that will not be easily met with this approach. For example, a user may require a complex query that makes use of data from several main tables and EAV tables. In these cases, we may create specialized reports within Cognos, or we may perform retrievals, directly against the database, on the user's behalf.

In addition to the technical challenges, the development of BTRIS has required addressing a variety of policy issues that are beyond the scope of this paper. We have been successful at overcoming these issues in ways that address human subjects protection, privacy, data ownership, data access, and data sharing concerns. Solutions have required combinations of administrative and technical methods.

As with any system, BTRIS is faced with a number of potential limitations, particularly with regard to scaling (as we add image and genomic data), scope (as we add new data from institutes) and performance. Thus far, however, we have been able to address these issues and are not yet close to reaching capacity. BTRIS is still very much in development, as we add new reports for identified data, explore creative ways to reuse de-identified data, and expand to include new sources and types of data. The NIH has demonstrated deep commitment to creating a repository that serves all of the NIH community and eventually the research community at large, for the betterment of the health of humankind.

Conclusion

BTRIS addresses a long-standing need to consolidate clinical research data across the NIH for a variety of purposes. Our design includes a combination of novel approaches, development has been rapid, and it is already successfully addressing the information needs of NIH researchers.

Acknowledgments

This research was supported by the Intramural Research Program of the NIH.

Scientific discovery workflows in bioinformatics: A scenario for the coupling of molecular regulatory pathways and gene-expression profiles

Alexandros Kanterakis, Giorgos Potamias, Giorgos Zacharioudakis, Lefteris Koumakis, Stelios Sfakianakis, Manolis Tsiknakis

Foundation for Research and Technology-Hellas, Institute of Computer Science (FORTH-ICS), Heraklion, Crete, Greece

Abstract

Scientific workflow technologies and tools have become an important weapon in the arsenal of the bioinformaticians and computational biologists. To support this view we present a typical exploratory data analysis scenario involving the combination of information from Gene Regulatory Networks and gene expression data. We further describe the implementation of this scenario using the Workflow Environment implemented in the context of a large EU funded project. In this process desirable features that similar environments should offer are identified and analyzed. The ICT platform presented is evaluated using the chosen scenario as a benchmark. Finally we conclude with an outlook to future work.

Keywords:

Bioinformatics, Semantics, Grid, Web services, Scientific workflows

Introduction

In the new era originated with the successful completion of the human genome sequencing projects molecular biology research has moved from the experimental laboratory bench to systems biology approaches enabled by the *in-silico* (computer-based) study of the huge biological data sets produced by the high throughput technologies such as DNA microarrays [1,2]. To tackle these challenges some new computational tools and techniques have been developed to offer complex data analysis and visualization. Scientific workflows [3,4] present an "umbrella" term to describe the use of computational tools that help to automate data collection, analysis and processing tasks of scientific experiments.

This paper aims to present a complex, yet characteristic bioinformatics scenario and its implementation through the scientific workflow environment implemented in the context of an FP6 EU funded project with the acronym ACGT (Advancing Clinico-Genomic Clinical Trials on Cancer: Open Grid Services for improving Medical Knowledge Discovery, http://www.eu-acgt.org/). The objective of the ACGT project is to develop and test an ontology driven, semantic grid services infrastructure enabling efficient execution of discovery-driven analytical workflows in the context of multi-centric, post-genomic clinical trials [5].

An indicative bioinformatics scenario

One of the most significant sources of genomic functionality stems from Gene Regulatory Networks (GRNs). The compilation of GRNs known today was a complicated effort since it demands the combination and distillation of numerous and dispersed source of information originating mainly from the biomedical literature. As a side effect, devised GRNs are far from complete since, not all genetic interaction are known and the one that are already modeled have not been fully documented. Another issue concerns the fact that each GRN models a separate cellular functionality but this abstraction is rather obsolete. Today, while we move towards the realization of the systems biology vision, we tend to view genetic interactions as parts of a holistic and general mechanism that govern the cellular functionality. Therefore, we need to locate all the different interactions depicted in GRNs and to examine them out of the context of a specific and isolated cellular function (i.e. apoptosis, cell cycle, signaling etc) and move to a more unified and systemic point of views [6].

Decomposition

The first step of our approach is the decomposition of known and established GRNs. Using as our major source of GRNs the KEGG repository [7], we acquired all available regulatory networks related to cellular processes in their special KGML format (http://www.genome.jp/kegg/xml/). As regular XML files, the GRNs encoded through KGML can easily be parsed and modeled as a usual directed graph where, vaguely speaking, genes are the nodes and molecular interactions are the edges. Through the devise and utilization of a specific algorithm we can identify all possible paths contained in each graph. A path is a sequence of nodes and edges that could be followed in a graph in order to form a route from one node to another. Just a single presentation of a node or an edge is permitted in a path. In our effort to manage the paths as molecular functions, we assigned additional values to each gene according to its functional state in the path. We assume that each gene possess a particular functional role either by being in an "ON" or "OFF" state [8]. These values represent the possible activated/non-activated states or, expressed/non-

expressed levels of a gene during a certain cellular process. Moreover, these values are determined by the semantics of the interaction between two genes. Namely, the characterization of a gene in a path as being on an "ON" or "OFF" state is unambiguously specified by its preceding direct regulatory links (edges) with other genes. According to the semantics of the KGML file there are various types of gene interactions but since the functionality of many of them is similar we narrowed down to four basic different kinds of molecular interaction: 'activation', 'inhibition', 'association' and 'disassociation'. These interactions determine the "ON" / "OFF" state of a gene according to the following rules: If a gene is the first node of a path then it should be "ON". Otherwise, if its preceding relation is 'activation' then this gene should be "ON", and if it is 'inhibition' it should be "OFF". In case that the previous relationship is 'association' then the gene is considered to posses the same state as the previous gene in the path whereas, for a 'disassociation' relation, the gene is considered to posses the opposite state of its preceding gene in the path. The intuition that underlies these rules is that: if a gene is on an "ON" or "OFF" state there should be a reason for this. The linear reasoning that we provide goes opposite the direction of the path. As a generalization we could say that the state of a gene depends on two things: the state of its directly preceding genes in the path, and on the nature of its direct preceding interaction that govern its regulation. Thus, each path can be perceived as a history of events that explain the state of each gene.

Microarray Discretization

The set of paths with "ON"/"OFF" annotated genes comprise a functional decomposition of the available GRNs. Our aim is to verify the conditions under which these functions either "work" or "stay idle". This validation can be done by incorporating knowledge from microarray gene expression measurement over tissue samples pre-classified against two phenotypic categories, let "A" and "B". In order to validate the "ON"/"OFF" values of the genes in the paths we discretized the gene expression values into "High" and "Low" values [9, 10].

Combination

For each path Pi originating from the functional GRN decomposition we can determine if it is in an "operational" or in an "idle" (passive) state for any microarray sample Sj as follows: path Pi is considered to be operational for sample Sj, if (and only if) the genes that have "ON" values in Pi have "High" values in Sj, and respectively, the genes that have "OFF" values in Pi have "Low" values in Sj. If there is any misalignment between the "ON"/"OFF" values in the path and the respective "High"/"Low" values in the sample then, the path is considered to be idle for this sample. Applying this procedure for all samples then we can form a contingency table between the operational/idle states of a path and the "A" / "B" class phenotypes of the samples. Each entry in table represents the number of the microarray samples that belong to the "A" (or "B") class and are operational (or idle) in the path. By calculating the contingency table's Fisher's exact test figure we assess the significance of this association. Specifically, paths with low p (<0.001) indicate that they represent cellular functionalities that behaves differently between tissues belonging to class "A" and "B". Thus, by sorting all the paths in ascending p-value order, we gain insight to the cellular mechanisms that explain this differentiation.

Materials and Methods

It is common knowledge that the requirements for the management of the biological data are very demanding because of their size and complexity, quality properties (missing values or noisy data are frequent), and the inherent heterogeneity of the domain. These new requirements have given rise to modern software engineering methodologies and tools, such as the Grid [11] and the Web Services. These new technologies aim to provide the means for building sound and scalable data integration, management, and processing frameworks.

In order for these new technologies to become exploitable by the biologists and bioinformaticians a user friendly environment needs to be in place. This is an already recognized need, and a number of tools have been developed, such as the Taverna Workbench [12], Kepler [13], and Triana [14] to offer efficient and effective scientific workflow environments. The posted challenges related to the provision of state of art discovery processes in scientific workflows are well documented in [15]. In particular a major requirement is that the system should support the "reproducibility" of the results so that the same or other scientists can validate the whole process. Security and trust is another very important aspect of these environments, which means that the users trust the tools that will not inflict harm to their data or that their private data will be subject to unintended analysis by other users.

More specifically for the implementation of the scenario described above the following requirements should be satisfied:

- Secure controlled access to the user data. Although the general consensus is that the data should be shared in order to accelerate the scientific discovery process it is of course the right of the data curator not to share their data especially when sensitive patient information is the case. The microarray data used in the experiment are stored in the Grid Data Management System [16] in the user's private storage area and respective access rights require user's credentials.
- Access to "third party" publically available information sources. In particular the scenario requires the retrieval of the relevant gene regulatory networks from online stores such as the Kyoto Encyclopedia of Genes and Genomes (KEGG) [7].
- A number of processing steps need to be performed: decomposition of networks, discretization of microarray data, etc. For some of these tasks (e.g. discretization) there are available tools but for others the user should be able to enhance the functionality of the system by incorporating custom and reusable analytical methods and tools.

- The reliability and scalability of the system should guarantee that the end user would get the outcome of experiment in a logical time frame in spite of the complexity of the analyses or the size of the involved data sets.
- The system should be intuitive and reflect the user's way of thinking and assist to achieve his/her goals. Specifically, user friendliness and presentation of information at more domain specific and abstract user's conceptualization levels are important characteristics.
- Interoperability issues and heterogeneities among the tools and data sets should be resolved at the minimum cost and disturbance of the user. The use of metadata for the specification of additional aspects such as intent, policies, "meaning", etc., is a critical factor and ease to overcome such difficulties [17].

The ACGT Workflow Environment

To assist bioinformaticians in building their complex scientific workflows, a Workflow Editor and Enactment Environment, called WEEE [18], have been designed and implemented. They consist of a suite of graphical tools that allow a user to combine different web services into complex workflows. This environment is accessible through the ACGT Portal and therefore features a web based graphical user interface. It supports searching and browsing of a tool (service) registry and of respective data sources, as well as their orchestration' and composition through an intuitive and user friendly interface. The created scientific workflows can be stored in a user's specific area and later retrieved and edited so new versions of them can be produced. The designed workflows can be executed in a remote machine or even in a cluster of machines in the Grid so there is no burden imposed on the user's local machine since the majority of computation and data transfer of the intermediate results are taken place in the Grid where the services are run. The publication and sharing of the workflows are also supported so that the user community can exchange information and users benefit from each other's research. WEEE is based on the BPEL [19] workflow standard and supports the BPEL representation of complex bioinformatics workflows.

In the following section we discuss the approach we have followed in ACGT in order to support these requirements using the scenario described in the introduction as a "yardstick".

Results

The workflow implementing the bioinformatics scenario described above is shown in Figure 1. The workflow consists of various web services, each implementing a functional unit of the whole workflow scenario. The core services (activities) are the DiscretizationService ("EntropyDiscretize"), the DecompositionService ("decompose") and the CombinationService ("combine") which independently implement the corresponding functions mentioned previously. Besides these core activities, additional entities are introduced to either make feasible the interconnections between the activities or to further enhance the functionality. In the former case the FileService ("writeFile") is used for data retrieval and storage on the Grid and in the latter case a Biomoby service [20] is used for visualizing the GRN as an image. We have used the BioMoby web service called "getKeggPathwayAsGif", which, given a KEGG network identifier, returns a GIF image of the corresponding pathway.

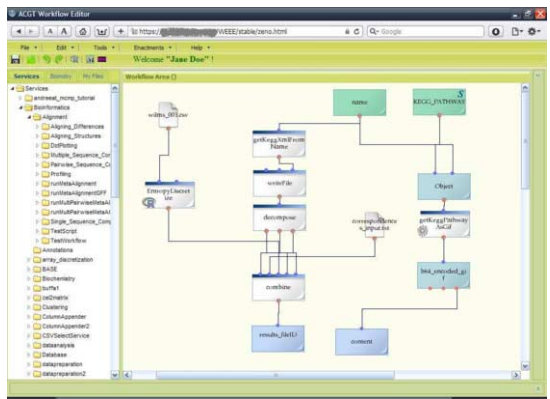

Figure 1 - The workflow implementing the coupling GRN/gene-expression scenario as realized in the ACGT Workflow Editor

The information is passed from one service to another by reference, using files on the Grid. This is done not only for performance reasons, but also for having a means to monitor and document the execution of the workflow, store intermediate results and re-use of data. Since BPEL supports the parallel execution of tasks, some of the services of the workflow are executed simultaneously by the Enactor engine of the ACGT Enactment Environment [18]. This inherent parallelization along with the usage of Grid resources, both in computation and storage terms, permits simultaneous execution of the same workflow with different parameters or input data resulting in significant up scale of the execution speed and the overall performance.

The implemented scenario was applied on an indicative Wilm's tumor gene-expression study [21]. We target the apoptosis GRN (KEGG identifier: hsa04210) as it engages prominent regulatory mechanisms for various cancer types and tumor states. The resulted significant paths are shown in Figure 2. As it can be observed, all the paths have a tendency to move towards the "Survival" or the "Death Genes" regions of the pathway. A pathological situation that leads constantly to the "Survival" or the blocking of the "Death Genes" region can be presumed to lead into endless proliferation of the cell. This finding can act as an indication for further analysis and research in this area.

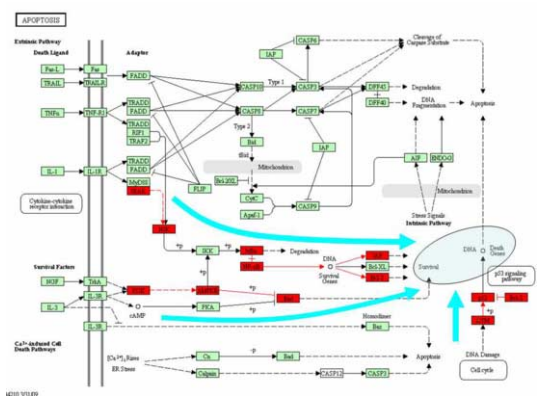

Figure 2 - If we portray the identified paths (red frames and connectors) as a layer on top of the apoptosis GRN then three primaries generic paths (light blue arrows) are emerged that lead towards cellular segments that are known to play vital role in the development (or suppression) of various types of cancer.

Discussion

The design and implementation of the workflow using the ACGT Enactment Environment, enables us to meet most of the above mentioned functional requirements

- The execution of the workflow is performed in a secure manner, using a Public Key Infrastructure (PKI) and access to private data is done only from authorized users. All activities are accessed using the end user Grid credentials and therefore authentication, authorization, and privacy are guaranteed.
- The design of the workflow is intuitive, following a data-flow analysis of the scenario and designing it using a "drag 'n' drop" web based visual editor. In particular the use of web technologies enables ubiquitous access and the straightforward sharing of the constructed scientific workflows.
- The decomposition of the GRN scenario to smaller functional steps enables the composition of the workflow by re-using existing ACGT tools and services, invoking also third-party services and accessing publicly available data, along with the private data on which only the user has access.
- The use of metadata, service, and domain ontologies, although not explicitly demonstrated in this scenario, enables the high level composition and orchestration of data analysis tasks.
- And finally the usage of grid resources and the parallel execution of various BPEL tasks, both of which has a proven record in terms of performance and scalability, results in a reliable execution of the scenario, which scales in a logical manner along with the scale of the input data.

Conclusion

The presented scenario tries to combine two already known sources of biomedical information in order to produce novel knowledge. The decomposition can be perceived as a disassembling of a partly known device into chunks of sub-mechanisms that can be more easily be tested and verified. Our testing platform is the microarray experiments conducted for certain disease types. In our application to Wilm's tumor, the identified paths revealed a more general and abstract path that might give more insights in the genomic regulations that happen during the advancement of the disease. The methodology does not only present an approach for the functional enrichment of microarray data - based on their abundance in specific pathways but also, it is able to reveal and identify regulatory-mechanisms (paths in gene regulatory networks) that discriminate and 'govern' the expression of specific phenotypes.

The presented methodology was also applied and tested on various clinico-genomic studies. In [22] it is utilized in the context of the breast-cancer (BRCA) domain and the gene expression profiling of BRCA patients targeting the Estrogen Receptor (ER) phenotypic categories. In [23] the methodology was applied on a well-known microarray study that targets the distinction between AML (Acute Myeloid Leukemia) and ALL (Acute Lymphoblastic Leukemia) leukemia sub-types. The ACGT scientific workflow environment was also utilized in the context of a real-world genotyping study that targets the discrimination between BRCA and normal patient samples through the identification of 100 SNPs (single nucleotide polymorphisms), measured with the Affymetrix 10K platform [24].

In this exercise the ACGT technologies and tools have succeeded in implementing such a scenario to its entirety and this fact gives more validity to the specific choices we have made and the approach we have followed. Nevertheless we acknowledge the fact that future work is needed in order to enhance the functionality and the utility of the system to the practicing bioinformatician. A particular aspect we are working on is with respect to the "reproducibility" of the workflow results which is strongly connected to the storage and management of the "provenance" information. Furthermore the use of graphical tools for the specification of complex experiments has its limitations. An experienced user may feel more "at home" if some scripting environment allows him/her to easily present his/her workflows in a declarative manner and it's on our agenda to research this direction further in the future.

Acknowledgments

The authors wish to thank the ACGT consortium for their contributions and various ideas on which the ACGT project was developed. The ACGT project is funded in part by the European Commission (FP6/2004/IST-026996).

A Framework for Comparing Phenotype Annotations of Orthologous Genes

Olivier Bodenreider[a], Anita Burgun[b]

Abstract

Objectives: Animal models are a key resource for the investigation of human diseases. In contrast to functional annotation, phenotype annotation is less standard, and comparing phenotypes across species remains challenging. The objective of this paper is to propose a framework for comparing phenotype annotations of orthologous genes based on the Medical Subject Headings (MeSH) indexing of biomedical articles in which these genes are discussed. Methods: 17,769 pairs of orthologous genes (mouse and human) are downloaded from the Mouse Genome Informatics (MGI) system and linked to biomedical articles through Entrez Gene. MeSH index terms corresponding to diseases are extracted from Medline. Results: 11,111 pairs of genes exhibited at least one phenotype annotation for each gene in the pair. Among these, 81% have at least one phenotype annotation in common, 80% have at least one annotation specific to the human gene and 84% have at least one annotation specific to the mouse gene. Four disease categories represent 54% of all phenotype annotations. Conclusions: This framework supports the curation of phenotype annotation and the generation of research hypotheses based on comparative studies.

Introduction

Scientific discoveries for improvement of human health typically begin "at the bench" with basic research, then progress to the clinical level. Studies using animal models play an important role in the generation of research hypotheses based on comparative genotype, phenotype and functional analyses, later tested in human clinical studies [1, 2]. The growing importance of animal models in translational research has given rise to the development of large, species-specific knowledge bases containing curated functional and phenotype annotations, in addition to gene sequences [e.g., 3, 4, 5].

Tools for comparing and contrasting annotations of orthologous genes have started to emerge as part of portals developed by model organism communities (see, for example, the graphs representing the functional annotations of genes across species on the Mouse Genome Informatics system[1]). The Gene Ontology has brought standardization to the functional annotation of gene products, making it relatively easy to compare functions across species. In contrast, phenotype annotation is less standard and the comparison of phenotypes across species remains challenging [6].

Data mining approaches to identifying gene-phenotype associations have been used [7] and orthology has been exploited in some studies [8]. In contrast to the word-based approach in [8], we specifically take advantage of the hierarchical structure of MeSH in order to aggregate diseases into high-level categories to facilitate the analysis of the results.

The objective of this paper is to propose a framework for comparing phenotype annotations of orthologous genes based on the MeSH indexing of biomedical articles in which these genes are discussed. The framework is applied to mouse and human orthologs. We outline two possible applications of this work, namely to support the curation of phenotype knowledge bases and to help researchers with hypothesis generation.

Materials

Several publicly-available data sources are used to relate phenotype annotations across species. Mouse to human orthology information is acquired from MGI. The association between genes and biomedical articles is provided by Entrez Gene. Finally, MeSH index terms corresponding to diseases are extracted from Medline.

MGI

The Mouse Genome Informatics (MGI) system is a knowledge base about the laboratory mouse developed at the Jackson Laboratory [4]. Among the information provided is mammalian orthology and, in particular, curated and uncurated lists of human genes corresponding to mouse genes. In addition to gene identifiers in the MGI system, cross-references to Entrez Gene identifiers are provided.

Entrez Gene

Entrez Gene is the gene-centric knowledge base developed at the National Center for Biotechnology Information (NCBI)

[1] http://www.informatics.jax.org/function.shtml

[9]. In addition to basic information about genes (e.g., symbols and names), Entrez Gene provides cross-references to other components of the Entrez system and to external resources. In particular, Entrez Gene compiles bibliographic references for each gene (with links to PubMed). These references are specific to a given gene cited as evidence for functional annotations, from the GeneRIFs[2], protein databases and model organism databases (GOA[3] for human genes and MDG[4] for mouse genes).

Medline and MeSH

Medline is a bibliographic database developed at the US National Library of Medicine, containing over 16 million citations. Medline citations are indexed with terms from the Medical Subject Headings (MeSH) thesaurus and are available through PubMed in the Entrez system.

The current version of MeSH contains 25,186 descriptors, 4,409 of which correspond to diseases (somatic and mental disorders). The hierarchical structure of MeSH makes it easy to aggregate diseases into top-level disease categories (24 including mental disorders).

Methods

Acquiring phenotype information

Starting from the list of orthologs, we use links established between Entrez Gene and PubMed to retrieve Medline citations for each gene, from which we extract the MeSH index terms corresponding to diseases. An overview of the links among resources is presented in Figure 1.

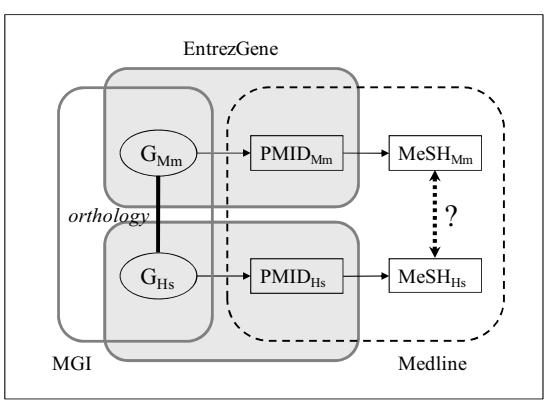

Figure 1- Overview of links among resources

List of orthologous genes

The list of human genes orthologous to mouse genes was downloaded from MGI[5]. Of the 17,796 pairs of genes, 24 were eliminated because no cross-reference to Entrez Gene was provided. Three additional pairs were discarded, in which multiple human orthologs were listed for a given mouse gene. In this case, the curated orthology pair was selected over the computed one. A total of 17,769 pairs of genes remained. Entrez Gene identifiers were available for all 35,538 genes.

Bibliographic references for genes

The association between genes from Entrez Gene and Medline citations from PubMed was queried from the Entrez system using the Entrez Programming Utilities[6]. More specifically, we used the *elink* service to retrieve links from the *gene_pubmed* table. The resulting XML file was processed with XSLT transformation in order to extract pairs of identifiers for the gene (Entrez Gene ID) and the related Medline citations (PubMed identifier or PMID). At least one bibliographic reference was available for all but 552 genes. Orthologous human and mouse genes were associated with a total of 357,008 unique Medline citations.

Disease categories for genes

These 357,008 Medline citations were downloaded in XML format using the *efetch* service and post-processed with XSLT transformation in order to extract the MeSH descriptors from each citation. A total of 5,862,632 MeSH descriptors were extracted and mapped to their identifiers and top-level categories using a local MeSH database. The position of each MeSH descriptor in the hierarchy is indicated by a "tree number". The first node of the tree number refers to the top-level of the hierarchy. For example, the tree number for the descriptor *Megacolon* is C06.405.469.158.701, indicating that it is part of the category *Digestive System Diseases* (C06). Diseases can be related to more than one category.

Linking genes to disease categories

As shown in Figure 1, the various datasets under investigation all share some identifiers: Entrez Gene identifier between orthology data and Entrez Gene, PubMed ID between Entrez Gene and Medline, and MeSH identifiers between Medline and the MeSH thesaurus. These shared identifiers make it possible to chain the various datasets in order to create a link between a given gene and the MeSH disease categories through bibliographic references for this gene. The MeSH disease categories for a given mouse gene can easily be compared to the MeSH disease categories for its human ortholog.

We used Semantic Web technologies (RDF, the Resource Description Framework and related tooling) to process these datasets, because it is well adapted to handling linked data. In practice, the various datasets were converted to "N triple" format. A total of 1.4 million triples were generated and loaded in the open source triple store Virtuoso[7]. We used the RDF query language SPARQL to query the triple store (Figure 2). Two queries were used to retrieve all MeSH disease categories for each gene in a given pair of orthologous genes. A total of 106,454 such associations were exported for further analysis.

Figure 2- SPARQL query for retrieving associations between human genes and disease categories

Comparing phenotype information

Two major types of analyses were carried out, from the perspective of genes and from that of phenotypes. For each pair of orthologous genes, we compared the vectors of disease categories between the two genes in the pair in order to determine if phenotype annotations tend to be the same at the level of disease categories. We considered that a gene was associated with one disease category as soon as the gene was associated with one disease from this category. In practice, we recorded which disease categories were common to the two genes in the pair and which were specific to each species. (No similarity metrics were used to compare the vectors of disease categories for pairs of orthologous genes).

For each disease category, we computed the number of pairs of orthologs for which both genes are annotated to this disease category and, conversely, the number of pairs for which the phenotype annotation was specific to one species.

Results

Of the 17,769 pairs of orthologs under investigation, 11,111 exhibited at least one phenotype annotation for each gene in the pair. The remaining pairs were discarded because no phenotype annotation was available for the mouse gene (1241 pairs), the human gene (3625 pairs) or both genes (1792 pairs).

Perspective of genes

Overall, 26,459 disease categories were common to both orthologous genes, 21,854 were specific to human genes and 20,032 were specific to mouse genes. The number of disease categories per pair of orthologs ranges from 0 to 15, with a median of 2 disease categories common to both genes. There is a median of 2 disease categories specific to the human and mouse orthologs. The percentage of disease categories in common between human and mouse genes is 55% for human genes and 57% for mouse genes. Details of the distribution are shown in Figure 3.

Among the 11,111 pairs of orthologous genes with both human and mouse phenotype annotations, 81% have at least one one phenotype annotation in common, 80% have at least one phenotype annotation specific to the human gene and 84% have at least one phenotype annotation specific to the mouse gene.

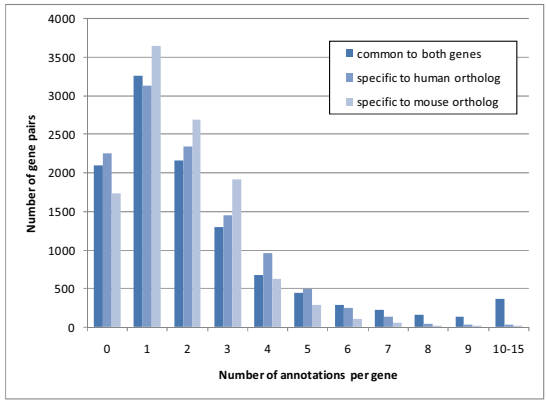

Figure 3- Distribution of the number of phenotype annotations per gene (for the 11,111 pairs of genes)

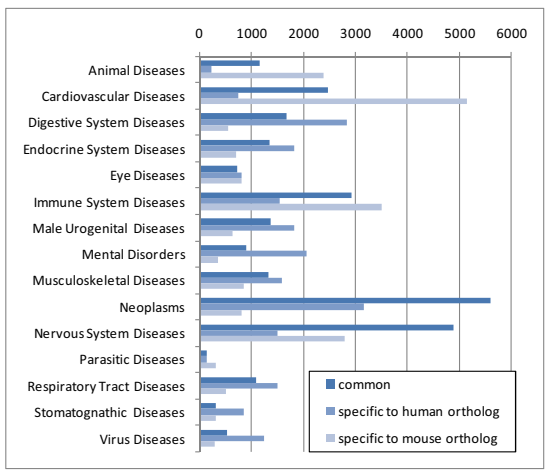

Figure 4- Distribution of the number of gene for each top-level disease category.

Perspective of phenotypes

Of the 24 top-level disease categories in MeSH (including mental diseases), 15 were reached through the phenotype annotations of the 11,111 orthologous genes. As shown in Figure 4, four disease categories represent 54% of all phenotype annotations. These are *Cardiovascular Diseases*, *Immune System Diseases*, *Neoplasms* and *Nervous System Diseases*. Within each category, the repartition between common and species-specific annotations varies widely, with a majority of common annotations for *Neoplasms* and *Nervous System Diseases*, and mostly mouse-specific annotations for *Cardiovascular Diseases*.

Extended example

A clinical researcher interested in the molecular genetics of congenital hypothyroidism could go to Entrez Gene, type "congenital hypothyroidism" and get back such human genes as TPO, TSHR and TG. A translational researcher would easily find out that their mouse orthologs – Tpo, Tshr and Tg – are also associated with the same phenotype.

The translational researcher might be further interested in identifying mouse genes associated with congenital hypothyroidism for which the human ortholog is not. Such genes would indeed be potential candidates for association with congenital hypothyroidism in human.

Using our framework, we start from the MeSH term *Congenital Hypothyroidism* and identify the PubMed articles indexed to this term for which there is a link to a mouse gene. A list of 28 such mouse genes is obtained. We then use orthology relations from MGI to point to the human orthologs of these genes. Ten human orthologs including TPO, TSHR and TG are associated with *Congenital Hypothyroidism* through one or more PubMed articles and are discarded, because their link to the disease is already known. The remaining 18 genes are potentially novel human genes for congenital hypothyroidism.

Among the 18 genes is THRB, ortholog of the mouse gene Thrb associated with congenital hypothyroidism. Although no GeneRIF or functional annotation links THRB to any PubMed article indexed with *Congenital Hypothyroidism* (as of October 15, 2009), a search on PubMed for "THRB AND congenital hypothyroidism[mh]" yields one recently published article (PMID: 19318451) [10], indexed with *Congenital Hypothyroidism*, confirming the association between congenital hypothyroidism and THRB mutation. This example illustrates the lag between the publication of an article and the availability of the knowledge extracted from this article in model organism knowledge bases.

Finally, there are also 12 human genes associated with *Congenital Hypothyroidism,* for which the mouse ortholog is not. The 12 mouse genes could be investigated for potential association with congenital hypothyroidism in the literature in order to ensure the completeness of phenotype annotations for the mouse genes.

Discussion

Applications

Supporting phenotype annotation

By linking genes to MeSH phenotypes, this framework provides a tool to biocurators responsible for phenotype annotation. Starting from a given gene, it helps retrieve relevant articles based on the MeSH indexing of diseases. Curators responsible for a group of genes can easily scan new disease-related articles and flag them for review. Conversely, curators responsible for a group of diseases are provided with the list of genes in relation to which a given disease was discussed.

This study shows that there is a large reservoir of species-specific annotations, i.e., annotations to a given disease category in one species for which there is no equivalent in the ortholog. This information could be used for inferring phenotype annotation from sequence similarity in a way similar to functional annotations to GO "inferred from electronic annotation" (IEA).

Both supporting curation and transferring annotations from other species contribute to address the incompleteness of annotations [11].

Generating novel hypotheses

In the era of translational research, easy access to comparison of phenotype annotation between orthologs can help researchers generate novel hypotheses. Phenotype annotations specific to the mouse with potential therapeutic implications can be explored in humans. Conversely, the set of mouse-specific genes associated with a given disease in the mouse provides candidates for exploration in humans for the same disease. Moreover, annotations specific to the human species may be used to evaluate the molecular markers involved in processes in a mouse model that mimics essential elements of human diseases and to analyze mutant mice carrying specific alleles [12].

Limitations

In our present investigation, the level of granularity for phenotypes is limited to a few dozen disease categories, which is too coarse for a detailed comparison of phenotypes across species, as no single gene is responsible for cardiovascular diseases as a whole. This limitation can be easily addressed by our framework in which all MeSH disease terms are recorded before being aggregated into disease categories for analysis. The example presented earlier demonstrates that a disease such as congenital hypothyroidism can be analyzed individually. However, it might also be useful to extend the framework to physiological phenomena (e.g., bone growth) for phenotypes for which no clinical information is available. Such preclinical phenotypes would also be easier to align with annotations to the Mammalian Phenotype Ontology [13]. In future work, we also plan to investigate the use of semantic similarity measures among MeSH terms for the aggregation of diseases into finer-grained classes.

Generalization

In this paper, we focus on phenotype annotation of human and mouse genes. However, the framework we propose can easily be extended to other species. Orthology relations available from Entrez Homologene can be used in the absence of (or in complement to) curated orthology relations. GeneRIFs are recorded regardless of species and functional annotations to the Gene Ontology (with reference to biomedical articles) are provided by several dozen model organism databases. Finally, MeSH indexing is available throughout Medline. Therefore, links between genes and disease categories can be established for virtually any species. As mentioned earlier, this framework would benefit from being extended to the annotation of physiologic phenomena in addition to diseases, especially for non-mammalian species, such as yeast and fruitfly, for which phenotype information may be recorded at a preclinical level.

Technological considerations

In our experience, Semantic Web technologies including RDF and triple stores greatly facilitate the integration of datasets, especially when shared identifiers are present across datasets. The SPARQL query language was useful for formulating basic queries (e.g., list the disease categories for each gene) and export the data, with satisfactory performance (under one minute). More complex queries could be formulated (e.g., list of the disease categories common to orthologous genes). However, the absence of straightforward mechanisms for expressing negation in SPARQL makes it difficult to formulate queries such as listing disease categories specific to one species. We resorted to simple *ad hoc* programming (including differences between files) in order to carry out the analysis of annotations specific to a given species.

Conclusions

In this paper, we propose a framework for comparing phenotype annotations of orthologous genes based on publicly-available resources integrated through Semantic Web technologies. We show that there is a large reservoir of species-specific phenotype annotations for mouse and human orthologs. The proposed framework supports the curation of phenotype annotation and the generation of research hypotheses based on comparative studies. In contrast to popular resources such as Entrez Gene or GeneWiki, this integrative framework not only supports navigation between gene and phenotype resources, but also the computational analysis of the annotations.

Acknowledgments

This research was supported in part by the Intramural Research Program of the National Institutes of Health (NIH), National Library of Medicine (NLM). Our thanks go to Ramez Ghazzaoui who helped set up Virtuoso.

Abstract

Analyzing microarrays data is still a great challenge since existing methods produce huge amounts of useless results. We propose a new method called NoDisco for discovering novelties in gene sequences obtained by applying data-mining techniques to microarray data. Method: We identify popular genes, which are often cited in the literature, and innovative genes, which are linked to the popular genes in the sequences but are not mentioned in the literature. We also identify popular and innovative sequences containing these genes. Biologists can thus select interesting sequences from the two sets and obtain the k-best documents. Results: We show the efficiency of this method by applying it on real data used to decipher the mechanisms underlying Alzheimer disease. Conclusion: The first selection of sequences based on popularity and innovation help experts focus on relevant sequences while the top-k documents help them understand the sequences.

Keywords:

Information retrieval, DNA microarrays, Alzheimer disease

Introduction

Alzheimer's disease (AD) is one of the most common forms of dementia. In 2006, more than 26.6 million cases of Alzheimer were declared. Due to the increasing number of cases (expected to be multiplied by 4 in 2050), discovering genes involved in AD is becoming a priority for the biomedical community [1,2].

In recent years, DNA microarrays have been successfully used for numerous applications. They allow researchers to compare gene expression in different tissues, cells or conditions [3,4] and provide some information on the relative levels of expression of thousands of genes among samples (usually less than a hundred). Nevertheless, due to the amount of data available, processing them in a way that makes biomedical sense is still a major issue. Data mining techniques, such as [5,6,7], play a key role in discovering previously unknown knowledge and, in this context, it has been shown that they could be of great help to biologists in identify subsets of microarray data that could be useful for further analysis [8]. However, the amount of results obtained with these techniques is still huge and cannot be easily analysed by the experts.

In [8], we proposed a general process, called *GeneMining* based on the mining of sequential patterns. The process starts with a table produced thanks to static experiments we conducted to check the levels of expression of the genes. Each column corresponds to a microarray and each line to a gene. Each microarray measures the intensity of the gene that corresponds to the numerical value in a given cell. We describe in [9] an efficient algorithm to extract frequent patterns of correlated genes ordered according to their level of expression. We extract only patterns that distinguish classes of individuals (e.g. AD vs. healthy). An example of such a pattern is *<(MRVI1)(PGAP1,GSK3B)>,80% AD,10% H* meaning that *"For 80% of AD individuals and 10% of healthy individuals, the level of expression of gene MRVI1 is lower than those of PGAP1 and GSK3B, whose levels of expression are very close".* Although this method was useful, the way to select relevant patterns was not efficient. Depending on the values of parameters, we obtained from 1,000 to 100,000 patterns that were not easy to interpret.

In addition to the problem of the number of patterns, biologists have to face other difficulties. First, they have to link the spot on the microarray to a gene. As no standard exists for specifying names of genes, this is a difficult task. Second, they have to look for relevant publications concerning the genes that interest them. Although some tools are now available to automatically extract information from microarray data [11,12], there is no user-friendly tool to search the literature for sequential patterns.

In this paper, we focus on sequential patterns and our aim is to discover novelties to help biologists analyze how genes interact. Our contribution is three-fold: (i) We first help biologists select relevant sequences according to a specific topic and then to identify both popular genes (often available in the literature) and innovative genes (associated with popular genes in the patterns), (ii) for each sequence, we propose the top-k

relevant documents in the literature for their interpretation, (iii) we propose a visualization tool to underline the relationship between a pattern and its associated documents.

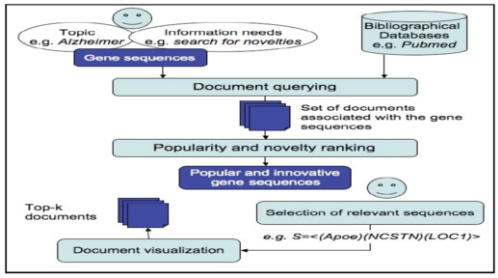

Figure 1- The NoDisco general process

General Process

Figure 1 illustrates the general process of NoDisco, an aid-tool for discovering innovative genes. Entries of the system are gene patterns obtained with an algorithm such as [9], some user information (e.g. study of Alzheimer disease) and a web-service to a bibliographical database such as PubMed. The workflow is organized in the following steps:

1. Document querying: Depending on the topic of interest `T` (e.g., Alzheimer), the tool generates a set of queries (for each sequence `S`) in order to extract documents associated with the topic denoted $Qset_{S,T}$.
2. Popularity and Novelty Ranking: For genes and gene sequences, a popularity rank (taking into account the number of references to the gene in the literature) and a novelty rank (non popular genes linked to popular ones) are computed.
3. Selection of Relevant Sequences: Popular and innovative sequences are proposed to the expert so he can select some of them depending on the information he is looking for.
4. Document Visualization: Top-k documents associated with selected sequences are organized in a sophisticated way for visualisation.

We now describe the process in more detail.

Document querying

For each sequence, a query is submitted to the PubMed Web Service to compute a popularity and novelty score for the sequence. Queries are defined as follows:

Query syntax: A query based on *n* terms with *n-1* operators returns *m* documents:

$$Q(term_1\ op_1\ term_2\ op_2\ \ldots\ op_3\ term_n) \rightarrow \{d1,\ldots,dm\}$$

The operators can be: 'AND, 'NOR' and 'OR'. The number of documents retrieved by a query is denoted $|Q(Terms)|$.

Gene designation: As detailed in [13], recognizing biological objects in natural language is a very difficult task for many reasons: The general lack of annotator agreement and naming conventions, excessive use of abbreviations, frequent use of synonyms and homonyms, biological objects often have names consisting of many individual words, such as '*human T-cell leukaemia lymphotropic virus type 1 protein*', etc. For all these reasons, in the query, it is not possible to directly use the names of a gene embedded in such a sequence. So, with the Entrez gene[1] Web Service, we first look for all aliases of the genes and store them in a contextual Gene Dictionary called $DicG_{all\_id}$ (a dictionary by type of microarray). For example, in $DicG_{all\_id}$ one alias for the gene *Apoe* is *Apolipoprotein E*.

Query about sequences: To build a query associated with a gene (e.g. *Apoe*), we group all aliases found in $DicG_{all\_id}$ with the operator *' OR'* (e.g. *Q(Apoe OR Apolipoprotein E)*) . To build a query associated with a sequence (e.g. *<(Apoe)(VAMP2)>*) , we compose the previous aliases of the two genes with the operator '*AND*' (e.g. *Q((Apoe OR Apolipoprotein E) AND (VAMP2)))*. In the rest of this article, we use the term *Q(gene1)* for $Q(gene_1\ OR\ al_1\ OR\ al_2\ OR\ \ldots)$ where $al_1, al_2, \ldots$ are aliases of the gene $gene_1$.

Topics of interest: Not all the documents retrieved using the name of a given gene will be relevant for the biologist. Their number can be reduced by using the parameters available in the PubMed search engine such as:

- Standard parameters: Author, date, journal publication, language, accessibility (full or free text, abstract).
- Parameters about the topic: Type of article (clinical trial, editorial, etc.), species (human, animal), sex (male, female), journal topic, etc.

For example, to build a query associated with the sequence *<(Apoe)(VAMP2)>* and the topic *T= ' Alzheimer'* , we compose the preceding query and the topic with the operator *' AND'* : *Q((Apoe OR Apolipoprotein E) AND (VAMP2) AND Alzheimer).* Operators can also be used to specify the terms of the topics (e.g. *T= " human AND female").*

Popularity and Novelty Ranking

We use the number of documents retrieved for each gene to rank them according to their popularity and novelty.

Popularity of a gene: A gene G_i is *popular* if the number of documents dealing with this gene in the literature is greater than the defined threshold *pop_min_gene*. For each gene G_i in $DicG_{all\_id}$, its popularity, $Pop_{Gi,T}$, according to a topic T is obtained as follows:

$$\forall G_i \in DicG_{all\_id},$$

$$Pop_{G_i,T} = \begin{cases} 1 & \text{if } |Q(G_i,T)| > pop\_min\_gene \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

[1] http://www.ncbi.nlm.nih.gov/sites/entrez?db=gene

For example, if *pop_min_gene=100* and $|Q(ApoE,Alzheimer)| = 3805$ then *ApoE* is popular.

Popularity of a sequence: A sequence S_i is *popular* if the proportion of popular genes in S_i is greater than the defined threshold *pop_min_seq*. For each sequence S_i, we compute its popularity, $Pop_{Si,T}$, according to a topic T. Let PS_i be the set of popular genes in a sequence S_i:

$$\forall S_i \in SP,$$
$$Pop_{S_i,T} = \begin{cases} 1 & \text{if } \frac{|PS_i|}{|S|} > pop\_min\_seq \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

For example, *S=<(Apoe)(NCSTN)(LOC153222)>* is a popular sequence for *pop_min_seq=0.5* because *Apoe* and *NCSTN* are popular ($|PS_i|/|S|=2/3$).

Innovative genes: A gene G_i is in *an innovative relation* with popular genes if the number of sequences associating G_i with popular genes is greater than the defined threshold *new_min_gene*. For each gene G_i of $DicG_{all\_id}$, we compute its novelty, $New_{Gi,T}$, according to a topic T. Let $Pseq_{Gi}$ be the set of popular sequences containing G_i:

$$\forall G_i \in DicG_{all\_id},$$
$$New_{G_i,T} = \begin{cases} 1 & \text{if } |PseqG_i| > new\_min\_gene \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

For example, *PUM1* is an innovative gene because it is present in more than *new_min_gene* popular sequences.

Innovative sequences: A sequence S_i is *innovative* if the proportion of innovative genes in S_i is greater than the defined threshold *new_min_seq*. For each S_i, we compute its innovative score, $New_{Si,T}$, according to a topic T. Let NS_i be the set of innovative genes in a sequence S_i:

$$\forall S_i \in SP,$$
$$New_{S_i,T} = \begin{cases} 1 & \text{if } \frac{|NS_i|}{|S|} > new\_min\_seq \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

For example, if *new_min_seq*=0.5 then s*=<(Apoe) (LOC90624)(PUM1)>* is an innovative sequence as *PUM1* and *LOC90624* are two innovative genes ($|NS_i|/|S|=2/3$).

At the end of this step, we have reduced the initial set of sequences to two sets, popular and innovative sequences, which can be proposed as relevant sequences for the experts.

Top-k documents: To help the expert analyze a sequence S_i, we look for the Top-k documents. To this end, we ask PubMed to retrieve all documents D associated with genes in S_i and we rank them using the two following methods.

First, we compute the score S_{di} for a document d_i published in *the year d* and dealing with the g genes. Let *MinA* (resp. *MaxA*) be the year of publication of the oldest document (resp. the year of publication of the most recent document). Let *MinG* (resp. *MaxG*) be the minimum (resp. maximum) number of genes cited in the documents of D. $\langle$ is a coefficient. We then rank the documents according to the equation 5. $S_{di} \in [0,1]$. $\langle \in [0,1]$. The value $\langle=1/2$ gives the same weight to both components of the formula.

$$S_{d_i} = (1-\alpha) * \frac{(MaxA-d)}{(MaxA-MinA)} + \alpha * \frac{(MaxG-g)}{(MaxG-minG)} \quad (5)$$

Second, in the documents described by the two criteria (year of publication and number of genes), we look for the Pareto points [14]. These points correspond to documents that are not dominated by others considering both criteria (i.e. they are the best ones considering one criterion alone and the best compromises based on both criteria). We then select k documents in these points. Finally, for the top-k documents, we obtain a rank that can be used by the expert to analyze a sequence[2].

Experiments

Case study

In the framework of the PEPS-ST2I Gene Mining project, we mined real data produced by analysis of DNA microarrays (Affymetrix DNA U133 plus 2.0) [10]. The aim was to decipher brain aging mechanisms. Aging is the primary risk factor in neurodegenerative disorders such as Alzheimer's disease. We analyzed the transcriptome from the temporal cortex of *Microcebus murinus*, a relevant primate model because as they age, some of them present the same lesions observed in human brains affected by Alzheimer's disease. Primates were divided into 3 groups: 6 young adults, 10 healthy aged and 2 aged with Alzheimer's disease lesions. We used DBSAP [10] to discover sequential patterns with several parameters. In the worst case, we obtained approximately 50,000 gene sequences. The longest sequence was composed of eight genes. These sequences can be used to distinguish between AD animals and healthy animals. However, as this number of sequences is too huge, the process of interpretation described in [9] cannot be directly applied on these sets of sequences.

Evaluation of popular and innovative sets

To identify relevant sequences, we analyzed popular and innovative genes and gene sequences. The topic we sued was "Alzheimer" and we varied the four other parameters: *pop_min_gene* (10, 50, 100), *pop_min_seq* (0.25, 0.5, 0.75), *new_min_gene* (5, 10, 30), and *new_min_seq* (0.25, 0.5, 0.75). We obtained quantitative results that varied with the values of

[2] Information on the visualization tool is available at: http://www.lirmm.fr/~bringay/Bringay/MedInfo/MedInfo.html

the parameters[3]. For example, from a set of 50,000 sequences, with the parameters *pop_min_gene=100, pop_min_seq=0.5, new_min_gene=10,* and *new_min_seq=0.5*, we obtained *336* popular and *208* innovative sequences. The important issue is that we defined two sets of sequences in a quantity which allows the use of the process described in [9]. The choice of the parameters depends on the number of sequences we define at the beginning of the process.

Evaluation of the ranking documents

In the first part of these experiments, we showed that we were able to help experts to select relevant patterns. The next step was to evaluate the quality of the NoDisco documents associated with these patterns. To this end, we arbitrarily selected five popular sequences (see figure 2) and studied them in collaboration with experts. We built three sets of ranked documents: (i) We ranked them according to their S_{df} score ($\langle$=1/2), (ii) We chose the first Pareto points, (iii) We extracted the first documents returned from PubMed using the names of the genes.

seq 1: ADAMTS9-APOE-KCNC1-PTPRA-LOC284214
seq 2: GSTO1-VAMP2-SMARCA2-PTPRA-UBE1DC1-CART
seq 3: ADAMTS9-PML-UBN1-FAT-SRRM2
seq 4: ADAMTS9-PML-PRLH-FAT-NBS1-RBX1-LOC284214
seq 5: ADAMTS9-PLXNA2-GSK3B-FAT-FLJ11029-DNAJB6

Figure 2- Five gene sequences

Are the documents returned by the different methods the same? For each pair of methods, we computed the number of shared documents considering the 10, 20 … 100 first documents in each ranking list (see Table 1). Results corresponded to the average number of documents obtained by the five sequences. For instance, we compared the 30 first documents sorted by PubMed and S_{doc}. In this case, we obtained an average of 4% of shared documents with both methods. Table 1 shows that the three approaches returned different documents (i.e. we extracted new knowledge that was not discovered by querying PubMed alone). These experiments were based on a large number of documents (1,083 different documents returned using our approaches).

Finally, the number of documents returned by the different approaches with the five sequences was very different. Table 2 shows that method S_{doc} returned a larger number of documents. This specific retrieval task (i.e., by generating a specific query) may be very useful for experts. This result can be explained by the fact that our method S_{doc} takes into account synonyms to extract relevant documents. The number of documents returned by the Pareto method was low because this method rejects all documents that are not in the Pareto front (i.e. dominated documents [14]).

[3] Due to lack of space, all results are not reported here, but are available at: http://www.lirmm.fr/~bringay/Bringay/MedInfo/MedInfoResults.pdf

Table 1- Search for shared documents with the three methods

No. of doc.	10	20	30	40	50	60	70	80	90	100
%PubMed vs. S_{doc}	0	2	4	4	4.8	4.3	4.2	4.2	3.7	3.4
%PubMed vs. Pareto	2	2	2.6	2	1.6	1.3	1.1	1	0.9	0.8
%Pareto vs. S_{doc}	0	0	2	2	2.8	7	6.5	5.7	5.1	4.6

Table 2- Number of documents retrieved with the 3 methods

Methods	PubMed	S_{doc}	Pareto
Number of doc.	404	537	225

Are the documents returned by our methods relevant? To go deeper into the analysis of the documents, we asked an expert to analyze the abstracts of the first documents retrieved. He manually analyzed the 10 first abstracts retrieved by *seq1* and *seq2* using our three ranking methods (60 documents were manually analyzed). He classified them in five groups: (1) *Relevant*; (2) *Too old* (e.g. documents published before 2000 were not relevant because they were published before the creation of the Affymetrix DNA microarray) (3) *Semantically not relevant* (e.g., documents with the term CART in their summary meaning Classification And Regression Tree instead of the gene CART) (4) *Off the topic* (e.g. documents retrieved in a journal of acupuncture are not relevant for biologists) (5) *Not related to the sequence.* When no term corresponding to one of the genes or to one of the aliases occurred in the abstract, the expert was unable to evaluate the relevance of a document. The classification is summarized in Table 3.

Table 3- Evaluation of the documents by the expert

Evaluation	PubMed	S_{doc}	Pareto
1	13	6	9
2	0	4	0
3	2	6	0
4	1	1	2
5	4	3	9

Queries based only on PubMed returned the best rate of relevant documents but the results of the two other methods (S_{doc} and Pareto) can be easily improved: The noise corresponding to irrelevant documents can be easily reduced by adding domain knowledge to our method.

First, we can consider documents published before 2000 to be less important. For example, we retrieved several documents dealing with PTP (Pancreatic Thread Protein), published before 1999. These documents were not relevant for the biologists concerned, who were looking for information about PTPR4, Tyrosine Phosphatase Receptor, tested with microarrays. These two proteins are linked by the same alias, but we can distinguish between them by the publication date.

Second, we can extend the topic to similar topics. For example, we did not retrieve any documents with the association VAMP2 and AD but had better result with “aging”. When a query does not produce the expected result, the topic can be extended by consulting a list of related topics. The concept of

family can be used in the same way. The genes are organized according to their properties or functionalities. For example, KCNC1 did not produce result with AD, but KCNC (subunit of the potassium channel family) did produce results. Thus, when there is no result, the query can be extended by using the family as the term of the query instead of its alias.

Discussion

Some tools are now able to mine the biological literature. BioMinT [15] is an easy-to-use information retrieval and extraction tool targeted at online biomedical literature. This tool retrieves relevant documents and proposes a range of relevant outputs. However, the tool is not dedicated to the analysis of genes. From a set of genes defined by the user, MedMiner [11] filters and organizes large amounts of textual and structured information retrieved by public search engines (GeneCards and PubMed). GoMiner [12] goes a step further and uses the Gene Ontology (GO) to identify biological processes, functions and components in a list of genes, and generates hypotheses to guide further searches.

Although existing tools are very powerful, they are not dedicated to the analysis of gene sequences produced by analysis of DNA microarrays. With NoDisco, popular sequences can be identified that will be useful to biologists to validate the gene sequences they identify. Indeed, these sequences are composed of genes that have already been linked in the literature and are well known. It is also possible to identify innovative sequences, revealing surprising associations of genes, which can draw the attention of the biologist to unknown gene interactions. For example, the expert who collaborated with us identified an innovative gene ADAMTS9. This gene is not yet known to be involved in Alzheimer disease (i.e. there is no publication dealing with ADAMTS9 and "Alzheimer"). However, in the sequences, this gene is linked to popular genes that are well known for their implication in Alzheimer disease. Moreover, the expert underlined the fact that two other genes in the same family, ADAM9, ADAM10 and ADAM17, have already been linked to Alzheimer disease, so the link between ADAMTS9 and Alzheimer needs to be studied.

Conclusion

The development of DNA microarray technologies and the explosion of online scientific biological literature overwhelm the ability of researchers to take full advantage of available knowledge. In this paper, we presented the NoDisco process which enables biologists to select relevant sequences obtained from DNA microarray analysis. According to a topic, biologists can identify popular and innovative genes along with the sequences in which these genes appear. We also linked gene sequences to the top-k documents in order to facilitate their interpretation. As discussed in the Experiments section, the relevance of the ranking in NoDisco can be easily extended to include domain knowledge. Moreover, NoDisco can be extended to other areas involving medical or pharmacological information. More generally, NoDisco can be used to organize the information retrieved from any arbitrary PubMed search.

[a] *Institute for Medical Informatics (IMISE), University of Leipzig, Leipzig, Germany*
[b] *Clinical Trials Centre Leipzig (ZKS), Leipzig, Germany*

Abstract

Healthcare and medical research in Germany are heading to more interconnected systems. New initiatives are funded by the German government to encourage the development of Integrated Research and Treatment Centers (IFB). Within an IFB new organizational structures and infrastructures for interdisciplinary, translational and trans-sectoral working relationship between existing rigid separated sectors are intended and needed. This paper describes how an IT-infrastructure of an IFB could look like, what major challenges have to be solved and what methods can be used to plan such a complex IT-infrastructure in the field of healthcare. By means of project management, system analyses, process models, 3LGM²-models and resource plans an appropriate concept with different views is created. This concept supports the information management in its enterprise architecture planning activities and implies a first step of implementing a connected healthcare and medical research platform.

Keywords:

Medical informatics, Hospital information systems, Integrated advanced information management systems, Biomedical research, Clinical trials, Information management, Systems analysis, Information system models, Translational medicine.

Introduction

Integration of inpatient and outpatient Care in Germany

From an information management point of view, healthcare in Germany is strictly separated in two sectors: outpatient (practitioners and specialists) and inpatient (hospitals) treatment. Both sectors have had different information systems, no common communication standards, no harmonized electronic health records and no common IT-infrastructure which they can share. Because of demographical change, improvements in medicine and following increase of costs, the German government started at least two major strategies to reform this situation. One example is "Integrated Care" which allows process-oriented, interdisciplinary and trans-sectoral networks between practitioners and hospitals [1]. The second example is the German electronic health insurance card and the underlying IT-infrastructure which will provide a shared platform for administrational and medical data [2].

Integration of Healthcare and Medical Research in Germany

Likewise there is a strict separation between care and research. Medical research is commonly organized in clinical trials and studies. To coordinate studies competence networks with focus on selected diseases were built [3, 4]. A competence network consist of a coordination center which controls the trials and collect the medical data from the study centers (about 20-100) which are performing the trials [5-7]. To avoid reinventing the wheel in every competence network the German Telematikplattform für Medizinische Forschungsnetze (TMF) e. V.[1] gives support in common issues like legal, ethical and questions of quality management furthermore in IT-projects, biobanking and privacy concepts [8].

The next and current integrative step is to improve medical research by considering cause and effect of a disease and encouraging translational medicine as a two-way road between research and treatment [9]. Since 2008 this has been done in Germany by funding "Integrated Research and Treatment Centers" (IFB) by the German Ministry of Education and Research (BMBF) [10]. Translation here means accelerating knowledge transfer between basic research, patient-oriented research and clinical application. An IFB is focused on a selected disease like a competence network but in a wide (cause and effect) and interdisciplinary way flanked by offers for young researchers and professional education. To obtain these goals new structures in organization and infrastructures especially IT-infrastructures are needed.

Major Challenges

Establishing an IT-infrastructure for better integration of patient care and medical research, i.e. for efficient support of translational medicine leads to considerable challenges. These challenges range from technical to financial issues [11].
In this paper we will focus on the Integrated Research and Treatment Center at Leipzig University Medical School and Leipzig University Hospital (LUH). This center integrates

[1] http://www.tmf-ev.de

research and treatment for adiposity diseases. We will deal with the challenges by answering the following questions:

- *Screening and Tagging*: How to identify patients as being at risk of adiposity? How to recruit the identified patients as attendees for clinical trials and refer them to the IFB for treatment?
- *Integration of information systems*: How can medical data of patients being treated within the IFB be collected in the respective information system of the hospital and afterwards made available in the information system of clinical trial management organization?
- *Pseudonymization:* How medical data originating from patients' treatment can be reused for research and clinical trials without violating patients' privacy?

Methods

Based on an analysis of the business processes the architecture of the IT-infrastructure can be designed. Doing so we applied the following methods:

Process Modeling

Flow charts [12] have been used for modeling the business processes. Note that 'business' does not imply a focus on administrative aspects but implies a holistic view on the patient related processes constituting the business of an IFB.

The simplicity of flow charts is their advantage. So even persons involved in IFB who are not familiar with business process modeling can understand it and are able to collaborate specifying the processes.

After having modeled the processes we enhanced the resulting flow chart with assignments of information system components to be used.

The enhanced FC (eFC) served as a specification for the architecture of the IT-infrastructure.

Modeling Enterprise Architectures

There are several modeling approaches to support information managers in healthcare in enterprise architecture planning. Based on our experiences in modeling information systems of institutions in healthcare [13] we decided to use the three layer graph-based meta model (3LGM²) [14] for this integrated IT-infrastructure as well. Based on 3LGM² the 3LGM²-tool [15] was developed to support modeling of information systems in health care. 3LGM² distinguishes an information system in a domain layer to describe enterprise functions and processed information, a logical tool layer to describe application components and the communication between them and a physical tool layer to describe hardware components. Interdependencies between concepts of different layers are described as so called inter-layer-relationships. 3LGM²-tool has important features to work with sub-models and doing analyses on the modeled information system.

In order to link the process model to the architecture model we extracted the 'activities' of the eFC and mapped them onto functions at the domain layer of the 3LGM² based architecture model.

Systems Analyses

Existing 3LGM²-models of the Leipzig University Hospital (LUH) and reference models for information system architectures [16] were used for system analyses. Furthermore models and experiences from previous projects in competence networks in the Center of Clinical Trials Leipzig[2] and from activities in the TMF [17] were included.

Results

Process model

There are several processes in the IFB needed to subscribe patients and to analyze their data with respect to the referral to IFB. The process model in Figure 1 shows some of these processes, their requirements and the data used. The processes at IFB can be divided into two steps. At first step, there is a need to identify, tag and follow-up patients during the conventional treatment at LUH (light gray boxes). The second step is to enclose these patients in trials at the IFB (dark grey boxes). Both processes need a seamless integration of application systems in LUH and application systems in clinical research. It is indicated where single processes are located by assigning annotations of information system components to processes (links with dotted lines).

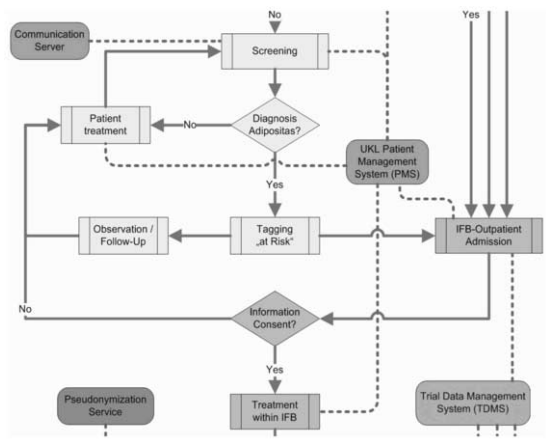

Figure 1 – Model of workflow

The processes consist of sub-processes, which give detailed information about single steps. The process "Screening" for example describes how patients could be identified from a hospital information system [18]. To achieve this, patient records have to be scanned for relevant items. Based on this item data, scores (e.g. body mass index) and ratings were calculated. These scores and ratings are required to support a doctor's decision of the following processes. So she/he can decide

[2] http://www.zks.uni-leipzig.de

whether the patient continues the conventional care process or is suitable for treatment within IFB.

All processes have to comply to legal aspects of data privacy and data security.

Domain layer

The process model is a good preparation for 3LGM²s domain layer. In this layer a more detailed view on the processes is possible. In Figure 2 relations between functions (rectangles) and object types (ellipses) are modeled. Activities of the eFC have been mapped onto respective functions.

This approach leads to a clear understanding of the information objects and how they are linked with functions and therefore activities from the process model.

In the part of the domain layer shown in Figure 2 there is a function called "test person administration". This function is a sub-process of "IFB-Outpatient Admission" from eFC. It is linked with several object types like "master data", "covering letter" and "target date" which are needed for this task or which are interpreted.

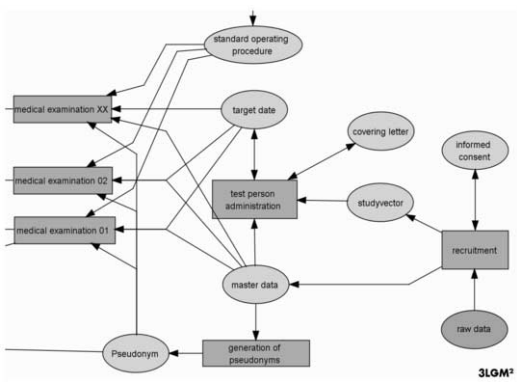

Figure 2 – 3LGM² domain layer

Logical tool layer

The concept for the information systems architecture at its application systems' layer is outlined in Figure 3. This concept includes not only Leipzig University Hospital (LUH) but third parties contributing to this project as well. Patient care in LUH and at third parties is supported by their application systems for patient management (PMS), intensive care unit management (PDMS), laboratory (LIS) and so on. Trial data is stored and trial management is supported by the trial data management system (TDMS).

There are two ways for data capturing. First data collected in PDMS and LIS can be sent to the TDMS. The second way is to capture data using electronic case report forms (eCRF) provided by the software used for the TDMS. The eCRF modules will be used in the context of clinical documentation and therefore in parallel to using the PMS. Integration can be provided by "context integration" techniques; but it still has to be decided whether the HL7 related CCOW standard or service oriented portals shall be used [19].

According to data privacy and security constraints the separation of data in treatment and research contexts will be guaranteed by using Study Identification Codes (SIC) in the context of trials instead of Patient IDs, which are used in the treatment context. A Pseudonymization Service [20, 21] will provide an appropriate SIC for a PID on request. The Pseudonymization Service will store a list of PIDs and corresponding SICs, but no more identification data.

MDAT delivered to TDMS may be passed to the Biobank Management System where applicable.
Because of the high amount of data of high throughput sequencers their data is stored in a separate application system which is designed to handle genetic data (GeWare).

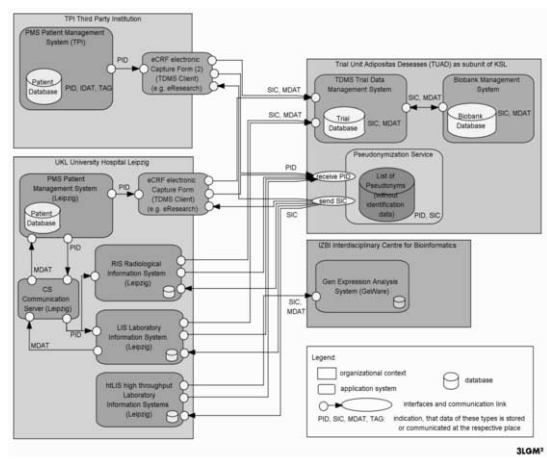

Figure 3 – 3LGM² logical tool layer

The sub-model of application systems in Figure 3 is related to the activities in the workflow as described in Figure 1 and linked with the domain layer in Figure 2 as part of the whole 3LGM²-model. These links associate functions with application systems and object types with data bases, interfaces and communication links. In summary the logical tool layer explains how the activities will be supported by application systems.

Physical tool layer

3LGM² also supports modeling hardware components of an information system. A part of the physical tool layer of IFB is shown in Figure 4. Hence an overview of the planned network components, servers, laboratory hardware and workstations is modeled (boxes in Figure 4). Locations, information about network links (e.g. network type, link speed), operating systems and a lot of additional metadata is included, too.

Inter-layer-relations to the logical tool layer describe for example links between application systems and physical hardware. In this way it is modeled that e.g. TDMS and LIS is

planned for installation on a dedicated server with defined parameters on a specified location and environment.

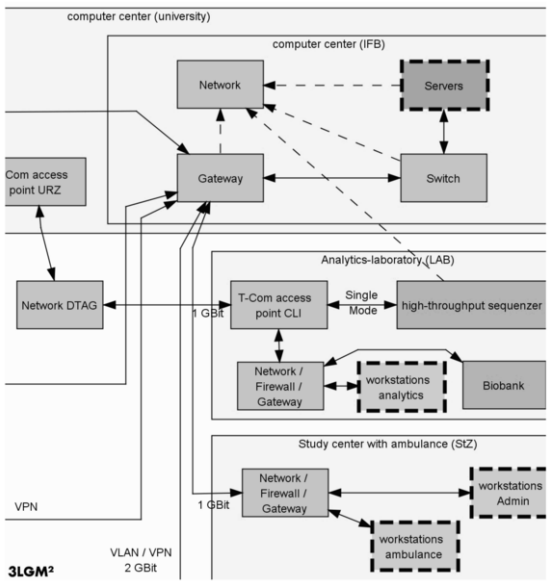

Figure 4 – 3LGM² physical tool layer

Discussion

All models presented here are based on information available at the beginning of this ambitious project. Thus we could not report on an implemented IT-infrastructure but on the models serving as the blueprint for the implementation and on the methods used to achieve the models. Hence this approach is not validated until now.

We are sure that during the implementation of single working packages the models will have to be refined to synchronize them with reality. This is needed to keep track of the work in progress.

Some changes are predictable. The role of the communication server (CS) in the hospital information system (HIS) is an example. At the logical tool layer of the current 3LGM²-model, the CS supports the screening process by processing HL7 messages. This is a possible way but there are other suggestions and ideas to support the screening process like mentioned in this overview [18] or perhaps in a single source approach [22]. So new information system components in logical tool layer could appear, like a data-warehouse which collects medical data of the HIS. Another example is the rollout of the German health insurance card and their underlying IT-infrastructure. This infrastructure could help to connect third party health organizations much easier. But today there is no final date known, when all needed features will be available.

We found, that the model based approach presented here provides effective support in designing a complex IT-infrastructure for translational medicine. Process analyses help to understand the processes which are needed for IFB. A 3LGM²-model proceeds clear functions and object types from the process model and is able to describe the connected application systems, data bases and their communication relations and furthermore network and server hardware which are hosting all components from the logical tool layer.

Conclusion

As shown in this paper, major challenges have to be solved to plan an IT-infrastructure for an Integrated Research and Treatment Center. Especially screening and tagging, integration of information systems and pseudonymization have to be realized.

Screening and tagging are necessary functions to make sure that patient being at risk of adiposity can be identified and both be recruited as attendees for clinical trials and referred to the IFB for treatment. The outlined modifications of the information systems illustrate in multiple views how this could be achieved.

The integration of both the information systems in context of care and the information systems in research context leads to an IT-infrastructure we searched for. This integrated IT-infrastructure is able to support the specified processes.

Especially in healthcare data privacy is one of the most important constraints. So an integrated IT-infrastructure has to implement facilities to ensure this. Besides implementing features of application and network security the use of a pseudonymization service guaranties a reuse of medical data originating from patients' treatment or research and clinical trials without violating patients' privacy.

Abstract

Integrating biomedical research and patient care is a challenging issue requiring interoperability solutions. During a clinical trial, clinical data are captured twice, first in the Electronic Health Record (EHR) and then in the Clinical trials Data Management System (CDMS). The aim of REUSE (Retrieving EHR Useful data for Secondary Exploitation) project is to provide a single source solution for electronic data capture to the investigators of a university hospitals involved in a multi-centric clinical trial. We first investigated the differences between the workflows of patient care and biomedical research to specify the use of EHR for clinical trials. Then we defined a semantic interoperability framework in order to enable the reuse of EHR clinical data and implemented a mediator that transforms CDISC Operational Data Model (ODM) XML into proprietary XML document templates of different EHR solutions and vice-versa. Implementing electronic data capture for biomedical research within EHR eliminates redundant data entry, thus improving data quality and processing speed. Moreover, unlike other initiatives such as IHE integration profile "Retrieve Form for Data Capture" (RFD), the REUSE approach ensures that all clinical data is kept in the EHR whatever the context of data capture is.

Keywords:

HL7, CDISC, ODM, IHE profile, RFD, Electronic health record, Clinical data management system, Biomedical research, Clinical trial, Cardiovascular, Single source.

Introduction

The role that EHR could play in a biomedical research context has been investigated in many recent works. Clinical data in EHR may be useful during the design phase providing a better understanding of real patient population; during the instruction phase, by improving patient recruitment in clinical trials, as well as during the implementation phase by optimizing clinical data entry or adverse event reporting [1-4].

Current information systems for patient care on one hand, and for biomedical research on the other hand, are completely disconnected, even in university hospitals which have the most successful implementations of Electronic Health Records (EHR).

Since, there is evidence for a relevant overlap of routine and research oriented documentation [5,6], interoperability between Electronic Healthcare Record (EHR) and Clinical trials Data Management System (CDMS) for research would be of major advantage. Factors limiting EHR/CDMS interoperability are related to organizational, regulatory and technological issues.

From an organizational point of view, patient care and clinical research processes are very different. Furthermore, the functionalities expected from EHR and CDMS differ significantly in these two contexts. Recent efforts have been made to expand the functionality of EHRs for their use in clinical research.

As an example, the HL7 EHR System Functional Model [7] provides a reference list of over 160 functions that may be present in EHRs. Its functionality has been recently expanded by the global EHR/CR Functional Profile Project [8], a collaborative effort to expand and adapt the functionalities of EHR and associated systems, networks, and processes to support clinical research.

From a regulatory point of view, health data processing is subject to different constraints in patient care and biomedical research. Concerning data security and system validation, requirements for CDMS are also subject to higher constraints than for EHR. In the USA for instance, a system used to manage clinical trials data needs to comply with the FDA [9] Guidance "Computerized Systems Used in Clinical Investigations" (CSUCI) [10].

Finally, from a technical point of view, the standards for archiving and transmitting health data are defined by different organizations. On one hand, in the domain of biomedical research, the CDISC (Clinical Data Interchange Standards Consortium) organization [11] was created in 1997 by a group of individuals from pharmaceutical companies, clinical research organizations and software providers, working closely with the US FDA in order to develop platform-independent standards that support the electronic acquisition, exchange, regulatory submission and archiving of health data.

In 2001, CDISC published the first version of its Operational Data Model (ODM) [12], that defines the different types of information related to clinical trial: clinical trial metadata (definition of protocol and used items), baseline data of the clinical trial (e.g. the normal values of laboratory tests), user's administrative data (access rights and user profiles), patient clinical data and audit trail data (tracking data changes).

On the other hand, for patient care, the efforts of structuring health information and communication systems, are carried out within the European (CEN TC 251) [13] and international (HL7, Health Level 7) [14] committees for standardization. With regards to the EHR, in 2003 the Reference Information Model (RIM) proposed by HL7 became an ISO standard [15], from which are derived the models of both messages and documents (such as Clinical Document Architecture (CDA)) [16]. In order to facilitate the integration of patient care and biomedical research information systems, efforts have been initiated between HL7 and CDISC within the RCRIM (Regulated Clinical Research Information Management) technical committee of HL7, in which NCI (National Cancer Institute) [17] and FDA are actively involved. As part of these efforts, the BRIDG project aims to create a Domain Analysis Model covering the entire field of biomedical research and to develop common semantics for the different actors (hospitals, clinical trials sponsors, health authorities, etc.) [18-20].

We identified some initiatives that propose solutions for integrating information systems for patient care and biomedical research [21,22].

According to the CDISC Electronic Source Data Interchange Initiative [23], we can distinguish three different solutions for EHR/CDMS integration. First in the "*source data extraction and verification"*, part of the source data are extracted from the EHR, the investigator has to verify that the extracted clinical research data from the EHR reflect the source data required for the clinical trial before they are to a separate clinical trial database (CDMS)). In the "*single source"*, source data are all captured into the EHR and the clinical trial data are exported to the CDMS. In "*EHR used as CDMS"*, the source data are all captured into the EHR which is the clinical trial database (CDMS). Many pilot projects have implemented one of these different types of EHR/CDMS integration solutions allowing the reuse of patient care data, but with rare exceptions most examples consist of institution-specific approaches that do not use standards and thus lack the broad interoperability required for multicenter trials

Among "*source data extraction and verification"* solutions, Integrating the Healthcare Enterprise (IHE) published the Retrieve Form for Data-capture (RFD) "integration profile" [24]. Combined with the Clinical Research Content Profile, this integration profile provides a method of data capture within a used application (e.g. an EHR) that meets the requirements of an external system (e.g. a CDMS). An IHE "integration profile" is a real situation describing exchanges of information, called "transactions" of different components of a distributed health information system, called "actors". IHE provides guidelines for implementing these "transactions", using established computer standards such as HL7 or DICOM.

The RFD profile specifies a solution to integrate EHR and CDMS. If an external organization needs to collect clinical data as part of a clinical trial, the RFD profile will allow the EHR user (study investigator, for example) to access to the electronic Case Report Form (eCRF) of the clinical trial without leaving the EHR, and enter the required information so that they are collected by the external agency. However this solution still constrains the clinician to provide and manage two distinct data sources, duplicating data entry from one to another except for only several items described in the Clinical Research Content Profile.

In this context, the objective of REUSE (Retrieve data in EHR Useful for Secondary Exploitation) project is to provide a "single source" integration solution between EHR and CDMS using international IT standards (CDSIC, HL7) and to evaluate it in the hospital context of Assistance Publique-Hôpitaux de Paris (AP-HP).

In this paper, we first describe how we modeled the biomedical research process in a university hospital environment in order to specify the use of EHR in this context. Then we present the design and implementation of the "single source" solution between EHR and CDMS that takes into account the regulatory constraints of biomedical research and addresses semantic interoperability issues. At last we present the experimentation of the REUSE architecture in the context of a multi-centric clinical trial in the cardiovascular domain.

Material and methods

Material and context: AP-HP clinical trial "Arcadia"

The AP-HP is the most important French University Hospital Organization (38 hospitals with about 23,000 beds , 1400 one-day care, 850 capacities of care at home and 1,000,000 hospitalized patients per year; 90,000 employees including 19,000 physicians).

The aim of the New Information System (NIS) project of the AP-HP, is to implement the EHR Orbis ® (AGFA Healthcare ©). However some hospitals such as the Georges Pompidou European Hospital (HEGP) already have an EHR e.g. DxCare® (Medasys©) [25].

In AP-HP, biomedical Research is carried out within 18 Research Institutes; 8 Clinical Investigation Centers (phase I & IIa, Pharmacokinetic/Pharmacodynamic (PK/PD), etc.), 10 Clinical Research Units and 100 INSERM teams. The AP-HP direction of the biomedical research promotes electronic data capture and some experiments are conducted in different hospitals. Within the HEGP Clinical Research Unit several Clinical Data Management Systems (CDMS) are being evaluated such as OpenClinica® (Akaza Research©) or Marvin® (XClinical©) [26].

Arcadia is a biomedical research study conducted at HEGP Clinical Research Unit in the cardiovascular domain that was classified in the "common care" field of French law. The use of EHR as data entry solution was subjected to the favorable opinion of a Committee for the Persons Protection (CPP) [27], which are the French Institutional Review Board (IRB).

Business analysis and design of REUSE

We conducted a series of meetings with the AP-HP managers (from AP-HP direction of the biomedical research), clinicians and researchers (from the Clinical Research Unit (CRU) of HEGP)) in order to carry out the business process models describing the clinical trial implementation activity in a context of institutional sponsorship in France. Then we defined the different stages composing the process which could be simplified and automated thanks to a use of the EHR.

We integrated into the process models elements from the BRIDG dynamic model comprising the use cases and the diagrams activity of clinical trials. We also took into account the CDMS specifications defined in the FDA guidelines "CSUCI" and in the EHR Functional Model, extended to biomedical research.

REUSE implementation

The REUSE architecture implements the “single source” concept so that all data, whether entered in the patient care context or in the biomedical research context, are stored and accessible in the EHR. We developed modules that allow: 1) to import within the EHR a SNOMED encoded electronic case report form (eCRF) of a clinical trial, 2) to align existing clinical data with the eCRF data elements and 3) to export the clinical trial data towards a CDMS.

We used JAVA programming language for its stability, its large selection of library and because it is platform-independent, particularly JDOM Application Program Interface (API) [28] for its simplicity compared to SAX and DOM parser [29] and for the richness of its functionalities.

Results

Process models and functional perimeter of REUSE

We modeled the biomedical research activities of institutional sponsorship in a university hospital and specified the functional perimeter of the EHR within this context.

The activity diagrams made it possible to better analyze the main phases of a clinical trial: the submission phase where the principal investigator and the CRU edit the research protocol and submit it to the sponsor; the instruction phase where the CRU prepares all the tools for the data management and completes the regulatory and financial tasks and the implementation phase during which the patients are included (information of the actors, inclusion lists, patients consents) and the data captured before monitoring and statistic analysis. This analysis made it possible to better identify the role of the main actors at the time of each activity of the clinical trial implementation process (physician-investigator, methodologist, Structure Coordinator, Clinical Trial Coordinator (CTC), statistician, Data-Manager, Clinical trial technician (CTT), Clinical Research assistant (CRA), Administrative and Financial Manager (AFM) and sponsor). The REUSE business process diagram has a hierarchical structure: each modeled phase is made up of several structured activities, themselves made up of sub-activities. In total, it is composed of 15 activity diagrams from which we identified 7 activities and tasks likely to be simplified and automated, thanks to the use of the EHR: "To develop a clinical trial database", "To propose a data-management plan", "To develop eCRF", "To carry over existing data in the EHR", "To modify administrative patients data", "To modify data of clinical research", "To Monitor data» (Figure 1).

Each activity included in the functional perimeter of the EHR is described by a sequence diagram specifying the actors’ interactions using EHR within the REUSE solution.

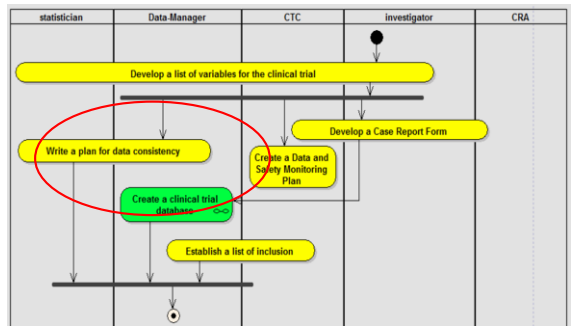

Figure 1- Example of process activities of clinical trial implementation which can benefit from the use of the EHR: "To create a clinical trial database" and "To propose a data-management plan"

REUSE implementation

We defined the “Retrieve & Integrate Form for Data capture” (RIFD) integration profile in order to implement the “single source” concept for the REUSE project (Figure 2).

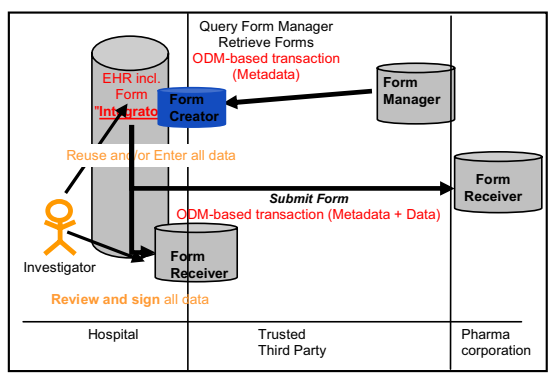

Figure 2- Actors and transactions involved in the "Retrieve & Integrate Form for Data Capture" (RIFD) integration profile proposed

The “Retrieve & Integrate Form for Data capture” (RIFD) integration profile consists in three component or “actors”: “Form Manager”, “Form Creator” and “Form Receiver” and two transactions “Query-Retrieve Form” and “Submit Form”.

The transaction "Query-Retrieve Form"

This transaction consists in importing within the EHR an eCRF of clinical trial provided by the Contract Research Organization (CRO). It relies on an ODM message to transfer the metadata of the eCRF from the "Form Manager" to the "Form Creator". Then, the eCRF is encoded using SNOMED v3.5 VF codes as much as possible and integrated into the EHR. The pre-filling process of the eCRF by pre-existing clinical data in the EHR is achieved through mechanisms specific to the EHR. These mechanisms are based on mappings between clinical items of different forms (used in a patient care as well as in biomedical research context) and SNOMED v3.5 VF used as pivot terminology.

The transaction "Submit Form"

This transaction consists in exporting the data of the clinical trial captured in the EHR towards the CDMS. It relies on an ODM-based transaction between the "Form Filler" and the "Form Receiver". Data validation is done in the CDMS, i.e. in an application which the management depends neither on the investigator nor on the sponsor.

The "Retrieve & Integrate Form for Data capture" (RIFD) integration profile was implemented by the EHR DxCare® (Medasys©) and the CDMS Marvin® (XClinical©).

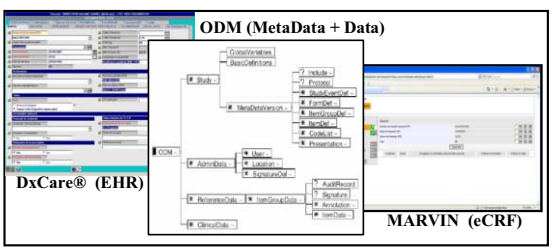

Figure 3- Export of clinical data and meta-data of a clinical trial from the EHR (DxCare, Medasys) to CDMS (MARVIN, XClinical) using the REUSE CDISC ODM mediator.

In HEGP, in the context of the "Arcadia" multi-centric study, figure 3 shows how the CDISC ODM mediator allows transferring data entered into the EHR to the CDMS.

Within the EHR, the ARCADIA study consists of seven forms: Inclusion, initial evaluation, initial abdominal imaging, initial neurovascular imaging, sample, adverse events, and serious adverse events. In using the CDISC ODM mediator, the forms and responses to questions of each patient participating in the clinical trial, have been respectively transformed into Study Event and Subject Data and been generated in the ODM output file with ensuring that the meaning of the data is appropriately preserved, so that the receiving system (ie, researchers) could appropriately use the data.

Discussion and Conclusion

We have modeled the implementation process of clinical trials of institutional sponsorship in a university hospital in order to design, develop and test an integration profile between Electronic Health Record (EHR) and Clinical Data Management System (CDMS) and exploit the EHR clinical data for biomedical research.

The benefits for the health care professionals consist on the economy of a double entry, which is error-prone and time consuming. The benefits for the CRU are to facilitate the data monitoring quality in the electronic Case Report Form. The automatic transfer of data reduces the risk of error, monitoring focuses on data that are not pre-filled from the EHR. Last but not least, due to the "single source" approach that we have adopted, the benefits for the patient are related to the storage in the EHR of all clinical data collected either in a patient care context or a biomedical research context. We believe that considering the EHR as the single source of data may improve patient safety insofar as some of the data collected in a biomedical research setting, such as adverse events of treatment delivered in the clinical trial context, are likely to be useful to support diagnosis and treatment of the patient.

Unlike the RFD IHE profile the "Retrieve & Integrate Form for Data capture" (RIFD) integration profile, that we have implemented in REUSE, not only allows displaying an eCRF within an EHR, but also importing and integrating it in the EHR. This increases the possibilities of pre-filling the electronic Case Report Form (eCRF) compared to what is proposed in the RFD IHE profile. Indeed, even when the RFD profile is completed by the Clinical Research Data capture (CRD) profile [30], the pre-filling of the eCRF is limited to some predefined clinical items. These items are selected from the content modules of IHE Continuity of Care Document (CCD) [31] because they are common to patient care and biomedical research. This set of items, defined generically for every clinical trial, will be by nature limited and therefore, from our point of view, will only slightly address the double entry issue.

An interoperability framework and the use of data standards (HL7 or CDISC "templates" and reference terminologies) are essential for any successful implementation of a data collection system designed to reuse patient data in the context of multi-centric clinical trials. Multicenter trials require data from different sites to be submitted to a central data center, with whom the site's relationship may exist for only a single trial. For reuse of patient care data to be feasible, data collection methods must be easy to implement and use, and must minimize disruption at the clinical site.

Furthermore, successful adoption of IT systems has always been a challenge involving numerous social and organisational factors. The understanding of end user needs and workflow is a key element of the REUSE project. Indeed, these factors must be considered even more carefully when considering a fundamental re-engineering of an enterprise like clinical research enterprise.

Standards have the potential to make this possible by allowing investigational sites to use existing systems without the burden of data transformation.

The main drawback of the "single source" approach is that a new "actor" – "Form Creator" - has to be implemented by the EHR in order to integrate eCRF designed using the CDISC ODM format.The experience gained during the project REUSE should allow us to build an interoperability framework using HL7 and CDISC standards, by developing and implementing the content standards such as a clinical note input templates and eCRF templates derived from protocol specification.

This will facilitate the implementation of Single Source solutions in a European multi-centric context including different vendors, different CROs and different sponsors.

Acknowledgments

We would like to express our gratitude to the staff of HEGP, particularly the staff of URC and the computer department, Mr Nicolas DE SAINT JORRE and Prof. Joël MENARD.

10 Years Experience with Pioneering Open Access Publishing in Health Informatics: The Journal of Medical Internet Research (JMIR)

Gunther Eysenbach[ab]

[a] *Centre for Global eHealth Innovation, University Health Network, Toronto, Canada*
[b] *Department of Health Policy, Management and Evaluation, University of Toronto, Canada*

Abstract

Peer-reviewed journals remain important vehicles for knowledge transfer and dissemination in health informatics, yet, their format, processes and business models are changing only slowly. Up to the end of last century, it was common for individual researchers and scientific organizations to leave the business of knowledge transfer to professional publishers, signing away their rights to the works in the process, which in turn impeded wider dissemination. Traditional medical informatics journals are poorly cited and the visibility and uptake of articles beyond the medical informatics community remain limited. In 1999, the Journal of Medical Internet Research (JMIR; http://www.jmir.org) was launched, featuring several innovations including 1) ownership and copyright retained by the authors, 2) electronic-only, "lean" non-for-profit publishing, 3) openly accessible articles with a reversed business model (author pays instead of reader pays), 4) technological innovations such as automatic XML tagging and reference checking, on-the-fly PDF generation from XML, etc., enabling wide distribution in various bibliographic and full-text databases. In the past 10 years, despite limited resources, the journal has emerged as a leading journal in health informatics, and is presently ranked the top journal in the medical informatics and health services research categories by impact factor. The paper summarizes some of the features of the Journal, and uses bibliometric and access data to compare the influence of the Journal on the discipline of medical informatics and other disciplines. While traditional medical informatics journals are primarily cited by other Medical Informatics journals (33%-46% of citations), JMIR papers are to a more often cited by "end-users" (policy, public health, clinical journals), which may be partly attributable to the "open access advantage".

Keywords:

Medical informatics, Publications, Knowledge translation, Medical informatics education, Bibliometrics

Introduction

Between 1987 and 2006, over 77,000 medical informatics articles were published, in 4,644 unique journals [1]. Being a highly interdisciplinary field, it is difficult to determine what constitutes a "medical informatics" journal. In the mid 90ies, several studies independently attempted to identify a core set of medical informatics journals [2-5], based on cocitation analysis and Medical Subject Headings (MeSH) co-occurrences. Another approach to identify "medical informatics" core journals is to consult the Thomson/Reuters Journal Citation Reports (JCR) database, which assigns subjects to journals. Currently, the JCR 2008 (the most recent version as of March 2010) lists 20 journals in the "medical informatics" discipline. Traditional medical informatics journals are poorly cited and the visibility and uptake beyond a relatively small medical informatics community remains limited [6].

At the end of the 90ies, all journals identified as "core medical informatics" journals using the methods above had the following in common: 1) they were published by professional publishers, with authors signing away their copyright as a condition for publication; 2) all had a "paper" counterpart, none of them were "electronic-only" journals; 3) all medical informatics journals were subscription-based journals, none was freely available.

In addition, it became clear that the Internet had a major impact on medicine and public health, as well as on the discipline of medical informatics itself, without any journal covering specifically this field. The *Journal of Medical Internet Research* (JMIR, www.jmir.org) was created to fill this gap [7]. Perhaps even more significant was the fact that the Internet itself as a disruptive technology allowed a change in the publishing model, bypassing traditional intermediaries (publishers), leaving ownership and control of published works in the hands of the scientific community. JMIR was created with these values in mind.

This report chronicles the first 10 years of this ongoing experiment, during which JMIR has risen to the top ranked journal in the Medical Informatics journal, by Thomson/Reuters Impact Factor (IF). While the author recognizes that the Journal Impact Factor is an inadequate and questionable metric of "quality" (in particular if used as proxy for article quality), it is one important metric to compare journals with each other. In this paper, we also go beyond comparing IFs, and look at the origin of the citing articles. One of the underlying hypotheses to be explored is the role of the open access policy for helping the *Journal of Medical Internet Research* to achieve a re-

spected place in the community, without the marketing budget of a large publisher.

Materials and Methods

Journal Details

History

The JMIR editorial board was assembled in 1998 and the first articles were published in August 1999. JMIR was conceived and founded by Gunther Eysenbach, MD, MPH who continues as Editor and Publisher of the journal. At the time JMIR was the first international scientific peer-reviewed journal covering all aspects of research, information and communication in healthcare using Internet and Intranet-related technologies. As a publisher of a journal about the Internet, the founding editor was also dedicated to using and experimenting with the Internet as a communication vehicle [7].

This included making all articles immediately electronically available on the Internet, free of charge for the reader, a model which is now known as "open access" publishing. It should be stressed that while "open access" publishing has now become more prevalent and accepted, at the time of creation, JMIR was an early pioneer of this model. Other open access journals (such as BiomedCentral journals, which launched in 2000, or the PLoS journals, which launched in 2003/2004) as well as other significant developments such as PubMed Central (which launched in 2000) were not existing at the time of the JMIR launch.

Table 1 – JMIR Milestones Timeline

1999: Launch
2001: NLM/Medline indexing
Dec 2002: named Official Journal of IHCC (Internet Health Care Coalition)
Aug 2003: named Official Journal of SIM (Society for Internet in Medicine), abandons *Medical Informatics and the Internet* (Taylor & Francis) as Official Journal
Nov 2003: Use of OJS 1.0
Nov 2004: Major site relaunch: PDFs available, all articles available as XML
2005: ISI begins monitoring JMIR
2006: JMIR in PubMed Central
2007: First Impact Factor (2006) published by ISI: 2.9 (#2/20 in Medical Informatics [MI], #6/56 in Health Care Sciences & Services [HCSS])
2007: Upgrade to OJS 2.0
2007: 30k SSHRC grant for open access journals
2008: Impact Factor (2007): 3.0 (almost the same as the #1 JAMIA: 3.1)
2008: 90k SSHRC grant for 3 years
2009: Founding member of the Open Access Scholarly Publishers Association (with BMC, PLoS, and others)
2009: Impact Factor (2008): 3.6 (now ranked #1 in MI and #2 in HCSS)

Scope

JMIR publishes manuscripts on all aspects of research, information and communication in the healthcare field using Internet and other eHealth technologies. This field overlaps with what is called "consumer health informatics", or – more recently – Medicine 2.0 or Health 2.0 [8] (which is highlighted by the fact that the journal now co-sponsors an annual Medicine 2.0 conference – http://www.medicine20congres.com). The journal also publishes original research on development, evaluation, and application of other (non-Internet) e-technologies in the health care setting (e.g. m-health applications). JMIR targets a broad readership consisting of health professionals, policy makers, consumers, health informaticians, developers, researchers, hospital and health care administrators, and e-health businesses.

As eHealth is a highly interdisciplinary field JMIR invites research papers from a range of disciples including the medical sciences, the computer, behavioral, social and communication sciences, psychology, library sciences, informatics, human-computer interaction studies, and related fields.

Business Model

Open access journals can, by definition, not create revenue through subscriptions. In order to cover the publishing costs, which include professional services such as hosting, copyediting, XML tagging/typesetting etc., novel ways of creating revenue had to be found.

JMIRs business model is unique as it creates its primary revenue streams from personal and institutional memberships, in addition to article processing fees, and sale of PDF reprints. Institutional memberships for departments or institutions such as research centers, universities, and corporations, provide reduced or waived author publication fees for employees, faculty, or students of the institution or department. Many academic medical informatics departments are an institutional member of JMIR. Institutional memberships start at $900 per year, which allows their faculty and students to publish free of charge in JMIR.

While HTML versions of all material in the journal are freely available, PDF versions of individual articles, entire issues and topical article collections ("e-collections") are available for a fee (or freely available for members). An additional revenue stream are a nominal submission fee (currently $90), as well as the optional fast-track fee. The journal also accepts advertisements including Google Adsense on the web site as a source of additional income.

As of September 2009, the journal has almost 400 paying members. As a result, the proportion of funding coming from member contributions is increasing steadily, with over half of the revenue coming from memberships and only 25% from article processing fees. Between 2004 and 2006, JMIR has doubled its total revenue, which now exceeds $100,000 per year.

Review Process

Manuscripts are first reviewed by the Editor who decides whether the manuscript meets the criteria specified in the in-

structions for authors and whether it fits within the scope of the journal. Manuscripts are then sent to an external expert for peer review. Authors are required to suggest at least two peer reviewers. The identity of JMIR reviewers is revealed if the manuscript is published (they are acknowledged in each manuscript), unless requested otherwise by the reviewer, but anonymous during the review process and in case of rejection. Approximately 30-40 percent of unsolicited articles are accepted for publication. The Journal is currently (2010) experimenting with open peer-review models, where submitted articles and their abstracts are listed on the website and any reader can sign up as peer-reviewer (submitting authors can opt-out of this model).

As frustration over traditional turnaround times was one of the original motivations for creating JMIR, editors seek to review and publish manuscripts very quickly. A unique feature is that if authors chose to pay for the journals "fast track" review option, a publication decision is *guaranteed* within 3 weeks and publication within four weeks. Otherwise, the journal attempts to complete the review and publication process as quickly as possible but does not guarantee a specific timeline.

Rights Management

JMIR papers are published under the Creative Commons Attribution License. The license grants others permission to use the content in whole or in part, and insures that the original authors and the journal are properly credited/cited when content is used.

Editorial Board/Governance

The journal has an elected editorial board that has responsibilities such as acting as section editors that oversee the review and editing process for specific sets of manuscripts. The journal also seeks guest editors interested in compiling special theme issues of the journal.

Indexing/archiving

JMIR is indexed or abstracted in a wide variety of bibliographic databases, reference sources, and alert services, including Medline and over 20 other databases. It also deposits full text articles in PubMed Central. A full listing of these can be found on the journal web site, (http://www.webcitation.org/5NwssREcf)

Structure, Content and Formatting

JMIR's article section is organized into yearly volumes and quarterly issues. Open access versions of articles are published in HTML. PDF versions are available for a fee and to individual and institutional members. A variety of manuscript formats are published including editorials, original articles, viewpoints, literature reviews, short papers and letters.

Technical Implementation & Innovations

Automatic XML Production with OrangeX

Since 2002, JMIR is using a LAMP-based (Apache/MySQL/PHP) online manuscript management and publication system, code-named OrangeX, which is a heavily customized and expanded version of the Open Journal System (OJS), an open source journal management system available from the Public Knowledge Project (PKP, 2007). OJS required extensive redevelopment, as it has multiple severe bugs and usability issues, and originally did not support an XML-based publishing workflow. The JMIR development group donated the code and workflows/plugin ideas developed for JMIR as open source to the OJS project. For example, the XML/PDF functionality of OJS and many other plugins have been developed by the JMIR group (MJ Suhonos and Juan Alperin).

The most significant development of the OrangeX modules is a fully OJS-integrated system to generate Pubmed Central-compatible XML documents, from OJS-based metadata and through a conversion of word-documents to XML. OrangeX also automatically checks and corrects cited references against bibliographic databases such as PubMed. Earlier versions of the XML conversion and reference checking software module – which was made available under a GNU license - has formed the basis for the Lemon8-XML software [9], which is a standalone, non-OJS integrated version. OrangeX is not currently released as open source software, but the JMIR group offers hosting of open access journals on the OrangeX platform.

Other Innovations

The journal has been innovative in a number of areas, including: 1) first journal to use screening software to check for plagiarism of material published on the web; 2) development of the WebCite system (www.webcitation.org), which supports permanent archiving of web material cited by authors [10], now adopted by hundreds of other journals; 3) open peer-review models.

Impact Analysis

Analysis of the impact of a journal can come from two sources: Quantitative citation analysis, and qualitative feedback from authors. While we have anecdotal and qualitative evidence from authors reporting on the wide uptake of their works, in this paper we focus on quantitative data based on citation analysis, with benchmarking against other medical informatics journal. We selected 5 benchmarking journals from the Journal Citation Reports database (journals from the medical informatics subject category): Journal of the American Medical Informatics Association (JAMIA), International Journal of Medical Informatics (IJMI), Journal of Biomedical Informatics (JBI), Telemedicine and ehealth Journal, and Methods of Information in Medicine ("Methods").

We used the Web of Science database (Sept 2009) to analyze citations to JMIR and benchmarking journals. In order to determine the subject areas of citing journals, we searched for all articles citing JMIR (or benchmarking journal) articles which were published in 2007-2008. We then tabulated all subject areas of the citing journals and reported those which constitute at least 10% of the citing articles in any of the benchmarking journals. The journal subject areas are assigned by JCR staff. Note that a journal in JCR can belong to multiple subject areas (for example, JMIR belongs to "Medical Informatics" and "Health Sciences and Health Services Research").

Impact factors (defined as the average number of citations to those papers that were published during the two preceding

years) were extracted from the Journal Citation Reports (JCR) database (Thomson/Reuters 2009), searched in October 2009.

Results

Reach and Readership

JMIR has grown to be a very widely read journal with approximately 60.000 pageviews per month (Sept 2009, Google Analytics), and 25-30.000 visits per month. The Alexa Traffic Rank was 440.860 in March 2010 (benchmarked against JAMIA, which is ranked 2,551,028 by traffic). Approximately 24,000 readers subscribe to e-mail notifications of publications (as of Sept 2009).

Impact

The Journal Impact Factor has steadily grown. In 2009, with publication of the 2008 impact factor, JMIR is now the top-ranked journal in the Medical Informatics category (Figure 1), as well as in the Health Sciences and Health Services Research Category (not shown; review journals excluded). While Thomson-Reuters only began publishing an "official" impact factor for JMIR in 2006, previous inofficial impact factors for 2004 and 2005 suggest impact factors of about 2.5 – 3.0.

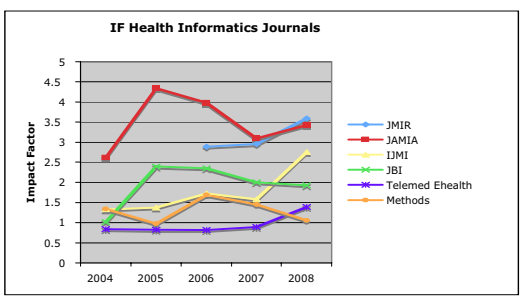

Figure 1- Ranking of Medical Informatics journals by Reuters/Thomson Impact Factor 2004-2008

Citing Journals

In order to explore differences in citation patterns between JMIR and the benchmarking journals we looked at the subject areas of the source journals citing articles from JMIR (or the benchmarking journals). Figure 2 illustrates the subject areas of journals citing articles in JMIR and other medical informatics journals (Note that JBI is also cited by journals from the disciplines "Biochemical Research Methods", "Biotechnology & Applied Microbiology", and "Mathematical & Computational Biology" which are not significant sources of citations for the other journals and which have been omitted from the figure).

As seen in Figure 2, 28% of articles published in 2007/2008 in JMIR were cited in Medical Informatics journals (first vertical bar), a figure which is higher in most other Medical Informatics journals, which tend to be cited primarily by other Medical Informatics journals. In contrast, JMIR is more often cited by "applied" and clinical journals, including those dealing with public health and health services research.

Discussion

Over the course of the last decade, the *Journal of Medical Internet Research (JMIR)* has emerged as an influential and sustainable dissemination tool for health informatics research, despite limited resources and manpower. It is difficult to decide whether the observed quantitative (Figure 1) and qualitative (Figure 2) differences in citation patterns are a result of the open access policy or a result of the editorial policies (or – most likely – a mix of both), but it can be argued that they are – at least partly – attributable to what has been called the "open access advantage" [11]. While the "hard" evidence of an open access citation advantage comes from a citation analysis of articles from a "mixed model" journal (PNAS) [12], these data are complemented by narratives of JMIR authors who often report that their work has been used and taken up by unexpected sources.

Thus, it has been argued that the open access advantage has three components [11]: (1) a citation count advantage (as a metric for knowledge uptake within the scientific community) [12], (2) an end user uptake advantage (end-users being patients, policy makers, clinicians), and (3) a cross-discipline fertilization advantage, meaning that knowledge is more easily discovered and absorbed by scientists from other disciplines. While cross-journal comparisons are always confounded by differences in editorial policies and differences in article selection criteria, data provided in Figure 1 and Figure 2 are consistent with these three hypotheses, showing not only more citations, but also citations coming from a wider area of applied disciplines, instead of just medical informatics, computer and information science journals.

Knowledge users who are not researchers (policy makers, consumers, journalists) do not necessarily read scientific publications. In our 10 years of experience with this journal (JMIR), we have received many anecdotal reports from authors and research users testifying that open access publication can help to bridge this gap. Policy makers and end-users are much more likely to "google" for evidence than to do a formal literature search [13], and even if they come across a subscription-based scientific paper through Google, they are unlikely to actually order it. Only if a publication is open access will end-users skim and eventually read it, or contact the author, after they discovered that it is relevant to the policy (or practical) question at hand. We know that JMIR is used as much by patients and other nonresearchers (eg, policy makers) as it is by eHealth researchers, and we know from our authors that they are often contacted by "atypical" readers (knowledge end-users) who bumped into their article by pure chance, which they would never have done had the article been published in a subscription-based scholarly journal.

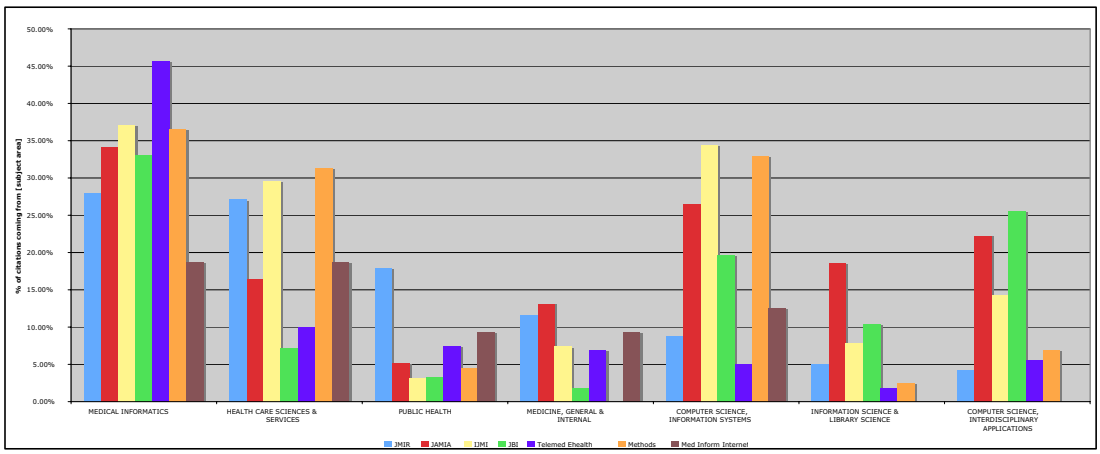

Figure 2 – Subject areas of citing journals

While these findings seem to support the Open Access Advantage, especially in regards to facilitating and broadening the knowledge transfer within and between disciplines, it should be noted that generating revenue with the Open Access model is difficult. As many societies rely on income from their journals, Open Access as a business model is not appealing to them. JMIR has been fortunate to enjoy an increasing circle of institutional support from leading academic medical informatics departments, providing an alternative knowledge dissemination model.

While JMIR has been one of the a pioneer of open access publishing in health informatics (and in medicine at large), other Open Access journals have recently been created in the field (none of which indexed in ISI/JCR yet), using a similar model, e.g. BMC Medical Informatics and Decision Making, Indian Journal of Medical Informatics, Open Medical Informatics Journal (a commercial journal published by Bentham, a publisher who has recently been criticized over quality issues [14]), the Journal of Health Informatics in Developing Countries, The Electronic Journal of Health Informatics (eJHI), an official publication of the Health Informatics Society Australia. JAMIA, also has (in 2010) started to offer an open access option for authors, where they can pay $2000 to make the article open access.

Acknowledgments

We thank SSHRC (Social Sciences and Humanities Research Council of Canada) for supporting JMIR; as well as all JMIR institutional/departmental members and individual members, who are supporting JMIR with their membership fees.

Abstract

For high quality research in biomedicine an operable biobank is essential. In order to make optimal use of the material and the huge amount of data a sustainable IT-infrastructure is indispensable. Therefore, we developed a concept for the IT-infrastructure of a biobank for an academic medical center. The conclusions for this concept are deduced from our experience with the biobank and IT-infrastructure of a clinical research unit. Our results indicate that the IT-infrastructure plays a pivotal role in successfully establishing a biobank. Several aspects of the IT-infrastructure are similarly found in other areas as, e.g. data protection and storage and quality management. Finally, we conclude that although a research database is not required for operating a biobank, the need for it will definitely emerge, especially with regard to personalized medicine and high-throughput gene expression analysis.

Keywords:

Biomaterial, Biobank, Biobank software, IT-infrastructure, Repository

Introduction

Biomaterial for research

Many medical research projects and clinical trials include endpoints requiring patho-histological reports, biomolecular tests and survival data. Therefore, it is indispensable to sample and store biological material to conduct clinical trials for finding biomarkers, improving existing, or developing new therapies, and to get statistically reliable results. Without enough high quality biomaterial many projects struggle or fail [1]. One solution to prevent the fast disappearance of biomaterial especially after the end of funding or in a follow-up phase, e.g. in a clinical trial, is a sustainable biobank (Fig. 1). Furthermore, providing a biobank with a solid IT-infrastructure increasingly becomes a criterion deciding about whether a grant application is accepted or not. It is worth to mention that in the beginning of a clinical trial the collection of adequate biomaterial is usually progressing slowly (not depicted in Fig. 1). A biobank should provide long-term storage of high quality biomaterial for research purposes. According to a definition of the German Ethics Council a biobank is the connection of a collection of human body materials and person-related data [2]. The biomaterial increases its value in combination with associated clinical patient data (MDAT) of the clinical trial. To administrate this huge amount of data a sustainable IT-infrastructure is indispensable.

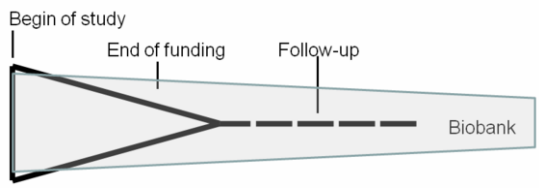

Figure 1- Availability of biomaterial during a clinical trial in comparison with a biobank

The biobank of the clinical research unit 179

In Goettingen the clinical research unit (KFO) 179 funded by the German Research Foundation (DFG) has the goal to develop an individualized therapy for the treatment of locally advanced rectal cancer. The standard treatment currently involves a preoperative radio-chemotherapy (RT/CT) followed by surgery, and an adjuvant chemotherapy. Beside the reduction of tumor size the striking advantage of preoperative RT/CT is the highly significant decrease of local recurrence [3]. Unfortunately, tumors respond very differently to the therapy ranging from complete response to resistance resulting in a survival benefit for only a subset of preoperatively treated patients [4]. Additionally, some patients suffer from severe side effects. For accomplishing their goal of a personalized medicine, the scientists perform experiments, like gene expression analysis, and promoter methylation analysis. For all these experiments they need high quality biomaterial of rectal cancer patients (normal and tumor tissue, as well as blood) that is taken at the initial staging examination of the tumor before

preoperative therapy is given. Moreover, blood samples are drawn during the therapy and of course, the resected cancer is formalin fixed and paraffin embedded to assess the response of the tumor to the neoadjuvant therapy and to finally determine the TNM staging. Thus, the biomaterial collected from rectal cancer patients within the KFO 179 is in the first line used to examine the biological basis of the individual tumor response in patients with rectal cancer. The material is then enclosed into the biobank and can be used by the researchers of the different sub-projects to answer their individual scientific questions. Having the administration data of the biomaterial and the MDAT in validated databases that are included in a sustainable IT-infrastructure has the advantage for the researchers to have an overview about the available material of each patient and the data that were already collected with this material.

Aspects to be considered when establishing a biobank

Although, biobanks are a good idea to counteract shortage of biomaterial, their establishment and maintenance should not be underestimated. There are a lot of aspects which need to be considered besides the storage of biomaterial. The most important aspects when establishing a biobank are in a chronological order:

1. the patient informed consent
2. ethical aspects
3. classification of the biomaterial by one single observer to avoid interobserver-variability
4. data security and protection
5. storage of biomaterial and its quality management
6. rules how to treat specimens with a different purpose of use
7. rules for the transfer of biomaterial to third parties

At the moment there are no biobank-specific laws in Germany, thus the work group biobanks of the telematic platform for research networks (TMF), consisting of scientists and researchers operating biobanks themselves, evolves guidelines, check lists, and privacy models for biobanks [5, 6].

Objectives

A medical center wide biobank would have the advantage that scientists with a specific research question requiring rare samples have a bigger chance to find sufficient samples to answer their question. Therefore, we want to develop a biobank concept with a focus on the IT-infrastructure for a whole academic medical center.

Materials and Methods

Approaching a biobank solution for an academic hospital

The concept for a biobank solution for an academic medical center is mainly based on our experience with the evolution of the biobank software from a remote data entry (RDE)-system for the KFO 179 biobank and supplemented by a literature research analyzing the requirements for larger biobank IT-infrastructures.

Developing a remote data entry system into a biobank software

Since 2007 several existing research projects affiliated with the Department of Medical Informatics at the University Medical Center in Goettingen recognized the need for a professional IT-support for their biomaterial collections. As a first effort, we developed a prototype system for the German Competence Network for Dementia based upon the existing remote data entry (RDE)-system (secuTrial). This product had several advantages over buying specific software, or completely developing software ourselves. Some of the advantages were: our RDE-system was validated in accordance with AMG/GCP, FDA 21 CFR Part11, good clinical practice (ICH-GCP), and TMF privacy models, the adaptation did not cause extra costs, and we were already experienced in setting-up clinical trials.

In 2007 the KFO 179 was founded. Due to its multitude of biomaterials to collect and several sub-projects involved, a web-based biobank software was needed. The continuation of the RDE approach allowed a role-based, audit trail equipped solution, despite the low IT budget of the project.

The KFO 179 biobank software in detail

Whereas the setup of the electronic case report forms for the clinical trials was a standard procedure, several challenges occurred setting up the biobank software. The existing functions of the RDE-system were improved according to the needs of the laboratory staff and a sample-oriented IT-based administration of biomaterial was developed, meaning that the data entry is barcode driven. The setup of the system required multiple redesign phases. Now, the system fully enables the monitoring of biomaterial quality in detail, documenting the storage, and capturing and documenting the respective usage. The basic data of the patients (IDAT) are stored in the study center. As the biomaterial collection does not only contain material and data from patients being treated in the University Medical Center, certain restrictions apply to the design of the IT-infrastructure. In order to fulfill the TMF privacy model, two separate software installations are required for the biobank [5]. One for the administration of the data of the biomaterial (BDAT) gained in the surgery and pathology departments and one installation for the pseudonymized MDAT, which are partially annotated by information from the hospital information system. Via an unambiguous barcode biomaterial specimens of patients can be linked with the information in the biomaterial database. The pseudonym of the patient can be linked to the MDAT in the second database only via an additional list, storing the pseudonym from the biomaterial database in connection with the pseudonym of the MDAT database. Both, BDAT and MDAT can be joined for research aspects via a mapping table. All results should finally be stored with a different pseudonym in a research database. De-identification of a patient is just possible in the study center keeping the IDAT.

The insights gained during this evolutionary process are very valuable for the design of a concept for larger biobanks.

Literature research for larger biobank IT-infrastructures

To identify the demands on biobank software for serving the purpose and fulfilling the TMF privacy model, a literature

research of requirements for biobank IT-infrastructures was performed by analyzing scientific literature and product information from providers of biobank information systems. Key words for the search in PubMed and google scholar were: biobank, biobanking, biorepository, IT-infrastructure, biobank software, biobanking software, BIMS, biorepository software.

Results

In our development process along with the literature research, we found the following points to be most crucial for an IT-infrastructure for a biobank.

Quality assurance

Quality assurance for biobanks has to take place on different levels: from monitoring of the samples to complete annotations during data entry into the database to Standard Operating Procedures (SOPs) describing what to do in case of a power failure.

Within the central laboratory of the KFO 179 the temperature of the samples is monitored manually. The temperature could also be manually entered into the RDE-system, but a direct communication between freezer and biobank software is not possible due to a lack of the necessary interface. That the temperature should be monitored was demonstrated in a study showing that a cyclic (5 times) temperature change from -196 to -150 °C reduces the viability of embryonic neurotissue cells to 50 % [7]. Having the appropriate interface, monitoring of single samples covering the temperature profile and freeze-thaw cycles over the whole life-span of a samples is possible[1].

In the KFO 179 data are entered into the RDE-system by the laboratory personnel for each single sample comprising two entry steps. In a first step, the barcode, the name of the person taking the sample, the date when the sample was taken, the patient`s pseudonym, and the sample`s origin are entered. After the isolation of e.g. RNA from this sample and its quality assessment (taking place just in the central laboratory), the RIN (RNA integrity number) describing the degradation state of the RNA [8], and other quality parameters are entered into the respective form in the RDE-system. Moreover, the storage location, the description of the type of isolated material, and the exact amount and concentration are documented. If a scientist wants to use the same sample for research, the RIN gives information, whether the sample could be used for a certain research purpose. The workflow of the KFO 179 is in accordance with literature mentioning that before samples are included into the biobank, a quality assessment should take place to determine the purity and degradation of e.g. tissue samples [9].

The RDE-system used by the KFO 179 is equipped with an audit trail and a role-based access control. On the data level a check for plausibility such as defined ranges for distinct values exists. Due to the structure of the software (originally designed for clinical trials) based on visit plans, it is not possible to determine whether a single storage location for biomaterial is entered twice, neither to allocate free storage places nor to give an overview about the storage places and their capacities. An identification of duplicates can just be performed after the export of the data and an analysis with statistical analysis system (SAS). In comparison to the literature, the RDE approach has some disadvantages[1].

In addition to high quality biomaterial, high quality annotations are also required. It must be documented what type of biomaterial is stored (using, e.g. the ICD classification), when and with which method it was extracted, purified, and preserved, and how the material was stored during its life-cycle.

In the central laboratory of the KFO 179 an alarm system is installed. In case of a power failure the laboratory personnel follows an emergency plan including a defined workflow for saving samples. This KFO 179 concept is in accordance with literature describing the need to set up a concept in the form of SOPs describing what to do in events of power failure or broken freezer systems [10].

Document and workflow management

The KFO 179 uses a web-based portal system run by the Department of Medical Informatics to save essential documents like study protocols or SOPs. These documents are stored in distinct folders for each sub-project. In addition, the portal offers access to several applications so that the progress can be monitored and collaborations can be fostered. It is described that certain laboratory information management systems (LIMS) are able to directly provide such document storage services without the need for an additional portal[1].

Search functions

In order to allow long-term sample scheduling, researchers need a permanent overview of samples present in the biobank.

Within secuTrial it is possible to get overviews of the biomaterial present in the biobank including a sorting function. For more complex queries, the data needs to be exported and analyzed with SAS. The same applies to the statistical analysis after the end of the study. Some LIMS[1,2] allow a detailed query to work with the biomaterial in the biobank.

Sample request and distribution

One function of biobanks is the storage of biomaterial. Therefore, an essential aspect is how to deal with sample requests and how to serve them.

Within the KFO 179 a transfer of biomaterial to the single subprojects works as follows: A scientist asks for biomaterial in the central laboratory and gets it and the transfer is manually recorded in the RDE-system. The access to MDAT is controlled by a data management and safety committee (DMSC). A transfer of biomaterial to third parties is not planned so far. Our literature analysis revealed that a biobank should offer a web-based possibility to request, and if possible, also to search for samples [10]. In this way, the whole process could be documented at the same time. To minimize errors in issuing samples to third parties and to be in agreement with data protection laws, an IT-supported identification method like RFID

[1] See: http://www.starlims.com/Biobanking_Brochure_final.pdf
[2] See: http://www.biofortis.com/products/labmatrix

tubes or the more common barcode tags should be used on each sample instead of identifying data of the patient. The transfer of MDAT and biomaterial to third parties should just take place in anonymized form [5].

Development of a concept for an IT-infrastructure for an academic medical center wide biobank

Covering the aspects to be considered when establishing a biobank (see introduction), we can deduce the following concept for an academic medical center considering the KFO 179 solution and the literature research:

(1.) The usage and transfer of samples have to be described very detailed in the patient informed consent. The patient has to be informed, whether the sample and the generated data are used only in a specific scientific area, e.g. cancer research, or generally for research purposes. Moreover, it must be possible for the patient to withdraw the consent at any time.

(2.) Ethical aspects: A DMSC must be installed to preserve the safety of patients. In addition, it secures the reliability of the data, which has to be guaranteed, and the transparency of the working processes within the projects.

(3.) To avoid interobserver-variability, all observers have to synchronize their classification methods. Within a clinical trial there should be only one single observer examining the biomaterial and for example staging it. A central image-bank could be one solution to solve this problem.

(4.) Data security and protection: Role-based access control, encrypted transfer of data into the RDE-system, separate storage of MDAT, IDAT, and BDAT, and pseudonymization of the data must be given. The IT-infrastructure must be setup according to data protection laws, TMF guidelines [5], and requirements of the ethic committee of the respective academic medical center.

(5.) Quality assurance must take place on all levels. Especially for a larger biobank it is necessary to ensure high quality biomaterial as well as very detailed annotations. The temperature profile of each sample should be monitored. Thus, an increase in temperature due to a defect or a power failure could directly lead to a warning message to the responsible persons and counteractions could be taken immediately. Unless one directly uses room-temperature sample storage for DNA or RNA obviating the need for freezers [11]. The entry of data into the biobank software must be controlled by a role-based access control and the values added into the fields of the forms should have plausibility checks also for duplicates of barcodes or storage locations. The data entry into a biobank software depends on the state of automation of the biobank, i.e. whether robots are used for storage locations or making aliquots of samples [12].

(6.) It is necessary to store biomaterial of clinical trials for a long time. The progress of research is very fast and therefore it is important that researchers can use datasets of former trials e.g. to establish and validate new methods. In the KFO 179 such an older comparable dataset is used for examination aspects in order to reproduce the results. In case of different results it might be helpful to generate data of older samples again using the current technology. For reducing the problem of treating specimens stored with a different purpose and to label them and determine their content, it is necessary to anonymize them. Nevertheless, for a complete new biobank we recommend to first setup a functional IT-infrastructure including machines for reading samples, labeling, and storing them. Just upon the complete existence of the framework a biobank should start collecting samples.

(7.) A web-based tool for third parties to enquire biomaterial is essential. For the transfer of biomaterial to third parties a DMSC is required, controlling the giving away and required measures like anonymization. An interesting solution is practiced at the biobank of the Medical University in Graz, Austria. There, third parties are supported by the biobank to write research proposals. The biobank determines the availability of the required samples and performs all experiments within core facilities of the Medical University. Only the research result is given away to the third party upon payment[3]. Thus, valuable samples are not given away and a quality loss of the specimen caused by an interference of the cold chain can be excluded.

Finally, it is indispensable to avoid parallel solutions meaning that per academic medical center just one biobank should exist. Most importantly we recommend a new biobank software for an academic medical center, as the secuTrial approach has too many limitations and is not sufficient anymore.

Discussion

Our experience showed that around younger scientists there is a big acceptance of new ideas, whereas senior laboratory personnel tend to generally dislike changes. Nevertheless, existing skepticism is quickly released when the personnel realizes the simplifications, which such new ideas bring with them for the daily workflow.

On the one hand, compared to a distributed storage approach one central biobank has the advantage of saving costs regarding cooling facilities, alarm, and power back-up systems [10]. Optimally, the biobank should be linked to the central laboratory for health care to take over otherwise discarded samples. On the other hand, room must be created for many samples and it requires an elaborate workflow to secure continuous cooling of the specimens from the place of retrieval to the biobank freezers. Moreover, property issues and data sharing issues can easily inhibit the central approach. Therefore, a mature biobank software should not be depending on local issues.

The financial aspect of the biobank depends on the state of automation, e.g. machines for aliquoting, refractioning of blood, storage of samples, labeling of samples, but also on the software for the IT-infrastructure and the number of employees for the biobank.

An academic medical center wide biobank offers advantages and disadvantages to its scientists, although the advantages prevail. The main advantage is that scientists can revert to a larger selection of samples for their research. The fact that

[3] See: www.meduni-graz.at/1449

physicians would need to hand in all their samples gained from patients not used for medical examination into the biobank might be a disadvantage on the first sight. In reality this is an advantage, as it allows the blinding of the physician, who might have a double-role as clinician treating patients and scientist working with their material.

In the KFO 179 an emerging need for an easy-to-use research database (RDB) came up recently. So far, this lies beyond the possibilities of an RDE system. A suggestion for an IT-infrastructure for an academic medical center including a RDB is described in figure 2 [13].

The MDAT stored in the study database (SDB) are encrypted with a person identifier (PID), as well as the IDAT which are stored in a separate list. The BDAT in the biomaterial database (BDB) are organized via a laboratory identifier (LabID) and have a different patient pseudonym. Before researchers can start working with their data, e.g. combining gene expression results with MDAT, a mapping of the identifiers must take place preferably by IT. A RDB into which the matched datasets from SDB and BDB and genetic data could be imported via several interfaces could be searched by a query tool like i2b2 (informatics for integrating biology and the bedside)[4] [14, 15].

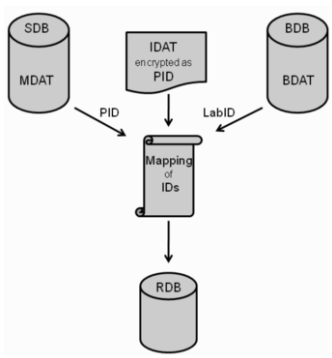

Figure 2- IT-infrastructure for an academic medical center in accordance with German data protection laws

Conclusion

A biobank for an academic medical center should be developed for every university paying special attention to the IT-infrastructure. The choice of software for the single components (Fig. 2) should be well-thought of as the IT plays a pivotal role. The need for a RDB will just slowly arise during operating the biobank, but the person in charge should at an early stage decide how a product could fit best into the existing IT landscape.

Abstract

Natural scientists such as physicists pioneered the sharing of computing resources, which led to the creation of the Grid. The inter domain transfer process of this technology has hitherto been an intuitive process without in depth analysis. Some difficulties facing the life science community in this transfer can be understood using the Bozeman's "Effectiveness Model of Technology Transfer". Bozeman's and classical technology transfer approaches deal with technologies which have achieved certain stability. Grid and Cloud solutions are technologies, which are still in flux. We show how Grid computing creates new difficulties in the transfer process that are not considered in Bozeman's model. We show why the success of healthgrids should be measured by the qualified scientific human capital and the opportunities created, and not primarily by the market impact. We conclude with recommendations that can help improve the adoption of Grid and Cloud solutions into the biomedical community. These results give a more concise explanation of the difficulties many life science IT projects are facing in the late funding periods, and show leveraging steps that can help overcoming the "vale of tears".

Keywords:
Healthgrid, Grid computing, Technology transfer.

Introduction

The Argon National Laboratory and CERN played leading roles in the breakthrough of Grid computing. Both institutes share a history in performing basic research in IT and providing IT services for users from the natural and applied sciences – mainly physics. In contrast, developing Grid services for life scientists has been carried out by numerous healthgrid initiatives. We use the term "healthgrid" to refer to the different initiatives developing Grid e-science services for the biomedical community, like caBIG, WISDOM, the French Medigrid and the German MediGRID. These initiatives are transferring the Grid computing technology into the life sciences [1].

"Technology transfer" is a concept which first appeared in literature in 1960s [2]. The term "technology transfer" is widely used to refer to transferring the technology developed in universities and governmental laboratories to the industry. Inter domain technology transfer was also addressed in several studies. We distinguish between knowledge transfer and technology transfer. According to Gilbert and Cordeyhayes [3], knowledge transfer refers to the ''scientific knowledge used by scientists to further science''. Technology transfer refers to the ''scientific knowledge used by scientists and others in new applications''. Healthgrid initiatives are conducting both.

The Grid computing technology transfer process is being carried out by academia and facilitated by government funding agencies. This has been an intuitive process using an exploratory approach. Some difficulties facing the biomedical community during this transfer can be understood through the Bozeman "Effectiveness Model of Technology Transfer" [4], which summarizes the research work on technology transfer. Grid and the emerging Cloud computing technologies are still in flux and thus their inter domain transfer process is subject to problems which are not considered in classical technology transfer models. Taking these differences into account, we can better understand some difficulties facing the transfer of Grid and Cloud technologies. In this paper we show to which degree the principles of technology transfer apply to building an e-science infrastructure for the biomedical community and make recommendations for an improved transfer process.

Materials and Methods

Dynamic-technology transfer

A common view of "technology" is to consider it as a physical entity, a "tool", which is the outcome of a production process and which can be transferred easily (for example by moving it to the target setting) [4]. In contrast, Sahal and Bozeman [4, 5] consider technology as the product as well as the knowledge and methodology to use this product. In our case, the Grid knowledge transfer is not separable from the Grid technology transfer process. Alike Sahal and Bozeman anyhow, we do not consider the applications of the (Grid) technology a part of the technology transferred. The biomedical use cases follow different goals than applications in physics or astronomy. The latter are foremost data grids. Biomedical Grid computing applications are combinations of three types of Grid: data Grid, knowledge Grid, and compute Grid (see Figure 1).

Technologies in development are critical for the transfer process. This was questioned by Bozeman but not incorporated

into his model: "a technology is changed because there is an active attempt by its users or creators to change it. In other cases, the technology is changed by characteristics of its use or by changes in the physical and social setting within which the technology exists. When the functions and application environment changes, does that affect the meaning of the technology or its transfer?" [4]. We believe this question is crucial in our case, as the Grid and Cloud technology is designed to be extendable from the beginning. Known technology transfer methodologies, including Bozeman's model consider static technologies. Technologies under development are dynamic and require different methods. In the discussion, we present our experience and lessons learned with such transfer.

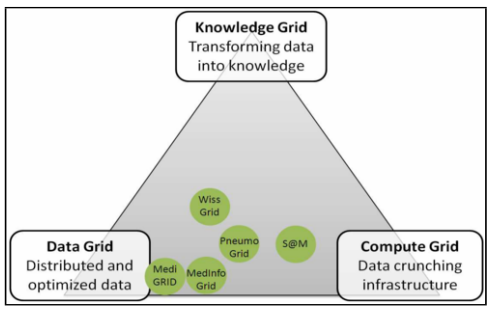

Figure 1- The three generic applications of biomedical Grid computing. A healthgrid is a combination of compute, data, and knowledge grids. MediGRID represents the first phase in transferring the Grid technology to the biomedical community in Germany. Services@MediGRID (S@M), PneumoGrid and MedInfoGrid are successors of MediGRID. WissGrid (Science Grid) is a third phase D-Grid project and involves different communities including life sciences.

The effectiveness model of technology transfer

Bozeman provided a "Contingent Effectiveness Technology Transfer Model'' to summarize the research work on technology transfer. "The model focuses on effectiveness, a perspective well-matched to a literature so often motivated by the search for what works" [4]. With the "what works" approach it is meant how to measure success in a technology transfer process. Five dimensions determine the effectiveness: the transfer agent, the transfer media, the transfer object, the demand environment, and the transfer recipient. The interaction between these dimensions determines the effectiveness of the transfer process. Therefore, the impact of technology transfer should be understood in terms of who is doing the transfer, how they are doing it, what is being transferred and to whom. The novel thing here is that there is no single notion of impact of a technology transfer process. We need to understand the effectiveness in terms of different dimensions, i.e. the goals of one participating party is not necessarily the same (sometimes even contra effective) for other parties. The effectiveness of the transfer can be classified in six deferent criteria: ''Out-the-Door'', Market Impact, Economic Development, Political Reward, Opportunity Costs, and Scientific and Technical Human Capital. Table 1 describes the dimensions of the effectiveness model and Table 2 describes the effectiveness criteria. More details about the model can be found in [4]. We focus on the special case of having Grid computing as the transfer object with the recipient being the biomedical community.

Technology transfer research agenda

Bozeman divided the political agenda to perform technology research into three paradigms:

The market failure technology policy paradigm assumes the free market "will lead to optimal rates of science production, technical change and economic growth" [4]. The government role is to remove barriers to the market, e.g. by providing regulations for intellectual property. The duty of universities is education and providing public domain research.

The mission technology paradigm premise is that the government supports research and development activities "in service of well-specified missions, in which there is a national interest"[4]. Examples are funded R&D from governments for national security, energy production and conservation, medicine and public health. This paradigm has expanded the role of universities to builders of the national technological interests.

The cooperative technology policy paradigm presumes that government's and universities' role is to perform research and to supply applied technology to society and industry. The cooperative technology paradigm emphasizes cooperation among industry, government, and university in the development of new and infrastructure technologies.

D-Grid and MediGRID

The D-Grid Initiative aims to assemble, set-up and operate a Grid infrastructure in Germany in three stages. D-Grid-I, 2005-08, was launched to design and develop Grid services for scientists. D-Grid-II, 2007-10, is designated to design IT services for scientists, industry, and business. D-Grid- III, 2009-11, extends the infrastructure with a knowledge management layer. The aim of MediGRID is to develop a Grid infrastructure for biomedical research. The MediGRID consortium is organized in modules distributed on academic departments and governmental laboratories. The D-Grid/MediGRID funding began following the mission paradigm and looking for a "market pull" of the technology. Unfortunately, the dissemination of the technology was difficult. Especially in life sciences, the requirement for high security and data protection standards proved to be a hindrance [6]. This resulted in a delay in creating a critical mass of users for the infrastructure. In order to enforce a market oriented infrastructure, the funding agency changed the paradigm later to a cooperative technology transfer approach. In the discussion, we show why this shift was early and not ideally suitable for healthgrids in Germany.

Results

The transfer agent – academia and healthgrid initiatives

The technology paradigm is the leading aspect in choosing the right transfer agent, whether it is a university, a governmental laboratory, or an industry partner. D-Grid started with a mission paradigm; it was natural to involve universities as the leading transfer entity. After the shift to the cooperative paradigm, the transfer agent continued to be the universities. Uni-

versities are basically sittings for research and education. The enforced technology policy forced them to take new responsibility in the technology development. In our case, MediGRID started as a research initiative from a department of Medical Informatics at the University of Goettingen. Academic medical informatics departments usually carry out interdisciplinary research in the intersection of computer science and life sciences. They are capable of importing new IT technology in an inter-domain technology transfer process. But they are not necessarily market oriented institutions. Whether academia succeeded in developing a market oriented infrastructure is still an open question. Nevertheless, MediGRID was able to attract some users from industry in its second phase.

The transfer media of Grid computing

This includes objects, like software and literature, and human activities, like meetings and workshops. ***Software:*** Grid middlewares were primarily developed for physicists, who mainly required storage capacity and job farming capabilities. There are three common Grid middleware: Globus, gLite, and Unicore. All are open source, which makes it easier to deploy, modify and adapt them, however this means they are in flux and are not stable technologies. An organizational framework, e.g. Service Level Agreements, is also still missing. ***Science Park:*** MediGRID consolidated the Grid computing activities in Goettingen campus to establish a Grid computing Science Park. Scientists from multiple disciplines formed the GoeGrid, in which physics, bioinformatics, humanities, libraries, computer science, and medical informatics are represented. Participants established an interdisciplinary academic course, in which discussions, demonstrations, and invited talks enriched the understanding of the technology. ***Literature:*** the available literature on Grid computing is vague and complex. The middleware documentations are not complete and contain mistakes. A solid experience with Linux and software development is a requisite to be able to work through the documentations. This has been a major hindrance in the transfer process.

The transfer object – e-science using Grid computing

The goal of building a healthgrid is to perform e-science in biomedicine. While this is a scientific aim, one enduring focus of technology transfer is whether the transferred technology has commercial potential [4]. The question in our case is rather whether Grid computing for medical application is currently ready to be commercialized (we offer our opinion in the Discussion). The second and third phase of Grid computing funding in Germany focused on developing business models for the use of the Grid. This was meant to enforce economical sustainability in a highly dynamic system that is still under development. While the fundamental research in Grid computing is more or less finalized, the methodology of importing life sciences IT applications, from the closed local environments into the open Grid environment, is still under development. Organized and focused interaction with industry is a prerequisite for technology transfer from basic research [4, 7]. Therefore, it is important to cooperate with and engage the life sciences industry to gain trust in the transfer object, before hard commercial criteria are used to evaluate the end objective. This is being tackled currently by Services@MediGRID.

The demand environment

The critical mass of demand for the technology is a major factor in determining the success of technology transfer, especially in life sciences [8]. We faced different difficulties in introducing the Grid technology to the life sciences community: the technology was new to the market and missing ready-to-use applications, the overhead to import existing IT-solutions into the Grid was high, and using the Grid for low level services (like data storage) demanded new skills of the user. This was led to a low acceptance of the technology. To overcome this, MediGRID moved to a market push policy in its second phase by building contacts to the biomedical firms and offering the needed support to import the application into the Grid.

Characteristics of the transfer recipient

The traditional recipients of healthgrids technology are researchers in academia, i.e. non-profit organizations. They depend mainly on public funding, which makes it challenging to develop an economically sustainable infrastructure similar to what e.g. engineering grids do - selling services to industries. The market push policy should help to reach a wider user group in industry and academia.

Table 1- Dimensions of the Contingent Effectiveness Model with corresponding in healthgrid initiatives.

Dimension	Focus [4]	Examples [4]	In Healthgrids
Transfer Agent	The institutions seeking to transfer the technology.	Government agency, university, industry and their characteristics	Mainly academia
Transfer Medium	"The vehicle", by which the technology is transferred	License, copyright, person-to-person, formal literature	Literature, Grid computing software, workshops
Transfer Object	The content and form of what is transferred	Scientific knowledge, technological device, know-how, and specific characteristics of each	The methodology of performing e-science using the Grid technology
Transfer Recipient	The organization or institution receiving the transfer object	Firm, consumer, group, institution, and associated characteristics	Biomedical/healthcare professionals, researchers, and companies
Demand environment	Factors (market and non-market) pertaining to the need for the transferred object	Price for technology, substitutability, relation to technologies now used, market shelters	New tools for physicians, E-marketplace for medical service providers, collaboration concept for researchers, new possibility for knowledge management [1]

Discussion

We show that the answer to whether the Grid technology transfer process was successful or not is multi-layered. Our experience shows that the Grid computing is mainly being evaluated according to market-oriented criteria. This is not suitable for measuring the success of healthgrids. Healthgrids should be evaluated according to the produced scientific and technical capital as well the new created research opportunities. Hence, the mission paradigm is more suitable for starting healthgrids. Especially for technologies under development like Grid or Cloud computing, funding in the mission paradigm shall last until a clear political reward is reached. This will pave the way for a market impact and the move to a cooperative funding paradigm (see Table 2 and Figure 2).

''Out-the-door'' criterion in healthgrids

The assumption here is that "transfer itself equates with success" [4]. As D-Grid-I followed this criterion, the technology was not ready to fulfill the needs of life scientists. Security extensions, information privacy concepts, and workflow extensions were missing. Therefore, MediGRID followed its own course, which was different from other D-Grid community projects, including physics, engineering, and astronomy. MediGRID put emphasis on analyzing the middleware, providing concepts for data protection, and building prototypes applications. In other communities' projects, scientists used "out-the-door" approach and were ready to use of-the-shelf Grid technology. Thus, "out-the-door" is a success criterion for most Grid technology transfer projects, but not for healthgrids.

Why do life science grids not have a market impact, yet?

Market Impact measures the effectiveness of the transfer process according to the commercial success of the technology in the new environment. In our case, the question is not whether the success of a healthgrid can be measured in terms of the market impact, rather when to do so in general. Whether a technology is ready for the market depends largely on the acceptance by the transfer recipient. In MediGRID one major factor influencing the acceptance was simplicity of access, thus, in MediGRID a main emphasis was put on having a web portal as main gate to the Grid resources. Portals for other D-Grid community projects were not an issue, since their users possessed enough IT skills to operate the resources on the command line. That physicists are willing to pay for Grids accessed via the Linux shell, does not mean life scientists will do the same. In technology transfer, it is wrong to put the technology in the market before it is ready. We believe the enforced change from the mission to cooperative paradigm in the German D-Grid was early for MediGRID. Not being ready for the market means little market results, and thus a false negative result. "… technology transfer with little market result has no place in the [cooperative technology policy] paradigm" [4].

Why is the political reward still minimal?

Receiving further funding is the main result of a political reward. Although healthgrids in Germany received further funding from the Federal Ministry of Education and Research, the funding was strategically dedicated towards commercializing the infrastructure. Despite of the involvement of users from industry in the second phase of MediGRID, we are still far from economical sustainability. The necessary political reward would be further funding from the Federal Ministry of Health or from partners from the biomedical industry, due to their roles in healthcare and life sciences. This is not yet reached.

Which opportunities do healthgrids establish?

Each transfer process yields alternative local benefits beside the intended goals of the transfer itself. Examples are the researchers who receive PhDs while working for a technology transfer project, using the received funds for a better internal evaluation of the institute, or changing the profile of the transfer agent. This is common in technology transfer projects. This criterion overrides the common concept of success to provide the effectiveness from the transfer agent's point of view. The various opportunities offered by D-Grid included PhD research, establishing new specialized research groups, starting follow-up projects, and offering infrastructure for academic courses. We believe that more emphasis should be put on considering and supporting such opportunities as a strategic goal in the future. Because Grid computing in life sciences is a young inter-disciplinarily field, the dissemination and establishing the field is an important part of the transfer process.

Table 2- technology transfer effectiveness criteria [4] with corresponding in healthgrid initiatives.

Criterion [4]	**Focus** [4]	**Relation to practice** [4]	**In healthgrids**
''Out-the-Door''	One organization receives the technology provided by another, no consideration of its impact	Common in practice	Uncommon
Market Impact	Has the transfer resulted in a commercial impact, a product, profit or market share change?	Pervasive in practice	Not yet reached
Economic Development	Similar to Market Impact but on a regional or national economy rather than a single firm or industry	Pervasive in practice	Not yet reached
Political Reward	Based on the political reward flowing from participation in technology transfer (e.g. increased funding)	Pervasive in practice	Minimal
Opportunity Costs	Examines alternative uses of resources and possible impacts on other missions of the transfer agent/recipient	A concern among practitioners, rarely considered	Common
Scientific and Technical Human Capital	Considers the impacts of transfer on the enhanced scientific and technical skills, technically-relevant social capital, and infrastructures (e.g. networks, users groups)	A concern among practitioners, rarely considered	Common

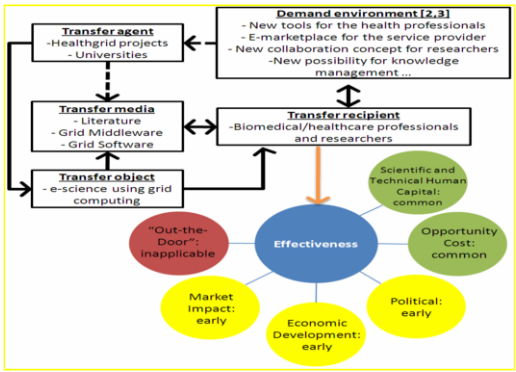

Figure 2- Contingent Effectiveness Model applied on the Grid technology transfer to the biomedical domain.

Scientific and technical human capital in healthgrids

Building up human scientific and technical capacity is as important as producing specific impact from a project [9]. Similar to Bozeman et al., we believe that scientific and technical human capital is a neglected criterion for measuring the technology transfer effectiveness in general [9], and in healthgrids in particular. An important mission of the technology transfer process is to increase the scientific human capital. Such capacities could be within a geographic area, a scientific and technical field, or an institution [4]. D-Grid/MediGRID was a vehicle to reach achievements in these three categories. Within Goettingen campus MediGRID initiated a Grid science park: the GoeGrid. Healthgrid started in Germany 2005 with one project; by 2009 four follow up projects are funded from the federal government. The department of Medical Informatics at Goettingen increased the number of scientific assistances and publications during this period. The "network-based concept of effectiveness" is another important concept [4], which couple the evaluation of technology transfer with impacts on interconnected scientific and commercial actors. The ongoing relations among networks of technology partners are more important to transfer effectiveness than the market factors [10]. MediGRID established in 2008 the "Grid Forum" to coordinate German Grid computing activities in the fields of medicine, medical research and life sciences. These achievements are not the defined goals of the intended technology transfer, but they are a significant and vital part.

Conclusion

Unlike classical Grid users, life scientists are not yet used to sharing computing resources. The government funded three step cross-pollination achieved interesting results, but fell short in some aspects. During the first funding periods it is accepted that the Grid platforms still suffer from stability and sustainability issues. According to the Bozeman-approach it was timely to reinforce industry involvement in the follow up funding periods in order to foster the market impact. However, different organizational and stability issues have hindered a broad market penetration. So the vale of tears still has to be stridden for life science Grids. This is about how collaborative work will be organized in the life sciences in the foreseeable future. Technology labels like Grid or Cloud do not make any difference in the subjacent problem. The problem lies in transferring a dynamic technology using the models and experiences of static technology transfer. In absence of well established models for dynamic technology transfer, we proposed a three steps strategy based on our experience with MediGRID/D-Grid: 1- building a strong scientific and technical human capital, 2- reaching a clear political reward while in the mission funding phase, 3- reaching out to the market and gradually ascent toward a market cooperative paradigm.

A Mobile Phone Based Telemonitoring Concept for the Simultanous Acquisition of Biosignals and Physiological Parameters

Hannes Kumpusch[a], Dieter Hayn[a], Karl Kreiner[a], Markus Falgenhauer[a], Jürgen Mor[a] Günter Schreier[a]

[a]*Safety and Security Department, AIT Austrian Institute of Technology GmbH, Graz, Austria*

Abstract

Congestive Heart Failure (CHF) is a common chronic heart disease with high socioeconomic impact. Conventional treatment of CHF is often ineffective and inefficient, since self-management is complex and patients are insufficiently involved in therapy management. With telemedical concepts, continuous monitoring of the health status can be ensured, and consequently therapy management can be adapted to the individual requirements of every individual patient. Therefore, a mobile phone based patient terminal for the concurrent acquisition of biosignals (e.g. ECG) and bioparameters (e.g. blood pressure) for patients with CHF has been developed and prototypically implemented. Usability and interoperability aspects were especially considered by using Bluetooth and Near Field Communication (NFC) technology for data acquisition and standardized data formats for transmission of the data to a central monitoring centre. Results indicated that even complicated measurements like the acquisition of ECG signals could be accomplished autonomously by the patients in an intuitive and easy-to-use way. Through the usage of IHE conform HL7 messages, self-measured data could easily be integrated into a higher-ranking eHealth infrastructure.

Near field communication, eHealth, Telemedicine, Mobile communication, ECG, Congestive heart failure, Interoperability

Introduction

Motivation for Telemonitoring of Congestive Heart Failure

Congestive Heart Failure (CHF) is defined as *"a complex clinical syndrome that can result from any structural or functional cardiac disorder that impairs the ability of the ventricle to fill with or eject blood."* Since self-management of CHF is complex and since patients are insufficiently involved in the state-of-the-art therapy process, patients' compliance to the given therapy management is often poor – resulting in a high rate of re-hospitalizations within six months after discharge and in poor quality of life [1].

Telemonitoring for patients with CHF provides advantages for not only the patients but also the healthcare system. The attending physician can carefully watch the overall health status of his patients by the monitoring of various health parameters, namely ECG, weight, blood pressure, heart rate, medication, and well-being. This enables the physician to adapt the therapy in due time – avoiding readmissions to the hospital, emergency cases and extraordinary treatment costs [1].

State of the art

In the last years, several systematic reviews concerning the benefit of telemonitoring in the management of CHF have been conducted. Chaudhry et al. state that telemonitoring may be an effective strategy for disease management in high-risk CHF patients [2]. Clark et al. conclude that telemonitoring programs have a positive effect on clinical outcomes in community dwelling patients with CHF [3]. Louis et al. [4] conclude that telemonitoring might have an important role as part of a strategy for effective CHF management. Seto et al. [5] deal with the cost-effectiveness of telemonitoring in the management of CHF. The results of the aforementioned systematic review suggest that although CHF telemonitoring will require an initial financial investment it will reduce costs in the long run. The cost reduction is particularly caused by the decrease in readmissions and travel costs.

Most of the aforementioned studies used rather complex patient terminals, which could not be used intuitively or were too expensive for a widespread usage. A success factor for the implementation of telemonitoring in the healthcare system is to provide the patients with an easy to use patient terminal for intuitive data acquisition at low cost.

The mobile phone as patient terminal

Mobile phones have already been used as patient terminals in several existing telemonitoring systems for the management of e.g. obesity [6], psoriasis [7], diabetes [8], asthma [9], and CHF [1]. Most of the mentioned systems have used mobile phones with numeric keypads for data entry and mobile Internet technology for the transmission of the data to a central monitoring centre. However, manual data entry often overburdens (elderly) patients, especially if they are not familiar with handling mobile phones.

While the acquisition of an ECG could be helpful in CHF therapy management, it also opens new challenges for the development of a mobile phone based patient terminal. In [10-13], systems for the acquisition of ECG signals in a telemonitoring scenario were introduced. All systems used mobile phones as patient terminals and Bluetooth for the communication between the ECG recorder and the mobile phone. None of these solutions has been evaluated in the course of a clinical study with respect to usability for the given group of patients. Most of the systems required the application of adhesive electrodes to the chest in order to record an ECG. The quality of the ECG strongly depended on the ability of the patients to apply the electrodes correctly, which may pose a problem for daily usage in a telemonitoring scenario. Furthermore, the presented ECG recorders seemed to be too complicated to be used by the patients autonomously.

Aim of the present work

It has been the aim of the present work to develop a patient terminal, which supports

1. an easy-to-use interface for acquiring bioparameters (e.g. blood pressure) and biosignals (e.g. ECG) and
2. the smooth integration of the patient terminal into existing eHealth platforms and hospital information systems.

The patient terminal should prototypically be implemented for the acquisition of home-monitoring data acquired by the patients themselves in the course of CHF therapy.

Materials and Methods

Wherever possible, standards were used for developing a prototype implementation of a telemonitoring system for CHF. These standards are shortly described in the following.

Communication protocols

One way for sending data from a measurement device to the mobile phone is Bluetooth. Therefore, prior to transmitting data in between the devices, the devices need to be paired using a PIN the user has to enter to the mobile phone. Bluetooth pairing is not an intuitive procedure and it may overstrain especially elderly patients. Therefore, an alternative easy-to-use method was demanded.

Near Field Communication (NFC) is an intuitive communication technique, allowing wireless data transmission over short distances. In the case of mobile phones, the maximum distance in between sender and receiver is about 1 cm. Data can either be exchanged between two active devices or in between an active device and a passive NFC tag. In the second case, information can be written on a tag (e.g. an identification number) and later on be read out by an active NFC device (e.g. mobile phone). Unfortunately, communication via NFC is rather slow and it is disconnected as soon as the devices are separated by more than about 1 cm. Therefore, transmission of large data such as a whole ECG file from a measurement device to a mobile phone via NFC is not possible in a reliable way.

Device Enterprise Communication (DEC)

The *Device Enterprise Communication* (DEC) profile as described in the IHE *Patient Care Device Technical Framework* [14] was used for developing the prototype. The DEC profile describes three actors: The *"Device Observation Reporter"* receives the data from the measurement devices, including these based on proprietary formats, and maps the received data into an HL7 *"Observation Result"* message. The reporter forwards the HL7 result message to the *"Device Observation Consumer"*. Additionally, a *"Device Observation Filter"* can be put in between the reporter and the consumer, transmitting only data that the consumer is expecting to receive [15].

Annotated ECG

ECG signals were encoded using the *annotated ECG* (aECG) data format. aECG is an HL7v3 message that has been developed by the HL7 Regulated Clinical Research Information Management Technical Committee. It is intended for the submission of annotated ECG waveforms by the sponsor of a clinical trial to the United States Food and Drug Administration (FDA) [16]. Like the DEC profile, aECG is based on the "Point of Care medical device communication (MDC) Nomenclature" of the ISO/IEEE X73 standard [17].

Backend server

All data acquired with the developed patient terminal were sent to an existing backend infrastructure including identity management, database, web-server, feedback service, interfaces to hospital information services etc.

Results

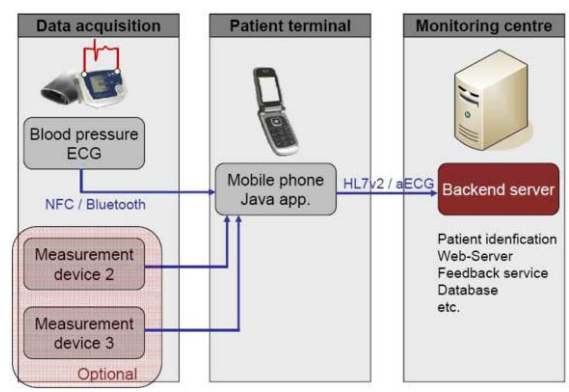

Figure 1- System architecture. A mobile phone based patient terminal collects data of several data acquisition devices and transfers them to a backend server via a standardized interface based on HL7v2 and annotated ECG (aECG).

A framework for acquiring bioparameters (e.g. blood pressure) and biosignals (e.g. ECG) has been prototypically implemented and integrated into an existing eHealth infrastructure.

A schematic representation of the system architecture is shown in Figure 1. The architecture is based on the *Device Enterprise Communication* (DEC). A J2ME based software application running on the patient terminal served as *Device Observation Reporter*. The backend server was used as *Device Observation Consumer*. As the *Device Observation Filter* is an optional part of the DEC profile, it has been omitted for the prototypical implementation.

Patient terminal – Mobile phone

A commercial mobile phone featuring wireless communication via Bluetooth and NFC (Nokia 6212 Classic, Nokia, Espoo, Finland) served as a patient terminal. A Java 2 Micro Edition (J2ME) based software application was implemented on the mobile phone. We used the Java Specification Request (JSR) 82 for implementing the Bluetooth protocol and the JSR 257 for NFC communication implementation.

Data acquisition – Measurement device

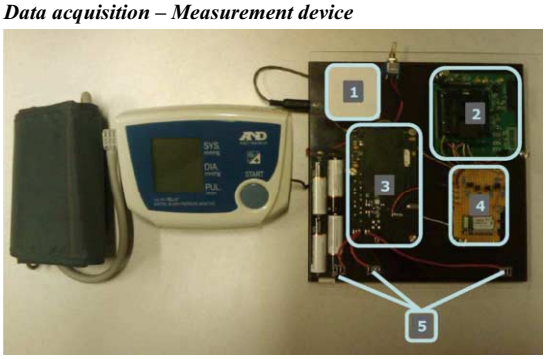

Figure 2- Prototype of the adapted blood pressure meter. 1) NFC Tag, 2) controller unit, 3) ECG module,4) Bluetooth module, 5) electrodes

In order to simultaneously acquire the ECG (Einthoven I), systolic and diastolic blood pressure, mean arterial pressure, and heart rate, an off-the-shelf blood pressure meter (UA-767 Plus BT, A&D, Tokyo, Japan) was used and extended.

An 8-bit single-channel 125 Hz ECG recording module (AIT Austrian Institute of Technology GmbH, Vienna, Austria) was added. For the prototype, the additional hardware was installed on a separate device connected to the blood pressure meter via cables. Three metal electrodes (left arm, right arm, driven right leg) were attached to the casing. These electrodes were to be touched by the fingers of the left and right hand.

Finally, a controller unit (MSP430F2410, Texas Instruments, Dallas, Texas, USA) was installed.

The system was equipped with an NFC tag (Mifare Standard 1K, NXP Semiconductors, Eindhoven, Netherlands) and a Bluetooth module (BNC4, Amber Wireless, Köln, Germany) enabling communication with the mobile phone. Figure 2 shows the hardware prototype of the adapted blood pressure meter.

Data transfer from measurement device to patient terminal

We combined the advantages of NFC and Bluetooth to develop an easy-to-use and reliable interface in between measurement device and mobile phone. The service ID of the Bluetooth module was written on the NFC tag on the adapted blood pressure meter and the Bluetooth connection was established by reading out this ID – without the need of any manual pairing procedure.

Data transmission from the blood pressure meter to the mobile phone was done in a proprietary data format. On the mobile phone, measured values were converted using an extensible mapping scheme. Every value and the corresponding unit were coded according to the MDC nomenclature of the ISO/IEEE X73 standard. For sending the data from the mobile phone to the backend server, the HL7v2 and the aECG standard were used.

Workflow

For data acquisition, the NFC tag on the blood pressure meter had to be touched with the mobile phone. The J2ME application started automatically read out the Bluetooth service ID from the tag and asked the user to take on the cuff of the blood pressure meter and to touch the ECG electrodes with his fingers. Next, the J2ME application sent a trigger impulse to the blood pressure meter, starting the inflation of the cuff. Thereafter, blood pressure measurement and ECG recording were done simultaneously.

The data were transmitted to the mobile phone via Bluetooth – using the service id stored on the NFC tag. The J2ME application analyzed the ECG signal and displayed a graphical representation of the current signal quality.

As soon as blood pressure data and ECG signals were available in sufficient quality, the data were automatically transmitted to the backend-system via UMTS. A device ID was added to the request, which was used to map the transmitted data to the patient.

The J2ME application guided the patient through this workflow, using a visual and acoustic interface – telling the patient, which step he had to take next.

Several measurements and processing cycles were performed successfully in various healthy volunteers.

Discussion

Usability

Effective and efficient treatment of CHF is one of the major challenges for healthcare systems and telemonitoring has been shown to be a useful tool for patients and physicians, increasing the overall therapy outcome. For telemonitoring, it is essential to provide the patient with an easy-to-use patient terminal for intuitive data acquisition. The advantage of mobile phones compared to other patient terminal technologies are their ubiquitous availability at low costs and their mobility. Limited resources concerning memory capacity and processing power, as well the small keypad and display are the main dis-

advantages of mobile phones. In the present work, the usage of NFC and Bluetooth technology completely eliminates the need to use the mobile phone's keypad for data entry. However, the limitation concerning the small display still is valid, even though much (but not all) information was provided to the patients visually and acoustically.

Manual inspection and automated detection of the ECG signals transmitted to the backend indicated that the signal quality would be sufficient for QRS detection and ventricular rhythm analysis. However, up to now no clinical validation of the system has been done. In a future study the usability of the system for CHF patients and the clinical benefit of recording ECG signals (additional to bioparameters as used for up-to-date CHF telemonitoring) will be evaluated.

Standardization and expandability

Initially, standardized data transmission throughout the whole system was intended. However, the adapted blood pressure meter used a proprietary data format. Therefore, standardizing the communication from the device to the mobile phone according to the (currently developing) Continua Health Alliance interoperability standard [18] is planned for the future.

In the management of CHF, it is important to monitor different parameters (ECG, weight, blood pressure, heart rate, medication, and wellbeing) in order to get a complete view on the health status of the patients. The DEC profile only supports physiological parameters (weight, blood pressure, heart rate). Parameters like medication or well-being are not in the scope of the current version of the profile. Additionally, as the current version of the profile does not define the standardized handling of biosignals like ECG, a concept for additional integration of biosignals was needed and has been implemented on the basis of the aECG standard.

Currently, the use case described only supports the acquisition of ECG and blood pressure data (systolic, diastolic and mean blood pressure, heart rate). For clinical usage, additional parameters (weight, medication, subjective parameters) have to be included in order to get a complete view on the health status of the patients. However, because of the modular architecture of the software and due to the use of standards, modules for the acquisition of further parameters could easily be integrated into the developed software.

Safety and security considerations

Up to now, the Bluetooth connection in between measurement device and mobile phone established via NFC by the use of the device's Bluetooth service address is un-authenticated and unencrypted. Therefore, in a clinical setting, an alternative way of establishing the Bluetooth connection via NFC may be required.

In 2007, the Bluetooth Special Interest Group (SIG) announced the new version of the Bluetooth core specification, namely Bluetooth 2.1. Among others, with Bluetooth 2.1 and through the usage of NFC, the initiation of this simplified pairing process can be automated. The only user action required for pairing is holding one device closely to the other. NFC handles the initiation of the pairing without further user interaction.

Unfortunately, Bluetooth pairing via NFC is an optional feature of Bluetooth 2.1, and mobile phones currently available only support this feature for sending images to electronic picture frames or printers. However, it is expected that in future devices this feature will be implemented for all Bluetooth devices.

Security issues are explicitly excluded from the DEC profile. As it is primarily intended for the usage in an encapsulated network (e.g. within a hospital network) data security methods are disregarded. For the use in a telemonitoring scenario, the profile has to be embedded into an additional "Security Framework" in order to ensure a secure end-to-end transmission of the acquired data and to be compliant with data protection regulations. For the development of the prototype, security aspects were also disregarded in the first step. Hence, further developments of the software will focus on the development of a security layer including an encrypted Bluetooth connection form the device to the patient terminal and encrypted data transmission over the Internet form the patient terminal to the backend server using HTTPs.

Identity management of personalized data (i.e. the assignment of a data set to a patient) is one of the big opportunities in future telemonitoring scenarios. Today entering username and password is the golden standard for personalizing data on the Internet. For elderly patients it may be hard to keep the username and password in mind and additionally entering data using the alphanumeric keypad is rather difficult. Identity management issues are also disregarded by the DEC profile. We chose to use a device ID, which was explicitly mapped to a patient ID, for assigning the data received from the patient terminal to a patient. Alternatively, NFC smart cards with personal patient IDs could be handed out to the patients and identification could be made by simply touching this ID whenever transmitting data.

Conclusion

An interoperable mobile phone based patient terminal for the intuitive acquisition of biosignals and physiological parameters was developed and implemented prototypically. Via the use of Bluetooth combined with NFC technology, an easy-to-use interface in between measurement device and mobile phone could be developed. Due to standardized transmission protocols, architectures and data formats, smooth integration of the patient terminal into existing eHealth structures was achieved.

Acknowledgments

The project was partly funded by the Styrian government, department 3, science and research (*Forschung Steiermark - Planung, Steuerung, Impulse - A3-22.E-4/2008-12*).

The Role of the Electronic Health Record in Support of Genomic Research

Vincent Normandeau-Babin[a], Hanad Nwilati[b], Sherif Abou-Elela[b], Andrew Grant[a]

[a] *Collaborative Research for Effective Diagnostics (CRED), Université de Sherbrooke, Québec, Canada*
[b] *Laboratoire de Génomique Fonctionnelle de l'Université de Sherbrooke (LGFUS), Université de Sherbrooke, Québec, Canada*

Electronic health records (EHR) are a source of information which could be used to better understand the chronological evolution of disease for optimising and innovating treatment. In parallel, translational research focuses on the analysis of gene expression signatures (GES) with the aim to diagnose subtypes of diseases in order to predict clinical outcome. The combination of genomic and clinical information is opening the opportunity to explore the concept of clinical phenotype. Here we present the first step of an overall informatics architecture for exploiting phenotyping information from an EHR for genomic research purposes. This work, developed in studies of gene expression for ovarian cancer, describes the use of EHR data to document specimen quality and clinical context with significant impact on the selection of specimens for genomic studies.

Quality of Electronic Nursing Documentation in Australia Aged Care: Approaches to Evaluation

Ning Wang, Ping Yu, David Hailey

Health Informatics Research Laboratory, School of Information Systems and Technology, University of Wollongong, Australia

Electronic nursing documentation (END) systems are increasingly deployed across aged care organizations in Australia and require evaluation to determine their effect on the quality of service. This presentation describes the development of approaches to the evaluation of END systems in aged care, and considers issues to be taken into account in the evaluation of service quality. Following the establishment of three evaluation goals, a nursing documentation audit instrument was constructed, using approaches derived from three information sources. The focus of the instrument was on documentation structure, format, process and content. The content validity of the instrument was tested by staff at an aged care facility and a high level of consensus was obtained. The audit instrument and related approaches will be used in a research project to evaluate the quality of electronic nursing documentation systems in aged care facilities.

Text classification requires labeled data which is generally scarce and creating additional labeled data requires manual annotation which is an expensive and time consuming task. In our recent work with medical text classification we adopted an iterative labeling process where physicians label instances in batches. Each batch is incrementally added to the training set and changes in outcome measures, such as area under receiver operating characteristics curve (AUC) and accuracy, are calculated. We realized that being able to predict the outcome at a given sample size would be useful and can inform our decisions to terminate labeling and/or learning. In this paper, we describe one such method based on non-linear curve fitting.

DISCOCLINI: a system for Biomarkers Discovery in Medical Functional Genomics data

Arriel Benis, Mélanie Courtine, Alain Venot

Laboratoire d'Informatique Médicale et Bioinformatique (LIM&BIO EA 3969), UFR SMBH, Université Paris 13, Bobigny, France

One of the difficult problems of data interpretation in the analysis of cDNA chips is that the number of expression levels per chip is very high compared to the number of chips. Our method, DISCOCLINI, consists in calculating all correlations in data and reformulating them to easily visualize variation patterns.

Towards a web-based environment which assists physicians in guiding ARV resistance treatment

Yashik Singh

Department of Telemedicine, Nelson R. Mandela School of Medicine, University of KwaZulu-Natal, Durban, South Africa

The aim of this study is the development of a web-based environment that offers various bioinformatics tools to assist physicians in determining the optimal highly active anti-retroviral therapy for individual antiretroviral resistant patients. The clinical environment will facilitate the analysis of the collated output from different interpretation gold standards and predicting the future resistance profile of a patient.

The future of clinical and translational research depends on the ability to gather, store, retrieve and analyze vast quantities and different kinds of data rapidly. These data sets consist of data ranging from genes and molecules to clinical parameters of individuals and characteristics of entire populations. Their acquisition, curation and comprehensive analyses will form the basis of modern medical practice, occupying a central place in the development of translational research and personalized medicine. The architecture employs standard Ontologies to provide a consistent and common data infrastructure for all clinical data at Mount Sinai. The Enterprise Data Translational Architecture (EDTA) is designed as a service oriented architecture (SOA) to provide researchers with optimal access to clinical genomic datasets in support of translational research and personalized medicine.

An Integrated Information Platform for a Biomedical Research Network: Concept and First Experiences

Petra Knaup[a], Christian D. Kohl[a,b], Justo Lorenzo Bermejo[a], Hartmut Dickhaus[a], Meinhard Kieser[a]

[a] *Institute of Medical Biometry and Informatics, University of Heidelberg, Heidelberg, Germany*
[b] *Coordination Center for Clinical Trials, University of Heidelberg, Heidelberg, Germany*

In biomedical research a variety of data like clinical, genetic and proteomic data are processed to gain new insights in diseases and therapies. In a transregional research network (TRN) different projects work together with data in different resources and in different formats. Providing an IT infrastructure that integrates these data enables cross-project analyses and provides an overview of available data and resources (blood, tissue etc.). For a German TRN on liver cancer we develop an integrated information platform for research data of 22 projects. Data will be stored together with meta-data to enable a generic approach. Major challenges are harmonization efforts on procedures and data structures as well as security issues.

Mutation Operator and its Effects on Protein Structure Prediction in Genetic Algorithms

Trent Higgs[a], Bela Stantic[a], Md Tamjidul Hoque[b] and Abdul Sattar[a]

[a] *Institute for Integrated and Intelligent Systems Griffith University, Queensland, Australia*
[b] *Discovery Biology, Eskitis Institute for Cell & Molecular Therapies Griffith University, Queensland, Australia*

We have used Genetic Algorithms (GAs) for the Protein Structure Prediction (PSP) problem, which utilise two main search operators: crossover, and mutation. However, in this paper, we have focused particularly on identifying optimal mutation that can be used to avoid local minima effectively. This is done by altering the chromosomes randomly within the identified range of rotational degree of freedom to provide better diversity to the search algorithms. We have identified the optimal range of rotational moves by empirically analyzing the instantiates of the conformational effects using the mutation operator applied on couple of proteins from the PDB.

Application of Biomedical Informatics to facilitate clinical use of gene expression microarrays in colon cancer

Guillermo López-Campos[a], Beatriz Pérez-Villamil[b], Alejandro Romera Lopez[b], Enrique Díaz Rubio[b], Fernando Martin-Sanchez[a]

[a] *Medical Bioinformatics Department, Institute of Health Carlos III, Majadahonda, Spain*
[b] *Molecular Oncology Laboratory, Hospital Clínico San Carlos, Madrid, Spain*

Biomedical informatics plays a key role in extracting meaningful information and knowledge from microarray experiments that could be used in clinical settings. In this work we show an example of how biomedical informatics tools can be applied with the aim of facilitating the integration and analysis of different information levels in a microarray-based colon cancer gene expression study although there remain challenges to be addressed toward clinical use of gene expression microarrays. The main result of these analyses show that phenotypic characterization based on "Duke stages" does not match to different molecular entities.

Sharing paths of exploration to support collaborative reasoning in genomic data analysis

David Hoyle[a] Peter Crowther[b] Mark Delderfield[a] Lee Kitching[a] Gareth Smith[a] Iain Buchan[a]

[a] *North West Institute for BioHealth Informatics, University of Manchester, Manchester, UK*
[b] *Melandra Ltd, Manchester, UK.*

A significant proportion of data analysis of modern large-scale genomic data sets takes place in an investigative, exploratory mode of working that helps to refine hypotheses. This typically proceeds by reviewing annotation meta-data associated with statistical results, with a view to using the annotation data to suggest refinements to the statistical models used. The researcher's exploratory path through the annotations also represents part of the overall evidence chain, and as such should be captured. We identify three distinct main aspects to the capture problem, i) automated capture of the images and meta-data of the viewed annotations, ii) replay of the captured images and meta-data, iii) a record of insights with discoveries shared with collaborators. We report a prototype capture tool, built around a Workbench for the analysis of large-scale genetic data sets that uses Rich Internet Application technologies to visually replay the captured exploratory paths taken.

Approaching the Nanomedicine field from Biomedical Informatics

Sandra Barriuso [a] Victoria Lopez-Alonso[a], Jorge Barrera [a], Victor Maojo [b], Fernando Martin-Sanchez[a]

[a] *Medical Bioinformatics Unit. Institute of Health Carlos III, Madrid, Spain*
[b]*Biomedical Informatics Group. Polytechnic University of Madrid, Madrid, Spain*

The new discipline of Nanoinformatics represent a solution to manage the new information arising from the fields of nanotechnology and nanomedicine. It aims at integrating it with existing biomedical informatics data, tools and methods. We present here an overview of several activities which have been carried out by our group to approach this new domain. For this purpose we have initiated the analysis of existing information resources in nanomedicine and developed a general framework and a catalogue to organise them. We have also adapted a knowledge management system to integrate nanomedicine available through the Web 2.0. Finally we are participating in several research projects (ActionGrid, NanoSost, Ibero-NBIC) and in standardization initiatives in this field (ISO Technical Committee 229 – Nanotechnologies. Joint Working Group1: Terminology and Nomenclature).

Stakeholder Analysis for Digital Preservation in Biomedical Research

Frank Dickmann, Sabine Rey

Department of Medical Informatics, University Medical Center Göttingen, Göttingen, Germany

This poster describes the implications of digital preservation on biomedical research from a national perspective. Preserving digital research data for long-term durations is an issue for every area of contemporary science. Looking for recommendations for a digital preservation infrastructure for research sites in Germany a stakeholder analysis was conducted. A stakeholder analysis describes the relevant environment aspects of a contemplated object: biomedical research extended by a digital preservation infrastructure. The results are prepared as an UML use case diagram and reflect requirements for biomedical research. These results are fundamental for a national solution for digital preservation. Legal requirements regarding privacy, retention times, and contractual relationships are of major concern. However, a concrete implementation is presently not available.

Hospital Information Disaster Recovery System and Simulation Drills

Sung-Woo Min[a], Jae-Ho Lee[b], Gi-Seoung Eo[a], Sang-Goo Han[a], Yong-Soo Lee[a]

[a] *Medical Information Team, Asan Medical Center, Republic of Korea*
[b] *Depart. of Emergency Medicine, University of Ulsan College of Medicine, Asan Medical Center, Republic of Korea*

Comprehensive and integrated Hospital information system has many advantages and can enhance clinical processes. Clinical data and application systems are critical properties of hospitals. Any problems causing unintended information service failure can result in disastrous consequences to clinical environment. Disaster recovery system (DRS) was developed for continuous information service even in disaster situation, medical record protection from hardware or data server failure, and seamless information service during primary server upgrade operation. Real-time updated and physical DR system was developed with Oracle Data guard solution. 13 times DR simulations were performed. Role transition times were 17.0±6.4 minutes. DRS showed short interruption time and it was very useful for primary system upgrade. Hospital disaster plan with DRS and regular drills are needed for real disaster situation.

Demography, Biometry and Monetary Influences – A Health Economic Evaluation of the Potentials of Short Cycle Monitoring for Elderly Cardiovascular Patients with Help of Tailored Telemedical Services

Alexander Mertens[a], Daniel Dünnebacke[b], Jan Henrik Dornberg[b], David Koch-Körfges [a]

[a] *Chair and Institute for Industrial Engineering and Ergonomics of RWTH Aachen University, Germany*
[b] *Research Institute for Operations Management (FIR) at RWTH Aachen University, Germany*

The approach presented in this paper defines a framework of new telemedical services for homely aftercare: The integration of all involved medical service providers (MSP) enables a media break free information flow and therefore offers a swift response in the case of an impending decompensation of the monitored patient. The collected data is locally independent and context rich accessible to all MSPs and supports a short cycle adaption within the rehab process. Incorporating the usability specifications required for elderly and retarded users, a cost efficient and adequate access to medical services in poorly developed regions becomes possible. Additionally, the quality of life itself is being raised with individualized value added services which offer a universal access to products and services that is also locally independent. This concept helps to engage the financial burden to the medical health system caused by the demographic change and actively reduces it. The medical support throughout the anastasis is systematically improved as well as the previously mentioned quality of life.

Quantitative Evaluation Trial for Functions Embedded in Currently Available Electronic Clinical Pathways Products

Shunji Wakamiya[a], Kazunobu Yamauchi[b]

[a] *Department of Ophthalmology, Kawasaki Medical School, Okayama, Japan*
[b] *Department of Management Science, Fujita Health University, Aichi, Japan*

No quantitative method is available to evaluate the functions of electronic clinical pathways (eCP) embedded in electronic medical records. Therefore, we developed new evaluation sheets in which the standard functions of eCP published in 2007 were modified to facilitate their quantification, and in which functions requested at Kawasaki Medical School Hospital were added when electronic medical records were introduced. eCP products by four vendors were evaluated quantitatively and each function was given a weight according to its importance. Moreover, we compared this quantitative evaluation to the subjective evaluation of four staff from the Committee of Clinical Pathways. The results indicated that the implementation of many functions differed among the four vendors, and the quantitative evaluations were comparable. The weights of each function may differ among hospitals due to differences in their medical background, and further studies regarding weighting are necessary. However, the method described in this study will be useful for quantitative evaluation of eCP functions.

ProSeniis: multi-parameter remote monitoring system for the elderly

István Vassányi[a], György Kozmann[a], Balázs Végső[a], István Kósa[b], Tibor Dulai[a], Dániel Muhi[a], Zsolt Tarjányi[a]

[a] *Dept. of Electronic Eng. and Information Systems, University of Pannonia, Veszprém, Hungary*
[b] *Ferenc Csolnoky County Hospital of Veszprém, Hungary*

Prevention and rehabilitation efficiency can greatly benefit from the application of intelligent, 24 hour tele-diagnostics and tele-care information systems. Tele-monitoring also supports a new level of medical supervision over the patient's lifestyle. In this paper we briefly present the aims and first results of the ProSeniis remote monitoring system. The novelty of the system is the unified and flexible processing of various signals retrieved from modern, body-worn devices in an efficient signal abstraction framework. The signals include motion sensors that record patient movement in the home, physiological signals and patient responses in tests performed on the GUI of the central home unit (Home Hub). We are currently testing the prototype system; public experiments will begin early 2010 involving volunteers with neurologic degenerative diseases as well as healthy elderly.

Supporting Teamwork Along the Dynamic Multi-disciplinary Care Pathway

Hessah Al-Salamah[a], Alysia Skilton[a], Alex Gray[a], Omnia Allam[a] , Dave Morrey[b]

[a] *Cardiff School of Computer Science, Cardiff University, United Kingdom*
[b] *Clinical Information Unit and Trust, Velindre NHS Trust, Cardiff, United Kingdom*

Teamwork, collaboration and coordination are key aspects of the patient-centric approach taken by modern healthcare. Adequate support for these aspects has yet to be achieved. This paper proposes using associations between patients, practitioners, care teams, professional roles, and the integrated care pathway to provide improved support for practitioners as individuals and as members of integrated care teams. It proposes context-based access to patient information, automated notifications and alerts, and change management support as the patient passes along the care pathway.

Transinstitutional Health Information System Architectures – a Literature Review

Wolfram Ludwig, Nathalie Gusew, Nils Hellrung, Markus Wagner, Klaus-H. Wolf, Reinhold Haux

Peter L. Reichertz Institute for Medical Informatics, University of Braunschweig – Institute of Technology and Hannover Medical School, Germany

Two approaches are widely discussed in the discipline of medical informatics as concepts to cope with the negative consequences out of the ongoing demographic change: health enabling technologies and transinstitutional health information system architectures. To realize their full potential, we feel that both technologies should be integrated to sensor-enhanced transinstitutional health information systems. Fundament of such integration is knowledge of the variables characterizing these innovative technologies. While assessing health enabling technologies elsewhere, in our work we present an overview of important dimensions of transinstitutional health information system architectures. Based on a systematic literature review of publications listed in PubMed, we identified relevant (1) user-groups, (2) operation and coordination concepts, (3) the functionality of current transinstitutional architectures in health care and analyzed (4) the basic information flow supported by them.

How could we improve Health Care with Enterprise Resource Planning Systems? – A Literature Review

Elina Kontio[a,b], Heljä Lundgrén-Laine[a,c], Juha Kontio[b], Heikki Korvenranta[c], Sanna Salanterä[a,c]

[a] *Department of Nursing Science, University of Turku, Finland*
[b] *Faculty of Telecommunication s and e-Business, Turku University of Applied Sciences, Finland*
[c] *Turku University Hospital,Finland*

The use of information systems in healthcare has increased rapidly during the last few years. These information systems are, however, stand-alone, independent and communicate poorly with each other. At the same time, healthcare operations are increasingly migrating towards process-based models. These kind of work flows need information systems that support decision making at different levels of the organization to improve the overall performance. Industry has used enterprise resource planning (ERP) in running and controlling processes. The question arises: could we use ERP also in health care - and if we could - in what way? Although there is a lot of evidence of the benefits of ERP systems in production industry, very limited evidence exists on the role of these systems in healthcare. We present a systematic literature review in order to analyze how ERP systems have been adopted in healthcare, and how these systems can improve healthcare.

Virtual Scenarios for diagnosis and rehabilitation of mentally disordered offenders and for men sentenced for domestic violence

Uno GH Fors[a], Kristina Sygel[b], Anna-Karin Svensson[b], Lotta Arborelius[d], Marianne Kristiansson[bc]

[a] *Department of Learning, Informatics, Management and Ethics (LIME), Karolinska Institutet, Stockholm, Sweden*
[b] *Department of Forensic Psychiatry, National Board of Forensic Medicine, Stockholm, Sweden*
[c] *Department of Clinical Neuroscience, Division of Forensic Psychiatry, Karolinska Institutet, Stockholm, Sweden*
[d] *Department of Clinical Neuroscience, Section for Psychology, Karolinska Institutet, Stockholm, Sweden*

Assessment and rehabilitation of mentally disordered offenders (MDOs) and of men prosecuted for domestic violence is performed in constrained settings, where social and cultural factors are missing. We have developed a simulation system, where scenarios in which violence might occur, can be realistically visualized. The system called Reactions on Display (RoD) allows the offender to choose from different scenarios, make decisions in certain situations, choose actions, see the reactions from victims and others and subsequently learn how to avoid violence. Results from two pilot studies have showed that RoD's interface and design were well received by offenders and professionals.

Physicians interrupted by mobile devices – relations between devices, roles and duties

Terje Solvoll[ab], Jeremiah Scholl[a], Gunnar Hartvigsen[ab]

[a]*Norwegian Centre for Integrated Care and Telemedicine, University hospital of North-Norway, Tromsø, Norway*
[b]*Department of Computer Science, University of Tromsø, Tromsø, Norway*

A common denominator for modern hospitals is variety of communication problems. In particular, interruptions from mobile communication devices are a big concern for many physicians. This study adheres to an interpretive research approach. 11 physicians were observed for a total of 135 hours during May and June 2009, and shows in which degree physicians are interrupted by mobile devices in their daily work, and in which situations they are interrupted. This study contributes to knowledge that could help us in designing and developing an interruption management system for mobile communication in hospitals.

MEDIS: An Italian Registry of Clinical Investigations on Medical Devices

Daniela Luzi[a], Fabrizio Pecoraro[a], Mariangela Contenti[b], Gregorio Mercurio[b], Fabrizio L. Ricci[b]

[a] *National Research Council, Institute for Research on Population and Social Policy, Italy*
[b] *National Research Council, Institute for Biomedical Technology, Italy*

Clinical Investigations (CI) on Medical Devices (MD) are one of the most important means of demonstrating MDs safety and efficacy under normal condition of use. In Europe the approval of CIs is carried out by each National Competent Authority (NCA) following European Directives, whose aim is to facilitate MD manufacturers to perform nationwide investigations and improve information exchange among NCAs that evaluate CI proposals and monitor their performance. An European registry that gathers information on CIs is at its initial developing stage within the wider context of the European Database on Medical Devices (EUDAMED), while only few countries have developed their own information system to monitor CIs. The development of these information systems at both local and European level facilitates the communication among different stakeholders ranging from NCAs and CI applicants to clinicians and general public.

In Italy the National Research Council is carrying out a project supported by Ministry of Health aiming to develop an information system (MEDIS, Medical Device Information System) that manages CI proposals and monitors CIs.

Clinician Transformation has to be Clinician Driven

Shashi Gogia[a], Anand N. Malaviya[b]

[a] *Indian Association for Medical Informatics and Indian Spinal Injuries Centre New Delhi India*
[b] *Dept of Joint Diseases, Indian Spinal Injuries Centre New Delhi India*

A clinician who had diversified into software development teamed up with a highly experienced Rheumatologist to create a standalone EMR for rheumatology services. This incorporates existing as well as evolving disease activity standards for an included CDSS. E-Prescriptions, Investigation reports as well as other hard copies which the patient can keep for his information are integrated. The application was launched in July 2007 after over two years of joint effort. Constant innovation and enhancement is still continuing. Use of the application has resulted in a transformation of our clinical workspace with faster patient turnover, efficient disease management, coordination between team members as well as better and extremely fast research output. This application is now being adopted for use by other Rheumatologists. We believe that this successful implementation – an actual clinical transformation - was related to the deep involvement and understanding of the processes required by the users i.e. the clinicians themselves. Luck, willingness to innovate and preexisting IT based environment were other factors helpful for success. The methodology used can be adopted by other specialties to produce relevant world class applications for such their fields. Similar to this example, we have been working in other specialties with albeit less success as the involvement of the relevant clinician is less so.

Using an Electronic Health Record to estimate the prevalence of overweight and obesity in children and adolescents and frequency of these diagnoses by physicians

Pablo Durán[a], Débora Setton[a], Paula Otero[ab], Julián Llera[a], Alfredo Eymann[a], Julio Busaniche[a], Daniel Luna[b], Fernán González Bernaldo de Quirós[b]

[a] *Department of Pediatrics, Hospital Italiano de Buenos Aires, Argentina*
[b] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*

Growth and nutrition assessment is an essential component of pediatric healthcare and a fundamental tool for the early detection of childhood obesity. We estimated the prevalence of overweight and obesity using anthropometric data from an EHR and compared it to the frequency of overweight and obesity diagnoses registered by primary care physicians. From 14743 patients aged 2- 19 years, 22.1% were overweight and 12.4% were obese. In contrast, the registry of the diagnosis of overweight in the EHR was 3.3% and 1.1% for obesity. Despite the use of more sensible references for screening obesity, a large number of patients remain undiagnosed. An EHR provides quick and easy access to anthropometric data and growth charts in the clinical setting for monitoring growth and early detection of children at nutritional risk. The objective of this paper is to estimate the prevalence of overweight and obesity in a pediatric population based on BMI data in contrast to the frequency of recorded diagnosis by primary care physicians, their referral to specialists and laboratory tests ordering using an EHR.

Implementing the WHO Child Growth Standards in an Electronic Health Record in Argentina

Paula Otero[ab], Débora Setton[b], Daniela Canosa[ab], Pablo Durán[b], Gastón López[a], Mercedes de Onis[c], Daniel Luna[a], Fernán González Bernaldo de Quirós[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*
[b] *Department of Pediatrics, Hospital Italiano de Buenos Aires, Argentina*
[c] *Department of Nutrition, World Health Organization, Geneva, Switzerland*

Assessing growth and development is a central component of pediatric care. The WHO Multicentre Growth Reference Study (MGRS) provides standards of growth of children living under favorable conditions in breastfed children up to 5 years. The web-based outpatient EHR has offered the possibility of entering growth measurements and chart the data entered on a matrix of XY coordinates. The chart is generated automatically by the EHR with a connected plot for each percentile curve. When Argentina adopted the WHO growth values as the national standard for children younger than 5 years old, these charts were implemented in the EHR. The graphic output was developed using a Java API that allowed creating interactive graphs with no limit in the amount of points helping in the quick implementation of the new standards. The aim of this paper is to describe the implementation of the weight and length/height charts from the WHO Child Growth Standards in an EHR to support pediatric growth monitoring.

Automated method to identify patients eligible for quality measures using an EHR: feasibility and accuracy

Christoph U. Lehmann, David Bundy, Harry Caughey, Sue Weimer, Lilly Engineer, Sean Berenholtz, Marlene Miller, David Silver

The US National Quality Forum (NQF) identifies and endorses measures that evaluate patient outcomes of healthcare. One family of NQF measures addresses whether patients using medications for which annual laboratory monitoring is recommended receive such monitoring. Identifying eligible patients by manually probing an electronic health record (EHR) is time consuming. We hypothesized that an automatic query would perform as well as manual reviewers in identifying eligible patients.

MedLAB1(ML1); a Software Defined Health Informatics Messaging Protocol for Medical Laboratory Technology

E. Adetiba[a], M. Eleanya[b]

[a]*Electrical & Information Engineering Dept., College of Science and Technology, School of Engineering, Covenant University, Ota, Nigeria.*
[b]*Chevron, Lekki Peninsula, Lagos, Nigeria.*

Electronic Hospital Records (EHR) are usually designed so that records from different vendors can exchange all data according to public standards. Health Level 7(HL7) for instance, is a voluntary consensus standard for electronic data exchange in health care environments. It defines standard message formats for sending or receiving data on patient admissions, registration, discharge or transfer, queries, orders, results, clinical observations and billing. However, in this work, we designed and implemented a proprietary messaging protocol suite for medical laboratory tests called MedLAB1 (ML1). ML1 is implemented in software and it contains medical laboratory records acquisition, retrieval and communication protocols which can interoperate seamlessly with HL7. Various medical laboratory tests that could be handled by ML1 are; chemistry test, culture diagnosis, heamatology, hormonal assay, urine analysis, urine microscopy diagnosis, acid fast bacilli, widal analysis and stool analysis.

Experiences integrating RIS/PACS into personal electronic health records

Oliver Heinze, Björn Bergh

Center for Information Technology and Medical Engineering, University Hospital Heidelberg, Heidelberg, Germany

The University Hospital Heidelberg is implementing a personal electronic health record (PEHR), to improve the information exchange between other hospitals, primary care givers and the patient itself. This article describes the concept of the automated transfer of clinical imaging data to the PEHR. On the basis of an ideal conceptual model a goal model was developed considering the local conditions. The common basis is a centralized pull model. Local primary systems are connected via HL7 and DICOM interfaces to the record. This integration concept is characterized by a highly complex message interaction involving several components and depends exceedingly on the local conditions. Thus, the solution is not as generic as originally intended. Not only the connection of additional partners can be complex and difficult but also a loss of functionality has to be taken. Nevertheless the integration of workflows can be supported better than traditional teleradiology may do. As a result pictures can be directly transferred into the record referenced to the case and to the patient.

Development of Monitoring System for Outcome Assessment in Off-Pump Coronary Artery Bypass(OPCAB)

Yujeong Kim[a], Hyomin Im[a], Moonsook Kim[a], Mina Hwang[b], Kibong Kim[c]

[a] *Division of Quality Improvement, Seoul National University Hospital, Seoul, Korea*
[b] *Center of Medical Informatics, Seoul National University Hospital, Seoul, Korea*
[c] *Department of Thoracic Surgery, Seoul National University Medical College, Seoul, Korea*

Introduction: The coronary artery bypass graft surgery was performed 4,000 cases annually in Korea and was rapidly increasing. Moreover, the Off-Pump Coronary Bypass (OPCAB) was one of the important clinical indicators in evaluating quality of care. Objectives: In order to monitor and manage the outcome of the OPCAB, we developed the EMR, CDW based monitoring system. Methods: It consisted of 4 systems; the mortality predicting system, the specified medical record, the warning pop-up and the Clinical Data Warehouse. Results: The monitoring systems were available in predicting the risk of the operation, explaining to patients, preventing the miss of the medical services and records, assessing the outcomes of the OPCAB. Conclusion: Our monitoring systems were useful in managing the quality of care in the OPCAB.

Ingest and Integration of Medical Data in a World with very little DICOM

Varun Bhagwan, Tyrone Grandison, Daniel Gruhl

Health Informatics, IBM Almaden Research Center, San Jose, CA

The Digital Imaging and Communications in Medicine (DICOM) standard has held and continues to hold promise for the transformation of the healthcare systems landscape. The promise is that of rich documents from arbitrary medical devices, with lots of helpful metadata, that enables the distribution, sharing, seamless viewing and automated analysis of different facets of a patient. Unfortunately, this vision has been slow to materialize in the marketplace for a number of reasons. However, there is still a critical need to construct longitudinal and complete views of a patient. In this paper, we describe how novel and reusable ingest and integration technology can be used to bridge the current chasm.

Collaboration of an Electronic Medical Record system and Data Warehouse in HIS

Masayuki Honda[a], Takehiro Matsumoto[a], Rin Ishitsuka[b], Akira Fujie[c]

[a] *Department of Medical Informatics, Nagasaki University Hospital, Japan*
[b] *Karin Corporation. Chiba, Japan,*
[c] *Fujie Planning Inc., Osaka, Japan*

A large scale Hospital Information system (HIS) generally consists of two parts, the On-Line Transaction Processing (OLTP) system and the On-Line Analytical Processing (OLAP) system. The electronic medical record (EMR) system is a main element of the OLTP system, and the data warehouse (DWH) system not only assumes many important roles as the OLAP system but serves as the backbone for keeping medical care of the institution in high level by providing the best practice cases to the EMR system. This paper will discuss the following points: the reason why OLTP and OLAP are necessary, and the roles of the DWH system.

Keywords:
HIS, EMR, Data warehouse

Lessons learned from migrating reports with IHE XDS

Eizen Kimura, Shinji Kobayashi, Ken Ishihara

Division of Medical Informatics, Medical School of Ehime University, Ehime, Japan

We have experienced the migration of the medical information system of Ehime University hospital at May 2009. As there were many variations of implementations for reporting system, the migration of report documents to the new system had many work-hour requirements. Under the migration process, the quality of data decreased by losing the data granularity and deformation. Developing the standard framework for document archiving is a critical component for everlasting document archive with keeping data quality high. Currently there is no standard of enterprise content management system for healthcare. This paper describes how we tried to apply IHE XDS based repository as the enterprise content management system in healthcare.

Development Journey for New Clinical Management System III for HKSAR of 7 million population

Anthony Cheung, Andre Greyling, NT Cheung

Information Technology Service, Hospital Authority, Hong Kong

For the past 15 years, the Hospital Authority of Hong Kong Special Administration Region (HKSAR) has developed and implemented a corporate application system named as "Clinical Management System (CMS)" for all 40+ public hospitals (28,000 beds), 40+ Specialist Outpatient Clinics, 70+ General Outpatient Clinics, associated Diagnostic Radiology Centers, associated Pathology Laboratory Centers and associated Pharmacies. At present, more than 35,000 clinical users including doctors, nurses, ward clerks, radiologists, radiographers, pathologists and pharmacists are using the CMS on a regular daily basis for carrying out the patient care delivery process via 17,000+ clinical workstations installed at every corner of the Hospital Authority. In terms of its workload, the current CMS has to take care the huge annual clinical activities for about 1 million admissions, 2 million emergency attendances, 14 million out-patient attendances, 15 million laboratory specimen tests, 51 million drug items dispensing & 3.6 million radiological examinations for 7 million citizens in Hong Kong.

Architecture Development for Interoperable EHR in Korea

Myoung-Rok Choi[a], Hye-Ryung Kim[a], Sun-Young Kim[a], In-Jung Hwang[a], Jae-Bong Bae[a], Yoon Kim[abc]

[a] *Center for Interoperable EHR, Korea*
[b] *Dept. of Health Policy and Management, Seoul National Univ. College of Medicine,*
[c] *Institute of Health Policy and Management, Seoul National Univ. Medical Research Center*

In major advanced nations, EHR introduction guaranteed by mutual management is being activated. In proportion to this trend, domestic market is also developing EHR architecture for effective EHR establishment. Accordingly this study is to suggest architecture development-business architecture and its application architecture based on such demand-in accordance with domestic treatment information. Henceforth this architecture model is supposed to support not only international sharing of information but also inter-hospital sharing.

Integrating Clinical Endoscopic Images into Electronic Patient Record - Pathway to Clinical and Technical Success

JKY Chan[a], WN Wong[a], J Tan[a], WWT Chan[b], KKH Tsang[b], AWM Cheung[b], NT Cheung[a]

[a] *Health Informatics, Head Office, Hong Kong Hospital Authority, HKSAR*
[b] *Information Technology, Hong Kong Hospital Authority, HKSAR*

This paper described a new function for capturing and sharing of non Digital Imaging and Communications in Medicine (DICOM) clinical images in a regional scale Clinical Management System (CMS) and Electronic Patient Record (ePR). Non DICOM Clinical images and photos were valuable clinical information supporting clinical decision-making and communication. Huge amount of clinical photos were taken using various modalities in clinical practices without effective capturing and sharing. A generic way of identifying patients, capturing and archiving images, sharing on a common platform and integrating into a longitudinal multimedia-enabled electronic patient record is therefore essential and of great value. The architectural framework and workflow integration of image capturing and sharing were designed and piloted for endoscopy image. Post implementation review on user feedback and system usefulness was done. Utilization rate, system performance and clinician feedback were encouraging. With the successful pilot, further roll out of the endoscopy image capture function was planned after enhancement of system performance.

Conflicts between terminology and EHR information models as obstacles to semantic interoperability: a scientific review

Louise Pape-Haugaard, Anne Randorff Rasmussen, Pia Britt Elberg, Stig Kjær Andersen

Medical Informatics Group, Department of Health Science and Technology, Aalborg University, Denmark

A focus on sharing knowledge is essential for ubiquitous care. Several terminological approaches can be taken to meet the challenge, when terminology models are used to provide a bridge across a range of standardized EHRs information models. Developments in standardized information models as presented by CEN EN 13606 and HL7 have strived for an intrinsic extensibility based on an ad-hoc methodology. We will address the role of terminology systems and EHR information models in achieving semantic interoperability and highlights issues that arise when combining these two domains. A review of scientific literature on information models and terminology systems is conducted with a purpose to categorize research and on obstacles concerned with combining terminology systems and EHRs information models. The majority of the papers analyzed in our review highlight that issues exists, however only a minority contains extensive discussions on these issues. Findings show that ambiguity is key and one attempt to solve this issue is to use terminology binding.

Non English Characters Representation for Patient Safety in the Electronic Health Record Systems – an International Issue

Wong CM [a], Wu SY [a], Sek CH [a], Lee CH[b], Lau KK[b], Chan KC[b], Cheung NT[a]

[a]*Health Informatics Section, Hospital Authority, Hong Kong SAR*
[b]*Information Technology Division, Hospital Authority, Hong Kong SAR*

Accurate patient identification is an essential component in providing both safe and effective diagnostic and therapeutic services. The name borne by individual patient is often the key to identify patients. Globally there is at least 20% of the population who bear names with Chinese characters only. It is therefore important to have the correct Chinese characters represented accurately in the Electronic Health Record. However, Chinese characters differ from the typical Western alphabet set in that there are multiple variants in the strokes in the Character Set. Up to 5% of all patients in Hong Kong bear names which are not listed in the ISO 10646 code lists. Therefore, it is imperative that an international common standard in the Standard Non-English Character Sets and Variants be instituted in order to allow correct representation and registration in a health registration system, Patient Master Index (PMI). This should be done in a consistent and unambiguous manner so as to achieve an accurate patient identification and to match with patient's associated artifacts.

Enhancing Patient Privacy and Security Via Complex Event Processing (CEP) and Legitimate Relationships Service (LRS)

Raed A. Haltam

UMIT - University for Health Sciences, Medical Informatics and Technology; Hall in Tyrol, Austria

We present a solution and a methodology that enhances patient's privacy and security in cross-organizational, regional and national healthcare provisioning models. The research was accomplished in the context of the Legitimate Relationship Service that is part of the United Kingdom's National Programme for IT (NPfIT). The solution monitors access requests issued by clinicians to patient information clinicians from multiple different organizations and issues alerts and notifications based on modeled event patterns. The solution employs Complex Event Processing (CEP) which stems from Event-driven SOA. HL7 messages are used are canonical event model and CDA documents as canonical Entities. We describe the solution in form of a logical view as a Reference Architecture(1) that can be reused in independent of the implementation and technologies. The reference implementation utilized hl7:QUPA_IN010000UK01 message as input basic event.

Using electronic health records in a rural setting (Uganda)

S. P. Ndira [a b], K. D. Rosenberger [a], T. Wetter [a], H. Mugeni [b], J. Royall [c]

[a] *Institute of Biometry and Medical Informatics, Heidelberg University, Heidelberg, Germany*
[b] *Sionapros Ltd, Kampala, Uganda*
[c] *National Library of Medicine, Bethesda, MD, US*

Quality and usage of medical data captured in rural settings typical of developing countries is an ongoing challenge. This research investigates the influence of continuous monitoring, evaluation and improvement of technical and non-technical aspects surrounding an electronic health records (EHR) system covering all critical hospital processes. Staff feedback and compliance with international EHR standards is used for continuous improvement, monitored through weekly meetings, integrated quality indicators and continuous observation. EHRs can be sustainably used in rural settings, if challenges encountered (technical and non-technical) are continuously addressed.

Utilising Open Source Medical Systems to Develop a Virtual Health Care Referral System in Kenya

Judy Wawira Gichoya

Moi University School of Medicine, Kenya

Health systems in Kenya and Africa are faced with challenges of lack of access to technology for accurate diagnosis and treatment. The labor force does not meet demands of a growing population with increasing health needs. Health specialists are few and prefer to remain working in urban areas thus limiting their consultations from rural areas to a minimum. Referral systems are limited by delays in access to care because of a poor road network and poor infrastructure. This poster describes the use of an open source medical records system (OpenMRS) to develop a referral system in such a situation for pathology specimens. This involves actual system development and implementation. This is done remotely and clinicians with internet access can view slides and comment on result aiding in diagnosis and referral.

Assessing information integration among discharge summaries and case report forms in an Electronic Health Record

Martín Waldhorn[a], Diego Giunta[b], Carlos Otero[a], Damián Borbolla[a], Daniel Luna[a], Fernan Gonzalez Bernaldo de Quiros[a,b]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*
[b] *Area of research in internal medicine, Hospital Italiano de Buenos Aires, Argentina*

Formerly in health systems, the case report forms (CRF) were held in parallel with the medical record without integration and with fragmentation of information. This increased the risk of losing important data. With the integration of these CRF with the medical record using the model of structured registry forms this problem seemed to be solved. Structured registry forms allows incorporating information quickly, systematic and with appropriate terminology controls. In the current health information system at Hospital Italiano de Buenos Aires, the information of the CRF are added to the electronic health record integrating the information. It was performed a retrospective, descriptive, cross-sectional study with review of secondary databases. We took two integrated processes (discharge summary registry and CRF registry), The objective of this study was to assess the contribution of these two different sources of data to the completeness of patient morbid history, using as indicators two highly prevalent comorbidities (arterial hypertension and diabetes) and acute clinical diagnosis (hyponatremia). We conclude that, information integration helps to maintain and/or complete the morbid burden of the patients.

The Clinical Information System response to an epidemic Influenza A H1N1

Fernan Gonzales Bernaldo de Quiros[a], Carlos Otero[a], Martin Waldhorn[a], Santiago Wassermann[a], Damian Borbolla[a] , Ariel Reynoso[a], Estela Salazar [a], Silvana Figar [b], Daniel Luna [a]

[a] Department of Health Informatics, Hospital Italiano de Buenos Aires
[b] Area of Epidemiology, Hospital Italiano de Buenos Aires

In early June 2009, the influenza A H1N1 epidemic had been dispersed around Buenos Aires. The Hospital Italiano created a system for identification and monitoring patients in the H1N1 pandemic. This study evaluates the temporal correlation between the fully implementation of the system and the evolution of the epidemic of influenza A. Materials and Methods: The system was integrated to the HIS and consisted of: 1) A portal for use by members of the committee created for the pandemic. 2) A Web page for institutional recommendations. 3) A website for the community. 4) A system for updating of administrative and medical information and 5) A system for patients identification and follow up. This study evaluates the temporal correlation between the epidemic curve and hospital Information Systems (HIS) applications during the swine flu epidemic time period from May 24th to July 11th, 2009.

Using Electronic Medical Records to Measure Guideline Adherence in Low-Resource Settings

Zach Landis Lewis, Claudia Mello-Thoms, Shyam Visweswaran, Rebecca S Crowley

Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA

The objectives of this study are to a) to evaluate the feasibility-of-use of structured outpatient EMR data to measure guideline adherence for treatment of AIDS in a low-resource setting, and b) to describe the characteristics of available EMR data that could be used to generate performance feedback for healthcare workers in a low-resource setting.

High-Level Query Language Support for EHRs Databases - Multi-step QBE Approach

Shelly Sachdeva, Subhash Bhalla

Graduate Department of Computer and Information Systems, University of Aizu, Aizu-Wakamatsu, Fukushima, 965-8580 (Japan)

Large scale adoption of electronic healthcare applications requires semantic interoperability. The new proposals propose an advanced (multi-level) DBMS architecture for common repository services for health records of patients. These also require query interfaces at multiple levels and at the level of semi-skilled users. In this regard, a high level user interface for querying the new form of Electronic Health Records (EHRs) has been examined in this study. Its aim is to decrease user effort and communication ambiguities, and increase user friendliness.

Personal Health Records functionalities reported in the literature

Santiago Wassermann, Alejandro Mauro , Jeronimo Aguilera Díaz, Carlos Otero , Daniel Luna, Marcela Martinez, Enrique Soriano, Fernán González B. de Quirós

Department of Health Informatics, Hospital Italiano de Buenos Aires

The Personal Health Records are seen as a powerful tool to empower patient, but there is no standard or specification on the functionalities that these systems should contain or in better words what it is and what services should offer. Due to the versatility of the various options of what Personal Health Record should provide and based on this problem, the objective of this paper is to analyze the functions of the Personal Health Record that have been published. This paper explores all types of Personal Heath Records and reviews the published articles that explain the different features of them. Also gives a brief resume of the experience of having and implementing a Personal Health Record in the Hospital Italiano of Buenos Aires.

The Medical Ecosystem – Personalised Event-based Surveillance

Kerstin Denecke[a], Avaré Stewart[a], Tim Eckmanns[b], Daniel Faensen[b], Peter Dolog[c], Pavel Smrz[d]

[a] *L3S Research Center, Hannover, Germany*
[b] *Robert Koch Institut, Berlin, Germany*
[c] *Aalborg University, Aalborg, Denmark,*
[d] *Brno University of Technology, Brno, Czech Republic*

Early detection and early response is a strategy for circumventing devastating public health events. Traditional systems for identification of potential health threats can be used to recognise long-term trends, but mostly fail in urgent cases and are of less use for unknown diseases. In this paper, the Medical Ecosystem (M-Eco) is presented, which is a framework that integrates processing resources for unofficial sources such as user generated content and traditional sources for the early detection of emerging health threats. M-Eco will emphasize adaptivity and personalised filtering so that relevant signals can be detected for targeting the needs of public health officials who have to synthesize facts, assess risks and react to public health threats.

Automatic recognition of health problems through the movement analysis

Bogdan Pogorelc[a,b], Matjaž Gams[a,b]

[a] *Department of Intelligent Systems, Jožef Stefan Institute, Ljubljana, Slovenia*
[b] *Špica international d.o.o., Ljubljana, Slovenia*

Due to aging of population, less people are capable of taking care for elderly. We propose an intelligent and ubiquitous care system for monitoring elderly in order to recognize a few of the most common and important health problems, observable through the movement. Movement is captured with wearable infra-red motion capture system, whose outputs are positions of tags at each moment. According to our approach positions of tags are transformed into specific features, relevant to the observed health problems, making the modeling of the health problems patterns more accurate. For the modeling, Support Vector Machines (SVM) machine learning algorithm is used, which classifies walking of user into walking with hemiplegia, Parkinson's disease, pain in the back, pain in the leg or nothing of those. The obtained classification accuracy is 85-95%. Also, the study of the impact of tag placement and noise level on the accuracy of detection of health problems is presented, as a guidance for future research.

How to Build a Corporate e-Pain Form and Pain Terminology?

Karen Szeto[a], Vicky Fung[a], Austen Wong[a], Alex Au-yeung[a], Hung Hung Tsui[a], Ricky Siu[b], Johnny Lam[b], Steven Wong[c]

[a] *Health Informatics Section, Hospital Authority, Hong Kong Special Administrative Region*
[b] *Information Technology Department, Hospital Authority, Hong Kong Special Administrative Region*
[c] *Queen Elizabeth Hospital, Hospital Authority, Hong Kong Special Administrative Region*

Pain has become the universal disorder and around 10,000 pain patients are treated in Hong Kong (HK) public hospitals annually. Pain management data are along scattered or manually captured and difficult to be studied. This paper describes how to develop a patient-event based problem-oriented electronic pain management form to improve data collection, clinical documentation and information sharing through electronic patient record (ePR) system in Hong Kong. A working group with multi-disciplines is set up to address the various and complex requirements. The framework of the pain form is confined to 5 major components: 1) pain survey by patient, 2) pain site & intensity, 3) pain diagnosis, 4) psychological and functional assessments and 5) progress notes. 1,096 pain terms are modified from International Association for the Study of Pain (IASP) chronic pain terminologies and then incorporated into a standardized Hospital Authority Clinical Vocabulary Table (HACVT) for pain diagnosis.

Partnering health service managers to create software that makes a difference: support for HIV and TB programme management at district and facility level

Hilton Snyder[a], Vera Scott[a], Gregory Adams[b]

[a]*The School of Public Health, University of the Western Cape, Cape Town, South Africa*
[b]*Independant consultant*

IN 2002 WHO [1] published a policy framework calling for close collaboration between HIV and TB programme structures and the integration of services in high prevalence settings such as South Africa. In response to this call a task team was established in Cape Town consisting of health service managers and facilitated by an academic institution (University of Western Cape) to develop an evaluation tool to promote integrated HIV/TB services and improve the quality of each programme component. Initially information was managed in Microsoft Excel but this proved to be inefficient, resulting in a need for a purpose-built software tool. Our objectives in this process were to incorporate the expressed information needs of our health service partners, to capture, warehouse and analyse the audit data and to produce automated and customisable reports. The end product was developed using Microsoft Access and Delphi and allows for rapid processing of audit data into useful information. It is generic allowing for widespread application and is compatible with existing health information systems.

A requirement engineering framework for the application of Web 2.0 technology in health care

Omid Shabestari[a], Abdul Roudsari[a,b]

[a]*Centre for health informatics, City University, London*
[b]*School of Health Information Science, University of Victoria,Canada*

Web 2.0 is a concept that provides the potential of more interaction in the web environment. To develop a successful Web 2.0 project it is essential to obtain the needs of its end-users. Traditional requirement engineering models are mostly based on initial development of requirements and consequent continuous management of them, whereas recent advances in web programming has facilitated the opportunity to collect data for requirement management via a prototype platform designed for such systems. Health care systems have special demands which should be considered during the requirement engineering process. The integration of requirement engineering with prototype phase of system can ensure access to requirements of remote-users which are not easy accessible in some of telemedicine projects. This article proposes a step-by-step guide through a framework for this process.

A Co-evolution Design Approach for Implementing Telehealth Homecare Support Systems

Athula Ginige and Anthony Maeder

School of Computing and Mathematics, University of Western Sydney, Campbelltown Australia

Telehealth homecare support systems are a rapidly growing area for eHealth, but their development has been hindered by their complex nature which makes it difficult to adopt standardized business processes or systems structure characteristics. Here we identify some of those difficulties and advocate the use of a co-evolution design approach. We show how this approach can be used to represent a generalised telehealth homecare support system, for direct implementation.

Integration and Information Sharing Needs in Cross-organizational Health Care

Irmeli Luukkonen[a], Anja Mursu[b], Mikko Korpela[a]

[a] *Healthcare Information Systems Research & Development Unit, University of Eastern Finland, Kuopio, Finland*
[b] *Salivirta & Partners, Jyväskylä, Finland*

Holistic patient care is a cross-organizational issue including information sharing between different health facilities via integrated information systems and other media. Designing the integration often starts with technical descriptions, neglecting broader scopes of study. In this study the results of two case studies, one in Finland and one in China, are combined. The cases were parts of larger technically driven projects, hosted by the local authorities, and aiming at developing computer-based information sharing between the organizations. In our case studies, the research objective was to explore the health professionals' information sharing needs with Activity Driven Needs Analysis and identify the spots for development in information sharing. The research group was partially the same in both cases. In this study, issues impacting the integration design decisions are categorized into four scopes. The results contribute to discussions preceding integration design decisions.

Impact of Potential Teratogenic Medication Alert System in the Emergency Department

Hye-Won Han[a], Ju-Yeon Oh[b], Ji-Suk Hyun[b], Eun-Sook Kim[c], Jae-Ho Lee[d]

[a] *Dept.of Pharmacy, Asan Medical Center, Republic of Korea*
[b] *Medical Information Team, Asan Medical Center, Republic of Korea*
[c] *Nursing Department, Asan Medical Center, Republic of Korea*
[d] *Dept. of Emergency Medicine, University of Ulsan College of Medicine, Asan Medical Center, Republic of Korea*

It has always been important to prescribe medications for reproductive-age women with considerations of teratogenic effects and potential fetal harm. To help healthcare providers make evidence-based decisions, we developed PLEASE (Pregnant Lady Early Access System for Embryo) in the Emergency Department. We could check whether reproductive-age women were pregnant or not, and also we could confirm whether medications were potential teratogenic or not by using PLEASE system at the appropriate time. After the implementation of PLEASE in the Emergency Department, the average prescription ratio of medications per person has fallen by 10 percent and the average prescription ratio of drugs defined by the FDA category X per person has fallen by 55 percent. Decision support alerts available at the exact moment of prescription for potential teratogenic medications for reproductive-age women could improve the safety in both patients and the healthcare providers by avoiding dangerous exposures to medications with fetal risks.

Development of a clinical information system in an Underserved Community Clinic: A Community Partnered Participatory Research Approach

Sheba M George[a,b], David Hindman[b,c], Chizobam Ani[b], Omolola Ogunyemi[a,b], Sukrit Mukherjee[a,b], Ramarao Ilapakurthi[a,b], Mary Verma[b,c], Richard S. Baker[a], Melvin Dayrit[c]

[a] *Charles Drew University of Medicine and Science (CDU), Los Angeles, CA*
[b] *Center for Biomedical Informatics, CDU*
[c] *Hubert H. Humphrey Comprehensive Health Center, Los Angeles, CA*

Community Partnered Participatory Research (CPPR) offers a research approach which addresses the barriers to Health Information Technology (HIT) use in medically underserved communities. It advocates for equal community and academic partnership. Here a team of academic informaticians and health care providers from a community health center, serving a mostly uninsured minority patient population, are together using a CPPR approach in order to develop a clinical information system) for improved diabetes disease management.

An Integrated Architecture for a Customized CDS Service from Heterogeneous CDSSs

Hye Jin Kam[a], Man Young Park[a], Woojae Kim[a], Duk Yong Yoon[a], Jeong Ah Kim[b], InSook Cho[c], Yoon Kim[d], Rae Woong Park[a]

[a] *Dept. of Biomedical Informatics, School of Medicine, Ajou Univ., Korea*
[b] *Dept. of Computer Education, Kwandong Univ., Korea*
[c] *Dept. of Nursing, Inha Univ., Korea*
[d] *Dept. of Health Policy and Management, Seoul National Univ., Korea*

Most clinical decision support systems (CDSS) are built-in subsystems or plug-in commercial software with low flexibility under many constrains. In this study, we proposed a platform-independent CDS service integrating two heterogeneous drug-drug interaction (DDI) CDSSs for a teaching hospital with established built-in Drug Utilization Review (DUR) system by integrating new rules and process of a general-purpose CDSS named 'U-brain': (1) data/service interface was designed between the CDSS and prescription system, (2) DDI decision making were performed by the inner inference engine of U-brain system and (3) an integrated DDI knowledge base was built in the U-brain system through reconstructions of two rule sets at hospital information system (HIS) site. From 4781 prescriptions of randomly selected 499 patients, the new CDS system reported 224 DDI alerts and showed 100% of sensitivity and specificity.

Collaboration in the real world as foundation for health robotics research for aged care

Karen Day, Priyesh Tiwari, Jim Warren

National Institute for Health Innovation, University of Auckland, Auckland, New Zealand

In many countries longevity is the norm. Healthcare becomes more complex as people age [1], opening up an opportunity for assistive robotic technology. Developing a healthcare robot requires input from a broad range of disciplines and skills – medical, engineering, management, psychology, computer science and health informatics. Interviews, observation and photographs were used to gain insight into how medicines are managed by residents and care givers in an aged care facility. Multiple perspectives were used to produce a medicines management process and a description of its context. Several worldviews were 'bridged' in this research resulting in an alignment of the research project team's efforts in preparing a robot that supports medication management.

EpiBasket: a prototype information system to support the epidemiological investigation of an emerging infectious disease outbreak

Weijia Xing[a,b] , Gilles Hejblum[a,b,c] , Alain-Jacques Valleron[a,b,c]

[a]INSERM, U707, Paris, France
[b]UPMC Univ Paris 6, UMR S 707, Paris, France
[c]AP–HP, Hôpital Saint-Antoine, Unité de Santé Publique, Paris, France

The epidemiological investigation of an emerging infectious disease outbreak requires a series of different designs, protocols and questionnaires. The de novo development of these protocols and questionnaires deployed upon outbreak alert results in a substantial detrimental delay for the understanding and control of the epidemic. We propose a new web application for facilitating the outbreak investigation. In this prototype of information system, the user is guided to select variables of interest in a proposed dataset based on the analysis of the available literature on previous similar outbreaks, and afterwards, the system provides ready-to-use forms to be used for the data collection of the desired epidemiological investigation. This new tool can save time, standardize the data collected during an outbreak, and facilitate collaboration at a national and international level.

Patient Trajectories and the Coordination of Work

Tobias Buschmann Iversen[ab], Line Melby[b], Pieter Toussaint[ab]

[a] *Department of Computer and Information Science , Norwegian University of Science and Technology, Norway*
[b] *Norwegian Centre for Electronic Patient Record Research, Norwegian University of Science and Technology, Norway*

The concept of 'patient trajectory' has been proposed in order to address the actual flow of events in clinical reality, as a counterpart of concepts such as 'plan', 'guideline' and 'protocol'. When using the patient trajectory concept for designing computer support for coordination of work, the complexity and ambiguity of the concept is seldom questioned. The patient trajectory is frequently presented as merely 'the sequence of events', a rather *uniform object without much internal structure*. This is less problematic when the focus is on supporting inter-trajectory coordination (coordination of different trajectories), as *coordinating them comes down to balancing overlap in time and pooled interdependencies with respect to the use of shared recourses*. However, it breaks down when the focus is on intra-trajectory coordination (coordination of work within a trajectory) as different actors require different representations of the patient trajectories.

Keywords:
Patient trajectory, Coordination, Design, Awareness.

Development of a Customised Free and Open Source Database for Routinely Assessing Waiting Times of Patients at Health Facilities

Gavin Reagon[a], Gregory Adams[b], Natasha Titus[a], Ehimario Igumbor[a]

[a] *School of Public Health, University of the Western Cape, Cape Town, South Africa*
[b] *Jitterbug Software, Cape Town, South Africa*

Long waiting times is one of the commonest complaints of people accessing public health care services. Hence decreasing excessively long waiting times would be a highly visible real and perceived improvement in quality of care of public health care service. In order to achieve this one would have to measure the extent of the waiting times, the mix of causes of high waiting times and develop solutions that effectively address the causes of the high waiting time. The difficulties encountered are developing a simple yet robust and standardised methodology, managing large volumes of data, cleaning the data in a standardised manner and producing standardised reports which allow causes of high waiting times to be easily identified. An action research approach to develop a methodology to achieve this, and a database which facilitates easy handling and standardised cleaning of data and produces automated reports, was employed. The database went through several cycles of appraisal and improvement until finally a stable and user-friendly database which met all the above objectives was developed.

What if "business process" is the wrong metaphor? Exploring the potential of Value Based Requirements Engineering for clinical software

Thomas Wetter[a] and Barbara Paech[b]

[a] *Institute of Medical Biometry and Medical Informatics, Heidelberg University, Heidelberg, Germany*
[b] *Institute of Computer Science, Heidelberg University, Heidelberg, Germany*

Low satisfaction of clinical software users suggests to challenge the prevailing "business process" metaphor underlying most present clinical software. We outline why Value Based Requirements Engineering, a new direction in software engineering, has the potential for better accepted software and how an empirical approach can lay the foundations for exploring that direction. Relations between value inventories and software properties are target of the present project phase.

[d] *Department of Medical Safety Management, Kyorin University Hospital, Tokyo, Japan*
[e] *Division of Finance and Accountant, St. Luke International Hospital, Tokyo, Japan*

In 2007, the director general of the Health Policy Bureau of Japan issued a government notice to promote role-sharing by healthcare providers. The notice recommended that co-medicals such as nurses, and clerks should expand their roles to enable sharing of roles between them and physicians. For example, nurses would be authorized to "adjust amount of medication" and clerks to "write prescriptions" under physician's guidance. We aimed to discuss how to redesign the business process, especially the prescribing process, rather than how to share physicians' work with co-medicals. However, arguments in this topic are rarely based on business process reengineering. The purpose of this study is to clarify and analyze the current prescribing process and suggest a solution that will promote sharing of roles.

Implementation and Evaluation of an On-line Prescription Check System using a Database of Drug Indications

Kengo Miyo, Kazuhiki Ohe

Department of Planning, Information and Management, the University of Tokyo Hospital, Tokyo, Japan

Medical incidents related the drugs, which have similar names but different effects, are occasionally reported in Japan. Thus we develop an on-line prescription check system using a database of drug indications. After implementation, we surveyed the rate of alerts and physicians' responses. 38,780 prescriptions were checked by our system in 1 month. The rate of alerts is 5% of total prescriptions and PPV is 65%.. 44 prescriptions were revised or canceled by physicians after alerting. It may prevent medication error. We concluded that On-line prescription check system using a database of drug indications is potentially effective in prevention of medication error.

Information security assessment tool for digital hospitals

Heitor Neves Gottberg[a], Roberto Silva Baptista[b], Ivan Torres Pisa[b]

[a] *Public Health Program, Dept of Preventive Medicine, Federal University of Sao Paulo, Brazil*
[b] *Dept of Healthcare Informatics, Federal University of Sao Paulo, Brazil*

Information technology security is usually a complex issue, involving international standards to allow public recognition. In healthcare, it gains complexity due the complex nature of operations and also dues country regulations that demand additional controls and accountability for the organizations Information Security Management System. But since the use of Electronic Medical Records and Hospital Information Systems is increasing, the organizations are pushed to face this challenge. This poster shows that we have developed a Web based tool to assess the current status of digital healthcare information security management in a hospital comparing to the recognized standards considering the business processes for confidentiality, integrity, availability and also the software features to provide protection of medical data. With this tool, hospital's IT (Information Technology) managers have a first report to start developing it's Information Security Management System (ISMS) or to check de adherence of the existing one to the standards on this subject.

An individualized web-based information supply system for home oxygen therapy patients

Mai Sumi[a], Masumi Azuma[b], Kyoko Ishigaki[b], Hiroshi Inada[b]

[a] Department of Clinical Trial Design and Management Translational Research Center Kyoto University Hospital, Kyoto, Japan
[b] Graduate School of Applied Informatics, University of Hyogo, Hyogo, Japan

The number of patients who require home oxygen therapy (HOT) is increasing in JAPAN. According to patient static data, there are large numbers of HOT patients in the patient who receives medical treatment at home. It is easy for them to repeat hospitalization and release. It is thought that the reason for one of the causes is that knowledge and coping process have not adhered to the body so that it is possible to correspond to an acute exacerbation appropriately. There are many systems that provide information to HOT patients, but they do not provide suitable information for patient's needs. The purpose of this study is to design an information supply system tailored to meet the specific needs of patients based on their individual conditions. From the perspective of evidence-based medicine, we built an information infrastructure to provide relevant information corresponding to data on individual patients. The system provides information in 11 categories and immediately displays suitable coping procedures for individual situations. The system also calculates Body Mass Index (BMI) and the quantity of oxygen they require, as well as determining the degree of urgency and the coping procedure.

[f]St. Jude Medical Medizintechnik Ges.m.b.H, [g]Medtronic Ibérica S.A., [h]Hospital Clinic I Provincial de Barcelona

Over the last decade, we have witnessed exponential growth in the number of Cardiovascular Implantable Electronic Devices (CIEDs) and their electronic and software complexity widening their function and application. However, due to limited processing capabilities restricted by size and power considerations, CIEDs need to be supported by standalone software running on data centers for remote monitoring. The objective of this work is to introduce the high level architecture of iCARDEA, an intelligent platform to semi-automate the follow-up of CIED patients through context-aware adaptable computer interpretable guideline models. CIED data and legacy Electronic Health Record (EHR) data are exposed through standard interfaces so that information about a patient's medical history can be used in the clinical follow-up workflow. An adaptive care planner employing clinical guidelines automates risk assessment generating alarms as appropriate. CIED patients are empowered with integrated Personal Health Records (PHRs) that enable informed and responsible participation in their health care and education. In this way, they may feel more secure and in control of their life.

Scanning strategy for transition to an Electronic Health Record

Daniela Canosa, Paula Otero, Bibiana Schachner, Alfredo Cancio, Matias Génova, Pablo Kozlowski, Enrique Soriano, Daniel Luna, Fernán González Bernaldo de Quirós

Department of Health Informatics, Hospital Italiano de Buenos Aires

The Hospital Italiano of Buenos Aires (HIBA) is a non-profit health care academic center. In 1998 HIBA began the implementation of a Healthcare Information System (HIS). Currently the inpatient electronic health record allows viewing the patient administrative data, order for further studies and visualize their results, referral request and display information from the patient's outpatient record and the scanned notes relating to the attention of the health team that are still on paper. The digitization project was initiated as a transition strategy for the inpatient electronic record. An Indexing Model was developed in order to result in a full migration to an electronic record. The aim of this paper is to describe our experience in this project, the creation of an ad hoc ontology of documents and stress the need for a multidisciplinary team working on projects of this magnitude.

Ruby implementation of the openEHR specifications

Shinji Kobayashi[a], Akimichi Tatsukawa[b,c]

[a] *Department of Bioregulatory Medicine, Ehime University Graduate School of Medicine, Ehime, Japan*
[b] *Narimasu Kosei Hospital, Tokyo, Japan*
[c] *Department of Medical Informatics and Economics, Graduate School of Medicine, University of Tokyo, Japan*

The openEHR project has developed the specification for future-proof interoperable electronic health record (EHR) systems. This project provides the specification and implementation on which the ISO/CEN 13606 standard is based. The implementation has been formally described in Eiffel, C# and Java, but not in scripting languages. A team from Japan has implemented this specification using the Ruby language for the efficient development of new healthcare computing environments and for investigation of the universal applicability of the openEHR specification.

Application Service Provider System for Healthcare with Data Mining Function

Hiroshi Takeuchi[a], Yuuki Mayuzumi[a], Naoki Kodama[a], and Keiichi Sato[b]

[a] *Department of Healthcare Informatics, Takasaki University of Health and Welfare, Takasaki, Gunma, Japan*
[b] *Life Science Division, Hitachi Software Engineering Co., Ltd., Yokohama, Kanagawa, Japan*

An application service provider system for healthcare with a data mining function has been developed. The system provides computer-based healthcare services over the Internet to advise customers on how to improve their lifestyles on the basis of association rules relevant to their health and lifestyle data. These association rules can be automatically extracted using a data mining technology on the server computer on the basis of customers' stored time-series health and lifestyle data that are transferred through their mobile phones or PCs. The healthcare adviser can send comments made up of the rules to the customers over the Internet.

Keywords:
ASP system for healthcare, Data-mining, Time-series data.

Deriving User Semantics from XML-Based Biomedical Warehouse

Roi Adadi, Anna Burla, Ariel Farkash, Carmel Kent, Yonatan Maman, Amnon Shabo

IBM Haifa Research Lab, Haifa University, Mount Carmel, 31905, Haifa, Israel

Maintaining a data and knowledge warehouse, built on a rich data model, is a major challenge to achieving semantic interoperability in the field of biomedical informatics. Promoting the adoption of worldwide accepted information standards, along with common terminologies, is a suitable path to achieving this goal. Once data from diverse data sources is integrated into the warehouse, the semantic richness of the warehouse model enables the sharing of data among information silos. However, the same richness and complexity of the data model poses a challenge for data consumers such as healthcare applications and analytics. These consumers eventually use a much more focused data model that is tailored to their semantics when accessing the underlying data. We describe a unique approach for addressing the tension between the wide warehouse model and the data consumer model, by introducing a framework for generating data marts, derived by the consumer's model and terminology.

Feasibility of Integrating Dental School Electronic Health Record Data to Facilitate Oral Health Research

Muhammad Walji, Paul Stark, Elsbeth Kalenderian, Joel White

[a] *The University of Texas Dental Branch at Houston, Houston, TX,*
[b] *Tufts University, Boston, MA,*
[c] *Harvard School of Dental Medicine, Boston, MA,*
[d] *University of California, San Francisco, CA*

There is a critical need or high quality data sources that can enable research, evidenced-based dentistry and improve patient care. In this project we determined the feasibility of integrating data from 3 dental school EHRs. The results suggest that dental EHR data may be a viable source for creating a large oral health dataset suitable for research.

Development of a Teleradiology web portal for the exchange of medical data using DICOM e-mail

Benjamin Schneider[a], Oliver Heinze[a], Kai Lederle[b], Gerald Weiser[b], Björn Bergh[a]

[a] *Department of Information Technology and Medical Engineering, Heidelberg University Hospital, Heidelberg, Germany*
[b] *Teleradiology, Mannheim University Hospital, Mannheim, Germany*

The Teleradiology/Emergency Medicine Network (TEN) in the Metropolitan Rhine-Neckar Region (Germany) enables the exchange of medical data [1]. However, the inclusion is difficult for technical and financial reasons for some partners like general practitioners (GPs). For that reason a web portal for the exchange of medical data within the TEN is under development. The DICOM e-mail standard [2] offers the base for the data exchange. The portal itself will be developed by Java Server Pages (JSPs) and Java Servlets. The data will be saved in a MySQL-database and a LDAP-server. The DocCheck service will be also integrated into the web portal. The concept has been finished and the portal is under development. The concept foresees that the web server is located in the demilitarized zone (DMZ) of the Heidelberg University Hospital and the database as well as the LDAP-server are running within the clinical network. The client server architecture will be realised by Servlets and JSPs. The portal offers the possibility to use the TEN for free.

Registers for networked medical research in Germany: Situation and prospects

Jürgen Stausberg[a], Udo Altmann[b], Gisela Antony[c], Johannes Drepper[d], Ulrich Sax[e]

[a] *IBE, Ludwig-Maximilians-Universität München, Germany*
[b] *Institut für Medizinische Informatik, Justus-Liebig Universität Giessen, Germany*
[c] *Kompetenznetzwerk Parkinson, Marburg, Germany*
[d] *Telematikplattform für Medizinische Forschungsnetze (TMF) e. V., Berlin, Germany*
[e] *Universitätsmedizin Göttingen, Germany*

Disease specific registers are important means of networked medical research. A study of the Telematikplattform für Medizinische Forschungsnetze (TMF), an umbrella organization of research networks in Germany, revealed a typical setting of "research registers". Based on this study, the TMF compiled recommendations concerning the organizational architecture as well as the development of research registers. Research registers mainly support clinical research through the generation of hypotheses, the identification of eligible patients, and the interfacing of clinical trials. Best practice in register organization differentiates five levels: executive, operations, IT-management, software, hardware. Development and organization oriented to best practice are a prerequisite for a successful and sustainable implementation of registers.

Using ICT & Electronics Technologies for an Effective Chronic Disease Management Model in Latin America

Amado Espinosa

Medisist, MEX

Policy makers across the world increasingly recognize that chronic disease management (CDM), is one of the most important challenges that health systems face. As a consequence, Telehealth Remote Monitoring emerges as a new e-enablement technology to further improve treatment and lower costs. Based on an integrated platform of microelectronic devices, telecommunication carriers and IT clinical systems, in previous uncontrolled patients treated with oral medications in a clinical practice setting were monitored. First results showed a good level of acceptance and a significant improvement of their physiological parameters.

Improvement of Patients' Privacy and Security in Seoul National University Hospital EMR system

Young-Ah Kim, Eun-Mi Jo, Chan-Hee Park, Min-A Hwang, Soo-Yong Shin, Kyung-Hwan Kim, Chun-Kee Chung

Medical Information Center, Seoul National University Hospital, Seoul, South Korea

As the EMR (Electronic Medical Record) system has been utilized, privacy and security of patient information has been highlighted as one of the most important issues in the EMR system. Therefore, Seoul National University Hospital (SNUH) surveyed current weak points in need of improvement in the SNUH EMR system, and made improvements to EMR in four aspects, including medical records access control, hospitalization privacy, privacy & security guidelines, and user policies. Consequently, SNUH received ISO 27001 information security management system certification for its EMR system.

Study on a Safety Management Method and Location Detection using Centralized Controlled Wireless LAN System

Katsuya Tanaka[a], Hidenao Atarashi[a], Izumi Yamaguchi[a], Hiroki Watanabe[a], Ryuichi Yamamoto[b], Kazuhiko Ohe[c]

[a] *Department of Planning, Information and Management, The University of Tokyo Hospital, Japan*
[b] *Interfaculty Initiative in Information Studies, Graduate School of University of Tokyo, Japan*
[c] *Graduate School of Medicine and Faculty of Medicine, University of Tokyo, Japan*

Recently medical information systems at patient's bed side are well-practiced using handy terminals or notebook computers via wireless network. For the stable operation of these wireless systems, network administrators need to keep the wireless network system healthy. In the management operation, the main task is to confirm the absence of unauthorized accesses via uncontrolled computers and the absence of unauthorized wireless devices that effects the operation of medical information systems. For the reduction of risks by such unauthorized devices, it is useful to establish an effective monitoring method of unauthorized devices on the wireless network.

Surveillance of ENT diseases in children during winter

Laurent Toubiana[a,b] and Paul Landais[a]

[a] *Université Paris-Descartes ; Faculté de Médecine ; AP-HP ; EA 4067 ; Service de Biostatistique et d'informatique médicale Groupe hospitalier Necker - Enfants Malades, Paris, France*
[b] *INSERM : Institut National de la Santé et de la Recherche Médicale ; SCEPID "Système Complexe et Epidémiologie, Paris, France*

Acute ear, nose, and throat (ENT) diseases in children mainly occur during the winter season and are the main sources of consultation. These pathologies are very frequent but their epidemiological surveillance is almost inexistent. In this context, we set up a national observatory. A cumulative number of 369,258 consultations was collected during the last 2 winter seasons. The incidence rate of the observed diseases was estimated. Time-space results were provided online by interactive and direct access, or by newsletters including weekly national and regional reports. This study demonstrates the feasibility of setting up each winter such a surveillance system, based on a new generator of a real time platform of surveillance that we developed. It is a support for better understanding winter spread of ENT diseases in children as well as a tool for public health decision making.

Analysis of the Use of Social Media for Adequacy Evaluation of Health Related Websites Based on Health on Net Code

Alex Esteves Jaccoud Falcão, Felipe Mancini, Fabio Oliveira Teixeira, Fernando Sequeira Sousa, Anderson Diniz Hummel, Daniel Sigulem, Ivan Torres Pisa

Health Informatics Department, Federal University of São Paulo, São Paulo, Brazil

The use of Web 2.0 technologies has increased. The use of these technologies for health related websites adequacy criteria is extremely relevant. This study shows that 90% of participants think that health related websites content assessment is important and 95% believe that Web 2.0 technologies are good to perform these evaluations. It is extremely important to spread through social media the ratings of health related content websites. This study is an evaluation of the use of Web 2.0 to verify the adequacy of health related websites according to criteria based on the Health On Net Code (HON).

Assessing the attitude of healthcare professionals towards the use of a mandatory Hospital Information system: An empirical investigation

Joseph Liaskos[a], Panagiota Lazarou[b], Stelios Daskalakis[a] and John Mantas[a]

[a] *Health Informatics Laboratory, Faculty of Nursing, National and Kapodistrian University of Athens, Greece*
[b] *Quality Improvement Department, University General Hospital ATTIKON, Athens, Greece*

The Unified Theory of Acceptance and Use of Technology (UTAUT) as proposed by Venkatesh et al. was applied, together with other research works in order to empirically assess the acceptance of technology in one of the largest and technology-aware hospitals in Greece. Forty nine participants provided feedback regarding the mandatory information system. Data analysis was conducted using a structural equation model, specifically partial least squares. Results indicate the important effect of facilitating conditions to performance and effort expectancy along with the very strong effect of performance expectancy to attitude towards use of technology and behavioral intention.

User Perception of the Effect of the e-Chasqui Laboratory Information System on Patient Care, Reducing Lost Results, and Nation-Wide Impact

Joaquin Blaya[a,b], Sonya Shin[b,c], Martin Yagui[d], Gloria Yale[e], Carmen Suarez[f], Luis Asencios[d], Carmen Contreras[g], Peter Cegielski[h], Hamish SF Fraser[b,c]

[a]*Decision Systems Group, Brigham & Women's Hospital, Boston, USA,* [b]*Partners In Health, Boston, USA,* [c]*Division of Global Health Equity, Brigham and Women's Hospital, Boston, USA* [d]*Instituto Nacional de Salud, Perú* [e]*DISA V Lima Ciudad, Perú* [f]*DISA IV Lima Este, Peru,* [g]*Socios En Salud Sucursal Peru, Peru,* [h]*Centres for Diseases Control and Prevention USA.*

There are limited data on the effects of laboratory information systems in resource-poor settings. The e-Chasqui laboratory information system was implemented in 12 of 34 health centers in two health districts of Lima, Peru. 3 years after implementation, personnel from the 34 health centers were given a written survey. The overall response rate was 93%. Though e-Chasqui users were more satisfied with the paper system than control HC users (p=0.005), they still preferred e-Chasqui (p=0.009). 70% of clinical users reported at least 1 in 10 patients expressing an unsolicited, positive opinion. A majority of those interviewed were missing at least 10% of results, while 70% of e-Chasqui users found results in e-Chasqui that were not on paper. All e-Chasqui users thought implementing e-Chasqui nation-wide would improve patient care.

Standardized terminology using SNOMED CT

Lena Englund[abc], Karin Ahlzén[ab]

[a]*Aalborg University, Denmark*
[b]*National Board of Health and Welfare, Sweden*
[c]*University Hospital of Lund, Sweden*

The needs for communicating clinical data between different health care practitioners are increasing, within as well as across national borders. To secure patient safety it is important that the context and content are not lost in the communication process. To explore the possibilities of SNOMED CT as a reference terminology for the Swedish health care system we compared the concepts and terms in a standard care plan for revision of hip replacement with concepts and terms in SNOMED CT. 82 % of the concepts of the standard care plan had a complete match in SNOMED CT. This study has shown that the use of SNOMED CT could be helpful for the retrieval and reuse of clinical data across organizational boundaries.

Evaluation of medical safety in an e-Health information system through incident reports management system

Takehiro Matsumoto, Masayuki Honda

Department of Medical Informatics, Nagasaki University Hospital

A new e-Health information system was introduced to Nagasaki University Hospital in June 2008. In this paper, the effect of medical safety by introducing new system is evaluated through incident reports management system. Although total number of incident reports increased after the new incident report management system was started in 2007, the number of reports with keywords of medication and drug injection decreased from 413 (21.2%) to 357 (17.0%) ($p<0.001$) and from 289 (14.8%) to 277 (13.2%) ($p=0.132$) after e-Health information system was updated respectively. The number of reports with more severe level of over "3a" which had keywords of medication or drug injection decreased, too. These results show the new e-Health information system was effective for medical safety at least on the medication and drug injection process.

Evaluation of migration to EHR with assistance of Document Imaging system

Eizen Kimura[a], Sumiko Akahori[a], Kuniko Okada[b], Teruo Aibara[b], Shinji Kobayashi[a], Ken Ishihara[a]

[a]*Dept. Medical Informatics of Medical School of Ehime University*
[b] *PSC Inc*

Currently many healthcare institutions try aggressive EHR introduction, it is far from achieving the complete paper-less stage. Document imaging system is useful for termination of paper-based clinical document. In this study we have developed the document imaging system cooperated with EHR to compensate the weakness of EHR. Analyze of document image system's log shows that EHR still has a critical defect in the user interface so that some physicians avoid adapting to routine usage of EHR. The result suggests that the harmonization of clinical workflow with paper document is the critical component of successful EHR introduction.

Keywords:
Document imaging system, EHR, Clinical document

A Comparison between the EMR Adoption Model[SM] and CMMI®

Haijing Hao[a], Yue Zhao[b]

[a] *Heinz College, School of Public Policy and Management, Carnegie Mellon University, Pittsburgh, PA, United States*
[b]*CMMI Lead Appraiser of Software Engineering Institute and CEO of Hualong Information Technologies Ltd, China*

This study analyzes similarities and differences between the EMR Adoption Model[SM] with the Capability Maturity Model Integration for Services (CMMI), which is a worldwide standard for process and quality improvement. EMR Adoption Model is a static standard for evaluating hospital's adoption of electronic medical record system. CMMI is not only is a standard, but it also a framework to guide organizations how to improve their levels within the framework.

Keywords:
EMR adoption model, CMMI.

Mobility in Intensive Care: Pre-Implementation Evaluation

Neşe Zayim[a], Deniz Özel[a], Başak Oğuz[a], Levent Döşemeci[b], Osman Saka[a]

[a]*Department of Biostatistics and Medical Informatics, Akdeniz University, Antalya, Turkey*
[b]*Department of Anesthesiology and Reanimation, Akdeniz University, Antalya, Turkey*

Mobile point-of-care solutions could help improve health care in areas where technology-based, high volume data are generated as in intensive care units, by enhancing possible ways to retrieve information anywhere and anytime. The purpose of this study is to explore clinicians' perceptions regarding mobile technology prior to implementation of mobile technology systems in a university hospital intensive care unit. Data about physicians' and nurses' perceptions regarding mobile technology were gathered by the questionnaire developed by the researchers. The participants are 27 physicians and 15 nurses. More than 90% of respondents said that computers had a potential to provide large benefits for clinical care, also 75% of respondents thought that use of computers would be enhanced with mobile technologies in the ward. Most doctors and nurses have positive opinion about usefulness and ease of use of wireless technology.

Evaluating the Use of an Electronic Dispensing Program for Antiretroviral Treatment at Two Public Health Facilities in KwaZulu-Natal, South Africa

Ravikanthi Rapiti, Denver Narainsamy, Vimal Singh, and Catherine Searle

Reproductive Health and HIV Research Unit, University of Witwatersrand

Reproductive Health and HIV Research Unit (RHRU) has implemented iDART, a dispensing software program at two public health facilities in KwaZulu Natal. This electronic dispensing system for capturing patient information of ART clients was seen as improving drug dispensation time as well improving reporting and the tracking of patients. An operational tool was developed to evaluate the utilization of the program and determine its effectiveness. As a result of the software, sites saw an increase in drug dispensation, health care workers proficiency in using an electronic patient management system and several other system improvements were noted.

[f] *AP-HP, Hôpital Tenon, Service d'Oncologie-Radiothérapie, Paris, France.*

Despite "multidisciplinary staff meetings" (MSMs) and the publication of clinical practice guidelines (CPGs), actual cancer management may still vary from CPG recommendations. Clinical decision support systems (CDSSs) are considered appropriate tools to promote adherence with CPGs. At the Tenon hospital (Paris, France), breast cancer MSMs occur once a week and local guidelines (CancerEst) were developed for breast cancer management. OncoDoc2 is a therapeutic CDSS that implements CancerEst CPGs. In 2005-2006, a before/after intervention study has been performed with OncoDoc2 in Tenon's MSMs. The adherence rate of MSM decisions with CancerEst CPGs significantly increased from 79.2% to 93.4% when the system was used. Since then, OncoDoc2 has been routinely used in a quality management process. We propose a categorization of non-adherent decisions.

Physician's Usage of Mobile Clinical Applications in a Community Hospital

Haijing Hao, Rema Padman, Rahul Telang

The H. John Heinz III College, Carnegie Mellon University, Pittsburgh, PA, USA

We analyze twenty-two months of usage data of mobile clinical applications by approximately 200 physicians in a community hospital in southwestern Pennsylvania in the United States. Applying a novel, semi-parametric, group-based, statistical methodology, we obtain developmental trajectories depicting how usage evolves from initial 'trial' adoption to long-term institutionalization. The analysis of trajectories of physician usage patterns indicate that physicians who began using the system within the first three months of deployment were heavier and more stable, routine users. Voluntariness of use and the availability of multiple channels of access to clinical information may also have impacted adoption of the technology.

A Scientometric Study of Medinfo Conferences Meeting Abstracts

Payam Kabiri[a, b], Farzaneh Aminpour[c, d]

[a] *Faculty of Public Health, Tehran University of Medical Sciences, Tehran, Iran.*
[b] *Academic Evaluation & Scientometry Center, Isfahan University of Medical Sciences, Isfahan, Iran.*
[c] *Scientometry Department, Medical Education Research Center, Isfahan University of Medical Sciences, Isfahan, Iran.*
[d] *Faculty of Management and Medical Information Science, Iran University of Medical Sciences, Tehran, Iran.*

Medinfo conference as the main presentation point of research done in the filed of health and biomedical informatics has been setup first in 1974. In the present research, we studied all the meeting abstracts of Medinfo indexed in the ISI Web of Science and evaluated them using scientometric indicators. The results showed that USA, Japan, France, Germany and England ranked accordingly based on the most ISI indexed abstracts of Medinfo conferences. The citation per paper average of Medinfo abstracts is 1.1 and its h-index is 14 which show the Medinfo abstracts usage and validity.

Development and application of the RFID system for patient safety

Eun-young Jung[a], Rae Woong Park[a], YongSu Lim[b], KugSang Jeong[b], DongKyun Park[b]

[a] *Department of Medical informatics, School of medicine, Ajou University, Korea,*
[b] *U-Healthcare center, Gachon University Gil Hospital, Korea*

Radio Frequency Identification (RFID) has been considered as an innovative technology to advance patient safety in the hospital. In order to improve medical accidents related to information mishandling of surgical patients, blood transfusions, and anti-cancer medication, we developed an RFID system that can be used in general hospitals. Our survey on the RFID system with 63 nurses and 20 patients who actually experienced the RFID system revealed a high level of satisfaction in terms of reinforcing the patient's safety in medical environments. Nurses surveyed had intention to utilize the RFID system for managing hospital assets and tracking patients later. For the full scale application of RFID system in hospitals, it is important to ensure information system stability, including the network system, and quantitative analysis of the effects of the system.

Do Electronic Information Systems Facilitate Errors in Medication Management?

Virpi Jylhä, Kaija Saranto

Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland

Human error is common when information management is conducted manually. Sometimes errors correct themselves; however, in the hospital context, if they lead to adverse drug events (ADEs), the consequences can be serious. This retrospective study aimed to identify types of ADEs related to information management via electronic information systems. The research questions were as follows: 1) What kind of ADEs have occurred? 2) What are the causes of these errors? The results of this study confirm previous studies indicating that accurate patient data has a major role in safe practices.

Keywords:
Information management, Medical errors, Information systems

Evaluation of innovative health IT applications: importance of usability studies in hospital settings

Marie-Catherine Beuscart-Zéphir, Ludivine Watbled, Régis Beuscart

Univ Lille Nord de France; INSERM CIC-IT-Evalab, Lille; CHU Lille; UDSL EA 2694; F-59000 Lille, France

This poster addresses the problem of the necessary evaluation of innovative Information Technology applications to ensure their safe transfer to the actual care providing environment. It focuses more specifically on the usability dimensions of such an evaluation. It describes at a national institutional level the installation of new centers for innovative technologies in charge of designing and applying proper evaluation methodologies to health IT applications.

Validity Insurance of Telemetric ECG Measurements

György Kozmann[a,b], Zsolt Tarjányi[a], Kristóf Haraszti[b], Krisztina Szakolczai[b], Vavrinec Szathmáry[c]

[a] *Department of Electrical Engineering and Information Systems, University of Pannonia, Veszprem, Hungary*
[b] *Research Institute of Materials Science, Hungarian Academy of Sciences, Budapest, Hungary*
[c] *Institute of Normal and Pathological Physiology, Slovak Academy of Sciences, Bratislava, Slovakia*

The insurance of measurement validity has a primary importance in home care measurements. In this paper the possible impact of ECG electrode misplacements and the different body positions on the signals transmitted has been analyzed, based on a large database of body surface potential maps. According to our results in the course of self-measurements considerable, diagnostically meaningful errors might be expected in the precordial leads, which might be even emphasized if the chest position of the patient is not defined properly.

[a] *Center for Biomedical Informatics at Mount Sinai School of Medicine, New York, NY*
[b] *World Trade Center Medical Monitoring and Treatment Program, Data and Coordination Center at Mount Sinai School of Medicine, New York, NY*

This poster describes a process for analyzing and recommending improvements for the WTC Medical Monitoring and Treatment Program regarding its clinical and operational workflow as well as the user interface of its data management system, a customized version of TrialDB. Heuristic evaluation and workflow analysis were performed to identify problems and improve the overall system. Two biomedical informatics researchers used seventy-four heuristic evaluation questions categorized in ten principles in order to understand the capability features of the TrialDB user interface. Workflow analysis was undertaken with discussions with the Deputy Director and a system architect of the WTC Medical Monitoring and Treatment Program to determine the redesign of data collection procedures. Overall, the evaluation methods were instrumental in identifying the problems that need to be resolved and recommending features that need to be integrated into the system, and the methods of analysis are applicable to the evaluation of other HIT systems.

Do machine translations increase the usefulness of summaries of MEDLINE abstracts? An interface evaluation with medical students and physicians in Peru

Miguel A. Ceccarelli[a], Walter H. Curioso[b,c], Fang Liu[d], Paul Fontelo[d]

[a] *Scientific Society of Medical Students ("SOCEMCH"), School of Medicine, Universidad Peruana Cayetano Heredia, Lima, Peru*
[b] *Universidad Peruana Cayetano Heredia,Lima, Peru*
[c] *Biomedical and Health Informatics, University of Washington, Seattle, WA, USA*
[d] *Office of High Performance Computing and Communications, National Library of Medicine, Bethesda, MD, USA*

Searching and reading MEDLINE citations and abstracts can be challenging for non-native English speakers. The objective of this paper is to evaluate the usefulness of an interface that incorporated an automatic machine translation of MEDLINE citations, short "bottom line" summaries and abstract from English into Spanish. Twenty one participants (5 physicians and 16 medical students) from a Peruvian medical school evaluated the perceived usefulness of the translations. Overall, Spanish translations were rated as "useful" to "very useful" (3.7/5, mode=4). We also found that more than a half of the participants (62%) and most of the suggestions were related to interface improvement (33.3%) already underway. Improving the search boxes and the translation were also suggested. A usability evaluation study with more participants and with special measurement instruments designed for web interfaces is planned.

Impact of Alert Specifications on Clinician Adherence: a Systematic Review

Reza Khajouei[a,b,c], Linda W. Peute[a,c], Maurice M. Langemeijer[a], Monique W. Jaspers[a]

[a] *Department of Medical Informatics, Academic Medical Center – University of Amsterdam, The Netherlands*
[b] *Kerman University of Medical Sciences, Kerman, Iran*
[c] *The first two authors equally contributed to this paper*

More than half of the alerts integrated into health care information systems are overridden by clinicians. A systematic review on studies evaluating alert specifications, such as alert type, design and message content, and their impact on clinicians' alert adherence was done. Use of colors and icons in alerts of varying severity and the presentation of alerts in an interruptive fashion based on their severity increased clinicians' adherence. Lack of clinical importance and correctness of alert information resulted in alert non-adherence. The amount of evidence generated on the impact of alert specifications on clinicians' alert adherence is limited. However, this review shows that a relation is apparent between alert specifications and clinicians' alert adherence.

A Scientometric Study on Health and Medical Informatics Literature

Farzaneh Aminpour [a,b], Payam Kabiri[c]

[a] *Scientometry Department, Medical Education Research Center, Isfahan University of Medical Sciences, Isfahan, Iran.*
[b] *Faculty of Management and Medical Information Science, Iran University of Medical Sciences, Tehran, Iran.*
[c] *Academic Evaluation & Scientometry Center, Vice Chancellery for Research, Isfahan University of Medical Sciences, Isfahan, Iran*

Few researches evaluated medical and health informatics literature. All published papers on medical or health informatics indexed by ISI Web of Science databases including Science Citation Index Expanded, Social Sciences Citation Index, Conference Proceedings Citation Index- Science, and Conference Proceedings Citation Index- Social Science & Humanities from the beginning of 1985 until the end of 2008 were retrieved. The results indicated that total 3123 papers on medical or health informatics have been indexed by ISI Web of Sciences which received 16630 citations between 1990 and 2008. The average citations per year were about 5 times. The language of the most papers was English. USA, England and Germany respectively published more papers than other countries. According to the results, running more researches in this field seems to be necessary.

Comparing Two Protocols for Head and Neck Cancer: a Cost-Effectiveness Analysis

Carla Rognoni[a], Stefania Rubrichi[a], Silvana Quaglini[a], Nicola Lucio Liberato[b], Lisa Licitra[c], Monia Marchetti[d], Thierry Gorlia[e], Jan Vermorken[f]

[a] *Department of Computer Engineering and Systems Science, University of Pavia, Pavia, Italy*
[b] *Internal Medicine Department, Azienda Ospedaliera della provincia di Pavia, Casorate Primo (PV), Italy*
[c] *Head and Neck Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*
[d] *Internal Medicine Department, Ospedale Cardinal Massaia, Asti, Italy*
[e] *European Organization for Research and Treatment of Cancer (EORTC), Brussels, Belgium*
[f] *Medical Oncology Department, Universitair Ziekenhuis Antwerpen, Edegem, Belgium*

A decision analytic model has been developed to perform a cost-effectiveness analysis on the addition of docetaxel to the standard treatment for Head and Neck Cancer (HNC). The point of view of the analysis is the Italian National Healthcare Service (NHS). The new therapeutic opportunity, while more or less doubling the cost, has been shown to significantly improve survival in two recent clinical trials. They evaluated the use of docetaxel in two slightly different protocols, i.e. ChemoTherapy + RadioTherapy (CT+RT) and ChemoTherapy + ChemoRadioTherapy (CT+CRT), respectively. To represent the disease progress, Markov processes have been included in the model. Data have been derived mostly from the two trials and, where not available, from literature and expert panel. Adding docetaxel is cost-effective leading to a cost of € 12,880 and € 8,820 per life year saved for the two protocols, respectively. The robustness of the results has been tested with a probabilistic sensitivity analysis.

Keywords:
Cost-effectiveness, Markov model, Head and neck cancer.

Obesity and Web 2.0: Psycho-educative Groups

Maria Assunta Zanetti[a], Ines Giorgi I.[b], Roberta Renati [a], Valentina Percivalle[a], Antonella La Manna[c], Flavia Magri[d], Maria Cristina Mazzoleni[e].

[c] *Unit of Internal Medicine and Endocrinology, S. Maugeri Foundation IRCCS, Pavia;*
[d] *Unit of Internal Medicine and Endocrinology, University of Pavia;*
[e] *Scientific Direction, S. Maugeri Foundation IRCCS, Pavia.*

We present a pilot research, that is in progress, by the Maugeri Foundation of Pavia, in collaboration with Department of Psychology of the University of Pavia. The purpose of this study is to investigate the effectiveness of applying the Information and Communication Technology (ICT) in the treatment of patients with obesity. In particular we want to compare the effects that two different way of treatments product on the patients: on one hand psycho-educational group face-to-face and, on the other hand, the association between a psycho-educational group face-to-face with psycho-educational group on line.

Transfer In and Out of Stroke Care Units: A Preliminary Study Using Bayesian Networks

Shyamala G Nadathur[a] and Jim R Warren[b]

[a] *Department of Medicine, Monash Medical Centre, Monash University, Melbourne, Australia*
[b] *Department of Computer Science, University of Auckland, Auckland, New Zealand*

Some reports have questioned the cost effectiveness of SCUs. Therefore the focus was to compare episodes treated by teaching hospitals with and without SCUs that experience ongoing care or transfers. The transfer-patients are often high users of the system; with an associated high cost. As a proof-of-concept Bayesian Network (BN) was applied to routinely collected public-hospital administrative data. The results demonstrated that SCUs mainly treat Subarachnoid haemorrhages whereas the non-SCUs the Cerebral infarctions. There were differences in the mix of admission types, care types, the hospitals transferred from and transfer destinations. Although the teaching hospitals with SCUs achieved shorter LOS, they treated younger patients with lower overall complexity than non-SCU teaching hospitals. This preliminary study demonstrated the value of BN to explore in an ad hoc manner the caseload, trajectory and outcomes recorded in hospital-administrative data. Studies such as this are important for gathering information on the current practices and creating opportunities for benchmarking and improving care.

Development and implementation of the Cyber Education Program for Quality management and patient safety

Hyunju Song[a], Sunyoung Park[a], Moon-Sook Kim[a], Ki-Ho Park[a], Jeong-Rul Lee[b]

[a] *Division of Quality Improvement, Seoul National University Hospital, Seoul, Korea*
[b] *Division of Education and Research, Seoul National University Hospital, Seoul, Korea*

As the importance of quality management in a hospital is increasing continuously, Seoul National University Hospital tried to find an effective way to educate staffs for quality improvement and patient safety. The web-based training program provided meaningful results. The objectives of the project are to develop education programs for quality improvement and patient safety for a hospital and to carry out the programs to all staffs in the hospital. The project was developed in three steps which are 1) writing manuscripts, 2) making storyboards and 3) programming. By and large, four programs were completed from the project. The researchers implement the project four times hospital-wide. More specific programs will be developed considering various types of jobs and roles. In addition, a way to evaluate the effectiveness and efficiency will be figured out in further research.

Impact of Computer-Assisted Education about Psychiatric Stigma on Medical Students

Oleg Lapshin[a], Evgeny Wasserman[b], Joseph Finkelstein[a]

[a]Johns Hopkins University of Maryland School of Medicine, Baltimore, MD, USA
[b]St. Petersburg State University School of Medicine, St. Petersburg, Russia

Stigma of psychiatric disorders among medical students may both preclude them from using mental health services and may affect their future professional lives. We assessed the impact of computer-assisted educational program about psychiatric stigma in 51 medical students attending large state university in Russia. The study results showed significant impact of the educational program on psychiatric stigma and knowledge about psychiatric disorders and stigma. The anti-stigma program was very well accepted by students. We concluded that computer-assisted anti-stigma interventions are useful and effective in medical students.

Keywords:

Factors Related to Learning Outcomes in New Healthcare Staff with the e-learning Orientation Program

Shih Yu-Shan[a], Lee Ting-Ting[b]

[a] Department of Nursing, Shin Kong Wu Ho-Su Memorial Hospital, Taiwan
[b] National Taipei College of Nursing, Taiwan

The purpose of this study was to explore the factors associated with learning outcomes in new healthcare staff receiving the e-learning orientation program. The data analysis contained 154 valid questionnaires, and 13 staff s' interview contents. New staff in this study had a positive attitude toward e-learning system. Perceived ease of use and perceived usefulness were critical factors for new staffs' satisfaction and continued intention to use the orientation program. In addition, four major themes emerged regarding the e-learning program: acknowledgement of the training program, benefit of e-learning, usability concern, and content suggestion. Therefore, understanding users' barriers and difficulties could improve learning outcome and further orientation program design.

Web 2.0 based Educational Intervention for Adolescents with Type 1 Diabetes: Design of a randomized controlled Trial

Santos, F R M[a], Bernardo, V.[a], Dib, S A.[b], Sigulem, D.[a]

[a]*Health Informatics Department - Federal University of São Paulo, Brazil.*
[b]*Department of Endocrinology- Federal University of São Paulo, Brazil.*

Web 2.0 can be a very good technology to build a framework for diabetes education and consequent evaluation of this education. Objective - The objective of the study is to evaluate the effectiveness of a web 2.0-based educational intervention, on glycemic control in adolescents with type 1 diabetes. Methods - A randomized controlled trial design will be used. 300 adolescents diagnosed with type 1 diabetes will be randomized into 3 groups: Web 2.0-based Intervention; Web Intervention and Control group. The evaluation of the educational program will be given by the following variables and instruments: HbA1c (Test Lab); Social Support, Resilience, Quality of Life and Knowledge about diabetes (Questionnaires). Discussion - Web 2.0 applications are emerging with educational potential. Following this trend, the present study design provides an innovative contribution to integrate and evaluate the web 2.0 resources into an educational intervention for adolescents diagnosed with diabetes.

Establishment of an Education System for Working Graduate School Students Using a Distance Education System

Nobuo Shinohara, Chieko Sakamoto, Hinako Toyama, Katsuko Toba, Shigekoto Kaihara

Graduate School of Health and Welfare Sciences, International University of Health and Welfare, Tokyo, Japan

In Japan, the demand for practical educational programs for healthcare professionals with full-time jobs is now increasing. However, students face a variety of difficulties in continuing their jobs at hospitals in order to attend graduate school, and hospitals may lose valuable staff members who choose to study rather than work. Therefore, it is important to prepare a graduate school environment that is compatible with the lives of working people. In April 2008, a Clinical Information Analyst Course for working Health Information Managers (HIMs) was established as a 2-year master's degree program at the International University of Health and Welfare Graduate School. In this course, we train HIMs to become clinical information analysts capable of analyzing clinical data using knowledge from a wide range of topics, including information technology, medical business and cancer registration. The objectives of the present study are to explain the approach of this course and to obtain knowledge about the establishment of an education system for working graduate school students. This course is a part of the Ministry of Education, Culture, Sports, Science and Technology (MEXT) project "Training Plan of Cancer Professionals".

Drop-out Causes in an E-Learning CME Course with High Retention Rate

M. Cristina Mazzoleni[a], Carla Rognoni[b], Enrico Finozzi[a], Maria Franchi[a], Beatrice Presciutti[a], Ines Giorgi[a]

[a] *Salvatore Maugeri Foundation IRCCS, Pavia, Italy*
[b] *Department of Computer Engineering and Systems Science, University of Pavia, Pavia, Italy*

E-learning efficiency regarding Continuing Medical Education (CME) has been proved but drop-out rate is quite high. The aim of the present work is to investigate the drop-out causes focusing on a course for nurses and physiotherapists (7811 users). An email was sent to 1393 drop-out users (17.8%) to investigate the possible causes of abandon that can be classified in 4 major areas: 1) lack of a real interest to attend; 2) presence of real interest but abandon due to reasons independent from the will i.e. lack of time or lost website address; 3) technical or usability problems; 4) disagreement with the educational model. About 18% of the users replied to the email within the following 2 weeks assessing lack of time as the first abandon cause (41.6%), maybe related to difficulties in considering e-learning education as a working activity.

Health Informatics Building Blocks (HIBBs) For Distance Learning in Low Resource Settings

Meryl Bloomrosen[a], Ted Shortliffe[a,b], Karl Brown[c]

[a] *American Medical Informatics Association, Bethesda, MD*
[b] *School of Health Information Sciences, University of Texas Health Sciences Center, Houston, TX*
[c] *Rockefeller Foundation, New York, NY*

The Health Informatics Building Blocks (HIBBs) project seeks to facilitate the acquisition of informatics and associated management skills by health care workers and leaders in local communities and health systems in low resource settings to improve their ability to use eHealth solutions (e.g., electronic health record systems) to strengthen clinical care and public health services. The HIBBs project, funded by the Rockefeller Foundation and managed by the American Medical Informatics Association, is initially focusing its efforts in Sub-Saharan Africa (SSA). A hallmark of the project is to develop ongoing collaboration with organizations in SSA that are providing clinical, research, and/or health informatics training to ensure the application of a locally-based, community-focused approach to the development and dissemination of HIBBs.

Inter-university clinical informatics education program for co-medical students*

Hinako Toyama[a], Jun Nishihira[b], Michio Naito[c], Tetsuo Kawamura[d], Shunji Wakamiya[e], Norio Sasagawa[f] and Akikazu Tamaki[g]

[a]International Univ. Health and Welfare, [b]Hokkaido Information Univ, [c]Fujita Health University, [d]Suzuka University of Medical Science, [e]Kawasaki Medical Welfare Univ., [f]Hiroshima International Univ., [g]University of East Asia

In order to promote the utilization of digital clinical information among co-medical staff, seven universities in Japan have planned to introduce the Electronic Health Record (EHR) system for education on the virtual private inter-university network (VPN) and to develop materials involving fictitious model patients used for learning team medicine via EHR. The EHR system and the associated educational materials have been evaluated by these seven universities. The materials for fictitious patients, including medical records, study results, and medical images, were added to a database developed for EHR education. This program was evaluated using a questionnaire administered to students and the administrators of hospitals employing students who have graduated.

Establishing a Core Medical Informatics PhD Program Curriculum in China

JiaLin Liu[a,b] , YingKang Shi[a] ,Rui Zhang[a],Jian Peng[a] ,Dong-chyan Liu[c], XiaoHai He[d],JinBo Fang[e]

[a] Department of Medical Informatics, West China Hospital/West China Medical School, Sichuan University
[b] Department of Otolaryngology, West China Hospital/West China Medical School, Sichuan University
[c] Computer Science College of Sichuan University
[d] School of Electronics and Information Engineering of Sichuan University
[e] Department of Nursing, West China Hospital/West China medical School, Sichuan University

The lack of medical informatics education and research infrastructure in China remains a major barrier both to the development of medical informatics as a discipline and high level medical informatics education. This paper introduces a core medical informatics PhD program curriculum in China, which will foster knowledge, skills, and abilities needed by current and future medical informatics leaders in professional applications. The PhD program will also minimize background differences from students with different professional training.

Health Informatics Education: Are we Building Capacity?

Alice Breton

Director e-Learning, Faculty of Health Informatics, Royal College of Surgeons of Edinburgh

Workforce development and associated professionalism are essential for leveraging the benefits of technology to improve healthcare delivery [1]. However there is limited knowledge about how health informatics education contributes to workforce capacity. This study reports the findings of a small online questionnaire of graduates to investigate why people choose to study Health Informatics and the impact of studying on their career. While the sample size is too small to provide generalisability it does offer a snapshot of Health Informatics graduates. The results indicate that they are mid career, from diverse backgrounds, with differing motivations for studying Health Informatics. While there is evidence of a positive impact on current roles and movement to Health Informatics roles, the amount of time spent on Health Informatics activities is not particularly high (52% spend less than 20%). Membership of a Health Informatics professional body is also low. These results mirror other studies highlighting the need for further information about the workforce [2,3].

The questionnaire analysis about the urgency and necessity of biomedical informatics education in a medical school

Dukyong Yoon, Rae Woong Park

Department of Bio and Medical Informatics, School of Medicine, Ajou University, Suwon, Republic of Korea

Although the number of medical schools which give a biomedical informatics education has been increasing in Korea, but there is no guideline for medical school students, yet. The result of this research analyzing perception of clinicians and biomedical informaticians could be foundational data for establishing a guideline. The questionnaire consisted of 32 questions related to detailed fields of biomedical informatics. On each question, respondents were asked whether it is urgent and necessary as curriculum for medical school student or not. The questions answered it's not only 'necessary' but also 'urgent' were 'Electronic medical record', 'Medical information system', 'Office programs', 'Graphic programs', 'Evidence based document research', 'Data back-up', and 'Arrangement of references'. These contents should be considered when the curriculum of biomedical informatics is made up.

Using Social Networking Sites When Hiring Informatics Job Candidates: A Preliminary Study

Brian E. Dixon

School of Informatics, Indiana University, Indianapolis, Indiana, USA

Employers and job seekers are using the Internet to find job candidates and opportunities, respectively. However, little is known about the use and attitudes towards social networking websites that supposedly support personnel selection. A preliminary study asked employers about their attitudes towards the use of online social networking sites. Surprisingly only a slight majority of respondents reported value in using online profiles in addition to traditional resumes and vitas when searching for a job candidate. Additional study and analysis is required to better understand how social networking sites can enhance personnel selection. Efficient and effective personnel selection is important given the worldwide lack of a sufficient informatics workforce.

Ancestry Estimation in a Web-based, Searchable Database of Orthodontic Case Files for Patient Care, Education, and Research

Philip J. Kroth[a,b] Heather J. H. Edgar [a,c]
Edward F. Harris[d] Summers Kalishman[b] and Shamsi Daneshvari[c]

[a] *University of New Mexico Health Sciences Library and Informatics Center, Albuquerque, NM*
[b] *University of New Mexico School of Medicine, Albuquerque, NM*
[c] *University of New Mexico Maxwell Museum of Anthropology, Albuquerque, NM*
[d] *Department of Orthodontics, University of Tennessee College of Dentistry, Memphis, TN*

In 2005, the Maxwell Museum of Anthropology accepted a donation of orthodontic patient records from an orthodontist who has been practicing in the Albuquerque area since the early 1970's. This collection represents a diversity of patients not often encountered in orthodontic training in the United States. A virtual, de-identified, web-based version of a subset of the collection is now being developed. Users can search for cases with particular characteristics of interest (e.g., patient ancestry, extraction patterns, diagnoses, and cephalometric parameters), then review sequential intra-oral and X-ray images to observe treatment outcomes. An innovative feature of the database is that it records multiple ancestry estimations, made at multiple points in time by multiple raters, along with a list of ancestry indicators on which the estimations are made (e.g., skin color, hair form and color, facial shape, name, and locality). This poster describes how the database can be used to overcome the limited diversity in the patient populations available to most orthodontics trainees. When this project concludes, the database will contain approximately 400,000 digitized images from 5650 individual cases.

From Strategy to Implementation: A Progress Report on AMIA's Global Partnership Program to Build eHealth Capacity in Low Resource Countries

Edward H. Shortliffe[a], Don E. Detmer[ab], William M. Tierney[c], Andrew S. Kanter[d], Barbara Brown[a]

[a] *American Medical Informatics Association, Bethesda, MD, USA*
[b] *Medical Education, University of Virginia, Charlottesville, VA, USA*
[c] *Regenstrief Institute; Indiana University School of Medicine, Indianapolis, IN, USA*
[d] *Earth Institute and Mailman School of Public Health, Columbia University, New York, NY, USA*

Shortcomings in the health information systems of low resource countries limit the availability of reliable clinical data for diagnosis, treatment, and public health. AMIA's Global Partnership Program (GPP) seeks to improve health care delivery systems and outcomes by increasing regional eHealth capacity in low resource countries. AMIA and its partners are leading a team of experts in developing scalable approaches to eHealth training to help address the need for a global informatics workforce and scholarly network. Planned activities include bidirectional movement of local multidisciplinary leaders and teams to build collaborative relationships among partnering institutional stakeholders, mobilizing support from decision makers and beneficiaries, and facilitating organizational change to introduce electronic health record (EHR) systems and to sustain their continued use. The GPP experience will offer valuable "lessons learned" in training and education for capacity building and managing high-quality, low-cost health care in low resource countries.

User Training of Patient Information System-Longitudinal Study in Central Finland

Tuula Kuusela, Kaisa Lemmetty and Eija Häyrinen

MediKes Information Management, Central Finland Health Care District, Finland

Health care professionals require versatile user training when adopting information systems. The first study was completed in November 2006 (n=290) and the second in June 2009 (n=420). The respondents were generally satisfied with the classroom teaching. Almost half of them had practised the use of information systems after the teaching in the training environment. The second study reveals training independently at work was in particular appreciated. Good learning results were obtained when practising with personal guidance after classroom training.

Public Health Informatics Capacity Gaps in Low Resource Countries

Jessie R.M. Legros[a], Anna Grigoryan[a], Tadesse Wuhib[a], Nosa Orobaton[b]

[a] *U.S. Centers for Disease Control and Prevention (CDC)*
[b] *Health Metrics Network (HMN), World Health Organization (WHO)*

The emergence of new, complex public health challenges in the 21st century demands that the public health informatics field strengthen its capacity to respond. The Health Metrics Network (HMN) and the US Centers for Disease Control and Prevention (CDC) and their partners are vital to collaboratively improve the global public health informatics infrastructure. This study represents an exploratory effort to assess public health informatics gaps in low resource countries. A review of the HMN assessments in 54 low resource countries notes the need for human resource capacity building in public health informatics. Findings suggest increasing level of awareness to support the training, deployment, and career development of public health informatics professionals. Investments from different public and private sources are required as part of a major intervention in the area of public health informatics capacity building. These data provide a foundation for future research and can be used to inform policy decisions regarding the design and implementation of public health informatics trainings in low resource countries.

Lifelong Learning – A Challenge for Education in Health Informatics

Ritva Karjalainen-Jurvelin[a], Kaija Saranto[b]

[a] *Centre for Training and Development, Aducate, University of Eastern Finland, Kuopio, Finland*
[b] *Department of Health and Social Management, University of Eastern Finland , Finland*

The health informatics field becomes more challenging as the technology advances. Health care professionals, with understanding of modern technologies, are expected to improve the quality and efficiency of health care. In health care effective use of information and communication technology sets needs for lifelong learning. Especially, improved knowledge and skills in implementation of health informatics is of high importance. To meet these needs the continuing educational program (40 ECTS) has existed since 1997. The aim of this study is to explore the success of learning and pedagogical methods, as well as to analyse the contents of the education modules. The education is based on the use of activity theory. The outcome measures of the program analyzed in January 2010 and feedback from the participants has been largely positive.

Data Capturer Internship Program at Health Facility Level, South Africa

Hlengiwe Ngcobo

The Health Information System for Data Capturers (HISDC) Project, an initiative by the National Department of Health (NDoH) aims to address both the inadequate opportunities for career development in the public sector as well as to build national capacity for data management at the level where health data is collected i.e. facility level. This project which is mapped to be implemented over a period of three years is in its second year of implementation. The project is implemented by a consortium comprising the Continuing Education at the University of Pretoria Trust, Health Systems Trust and the Health Information System Programme.

This paper describes research in progress. A survey was carried out to determine if Gen Y users are utilizing text messaging as a means of sharing health information with their family and friends. Survey was sent to 5000 students with a response rate of thirty eight percent. (n=1900) Results show that this cohort uses the text message function of their phones to share health information in differing degrees with family and friends and is also affected by the types of condition they are communicating about.

Identifying with other people suffering from alcoholism in an e-mediated and cross-cultural venue

Trond Nergaard Bjerke[a], Rolf Wynn[b]

[a] *Addiction Research, Psychiatric Research Centre for Northern Norway, University Hospital of Northern Norway*
[b]*Psychiatric Research Centre for Northern Norway,University Hospital of Northern Norway*

To reach a common ground for identification is regarded as one of the most important success factors for self-help groups. The members should be able to relate to each others' experiences so that they feel that they are part of the "we-ness". In this study we explored two Alcoholics Anonymous Internet groups with an international membership. The objective was to explore the members' experiences of participating in an international AA self-help group. The research questions are: How does using e-meetings, e-mail lists and electronic bulletin boards with an international and cross-cultural membership influence on the process of identifying and thus on the members' rehabilitation processes? Are they able to find a common ground of identification? Data were obtained over the course of one year by means of participant observation in two online AA groups and e-mail interviews with 11 online AA members. Results suggest that members can easily identify with each other. Two things seem to bridge the potential gap between members from different countries and cultures: The AA members' view of alcoholism as a global disease with similar symptoms, and the experience of AA`s conceptual framework as a universal language.

Comparing Diabetes Search Engines: HON vs Google

Shane Reti[ab], Michael Tierney[b], Henry Feldman[b], Celia Boyer[c], Charles Safran[b]

[a]*Department of General Practice and Primary Health Care, University of Auckland, New Zealand*
[b]*Division of Clinical Informatics, Harvard Medical School, Boston, MA, USA*
[c]*Health on the Net Foundation, Geneva, Switzerland*

Google search engine is one of the tools most used by consumers searching for health information on the world wide web. Several studies have examined the quality of information returned from Google and other public domain search engines, but none have compared a single disease focused search engine delivering certified content, and the rules clinicians apply to decide on website quality. We compare a general Google search engine with a customized Health on The Net (HON) search engine specifically designed to pre-filter HON certified websites for diabetes content. Across three stratified groups including primary care practitioners, informaticians, and diabetologists, we address quality as a response to the question " Which of these websites are you most likely to recommend to your patients ?". We then assess the rules clinicians apply to website decision making. Our in-progress pilot study suggests a preference for HON certified websites, with the dominant selection rules being 1. An absence of blogs or personal experiences, and 2. Pre-existing familiarity with the website. This poster will compare search results for Google and HON, and the selection rules clinicians apply across primary care practitioners, informaticians, and diabetologists.

An ontology for automatic generation of computer-based cognitive exercises

Silvana Quaglini[a], Silvia Panzarasa[b], Giorgio Leonardi[a,c], Mario Stefanelli[a]

[a] *Dipartimento di Informatica e Sistemistica, Università di Pavia, Italy*
[b] *Consorzio di Bioingegneria, Pavia, Italy*
[c] *Dipartimento di Informatica, Università del Piemonte Orientale, Italy*

Cognitive rehabilitation may take advantage of computer-based approaches which, compared to the traditional paper-based ones, allow the management of a big amount of stimuli. These stimuli may be reused and recombined to create new exercises, whose difficulty level should be adapted to the patient's performance. This work proposes an ontological organization of the stimuli, to support the automatic generation of new exercises, tailored on the patient's preferences and skills. The ontology has been integrated into an existing cognitive rehabilitation tool [1], to test the new functionalities made possible by this approach.

[c] *Sociedad de Diabetología y Nutrición del Uruguay*
[d] *Universidad ORT, Montevideo*

We developed a web platform to provide educational materials on diabetes for patients with diabetes type 2 and also to offer the possibility to interact with experts and other patients during 4 months. Patients were selected from health maintenance organizations HMO institutions in Montevideo, and after a survey about habits and knowledge about their condition, they were invited to a workshop to be introduced to the platform. Preliminary results show particular interest in nutrition subjects and passive participation.

Types of the Healthcare Information Provision e-Business on the Internet

Jeongeun Kim[a,b], Sunyoung Lee[c], Sukwha Kim[d]

[a]*College of Nursing, Seoul National University, Seoul Korea*
[b]*Research Institute of Nursing Science, Seoul National University*
[c]*Seoul National University Hospital* [d]*College of Medicine, Seoul National University, Seoul Korea*

The objectives of the study was to; firstly, define healthcare information provision industry, and classify/analyze healthcare information industry business models, secondly, propose strategic guidelines for healthcare information industry development. A survey was conducted to investigate private companies that provide healthcare information. Through literature review of previous researches on internet business model classification, four major model classification systems were chosen and healthcare information business models were classified. Appropriate guidelines were proposed based on the composite opinions derived from the participating companies. In order to realize the industrialization and development of health information provision industry, it is important to educate the general with the help of government and cooperation with field experts.

Developing a concept map for "increasing medication safety and patient compliance by developing patient-oriented mobile phone applications"; results of a conceptualization research

Alireza Ahmadvand[a], Forough Foroughi[b]

[a] *Department of Epidemiology and Biostatistics and Institute of Public Health Research, Tehran University of Medical Sciences, Iran*
[b] *Department of Clinical Laboratory Medicine and Anatomical Pathology, Shahid Beheshti University of Medical Sciences, Iran*

Medication errors are very common worldwide and potentially affect almost all patients especially those with chronic diseases. There have been a few reports in the literature of mobile phone applications for reducing medication errors. We decided to do an extensive literature review and gather the available evidences and prepared a knowledge-based process for developing patient-oriented mobile applications for medication safety and compliance which hopefully encourages healthcare managers and stakeholders to use our research results. This knowledge-based process for developing patient-oriented mobile applications for medication safety and compliance is helpful to patients and providers in: registering and updating the patient's medications, their dosages and timing; reminding to take medications on-time; checking for any interactions; finding related educational materials; and other usages.

Keywords:

A circular model for the e-Health at the household

Sara Marceglia[b,c], Luca Mazzola[a,c], Stefano Bonacina[c], Francesco Pinciroli[c]

[a] *USI-Com ITC & NewMinE – New Media in Education Lab, Università della Svizzera italiana, Lugano – Switzerland*
[b] *Fondazione IRCCS Ca' Granda Ospedale Maggiore, Policlinico, Milan - Italy*
[c] *Laboratorio di Informatica BioMedica e Sanità Digitale - Dipartimento di Bioingegneria, Politecnico di Milano, Milan - Italy*

In this paper we present a circular approach that takes into account all the processes starting from and arriving to the patient for household e-Health. The management of healthcare documents, the prevention based on the knowledge of risk factors and the support during therapy administration are the key points of the path. The circular model is based on the cooperation between different software tools, each devoted to a single phase of the whole process.

A study on the Linguistic and Functional Health Literacy and Chronic Disease Information

Eun-Jung Lee[a], Myonghwa Park[b]

[a]*Dongsan Medical Center, Keimyung University, Republic of Korea*
[b]*College of Nursing, Keimyung University, Republic of Korea*

Health literacy is one of major health issues in developing health education material and program The purposes of this study are to identify health literacy of the persons with chronic disease, to identify disease knowledge depending on a health literacy level, and to verify the correlation between them. Over 200 patients with hypertension or diabetics at a tertiary hospital were participated in the study. The survey was conducted using REALM (Rapid Estimate of Adult Literacy in Medicine) and S-TOFHLA (Short Test of Functional Health Literacy in Adults) as health literacy measurement tools, and disease knowledge measurement tools. The findings indicated that the health education and health care information need to be tailored according to the target user's health literacy and disease knowledge.

Health and wellbeing related information management in families with small children

Marilla Palmén[a], Mikko Korpela[a], Kaija Saranto[b]

[a] *Healthcare Information Systems Research and Development Unit, University of Eastern Finland, Kuopio, Finland*
[b] *Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland*

Understanding how families manage health and wellbeing related information in their everyday life is important in the design of appropriate information and communication technology (ICT) supported tools and services for them. The aim of this poster is to present a study in which we investigated health and wellbeing related information management activities and needs of families with small children taking Eastern Finnish families as an example. A qualitative study design was applied using the method of longitudinal virtual focus group discussion with eight households (n=8) over four weeks of time. Main information management activities were identified and grouped according to the different roles that families with small children play in society when seeking health and wellbeing: as users of health and social services, as consumers in the market of goods and services, and as citizens seeking a sense of wellbeing in its widest meaning. The study provides baseline understanding of everyday information management activities of families with small children to be applied further in ICT supported health and wellbeing service design.

Designing the Information Architecture for Personal Health and Wellbeing Systems

Marika Toivanen[a], Juha Mykkänen[b], Mikko Korpela[b]

[a] *School of Computing, University of Eastern Finland, Kuopio, Finland*
[b] *Healthcare Information Systems Research & Development Unit, University of Eastern Finland, Kuopio, Finland*

Access to the personal health information and knowledge related to personal conditions and situations promotes citizens' interest of wellbeing and promotes personal empowerment in managing personal information and wellbeing. When developing health and wellbeing systems for individuals we have to make design decisions which are justified by the needs of the individuals. We use an activity-driven approach in information analysis to ensure that individuals' real needs will be taken into account to define the information architecture that works as a tool for the design decisions. In this study we present the activity-driven information analysis aiming at the information architecture of personal health and wellbeing systems. As results we 1) analyse individuals' information management needs in their everyday life activities; 2) present a reference model for personal information analysis; 3) produce a framework for designing the information architecture for personal information management.

Design preferences and characteristics of a website for monitoring HIV medication adherence in Peru

Walter H. Curioso[a,b], Kristen Heitzinger[a], D. Alex Quistberg[a], Robinson Cabello[c], Ernesto Gozzer[b], Patricia J. Garcia[b], Ann E. Kurth[a], Wanda Pratt[a]

[a] *University of Washington, Seattle, USA*
[b] *Universidad Peruana Cayetano Heredia, Lima, Peru*
[c] *Via Libre, Lima, Peru*

The objective of this paper is to document design preferences and characteristics of a website monitoring the HIV medication adherence of people living with HIV/AIDS (PLWHA). The website is part of an mHealth solution that combines the use of short messaging services and the Internet to improve adherence to antiretroviral therapy. We conducted a qualitative study with adult PLWHA in a community-based clinic in Lima, Peru using focus groups. 26 HIV-positive individuals participated in four focus groups (20 men, 6 women). The participants reacted positively to the website and specified that they wanted the website to be confidential, socially interactive and easy to use). It was also important to participants that the website contain a motivational pet or character. There was no clear consensus on the aesthetic features of the website. This study suggests that PLWHA in this setting desire a confidential, easy-to-use, socially interactive website with animated characters to assist both their health care providers and themselves in monitoring their HIV medication adherence.

A Content Analysis of Information Exchange in an Arial Fibrillation Online Support Group

Natalia Lapshina, Paul J. Stozhkov, Joseph Finkelstein

Chronic Disease Informatics Program, Johns Hopkins University, Baltimore, MD

Atrial fibrillation (AF) affects about 2.3 million Americans, and increases the risk of embolic stroke by about 4-5 times. The goal of the present study was to analyze content of messages exchanged between participants in an online AF support group using qualitative methodology in order to identify and classify major topics which are being discussed by the group participants. Using Grounded Theory, we conducted a content analysis of 626 messages, which were grouped into seven categories. We described the content of messages in each category. In addition, proportion of initial posts and responses to them was analyzed depending on message category. Practical implications of qualitative analysis of messages posted on an online support group are discussed.

"Safer at Home" – Technology supported coordination & cooperation

Tom Pape, Åge Hestetreet

Lovisenberg Diakonale Sykehus AS, Oslo, Norway

"Safer at home" is a pilot project between Lovisenberg Diakonale Sykehus and 4 (of 15) local district administrations and the Agency for Nursing Homes in the City of Oslo. The objective is to investigate if and how information technology can improve the coordination between the hospital and the four districts and/or nursing homes – resulting in a better and more integrated health care for the individual patient.

Patient Involvement in a Software Development Project - Developing an Electronic Diary for Patients Suffering Extreme Obesity

Sturla Rising

Vestfold Hospital Trust, Clinic for Physical Medicine and Rehabilitation

Lifestyle diseases, such as obesity and its coherent complications, are a growing problem in the Western world. The combination of lifestyle related morbidity and an aging population will contribute significantly to widen the gap between healthcare resource availability and needs in most countries. In design – including that of software - user driven or participatory design methods of innovation have been promising when it comes to developing better products. Throughout this project, patients are used as resources in all steps of the interaction process that is involved in developing an electronic diary. The purpose is to investigate whether patients need special treatment during the process.

Web-based Individual Plan in Norway: An opportunity for improved cooperation?

Jorunn Bjerkan[a], Ragnhild Hellesø[b]

[a] *Norwegian Centre of Electronic Health Records (NSEP), Faculty of Medicine, Norwegian University of Science and Technology,*
[b] *Faculty of Medicine, Institute of Health and Society, University of Oslo*

"Individual Plan" (IP) is an approach to organizing multidisciplinary care in Norway. A web based tool, SamPro, is designed for supporting this planning. In a qualitative study we explored the challenges and opportunities that a web-based tool for IPs offers to patients and professionals in their collaborative care teams. Patients expressed they become empowered through communication and documentation possibilities. Plan coordinators experienced an improved overview in the plans. Being a system super user became an additional task for them. Other professionals involved in the groups did seldom collaborate and document through the system. They reported technical problems and insecurity more often.

Participatory Design of a Physical Activity Intervention for Latino Adolescents Using Facebook

Suzanne Bakken[a,b], Sunmoo Yoon[a], Olivia Velez[a], Po-Yin Yen[a], Daniel Stein[b]

[a]*School of Nursing, Columbia University, New York, N, USA*
[b]*Department of Biomedical Informatics, Columbia University, New York, NY,USA*

Persuasive technologies are interactive computing systems designed to intentionally change attitudes and/or behaviors. Little is known about the efficacy of harnessing such technologies to promote health among at-risk adolescents. We conceptualized Facebook, an innovative social utility used by more than 200 million people, as a "palette" for the delivery of multi-faceted, theoretically-based, and culturally and linguistically appropriate health promotion strategies. We are designing a Facebook application that will embrace the functional triad (tool, social actor, and medium) of roles for computing technology toward the goal of promoting activity. Persuasive strategies will target motivation for physical activity, perceived competence for exercising regularly, and perceived enjoyment of physical activity. During a summer education program, nine Latino adolescents participated in sessions to create preliminary designs and functional specifications for three components of the proposed application: physical activity mash-up, goal setting and activity monitoring, and reward/award structures.

Pioneering Territory-Wide Sharing of Radiological Examination Results in Hong Kong

MC Wong[a], J Tan[a], WN Wong[a], CHA Sek[a], KYJ Chan[a], NT Cheung[a], WMA Cheung[b], KWA Lam[b], WTW Chan[b]

[a] *Health Informatics, Hong Kong Hospital Authority*
[b] *Information Technology, Hong Kong Hospital Authority*

Under a Public-Private Interface (PPI) initiative, a pilot project was implemented to examine the feasibility of diverting patients to private healthcare providers to conduct radiological examinations, which enables prompter clinical care. Radiological examination results taken in private healthcare providers are electronically transferred to Hong Kong Hospital Authority (HKHA), the public healthcare provider in the territory, where the patients originally sought care. These results are further incorporated by HKHA IT infrastructure and be combined with the Authority's patient-based, longitudinal medical record. In this way patients are given more flexibility while selecting public or private radiology investigation services and prompter clinical decision can be made. This directly improves the quality and safety of patient care.

Radiological examination, Private-public interface, Patient care, Electronic patient record

An automated System for Brain Tumor Detection from MR Images

Qurat-ul-Ain[a], Sidra Batool Kazmi[a], M. Arfan Jaffar[a,b]

[a] *Department of Computer Science, FAST National University of Computer and Emerging Sciences, A.K. Brohi Road, H-11/4, Islamabad,*
[b]*Next Generation Intelligent Networks Research Center (nexGIN RC) FAST-NUCES Islamabad*

Radiologists carefully look into medical images, and diagnose a patient's disease by obtaining useful information and interpreting medical images with their experience, knowledge, and wisdom. Brain tumor identification is a crucial and complicated job for radiologist. Brain tumor identification form MR images consist of several stages. Segmentation is considered as an essential step in medical image analysis and classification. Manual brain MR images segmentation is a difficult task. Radiologist and other medical experts spend plenty of time for manually segmenting brain MR images and this is non-repeatable task. Therefore automatic segmentation of brain MR images is needed for accurately segmenting White Matter (WM), Gray Matter (GM) and Cerebrospinal Fluid (CSF) tissues of brain and performing this segmentation within short span of time. This is a very critical issue because wrong identification can lead to severe results. Major objectives of our system are following: 1) Classify the brain MR image as normal or abnormal accurately. 2) Perform segmentation within short span of time. 3) Provide a system to radiologist a system which is self explanatory and easy to operate 4) Enable the radiologist to accurately identify the region of tumor in MR image.

Automatic Threshold Measuring in Mammographic Density Screening

TaeHwa Han[a], EungJik Lee[b], JaiKuen Kim[c], RaeWoong Park[a]

[a] *Department of Medical Informatics, School of Medicine, Ajou University, Korea*
[b] *Seoul National University Alumni Hospital, Korea*
[c] *Department of Diagnostic Radiology, Ajou University Hospital, Korea*

This paper proposes an improving approach to quantitative classification of mammographic image density. Since the mid-1980s, some of studies have shown a moderate to strong statistically significant association between percent breast density and breast cancer risk. We propose the use of agglomerative hierarchical clustering which means an automatic decision of the threshold of segmentation. Current quantitative methods have some problems such as an automatic decision of threshold, lower percent breast density in digital mammograms and limitation of the brightness or pixel depth in 2D mammography, accordingly proposed method may have a role in routine mammographic analysis for the purpose of automatic decision of threshold.

Keywords:
Mammographic density, Breast density, Agglomerative hierarchical clustering, Threshold.

A Tool for the Evaluation of 3D Kinematics of Newborns at Risk

Dominik Karch[a], Keun-Sun Kim[b], Katarzyna Wochner[b], Joachim Pietz[b], M. Hadders-Algra[c], Heike Philippi[d], Hartmut Dickhaus[a]

[c] *Institute of Developmental Neurology, University Medical Center Groningen, Netherlands*
[d] *Center of Developmental Medicine, Frankfurt, Germany*

Quantitative analysis can help to improve the comprehension of human movements and their underlying control mechanisms. Furthermore it has been shown that certain characteristic movements are an indicator for the status of the central nervous system of newborns. This article introduces a tool which enables a detailed visualization and quantification of infant movements. Movements recorded with an electromagnetic tracking system can be transformed in order to reveal subtle movement features. The presented tool can be used to acquire a better understanding of infant movements and identify prognostic markers for neurologic impairments.

Evolution of Nanomedicine, Bioinformatics and Grid computing in medical bibliographic databases

Adrián Gómez, Sonia Benítez, Paula Otero, Maria Smith, Analía Baum, Daniel Luna, Fernán González Bernaldo de Quirós

Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Medical advances have experienced progress due to the emergence of Nanomedicine and Human Genome Project gave another vision to the Bioinformatics field. As data grows exponentially, Grid Technologies are needed to manage this kind of data. The objective of this study is to describe how these disciplines are represented in Medline. A search of text words was performed and each category results were analyzed. There is an accurate representation of Nanomedicine and Bioinformatics, in contrast of the lack of adequate representation of Grid computing in Medline. The objective of this study is to describe how Nanomedicine, Bioinformatics and Grid Computing are represented in Medline

A Sensor Enabled Smart Space for Health Research

Anthony Maeder and Simeon Simoff

School of Computing and Mathematics, University of Western Sydney, Campbelltown, Australia

The Smart Space research facility described here provides a laboratory environment for investigating technology-oriented aspects of new models of health care for out-of-hospital settings. It provides an instrumented, configurable space for simulating, modelling, observing and measuring health care activities using various new information and communications technologies (ICT). This environment allows a wide range of subjective and observational studies to be performed in tandem with gathering quantitative experimental results, using wearable ambulatory devices and embedded sensors. This is intended to help develop and improve new health care processes, allow benchmarking and evaluation of alternatives, facilitate collaboration between technology and health experts, and assure ongoing continuity of related research via e-Science mechanisms.

Enabling the Health Internet - Market-Friendly Information Extraction of Online Healthcare Sources

Christan Grant[a], Tyrone Grandison[b], Alfredo Alba[b]

[a] *Database Research Center, Computer & Information Science & Engineering Department, Univ. of Florida, Gainesville, FL, USA.*
[b] *Healthcare Informatics, IBM Almaden Research Center, San Jose, CA, USA*

The Health Internet is the future of American healthcare. It is the patient-facing system with information about you and your condition. Admittedly, the vision of the Health Internet is evolving as this paper is being written and many aspects of it will no doubt change within the next few months. However, there are several things that will remain constant. The primary one being that the Health Internet will be a portal that integrates data from many different online sources. Unfortunately, current techniques for acquiring this information from these sources may have significant negative effects. In order to support the continued creation of novel healthcare applications (like the Health Internet), we define a process to ensure best practices for both Web publishers and end users. These techniques allow for continued innovation while respecting the source's terms and conditions. In turn, all parties involve will avoid a dramatic decline in both traffic and revenue, while enabling the integration of health information for the greater good – the patient's wellness.

Use of Widget Technology to Rapidly Disseminate Medical and Treatment Information Directly to Health Workers' Computer Desktops and PDAs

Paul Galatowitsch[a], Antonio Urbina[a], Marko Andrus[b]

[a]*Division of HIV Medicine, HIV/AIDS Education and Traininings, St. Vincent Catholic Medical Center*
[b]*Streamedtech, New York, NY*

To assess the long term utility of using widget technology to disseminate instructional material on New York State Guidelines for post exposure prophylaxis (PEP) for HIV, the diagnosis and management of Acute HIV Infection (AHI), and implementing HIV testing in clinic settings. St. Vincent Medical Centers (SVH) in New York City, created an AIDS Widget application (AWA) to stream instructional data directly to providers' computer desktops via a Widget application. Users download AWA from a central website www.ceitraining.org. Results indicate that the innovative use of Widget technology may have substantial application for delivery of crucial health instruction/information and technology.

Collaborative international research on biomaterial in the age of Web 2.0

Martin Lablans, Frank Ückert

Department of Medical Informatics and Biomathematics, University Hospital of Münster, Germany

We propose a research infrastructure allowing participating biobanks and partners to manage, annotate and exchange sample stock among each other. Descriptive attributes are maintained utilizing a set of categorized annotations dynamically expandable by the users using Web 2.0-inspired techniques, thus covering any of the otherwise isolated individual and specialized annotation sets. A free, modular open-source client will allow to manage sample stock as well as to contribute to the infrastructure. The client can be used on multiple machines by several users simultaneously. Rights management allows delegating tasks, and automatic import of existing data is supported as well as secure online backup. The presented system will connect researchers from different fields of research by uniting their isolated and fragmented data and sample stock in a comprehensive, user-centric database to the benefit of international research and the patients.

Mobile Clinical Assistant in Hospital Information System (HIS) Environment: Are We Ready?

Nor Bizura Abdul Hamid[a], Datin S. Selvaraju[a], Siti Haslinda Mohd Din[a], Tilak Kola[b]

[a] *Planning & Development Division, Ministry of Health Malaysia*
[b] *iSOFT, An IBA Health Group Company*

Mobile Clinical Assistant (MCA) provides real time data entry for the clinicians and nurses in HIS environment. Observation showed that in an IT hospital, doctors and nurses tend to transcribe data on to a piece of paper and then keyed in the data into the system at their own convenience. This situation will jeopardize patient safety and defeat the purpose of ICT in improving patient care. To improve efficiency of nursing care, a pilot project on the use of mobile clinical assistant (MCA) was conducted in Serdang Hospital, Malaysia one of the hospitals with total hospital information system (THIS). The efficiency of nursing care was determined by measuring data latency before and after the implementation of MCA. The acceptance level of adopting MCA was also measured. The results showed that MCA did improved the efficiency of real time clerking for nursing care, however the acceptance level of adopting the technology is generally lower than expected.

Blackberry eLearning Platform for Interactive Patient Education

Jeffrey Wood, Eunme Cha, Joseph Finkelstein

Johns Hopkins University School of Medicine, Baltimore, MD

Cell phones can potentially serve as a powerful health communication channel. However, the value of cell phones for interactive patient education has not been studied systematically. We developed an interactive patient learning system for use on Blackberry devices to educate health consumers about hypertension and to enforce knowledge retention by questioning the user. The system uses the Blackberry's internet connection to retrieve hypertension information from a knowledge database and is guided by adult learning theories. Multimedia hypertension curriculum is delivered in an interactive format. The application was successfully implemented and tested on the BlackBerry 7100i smartphone with Nextel as a service provider. A feasibility evaluation demonstrated high acceptance by potential health consumers and statistically significant increase in hypertension knowledge score after using the mobile education platform.

Technical Feasibility Study of 3G Stroke Consultation

Mark Beattie[a], Paul McCullagh[a], Pat Lundy[a], Michael Power[b], Pauline Glenfield[c]

[a] *School of Computing and Mathematics, University of Ulster, United Kingdom*
[b] *Department Geriatric Medicine, Ulster Hospital*
[c] *Stroke Community Team, South Eastern Hospitals Trust*

The study assesses the potential for enhanced community based tele-consultation for stroke patients in the South Eastern Trust area of Northern Ireland. We have used a tele-consultation approach, which can be utilized by a health professional in conjunction with a scheduled home visit. It provides a synchronous telecommunications link to a consultant neurologist located in the main hospital. Third generation telephony (3G) provides wireless connectivity at 'mid-broadband' data rates (128-500kbps), and these services are becoming available in parts of the North Down peninsula. The technical feasibility study has shown that clinical tele-consultations for stroke follow-up is feasible given 3G duplex data rates of 500kbps. Lower rates 200-500kbps can sustain calls, albeit at poorer quality. Services are available in the larger population centres, less so in the more rural areas.

GALILEO: An Integrated Cardiology Teleconsultation System in Chile

Francisco Albornoz[a], Jaime de los Hoyos[b], Maurizio Mattoli[c]

[a] *Director of Interventional Cardiology, Hospital Las Higueras, Talcahuano, Chile*
[b] *Biomedical Informatics Career Director, Instituto Profesional DuocUC, Santiago, Chile*
[c] *Biomedical Informatics Academic, Instituto Profesional DuocUC, Santiago, Chile*

Timely evaluation of cardiologic patients by a specialist can be vital for their prognosis and outcome; in the Chilean public health context, high demand, lack of specialists and centralized imaging tests often result in waiting lists and delayed cardiologist assessment and intervention. GALILEO, a teleconsultation, teleimaging and tele-EKG platform has been in use since October 2008 in Chile's Bío-bío region, and has shown potential for significant reduction of time on patient referral to cardiologist response, reduction of patients' waiting lists for specialist assessment, overall positive impact on patient management and better use of the limited specialist time available versus the traditional patient referral system. This work's objective is to demonstrate these advantages.

Providing Easy Access to Visualization for Biomedical Research

Mathias Kaspar[a], Benjamin Loehnhardt[a], Nick Kepper[b], Dagmar Krefting[c]

[a] *Department of Medical Informatics, University Medical Center, Goettingen, Germany*
[b] *Genome Organization & Function, Bioquant and German Cancer Research Center, Heidelberg, Germany*
[c] *Department of Medical Informatics, Charité University Medical Center, Berlin, Germany*

With the MediGRID a Grid Computing Infrastructure for the German biomedical community was deployed as part of the German Grid Infrastructure D-Grid. Currently this foundation is used to build up an additional countrywide visualization infrastructure for biomedical researchers. Therefore three new visualization clusters were installed in 2009 to extend the MediGRID infrastructure. It is possible to use the clusters in different ways in response to the demands. By using an integrated and already deployed solution, researchers do not need to spend time and money to build up own systems. Further the communication between two or more professionals can be improved by shared visualizations. The sites are now working on standardized ways to utilize this infrastructure to reduce the threshold for naïve research users. The poster describes the architecture and functionality of this infrastructure.

Acquiring and analyzing epileptic seizure motion data – technical considerations

Samrend Saboor[a], Eva Schulc[b], Elske Ammenwerth[a], Fritz Hanser[c], Iris Unterberger[d], Christa Them[b]

[a] *Institute for Health Information Systems, UMIT – Univ. Health Sciences, Medical Informatics and Technology, Hall in Tyrol, Austria*
[b] *Institute for Nursing Sciences, UMIT, Hall in Tyrol, Austria*
[c] *Institute for Electrical, Electronic and Bioengineering, UMIT, Hall in Tyrol, Austria*
[d] *Department of Neurology at the University Hospital, Innsbruck, Austria*

Introduction: Epilepsy is one of the most chronic diseases. Sudden seizures cause the total loss of body control and result in a decreased quality of life. These seizures also impose a high risk of partly severe injuries. In order to detect any epileptic seizures, it is imperative to continuously monitor the patients. Current possibilities (e.g. combined video and electroencephalogram monitoring) are reliable but limited to stationary, short term observation. Thus, wearable systems with automated seizure-detection are needed. Here, accelerometer-based motion sensors seem promising. For the development of the required detection-algorithm, motion data of real epileptic seizures must be acquired and analyzed. Aim: This contribution describes the development of a comprehensive system for the acquisition and analysis of epileptic seizure motion data. Method: Requirements for system development were collected by combining literature review and qualitative expert interviews. The system development mainly applies open-source solutions. Results: A concise list of requirements for the acquisition of motion data. An easily usable data acquisition interface. A graphical analysis system that comprises mathematical processing functions. Conclusion: The developed systems help acquiring characteristic motion features of epileptic seizures that are essential for detection algorithms.

Mobile Learning Object in Advanced Cardiac Life Support: an application of a persuasive technology in nursing

Grace Dal Sasso[a], M. Sriram Iyengar[b], Cynthia Phelps[b]

[a] *Nursing Department and Nursing Informatics, Federal University of Santa Catarina, Florianópolis, SC – Brasil*
[b] *School of Health Informatics Sciences, UTHSC, Houston, USA*

The mobile learning stands out as a great chance to become the most used mean for learning, since the affording cost of the mobile devices is much lower than the cost of a computer. The research on m-learning must consider the importance of the student's mobility and learning not only on the technology. The aim of this study is to investigate the effect on the Nursing students´ learning through the application of the mobile learning object in CPR – ACLS with Guideview® program and the task load over the nursing students during the simulation in mannequin. The use of a cellular phone with the Guidevie® program in order to back up the nurse's decision during the Cardiac Respiratory Resuscitation service, has shown itself statistically significant related to the control group that used printer paper during the process. Therefore, besides acting as a learning support, the program can be comprehended as a procedure which is incorporated to the service in a persuasive way.

Standardizing Inter-Institution Care via Ontologically-Modelled Clinical Pathways

Syed Sibte Raza Abidi, Samina Raza Abidi, Ali Daniyal

NICHE Research Group, Faculty of Computer Science, Dalhousie University, Halifax, Canada

In this paper we pursue the standardization of care for a specific condition across multiple institutions. Our approach is to represent institution-specific Clinical Pathways (CP) using an ontological model and then aligning the common care activities between multiple CP, based on their semantic descriptions, to generate a standardized care model. We developed an execution engine that transforms the ontological standardized care model to a state-graph that can be executed with patient data and practitioner input at the point-of-care.

A Regional Guideline System for 40.000 Users – The Importance of User Participation and Management Commitment.

Knut Bernstein

MEDIQ, Medical Informatics and Quality Development, Copenhagen, Denmark

As a part of the regional quality strategy and as a prerequisite for accreditation in hospitals, the Capital Region in Denmark will implement a new system for providing easy access to valid, coherent and updated policies, guidelines and protocols. The implementation of such a system is mainly an organisational challenge. This paper highlights the importance of user participation and management commitment when developing a specification for an electronic guideline system. The main functionality of the required system is also described.

Ontology Modeling for Handling Co-Morbidities in Decision Support Systems

Samina R. Abidi[a], Jafna Cox[b], Jonathan Howlett[c], Michael Shepherd[a]

[a] *Faculty of Computer Science, Dalhousie University, Halifax, Canada*
[b] *Division of Cardiology, Dalhousie University, Halifax, Canada*
[c] *Department of Cardiac Sciences, University of Calgary, Canada*

This poster present a decision support framework for ontology based handling of clinical pathways (CP) of co-morbid Chronic Heart Failure (CHF) and Atrial Fibrillation (AF). Our knowledge management (KM) approach for synchronization of co-morbid clinical processes include; (i) knowledge synthesis-selection, interpretation, and augmentation of statements, logic and temporal relations within and across CHF and AF clinical practice guidelines (CPGs) to create CPs (ii) CP knowledge formalization-using semantically rich OWL constructs to unambiguously model implicit functional and temporal relations between concepts (iii) formalizing functional relations between care processes by defining co-morbid care plans to be executed in response to preconditions derived from both CHF and AF CPs (iv) execution of ontology in a clinical decision support system, named COMET, that after identifying a co-morbid incident can recommend appropriate care plans along with relevant information and protective measures to ensure patient safety.

Development of a Guideline-Based Decision Support System Prototype for Collaborative Primary Healthcare

Haifeng Liu, Jing Mei, Guo Tong Xie, Yue Pan, Jia Jia Wen, Zhi Guo Gao, Xin Ruo Sun, Xiang Ru Chen

IBM Research – China

Delivering effective and efficient primary healthcare services is crucial as it requires knowledgeable physicians who treat a wide range of diseases and periodical monitoring of patients. We propose to make the task easier by the collaboration of a guideline-based decision support system and a mobile communication platform through which the monitored patient data could be processed instantly. In particular, we focus on the demonstration of executing guidelines for long-lasting care process using a standard-based business process engine. As a result, we have implemented a system prototype which proves the effectiveness of our approach by running an exemplary guideline.

Clinical workflow and practice-based evidence

Mark Olive and Tony Solomonides

Bristol Institute of Technology, University of the West of England, Bristol, UK

Integrated care pathways (ICPs), a fine-grained form of medical guideline including the explicit recording of any deviation, have been perceived as overly prescriptive, limiting clinical freedom and promoting cookbook medicine. However, feeding the results of the analysis of 'variance' into the development of pathways could be an effective way of capturing evidence from practice. This paper is a summary of our research into the development and use of ICPs, and their research potential.

Web Catalogue of Electronically Published Clinical Practice Guidelines in the Czech Republic

Miroslav Zvolsky, Jana Zvarova

Centre of Biomedical Informatics, Institute of Computer Science, Academy of Sciences of the Czech Republic, Pod Vodarenskou vezi 2, 182 07 Prague 8

As a preliminary collector of information for decision support systems and due to the absence of web tools and services for clinical practice guidelines organization and searching in the Czech Republic the prototype of a specialized online catalogue was developed. The database allows the collection of 34 parameters for each document. Nowadays this web service includes information about more than 250 documents of clinical practice guidelines published electronically by Czech medical societies.

Towards Seperation of Medical and Workflow Knowledge in Modeling Clinical Guidelines: A Semantic Web based Framework for Executing Clinical Guidelines

Ali Daniyal, Syed Sibte Raza Abidi, Shirin Sharif, Ali Haider Zaidi

NICHE Research Group, Faculty of Computer Science, Dalhousie University, Halifax, Canada

We present a semantic web based framework for modeling and executing Clinical Practice Guidelines (CPG). Our modeling of CPG distinguishes between the medical and workflow knowledge inherent within a CPG. We have developed two OWL-based ontologies—a CPG ontology that models the medial knowledge, and a Clinical Workflow ontology that models the CPG's execution logic using UML Activity Diagrams and OWL-S. We have developed a CPG execution engine based on Place Transition Nets that allows both the verification of a modeled CPG and its execution at the point-of-care.

Correspondence between Guidelines for Antibiotic Treatment and Microbiological Outcome – Analysis of Cases of Pneumonia in the Swedish Intensive Care Registry

G Fransson[a], H Ahlfeldt[a], H Gill[a], S Walther[b], H Hanberger[c]

[a] *Dept of Biomedical Engineering, Medical informatics, Linkoping University, Sweden*
[b] *Dept of Medical and Health Sciences, Linkoping University, Sweden*
[c] *Dept of Clinical and Experimental Medicine, Linkoping University, Sweden*

To treat severe pneumonia needing intensive care you must have guidelines for what antibiotic to use based on knowledge of local antibiograms. The objective of this study was to compare national guidelines for pneumonia with antibiograms from ICU patients with pneumonia. Data from the Swedish national registry of intensive care have been used to set up a model for this comparison. Primary diagnosis of pneumonia was divided in two groups – hospital and community acquired respectively – by route of admission. In community acquired pneumonia we found a failure rate of 6 and 10 % for the two recommended treatment regimes respectively according to antibiogram. In hospital acquired pneumonia the rate of failure was 3 and 5 %. Since patterns of antibiotic resistance change over time it is very important to update guidelines on a regular basis. This method contributes to do such updates based on clinical outcome. To improve this method further there is a need for standardized terminologies and information models for semantic interoperability between clinical and laboratory information systems.

Unanticipated consequences of hospital-based insulin management improvement program

Joseph Finkelstein, Sherita Hill Golden, Joanne Dintzis, Eunme Cha, Miguel Munoz

Johns Hopkins University, School of Medicine, Baltimore, Maryland, USA

Hypo/hyperglycemia is associated with adverse clinical outcomes in the inpatient setting. We introduced a hospital-wide inpatient glucose management program at Johns Hopkins Hospital in January 2006 to facilitate uniform glucose management policies and staff education based on current clinical practice guidelines. During that time, a spectrum of initiatives were implemented to improve hospital-wide glycemic control, including a Hypoglycemia Policy (7/06), a diabetes nursing superuser program (1/07), a Hyperglycemia Policy, and uniform computerized subcutaneous insulin orderset (11/07). After implementation of the program, the frequency of hypoglycemia significantly decreased from 1/1/07 to 12/31/08. In contrast, the frequency of hyperglycemia increased from 1/1/07 to 12/31/07 but then began to decline after 1/1/08, following implementation of a hospital-wide standardized subcutaneous insulin orderset. These data are informative in identifying unanticipated consequences of an insulin management program focused entirely on hypoglycemia. A balanced approach in implementing insulin management guidelines is warranted.

[d] *Nursing Department, Asan Medical Center, Republic of Korea*
[e] *Performance Improvement Office, Asan Medical Center, Republic of Korea*

High-alert medications (HAMs) are associated with serious harmful events. Comprehensive medication safety improving strategy is needed to reduce adverse events related to HAMs, including limitation of access to drugs, standardization of orders, alert system for high doses and critical events, etc. Process analysis with activity diagram and error matrix regarding selected five HAMs was done. Clinical knowledgebase was made by pharmacists, nurses, PI experts, and IT experts. HAMs clinical knowledgebase composed of core message, adverse event type happened, drug interactions, monitoring items, similar drugs information, hospital clinical guidelines, and routine drug information. Prototype of HAMs decision support system was designed to use in computerized physician order entry system. HAM icons, core messages, and alert for overdose services included to this system.

Arden-Syntax-Based Clinical Decision Support Software

Karsten Fehre[a,b], Harald Mandl[b], Klaus-Peter Adlassnig[a,b]

[a] *Section for Medical Expert and Knowledge-Based Systems, Medical University of Vienna, Austria*
[b] *Medexter Healthcare GmbH, Vienna, Austria*

We describe an implemented software architecture for clinical decision support (CDS) based on the Health Level Seven (HL7) Arden Syntax for Medical Logic Systems. Arden Syntax's proven applicability as a medical knowledge representation and inference scheme makes it a good candidate for a service-oriented architecture for CDS systems. We developed a package of Arden-Syntax-based software components including compiler, rule engine, server, an integrated development environment (IDE), and web services for interoperability. We report on a large-scale implementation of this software system, which constituted the platform for an automated cockpit surveillance program for early identification and automated monitoring of hospital-acquired infections at 12 intensive care units (ICUs) serving adult patients, and 3 ICUs for neonatal care at the Vienna General Hospital. The Philips Care Vue intensive care medical information systems installed at the ICUs provide the necessary data. Arden Syntax, the service-oriented architecture, the extended medical knowledge packages, and the developed web-based user interfaces create a powerful tool for CDS at the infection control unit of this hospital.

Forward Chaining Inference vs. Binary Decision Support in an Electronic Health Record Application Based on Archetyped Data

Luciana Tricai Cavalini[a], Sergio Miranda-Freire[b], Timothy Wayne Cook[c]

[a] *Department of Epidemiology and Biostatistics, Fluminense Federal University, Brazil*
[b] *Medical Sciences College, Rio de Janeiro State University, Brazil*
[c] *National Institute of Science and Technology – Medicine Assisted by Scientific Computing, Brazil*

The implementation of computerized health information systems has a potential effectiveness related to the use of decision support engines. Decision engines based on Boolean logic are one of the most prevalent in current implementations, but the complexity of healthcare information does need more robust solutions, especially in fully implemented, semantic-sensitive, electronic health records. The purpose of this paper is to investigate the effects of two common approaches to decision support in Electronic Health Record (EHR) applications. The EHR uses archetyped data based on the multi-level modeling principles initially described in the openEHR specifications which were foundational to the formation of the ISO and CEN 13606 EHR standards. Forward chaining using CLIPS rules was compared to if-then-else constructs in terms of performance and code size. The results showed that forward chaining was much faster and required less coding, besides being more easily to maintain. The accuracy of the forward-chaining engine was 100%, considering the Boolean-based engine as the gold standard. This study confirms the validity of CLIPS-based inference engines for decision support in healthcare.

A View on the Current State of the MedFrame/CADIAG-IV Project

Dieter Kopecky, Klaus-Peter Adlassnig, Thomas Vetterlein

Section for Medical Expert and Knowledge-Based Systems, Medical University of Vienna, Vienna, Austria

CADIAG-IV is a data-driven fuzzy diagnostic expert system for computer-supported consultation in internal medicine based on the PC-based medical expert system shell MedFrame. MedFrame provides a medical institution with a set of powerful tools for developing knowledge bases and inference mechanisms and applying them as expert systems in clinical routine. CADIAG-IV is the first expert system completely based on MedFrame, significantly extending the usage of fuzzy concepts compared to its predecessors CADIAG-II and -III. After the implementation of the MedFrame core components, a high level inference engine for rule-based knowledge bases has been implemented and used for the realization of the CADIAG-II/-III inference process. In addition, the CADIAG-II/RHEUMA knowledge and patient data have been transferred from the original IBM host system to MedFrame. Currently, the realization of the CADIAG-IV inference, the integration of additional MedFrame components, and the implementation of the user interfaces is in progress. The results achieved so far confirm the applicability, correctness, and performance of the MedFrame concept and the CADIAG re-implementation.

A Decision Support System based on Meta-heuristics and MCDA for Healthcare Service and Technology Optimal Location

Gabriella Balestra[a], Chiara Foglietta[a], Laura Gaetano[b]

[a] *Dipartimento di Elettronica, Politecnico di Torino, Italy*
[b] *Dipartimento di Meccanica, Politecnico di Torino, Italy*

Regional managers must often deal with the necessity to correctly distributed healthcare services in their territory. The traditional approach taking into account only political considerations is risky. In order to improve the robustness of the solution it is better to add quantitative and objective information (such as patient numbers, travelling times and travelling distances) to the political criteria that control the decision-making process. In this work, we deal with the problem of choosing the facilities in which new expensive complex devices can be placed in order to improve the health care services offered by a regional health system.

Modelling a tool for evaluation of innovative therapies

Anastasiya Shtiliyanova[a], Fabien Feschet[a], Jean-Yves Boire[a] , Pascal Pommier[b]

[a] *Université d'Auvergne, Faculté de Médecine, Santé Technologie, Clermont-Ferrand, France*
[b] *Centre Léon-Bérard, Département de radiothérapie, Lyon, France*

Health economics are often related to the evaluation of health centres or the cost of innovative treatments, their reimbursement and effectiveness. In this paper we suggest an original model to evaluate a radiotherapy hospital network. Our study is based on informatics modelling and simulation. Its aim is to create a prototype for medical and economic evaluation. We suggest some hypothesis in order to evaluate the recruited population for each centre. Our design takes into account the characteristics of the patient, the description of the centre and the competition between health centres. The economic evaluation includes the cost description of a whole centre: construction investment and functioning. The final goal of our prototype is to compare different situations of recruitment and multiple health politics, referring real situations.

Allergy and cross-allergy medication decision support

Kell Greibe

Connected Digital Health in Denmark, Islands Brygge 39, DK-2300, Copenhagen, Denmark

Checking known allergies when prescribing is mandatory, but time consuming. Few (if any) clinical decision support (CDS) databases contain information on cross-allergy reactions. This new centralized CDS module makes access to allergy as well as cross-allergy alerts available to hospitals. A centralized CDS service based on SNOMED CT allergy structure and a specially developed cross-allergy table is configured to work together. The CDS will respond to automatic web service requests from the hospital electronic medication system (EMS) during prescription and return allergy and cross-allergy information and alerts. The result is clinically useful information physicians can use as a basis for a more effective and safer treatment.

[c] *Depart. of Endocrine Medicine, Asan Medical Center, University of Ulsan College of Medicine, Republic of Korea*

A computerized clinical guideline at the point of care is more efficient than a paper-based clinical guideline. Peri-operative diabetic care monitoring and support system were developed to enhance in-hospital care. It consisted of a computerized peri-operative diabetic blood sugar control guideline and diabetes alert monitoring system. The computerized peri-operative diabetic blood sugar control guideline was developed by diabetic center of Asan Medical Center, based on clinical data and existing paper-based clinical guidelines. The diabetes alert monitoring system was designed to monitor diabetic inpatients related data- hyperglycemia, hypoglycemia, abnormal hemoglobin A1C, inadequate anti-diabetic agents, etc. This system was managed by diabetes alert team in real-time. Effectiveness of this system and impact on improvement of diabetic care need more time.

[a] *Department of Health Informatics, Federal University of São Paulo, Brazil*
[b] *Institute of Computing, UNICAMP, Brazil*

The physical activity as well as exercise, have become allies in the prevention of diseases, especially those of chronic degenerative character. While it is agreed that the practice of physical exercise has a beneficial role for the health of the population, especially for the elderly; the health professional, because of a lack of specific training, has great difficulty to steer and guide their patients to a physical education professional to prescribe exercises that produce real benefits. The aim of this study is to diagnose behavior regarding physical activity, determine the optimal dose of exercise to be prescribed based on evidence, and integrate prescription of physical activity to the patient and medical records. This application, its validation and the evaluation of a new protocol could contribute directly to the prevention of chronic degenerative diseases.

Development of a clinical decision support system for facial growing analysis by the cervical vertebral maturation method

Roberto S. Baptista[a], Josceli M. Tenório[a], Anderson D. Hummel[a], Regina C. Coelho[b], Cesar Augusto C. Caetano[c], Cristina Lucia F. Ortolani[d] , Ivan T. Pisa[a]

[a] *Health Informatics Department, Federal University of São Paulo, Brazil*
[b] *Science and Technology Department, Federal University of São Paulo, Brazil*
[c] *FIAP, São Paulo, Brazil*
[d] *Universidade Paulista, São Paulo, Brazil*

Thinking about prevention and early treatment of dentofacial deformities, which require care, as correct diagnosis and proper planning, determine the stage of skeletal maturation is very important to identify the growth phase of the patient. New Cervical Vertebral Maturation (CVM) method was used as a foundation to build a clinical decision support system (CDSS). One of the advantages of this method is that there is no need for additional x-ray exposure, once the cephalogram is already part of the orthodontic documentation of the patient. This study presents a CDSS under development, that helps the orthodontist determining the optimal timing to treat a series of dentofacial deformities. To build this system, classifiers were evaluated using a open-source software package. A preliminary assessment showed that the CDSS inference engine (IE) presented 81.88% of accuracy, indicating that the CDSS can have better precision, quality and productivity on CVM analysis.

Clinical Decision Support System in Celiac Disease Diagnose

Josceli M. Tenório[a], Roberto S. Baptista[a], Vera L. Sdepanian[b], Ivan T. Pisa[a], Heimar de F. Marin[a]

[a] *Health Informatics Department, Federal University of São Paulo, São Paulo, Brazil*
[b] *Department of Pediatric, Federal University of São Paulo, São Paulo, Brazil*

Diagnosing celiac disease (CD) is a complex task as it has several signs and symptoms common to the other diseases. The gold-standard for CD differentiation is the biopsy analysis of the small intestine. This study aimed at developing and evaluating a web-based clinical decision support system, including an automatic classification tool to recognize cases of CD. The system was designed to be friendly, and useful for CD treatment and follow-up. Phase I of the study concerned the implementation of a web-based system that comprised an electronic form for data collection. This system's usability assessment was carried out using the System Usability Scale (SUS). Phase I made possible the creation of a framework for clinical data recording, as well as the standardization of medical investigation procedures. The mean SUS score of 83.5±10.0 obtained showed the system's high level of usability. The present study is expected to contribute to establishing a computational resource to help CD diagnosing.

A Clinical Decision Support System for Needs-driven Telemedicine Technology Development

MJ Treurnicht[a], Lvan Dyk[a], J Fortuin-Abrahams[b], NF Treurnicht[a], M Blanckenberg[c]

[a] *Department of Industrial and Systems Engineering, Stellenbosch University, South Africa*
[b] *South African Medical Research Council, Tygerberg, South Africa*
[c] *Department of Electrical and Electronic Engineering, Stellenbosch University, South Africa*

A telemedicine workstation was installed as pilot project at the Grabouw CHC in 2004/2005 to enable the communication of diagnostic information between CHCs and hospitals. Part of the eventual suspension of the pilot implementation of the telemedicine workstation at Grabouw CHC could possibly be attributed the fact that the technology-push phase was not preceded by a formal needs assessment. The paper presents the rationale and design behind a Clinical Decision Support System (DSS) to enable in future a needs-driven telemedicine workstation development.

A Comparison of Collaborative Filtering Methods for Medication Reconciliation

Huanian Zheng, Rema Padman, Daniel B. Neill

The H. John Heinz III College, Carnegie Mellon University, Pittsburgh, PA, USA

Maintaining an accurate list of a patient's medications is a very challenging task for which the current solution is a process driven medication reconciliation approach. In this study, we extend our original data driven approach through the use of collaborative filtering algorithms to improve the accuracy of the medication list and test them using medication data from a long-term care clinic. The results are encouraging and suggest several promising directions for the future, including embedding these methods in current medication reconciliation processes and evaluating them in actual clinical settings.

A Decision-support Program for the Analysis of Sexual Maturation – A Novel Approach

Ernesto Succi[a], Flavio Lichtenstein[b], Ivan Torres Pisa[b], Daniel Sigulem[b]

[a]Internal Medicine Department, FCM, Universidade do Estado do Rio de Janeiro, Brazil
[b] Health Informatics Department, Escola Paulista de Medicina, Universidade Federal de São Paulo, Brazil

Introduction: Adolescents represent roughly 21% of the population, constituting a group with low demands for health services, but pubertal development evaluation represents a challenge to primary care physicians (PCP), who provide the first line of medical attention. Objective: Provide non-specialist medical practitioners with information on puberty and sexual maturity, through a user-friendly, knowledge-driven instrument for point-of-service (POS) use. Methodology: develop a Java™-based, decision-making system related to puberty and sexual maturity capable of running on Mac™, GNU Linux and Windows™ OSs. Results: The clinical decision support system (CDSS) comprises a Java™-based inference engine with 127 production rules and graphical user interface. Based on the construction of the knowledge base a 591-entry glossary was generated for user help. Information was evaluated by comparing the results generated by the system and those reported by 9 specialist medical practitioners. The evaluation rendered by specialists and the system was statistically significant by 1% with 77% of the specialists and their respective groups. The user interface was positively evaluated regarding all aspects by 55 physicians. Conclusion: We have collected information on puberty and sexual maturity and used that to develop an CDSS comprised of 127 production rules. The system was evaluated and displayed adequate performance when compared with diagnoses reported by specialist medical practitioners, and its user interface was validated by physicians. Due to the fact this is an open-source, Java™-based system, we believe it is suitable for deployment in the public healthcare system.

Detection of High-Risk Patient for Drug Overdose in Renal Insufficiency

Woojae Kim[a], Ku Sang Kim[b], Hye Jin Kam[a], Man Young Park[a], Duk Yong Yoon[a], Rae Woong Park[a]

[a] *Department of Clinical Informatics, School of Medicine, Ajou University, Suwon, Republic of Korea*
[b] *Department of Surgery, School of Medicine, Ajou University, Suwon, Republic of Korea*

Drug overdose in renal insufficiency is a major source of inpatients morbidity and, even mortality. Traditional drug overdose detection information system requires reference knowledge base (KB). However, KB is hard to build up, and KB maintaining requires much efforts. The purpose of this study is to develop a simple and portable detection algorithm for high-risk patient for drug overdose in renal insufficiency, even without a renal dosing reference KB. The detection model uses support vector machine (SVM) algorithm and requires 7 usual patients' and doctors' information. The model showed 83.81% of accuracy and 0.78 of AUC.

Secondary data usage - driving quality change at point of entry in acute care settings

Simon Burrell, Judith Brett, Ann Bull, Michael Richards

VICNISS Coordinating Centre, Melbourne, Australia

Since 2002, infection prevention consultants (IPC's) in public hospitals in Victoria, Australia, have been collecting healthcare-associated infection (HAI) surveillance data on paper, and have been sending this into the VICNISS Coordinating centre (VCC) for collation, analysis and reporting. Some of these data are retrieved from existing electronic systems while other data has to be gleaned from the paper medical record. The VCC has developed a software application for the participating hospitals, known as SHIINe (Safer Hospitals Integrated Information Network) to facilitate HAI data collection, analysis and reporting. This software links to patient information systems, including the patient master index, theatre lists, and pathology systems. Through this, we hope to achieve more accurate and efficient data collection/input, to save IPC time, facilitate local report generation and achieve more timely, and hence more useful, data feedback. During integration of the SHIINe application into public hospitals, we found significant problems with data quality. These problems were not isolated to any one hospital or database. This finding prompted internal reviews of data entry / quality within these hospitals. Exposing the need for the electronic availability of quality data for secondary usage worked as an effective enabler for hospitals to improve their point of data entry practices. This made an important contribution to ensuring accurate and high quality patient data is recorded in these hospitals for purposes including and beyond HAI surveillance.

Clinical Information Systems – A Universal approach to Structuring the Clinical Artefacts and Elements

Gill Stonham, Sukai Wilkinson

Knowledge and Strategic Alignment, Care Records Service, Connecting for Health, United Kingdom

To develop a patient centric clinical system which has universal application across the full range of Clinical Pathways requires all clinical content artefacts to be uniquely named and structured, such that all elements can be re-used and that the needs of all clinical practitioners are recognised and supported. The key objectives were: 1) Harmonisation of language associated with the different professional groups and care settings, 2) Incorporating existing concepts in use across the NHS, including dependency models and classification schemas, 3) Demonstrating that generic, speciality initiated and disease focused actions could be grouped by pathway milestones along a Clinical Pathway, 4) To enable innovative changes to care delivery models

A Preliminary Assessment of the Clinical Knowledge Management Capabilities of Commercially-available Electronic Health Records

Dean F. Sittig[a], Adam Wright[b], Seth Meltzer[c], Blackford Middleton[c]

[a] *School of Health Information Sciences, University of Texas Health Science Center, Houston, TX*
[b] *Department of Medicine, Brigham & Women's Hospital, Harvard Medical School, Boston, MA*
[c] *Clinical Informatics Research & Development, Partners Healthcare System, Boston, MA*

We undertook a study to explore the availability of various clinical knowledge management features, functions, tools and techniques provided by nine commercially available electronic health record (EHR) vendors serving the U.S.A. marketplace. We developed and fielded a 17-question survey to make these assessments. The survey asked questions about 1) the vendor's electronic health record (EHR) product, 2) the clinical decision support-related system tools and capabilities that each vendor provide, and 3) clinical content. The majority of the systems were capable of performing almost all of the key knowledge management functions we identified. If these well-designed systems are coupled with the other key socio-technical concepts required for safe and effective EHR implementation and use, we expect that the transformation of the healthcare enterprise that so many have predicted, is just around the corner.

Towards an integration of workflows and clinical guidelines

Paolo Terenziani[a], Mauro Torchio[b], Salvatore Femiano[b], Alessio Bottrighi[a], Gianpaolo Molino[b], Stefania Montani[a]

[a]Dept. of Computer Science, Univ. del Piemonte Orientale "Amedeo Avogadro" Via Alessandria, Italy
[b]Az. Ospedaliera S. Giovanni Battista, Torino, Italy

The integration of workflows (WFs) and clinical practice guidelines (CPGs) modeling healthcare processes is a hot topic of research in Medical Informatics. Many computerized approaches have faced this problem, mostly extending current WF or CPG approaches to represent and manage integrated models which merge the content of both CPGs and WFs. We devised a case study, showing that there are many differences between CPGs and WFs as regards contents, focus, goals, users and editors. On the basis of such an analysis, we propose a different approach to integration. Our approach reconciles (i) the need of performing inferences on the integration of WK and CPG knowledge, with the users' requirements (ii) to focus only with the aspects of knowledge they are interested in, and (iii) to have a user-friendly representation of such a knowledge.

Unlocking Medical Archives with Multi-Modal Content to Deliver Enhanced Analytics

Karen Brannon, Sangeeta Doraiswamy, Tyrone Grandison

Health Informatics Group, IBM Almaden Research Center, San Jose, California

A large number of healthcare institutions have significant stores of medical archives in their data centers, archive rooms and virtual records centers. Unfortunately, these archives are often kept only for administrative and or legal reasons and are not leveraged to enable differential diagnosis or operation efficiency. The traditional focus by academia and industry on analytics of textual data stored in databases, content management systems and the Web must also be augmented to handle multi-modal data that is prevalent in medical archives. We present technology that allows the extraction of the informational value derived from analyzing these multi-modal archives and the integration of this value into the healthcare entity's core decision support and research systems, in order to improve the entity's analytic capabilities.

Collaborative and Distributed Guideline Modeling in the Dementia Domain: An Evaluation Study of ACKTUS

Helena Lindgren, Peter Winnberg

Department of Computing Science, Umeå University, Umeå, Sweden

The task of transforming informal knowledge residing in individual experts and in domain knowledge sources to formal structures in clinical decision-support systems (CDSS) is addressed in this work. The system ACKTUS is currently being developed for informing the design of the user interface of a web-based CDSS for dementia care, and for functioning as a tool for development and updating of the integrated knowledge in an international collaborative setting [1].

From Knowledge Management to Translational Research by Combining Clinical and Experimental Data with Public Available Knowledge for Breast Cancer Research

Andreas Dander[a], Ralf Gallasch[a], Werner Hackl[a,b], Heidelinde Fiegl[c], and Armin Graber[a]

[a] *Institute for Bioinformatics and Translational Research, UMIT, Hall in Tirol, Austria,*
[b] *Institute for Health Information Systems, UMIT, Hall in Tirol, Austria,*
[c] *Department of Gynecology and Obstetrics, Innsbruck Medical University, Innsbruck, Austria*

Breast cancer therapy is confronted with the problem, that after surgical treatment and adjuvant therapy metastases occur in nearly 20% of patients independently of the lymph node status. The prognostic and predictive factors available allow prediction of recurrence with only moderate accuracy. This results in the fact, that the major proportion of patients gets adjuvant therapy of different kind although only a minority needs it. To predict metastasis risk we want to identify a risk pattern consisting of different biomarkers of postmenopausal breast cancer patients. Additionally data from public databases and knowledge from MEDLINE is combined with the experimental data in the BioXM platform.

[d] *National Medical Library, Prague, Czech Republic*

Algorithms and recommended guidelines are one of the traditional tools for representation of knowledge in biomedicine. Using retrospective analysis of algorithms represented in medical literature and transformed into computer applications, we constructed a domain ontology of medical algorithms. This ontology is based on a phenomenological description of data processed by algorithms as indicators, which are transformed into other indicators.

Metadata for clinical knowledge resources

Gunnar O Klein

Dept of Microbiology, Tumour and Cell Biology, Karolinska Institutet, Stockholm, Sweden

Both health professionals and patients/citizen today firstly turn to the world wide web to obtain health related knowledge. Important issues are: 1) How to find relevant documents that are appropriate for the reader and situation and 2) How to ensure that the found knowledge documents have a sufficient or at least declared quality control process? One way to address these questions is to use a standard set of metadata to be provided for each knowledge resource. A standard first developed in Europe CEN/TS 15699 is further developed into ISO 13119. In this paper the following questions are raised: 1) What are the possible uses of a standardised set of metadata for knowledge resources in health? and 2) What are the basic principles of the new standard

Specialist Bayesian Pediatric Anthropometric System

Eduardo Adratt, Claudia M. C. Moro, João Dias

Health Technology Post Graduate Program – PPGTS /PUCPR Curitiba - PR, Brazil

Monitorng growth is an important resource for evaluating the health of individuals and society. However, many Brazilian children are cared for by doctors who have not been trained as pediatricians. This study deals with the proposal and validation of a decision making support system to assist doctors who are not pediatricians to interpret anthropometric and graphic growth data, assisting them to carry out procedures relating to patient investigation, referral and follow-up. The system used a Bayesian network.. Validation compared the performance of the system, as well as the performance of general practitioners and pediatricians in relation to a gold standard developed by specialists. The overall sensitivity of the system was 84.5% whereas that of the pediatricians was 55.1% and that of the general practitioners was 46.5%. Specificity was 78.2%, being very close to that of the other groups. The system showed itself to be statistically valid for implementation in public health services, its performance enabling it to be used not only by general practitioners but also by pediatricians.

Understanding Cognitive Artifacts: The Criticality of Multi-Method Study

Sharon McLane[a], James P. Turley[b], Adol Esquivel[c]

[a]*Lakeland Regional Medical Center, Lakeland, FL, USA*
[b]*School of Health Information Sciences, The University of Texas Health Science Center at Houston, TX, USA*
[c]*Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX, USA*

Cognitive artifacts are evidence of user knowledge and information needs. Cognitive artifacts have embedded clues to how they support the cognitive work of users. Developers often convert frequently used cognitive artifacts to IT applications. Before development of these applications, the purpose, value, use, and meaning of the cognitive artifact must be fully understood. Absent this understanding, these applications may increase the cognitive load of healthcare practitioners (HCP), increasing patient safety risks. Multi-method study of cognitive artifacts promotes a thorough understanding of how they support working memory, cognition, and critical thinking. This poster describes the iterative value of multiple methods to gain a robust understanding of personal clinical cognitive artifacts (PCCAT) prepared and used by nurses.

Appliance of a Agile Pattern Language Framework for Harmonizing the Intercommunication of Research Results in the eHealth Domain

Alexander Mertens, Philipp Przybysz, Diana Hermanns

Chair and Institute for Industrial Engineering and Ergonomics of RWTH Aachen University, Germany

This article presents an approach for arranging, allocating and interchanging the gain in knowledge and experience during projects of the eHealth sector and related domains. The know-how is transcribed into design-patterns, whose concept has proven its effectiveness in versatile areas. A framework for specifying the pattern-structure that meets the specific requirements of the medical domain is defined.

[c] *Faculty of Dentistry, Rennes, France*

Computer assisted diagnosis systems are required to improve diagnosis and compliance with clinical guidelines. Expert systems have shown their limitations as they are difficult to maintain, to check consistency and to update knowledge. Current ontology editors like PROTÉGÉ and associated tools enable easy building and maintainance of knowledge bases and allow automated consistency checking with reasoners as Pellet. Can these tools be used for computer assisted diagnosis? This study aims at creating an ontology of dental emergencies and evaluate diagnostic classification possibilities of current generic reasoning tools.

A Framework for Integration of Data from new Technologies into the Clinical Workplace

Murat Gök[a], Gunnar Nußbeck[a], Otto Rienhoff[b]

[a] *Personalized Health Monitoring-Ethics Project, University Medical Center, Goettingen, Germany*
[b] *Department of Medical Informatics, University Medical Center, Goettingen, Germany*

New technological developments, methods, and therapy procedures in health care lead to an overwhelming flood of individualized data. This huge amount of data needs to be faced at each encounter. A framework was developed to analyze the effects of the multilayer aspects of the information overload from new technologies even before these will be applied in practice to the patient physician communication in shared decision making processes. This framework is visually integrated into the hospital information system at the University Medical Center Goettingen.

Use of Fuzzy Logic in Quality Indicators and Applicability to the Arden Syntax

Robert A. Jenders

University of California, Los Angeles, USA

Background: Fuzzy logic constructs have been suggested for the Arden Syntax to represent imprecise reasoning. Prior work has demonstrated their widespread presence in clinical practice guidelines (CPGs). Objective: Assess the prevalence of these constructs in quality indicators (QIs) to determine their utility in Arden. Methods: Fuzzy constructs were tabulated in a corpus of 392 QIs. Results: At least 1 construct was present in 50 QIs (12.8%). A total of 70 constructs were present, including 52 characterizing the degree of a state, 15 characterizing some inference and 3 denoting some temporal association. Conclusion: Fuzzy logic occurs commonly in QIs but not as commonly as in CPGs. Fuzzy constructs in knowledge formalisms may facilitate implementation of QIs.

Terminology & Standards Integration: Development of an Institutional Structured Reporting System

Fernando Plazzotta[a], Fernando Campos[a], Diego Kaminker[a], Alfredo Cancio[a], M. Florencia Martínez[a], Jerónimo Aguilera Díaz[a], Daniel Luna[a], Enrique Soriano[a], Ricardo García Mónaco[b], Fernán González Bernaldo de Quirós[a]

[a] Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina
[b] Department of Radiology, Hospital Italiano de Buenos Aires, Argentina

A structured reporting system was designed to organize the radiological information into knowledge trees. Each one of these trees' concepts is represented in our clinical terminology server. The reports are generated and stored as a Clinical Document Architecture Release 2 including the narrative text, the links to the images, and each finding and observation represented as a coded entry.

Towards a process for Augmented Surgery Evaluation

Anne-Sophie Silvent[a], Stéphane Plaweski[b], Philippe Cinquin[a,c], Alexandre Moreau-Gaudry[a,c]

[a] *Clinical Investigation Centre – Innovative Technology, INSERM & CHU, Grenoble, France*
[b] *Clinique Universitaire de Chirurgie Orthopédique et de Traumatologie du Sport, Urgences SUD, CHU, Grenoble, France*
[c] *TIMC-IMAG Laboratory, UMR5525 University Joseph Fourier & CNRS, Grenoble, France*

Quality evaluation in the field of Augmented Surgery (AS) is strategic for public health policy. Such an evaluation is complex, multi-factorial and not standardized. It first implies to be able to discover and to formalize the knowledge on the domain targeted by the device and to structure it. This paper presents the application of this approach to the evaluation of the Delivered Medical Service (DMS) during navigated knee surgery. Encouraging results are reported: a new relevant criterion has been discovered for the DMS evaluation of a device in AS.

Association Rules Mining Based Clinical Observations

Mahmood Abdur Rashid[a], Md Tamjidul Hoque[b], Abdul Sattar[a]

[a]*Institute for Integrated and Intelligent Systems (IIIS),*
[b]*Discovery Biology, Eskitis Institute for Cell & Molecular Therapies, Griffith University,*

Healthcare institutes enrich the repository of patients' disease and/or risk factor related information in an increasing manner which could have been more useful by carrying out relational analysis. In this paper we have implemented Association Rules mining based a novel observation technique for finding co-occurrences of different clinical states (disease/s, risk factor/s) for a patient by using the healthcare/clinical data repository, applying different constraints (age, sexuality, profession) against the data.

Effect of change in life style on control of blood glucose in diabetes type 1 patients

Abdul Roudsari[a,b], Omid Shabestari[b]

[a]*School of Health Information Science University of Victoria,Canada*
[b]*Centre for health informatics, City University, London*

Diabetes Mellitus is a chronic disease which requires continuous monitoring. This control involves the recording of blood glucose measurements. Various changes in life style can affect blood glucose level but the overall balance is the result of these effects and changes in the dose of insulin. For better evaluation of changes in blood glucose, its deviation from the average value for each person in each period of the day was considered. In this research, the effect of some of these changes in life style including food intake, physical activity, napping, alcohol consumption, illness/ infection, menstrual period, stress and holiday/trip on blood glucose was evaluated. This study shows that in most of these changes in life style, the injected insulin dose is higher than required and should be better adjusted.

[a] *Center for Shared Decision Making and Nursing Research, Oslo University Hospital*
[b]*Faculty of Medicine, University of Oslo,*
[c]*Dept. of Behavioral Sciences, University of Oslo, Norway*

SiSom is a computerized, interactive assessment and communication tool to help children with cancer report symptoms and problems through animations, pictures and spoken text, and to assist clinicians in providing patient-centred care. In this exploratory study that tested effects of SiSom in patient consultations we found significant group differences in favor of the intervention group in number of symptoms addressed; level of child participation; and number of times the physician directly addressed the child. The study showed beginning evidence that SiSom can significantly improve patient-centered care for children with cancer.

Preliminary Estimation of the Disease Management Program in Japan: Relationship between Risk Factors and Medical Cost

Naohiro Mitsutake,[a] Takashi Fukuda,[a,b] Yuji Furui[c]

[a]*Institute for Health Economics and Policy, Tokyo, Japan*
[b]*School of Public Health, University of Tokyo, Tokyo, Japan*
[c]*The Twenty-second Century Medical Center, University of Tokyo, Tokyo, Japan*

Since the 2008 health care reform, medical care insurers have an obligation to provide a specified health examination and health guidance for all Japanese people aged 40 to 74. This policy aims to decrease the number of patients with metabolic syndrome and the medical expenditure. Health examination results submitted in Health Level 7 (HL7)/ XML format are currently stored in a national database. This database also stores medical fee claim data to be utilized not only for statistical tracking but also for academic research. This preliminary study aims to clarify the relationship between metabolic syndrome risk factors and medical cost using log-linear regression analysis. Our study suggests that the medical cost per person in the high-risk group was higher; however, the ratio of the cost per person in the high-risk group to the total medical expenditure was lower than that of the other groups. Therefore, medical cost containment in Japan depends not only on health guidance for high risk groups but also on health education for no-risk groups that aren't targeted in the current program.

Schematic Framework for Clinical Language Technology Development in Intensive Care

Hanna Suominen[a], Heljä Lundgrén-Laine[b], Sanna Salanterä[b], Helena Karsten[c], Tapio Salakoski[a]

[a] *Turku Centre for Computer Science (TUCS) and Department of Information Technology, University of Turku, Turku, Finland*
[b] *Department of Nursing Science, University of Turku, Turku, Finland*
[c] *TUCS and Department of Information Technologies, Åbo Akademi University, Turku, Finland*

Fluent patient information flow is a prerequisite for clinical decision making. However, the flow is fragmented in intensive care. We identify interfaces for language technology components to support the flow. We present the components of profile-building, support-to-writing, attention-focusing, summarizing and proof-reading in a schematic framework. It covers the entire intensive care process and enables developing comprehensive software solutions by tying components together.

Semantic Search for Clinical Evidence Using PICO Framework

Yuan Ni, Guo Tong Xie, Lei Zhang, Jing Mei, Han Yu Li, Sheng Ping Liu, Hai Feng Liu, Yue Pan

IBM Research - China

Evidence based medicine (EBM) aims to apply the best available evidence gained from the scientific method to medical decision making. To make a best practice of EBM, we need to provide users an effective and efficient way to find the useful evidences. In this paper, we describe a PICO framework [1] based semantic search engine for clinical evidences. Our system has three features. Firstly, our search engine supports the searching on specific PICO elements. Secondly, our search engine integrates well defined knowledge in healthcare domain, such as SNOMED CT [2] (Systematized Nomenclature of Medicine - Clinical Terms), such that more complete search results could be returned. Finally, we extract key information of an evidence and display it in search result snippet to assist the critical appraisal phase in EBM. A preliminary evaluation is conducted to demonstrate the effectiveness of our system by comparing it with the keyword search on Cochrane Database.

Manual alert input and activation is prone to missing and error. This paper illustrated the potential clinical benefits of an architectural model of continuously screening of clinical data in huge clinical data repository and actively feeding data into an integrated alert framework for automatic alert creation. To illustrate the feasibility of this generic model, a routine screening laboratory test results of Glucose-6-phosphate dehydrogenase (G6PD) in a huge data repository was continuously monitored, screened and fed into an alert framework where G6PD deficiency alert was automatically created in the electronic patient records according to pre-defined clinical criteria. Over three months after live run of the new services, 77 G6PD deficiency alerts were created by continuously screening of 2,073 G6PD reports among 34M of new laboratory results in the study period. Clinicians could be alerted and medication decision support would be activated to prevent clinicians from prescribing contraindicating medications. The model was shown to be performing, reliable and facilitating clinical care.

[b] *Bristol Institute of Technology, University of the West of England, Bristol*

This poster presents a project on information sharing needs in a UK Nutrition and Dietetics Service. Against the web of permissions and access levels in the existing system, results from the project were used to streamline the business and information management processes through mapping shared and private information, then designing and implementing an adaptable information repository with well structured management and storage frameworks. Training needs were analysed and mapped to improve practice and so efficiency, effectiveness and quality of existing and future information, as well as conformity to information governance requirements.

Automatic speech recognition for the generation of medical reports studies

Humberto Fernán Mandirola Brieux[a], Sebastián Guillen [b], Pablo Laguzzi[c].

[a] *Medical Informatics, Hospital Belgrano, San Martín, Provincia de Buenos Aires, Argentina*
[b] *Health Informatics Research, BIOCOM, Ciudad de Buenos Aires, Argentina*
[c] *Informatics Department , BIOCOM, Ciudad de Buenos Aires, Argentina*

We compare the performance of the computerized speech recognition system to convert voice medical radiological reports into text with the conventional hand transcription. We used the "Dragon Naturally Speaking Preferred Spanish version number 10" program. Automatic Speech recognition decreased the transcription time and reduced substantially the transcription costs. Speech recognition by computer is practical in radiological reports implementation. In our study, we found that hand writing transcription of digitized files of short Spanish radiological reports has an error of 5% compared to the gold standard. This grows to 13% when using the automatic speech recognition system, only 8% difference. Automatic speech recognition programs are useful for text transcription of short radiological reports in Spanish. We cannot say the same for other languages or clinical applications and, in each case, it would be advisable to test its efficiency.

Web-based Case Reports Retrieval System by TF*IDF Method

Shunsuke Doi[a], Tatsunori Tanaka[a], Takahiro Suzuki[b], Toshiyo Tamura[a], Katsuhiko Takabayashi[b]

[a] *Graduate School of Engineering, Chiba University, Japan*
[b] *Department of Medical Informatics and Management, Chiba University Hospital, Japan*

To learn from similar cases is one of the most important and beneficial processes for clinicians when they encounter a difficult case to make a diagnosis or decide treatment. Most of the databases of case records, however, were not available for comprehensive search. We built a database of more than 15,000 case reports from the Japanese Society of Internal Medicine as well as extraction of case reports from MEDLINE and conducted morphological analysis. Now we can provide to Japanese physicians the option to search for similar cases through the internet by using the TF*IDF method from JSIM homepage.

An approach for a medical ontology based on UMLS to improve information retrieval in German language clinical text documents

Georg Petritsch[ab], Stephan Spat[a], Christian Gütl[b], Peter Beck[a]

[a] *Institute of Medical Technologies and Health Management, JOANNEUM RESEARCH, Graz, Austria*
[b] *Institute for Information Systems and Computer Media, Graz University of Technology, Graz, Austria*

A large number of free text documents are created in clinical practice every day. These documents often contain critical information for clinical decision-making however automatic information extraction is complicated. Here we present an approach whereby an existing prototype for a medical information retrieval system is extended. Using a suitable knowledge representation, the mapping of German language free text terms and phrases to corresponding concepts is facilitated.

Using Semantic Relations Extracted from Medline for Biomedical Question Answering

Dimitar Hristovski[a], Thomas C Rindflesch[b]

[a] *Institute of Biomedical Informatics, Faculty of Medicine Ljubljana, Slovenia*
[b] *National Library of Medicine, NIH, Bethesda, USA*

It is challenging for biomedical researchers to stay current with the literature in their field. Information retrieval systems are widely used; however, they return documents that have to be read by the user to extract relevant information. We propose a methodology for question answering implemented in a prototype tool which returns answers (known facts) first, and only later the documents from which the facts are extracted. Our question answering methodology is based on semantic relations extraction from Medline with the SemRep natural language processing system. The extracted relations are organized in a database and made available for searching through a Web-based tool. Our approach is able to provide answers for a wide array of questions that arise in clinical work and biomedical research.

Presentation on a Method for Development of the Brazilian Health-related Content Web Search Portal

Felipe Mancini[a,b], Alex Esteves Jaccoud Falcão[a], Anderson Diniz Hummel[a], Fabio Teixeira[a], Fernando Sequeira Sousa[a], Thiago Martini Costa[a], Ivan Torres Pisa[c]

[a] *Postgraduate Program of Health Informatics, Federal University of São Paulo, São Paulo, Brazil*
[b] *Federal Institute of Education, Science and Technology of São Paulo, Guarulhos, Brazil*
[c] *Health Informatics Department, Federal University of São Paulo, São Paulo, Brazil*

The increase in the amount of available information on the world wide web is inexorable, which, on one hand, provides the web user with more information. On the other hand, however, web searches become increasingly more difficult to handle due to the increasing number of retrieved documents. The present study is a proposal of development for a Brazilian search portal specific for health-related content. The aim of such development is to provide web users, mainly the non-specialist ones, with the largest number possible of web pages relevant to their search terms and inferred search intentions. The usefulness of a search portal for web pages with health-related content is potentially enormous, and the challenge of its implementation is motivating.

A Framework for Multiscale Comparison of Three-dimensional Trajectories Based on the Maxima on Curvature Scale Space

Shoji Hirano, Shusaku Tsumoto

Department of Medical Informatics, Shimane University, School of Medicine, Japan

In this poster we present a multiscale comparison method for three-dimensional trajectories. In order to deal with the problem that zero-crossings of curvature cannot be determined for space curve, we focused on the maxima of curvature. In experiments we demonstrate that reasonable correspondences were obtained on the simple but noisy trajectories.

Keywords:
Multivariate time series, Multiscale analysis, Trajectory mining.

Data Mining validation model to predict future health care cost

Mónica Schpilberg[a], Vanina Taliercio[a], Daniel Vazquez Vargas[b], Silvana Figar[a], Hernán Michelangelo[a], Daniel Luna[a], Fernán González Bernaldo de Quirós[b]

[a] *Department of Epidemiology and Statistics, Hospital Italiano de Buenos Aires, Argentina*
[b] *Faculty of Natural Sciences, University of Buenos Aires, Argentina*

There is evidence that the use of a health care system is related to the health of its members (greater costs incurred poorer health status). An efficient manner to manage health care is through the identification of subgroups of patients with high-risk and resulting high costs, so as to optimize medical interventions. Clinical risk scores try to predict adverse medical outcomes based on clinical features and only a few scores are based on administrative data. The Health Information System allows us to design interventions based on the knowledge of possible future scenarios about health status of the assisted population. In our area, the Italian Hospital of Buenos Aires is a Health Maintenance Organization that currently assists 150,000 members whose information is systematized, standardized and stored in a Hospital Information system (HIS). In conjunction with SAS Institute, we created an analytical model. In this paper we propose to validate the model created.

Extracting Remarkable Temporal Patterns of Technical Terms in Medical Research Documents

Hidena Abe, Shusaku Tsumoto

Department of Medical Informatics, School of Medicine, Shimane University, Japan

In temporal text mining, some importance indices such as simple appearance frequency, tf-idf, and differences of some indices play the key role to recognize remarkable trends of terms in sets of documents. However, most of conventional methods have treated their remarkable trends as discrete statuses for each time-point or fixed period. In order to find their trends as continuous statuses, we have considered the values of importance indices of the terms in each time-point as temporal behaviors of the terms. In this paper, we describe the method to extract remarkable temporal patterns by using linear trends of importance indices of technical terms related to migraine drug therapy on the documents from MEDLINE.

Extraction of Drug Combination related to Liver Dysfunction

Akira Totoki[a,b], Suzuki Takahiro[a], Toshiyo Tamura[b], Katsuhiko Takabayashi[a]

[a] *Department of Medical Informatics and Management, Chiba University Hospital, Chiba, Japan*
[b] *Graduate School of Engineering, Chiba University, Chiba, Japan*

Today a great number of drugs are used in clinical medicine and because of such vast amount we cannot possibly research adverse reaction for all combinations of medicines. Here we searched adverse reaction (liver dysfunction) induced by medication retrospectively through ALT (GPT) temporal data and prescription history files at Chiba University Hospital. There were 3,240 cases of liver dysfunction which appeared during hospitalization in all 84,437 cases. We checked prescription histories of those cases and extracted each medication just before ALT reached its peak and calculated their appearance rate of adverse reaction. Some of them showed higher frequency in the combinations than monotherapy. These results require immediate medical consideration of specialists, though the method might be effective to search for the complicated or more than a three drug combination causing liver dysfunction.

Adverse Drug Events Detection by Data Mining of Electronic Health Records

Emmanuel Chazard[a], Grégoire Ficheur[a], Sanne Jensen[b], Peter Mc Nair[b,c], Régis Beuscart[a]

[a] *Medical Information and Records Department EA2694, University Hospital, Lille, France*
[b] *Health Informatics Unit, Corporate IT, Capital Region of Denmark*
[c] *Medical Genetics Laboratory Center, Kennedy Center, Glostrup, Denmark*

Adverse drug events (ADEs) are a public health issue. Their detection usually relies on spontaneous declarations and staff-operated reviews. The present work aims at (1) mining electronic health records to automatically identify ADEs (2) generating alert rules to prevent ADEs. Those rules will then be implemented into a clinical decision support system. Methodology: (1) data are aggregated in order to simplify their structure and to take the time into account. (2) cause-to-effect relationships are identified thanks to statistical methods. Results: data-mining of 55,000 hospital stays allows getting 255 validated rules in the field of anti-thrombotic agents and related ADEs. Other ADE-detection rules can be imported into the same repository and automatically evaluated in different medical departments. The results show the importance of segmentation and contextualization of the rules.

Case-Based Reasoning for Pediatrics Developmental Disorders

eiTan LaVi[a], Yuval Shahar[b], Mitchell Schertz[c], Shmuel Einav[a]

[a] *Biomedical Engineering Department, Tel-Aviv University, Israel*
[b] *Medical Informatics Research Center, Department of Information Systems Engineering, Ben Gurion University, Beer Sheva, Israel*
[c] *Institute for Child Development ,Kupat Holim Meuhedet, Central Region, Herzeliya, Israel*

While 1 in 5 children suffers from Pediatrics Developmental disorders [1] (PDD), PDD specialists are operating in IT darkness; their domain is ontologically and taxonomically ill-defined and no prototypical cases or clinical decision making models are available to assist them [2]. PDD is pressing for Medical Informatics solutions, yet no prior research has been dedicated to developing Decision-Support Systems (DSS) or methodologies for PDD [2, 3]. This ongoing research is being conducted on a real-life case-base from a major PDD clinic in Israel[b], with the primary objective of constructing a robust Case-Based-Reasoning (CBR) agent to perform CBR retrieval to predict diagnoses of new cases. Heretofore we have implemented and tested the retrieval and reuse modules of the CBR cycle. Ultimately, the significance of such work is in helping to lay the foundations for a CBR system which allows clinicians to objectively utilize the whole of their collective past experience in order to individually produce better decisions in diagnosis and treatment of developmental disorders.

An alternative data mining oriented approach to the analysis of the long-term glucose counter-regulation to hypoglycemia in continuous glucose data

Mette Dencker Johansen[a], Jens Sandahl Christiansen[b], Ole K. Hejlesen[a]

[a] *Medical Informatics Group, Department of Health Science and Technology, Aalborg University, Aalborg, Denmark*
[b] *Department of Endocrinology and Diabetes, Aarhus Sygehus, Aarhus University Hospital, Aarhus, Denmark*

The hypothesis of a long-term glucose counter-regulation to hypoglycemia has gained recent interest using continuous glucose monitoring technologies, but long-term studies are lacking. The aim of the study was to evaluate the phenomenon in continuous glucose monitoring data, without the assumptions regarding hypoglycemia time of day and manifestation of the long-term glucose counter-regulation found in the study designs of previous studies. We compared continuous glucose data and insulin data from people with type 1 diabetes after spontaneous hypoglycemic events with matched hypoglycemia-free control periods. No significant difference in sensor glucose was seen, but the insulin intake was higher for 24 hours after hypoglycemia. As insulin has hypoglycemic effects, blood glucose after hypoglycemia would have been elevated with similar insulin intake. The results are thus consistent with the hypothesized long-term glucose counter-regulation to hypoglycemia.

A Cluster and Decision Trees Analytical Comparison of Compliance and Persistence to Fixed-Dose Combination versus Single Agent Combination Therapy for the Treatment of Type 2 Diabetes

Femida Gwadry-Sridhar[a], Benoit Lewden[a], Scott Leslie[b], Michael Bauer[c], Ali Hamou[a]

[a] *I-THINK Research Lab, Lawson Health Research Institute, London, Ontario, Canada*
[b] *MedImpact Healthcare Systems, Inc. San Diego, California, USA*
[c] *Department of Computer Science, University of Western Ontario, London, Ontario, Canada*

The use of combination therapy aims to reduce pill burden and increase compliance. The use of novel analytical techniques (such as clustering and decision trees) that can model and predict the outcome of patient compliance are needed. The objective of this study is to (1) assess the long-term compliance and persistence patterns in patients initiating thiazolidinedione (TZD) and metformin (MET) for the treatment of type-2 diabetes, and (2) to determine the influence of preceding therapies (history of metformin and/or thiazolidinedione) on compliance and persistence. (3) To examine features common to compliance patterns using data mining and analytical methods.

[c] *Social Medicine Department, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto - SP*
[d] *Health Informatics Department, UNIFESP, São Paulo - SP*

Complications associated with kidney transplant and immunosuppression can be prevented or treated effectively if diagnosed in early stages with post-transplant monitoring. One of the major problems is diseases during the first year of the transplanted kidney. To this purpose we used different classifiers to predict events of nephrotoxicity and acute cellular rejection. The classifiers were evaluated according to the value of sensitivity, specificity and area under ROC curve. The technique that had the best sensitivity rate prediction for the submission to the transplanted kidney biopsy was SVM (LIBSVM algorithm) with sensitivity rates of 0.87 (accuracy rate 79.86; specificity 0.70; AUC 0.79). A critical error is estimated in 7.5%. These results are encouraging with rates of trial and error consistent with work purpose. The purpose of this study is compare different artificial intelligence techniques in the prediction of events of nephrotoxicity and acute cellular rejection (ACR) in renal transplanted.

Prediction of Early-Stage Chronic Kidney Disease in an HIV-Positive Population

Omolola I. Ogunyemi[a,b], Chizobam Ani[b], Francis Yemofio[b,c], Wilbert Jordan[b,c], Keith Norris[b]

[a]*Center for Biomedical Informatics*
[b]*Charles Drew University of Medicine and Science, Los Angeles, CA*
[c]*OASIS Clinic, Los Angeles, CA*

We assessed the feasibility of predicting an HIV-positive individual's two-year risk of developing chronic kidney disease (CKD) and examined the accuracy of several predictive models based on Bayesian networks, logistic regression, artificial neural networks and support vector machines. Our preliminary study used anonymized data from 92 patients currently seen at a specialty clinic for HIV-positive patients in Los Angeles (the OASIS Clinic). When the predictive models were trained and evaluated on the dataset of 92 patients using leave-one-out cross validation, the best predictive model was a Bayesian network model, with an area under the ROC curve of 0.693. The study suggests that computerized prediction of a CKD-free, HIV-positive patient's two-year risk of developing CKD is feasible. Risk prediction models developed for this purpose could assist clinicians in preventing or delaying the onset of CKD in HIV-positive patients.

Multi theme automatic quality detector for health web pages

Hind Lagahzli[a,b], Arnaud Gaudinat[b], Célia Boyer[b]

[a] *Polytech Grenoble*
[b] *Health On the Net Foundation, Geneva, Switzerland*

In the health information field, mechanisms to help assess quality appear to be more than ever a high priority need. The increasing volume of health information available online covers a large spectrum of health related topics. However, most of the time internet users have no indicators about the reliability of this information. State of the art approaches to address this problem consist of either machine learning algorithms or automatic evaluation with simple regular rules. In this poster, we present our multi theme reliability level based on a large corpus of low- and high quality web pages representing several health domains, complementary to our supervised detector based on generic quality criteria. We attempt to classify health web pages independently of the health domain, classifying them according to a scale of reliability. This study shows that an automatic recognition of low quality health pages was possible, with less than 2% error rate. However the question of domain dependency is still remaining and further studies are needed to evaluate the system's ability to deal with new health domain documents.

What about trust in a question answering system?

Sarah Cruchet[a], Arnaud Gaudinat[a], Célia Boyer[a], Thomas Rindflesh[b]

[a] *Health On the Net Foundation, Geneva, Switzerland*
[b] *National Library of Medicine, LHC, Washington, USA*

A question answering system (QA) aims to answer a question asked in a natural form. This paper presents a solution using an existing medical QA developed by HON and investigates whether the relevance and reliability of the answers extracted conforms to the standards of the quality and trustworthy health web pages analyzed. The evaluation focuses on the comparison of the results between the QA searches through trustworthy health documents and the Google database (which include certified and non-certified websites). Results are merged and classified by a medical expert. We use Trec-eval measures for the evaluation. As a result, for a set of 100 questions, we obtain a MAP of 59% and a MRR of 76% for QAHON_honcode. According to our results, the trustworthiness of the database used influence the relevance and accuracy of the answers retrieved by the HON QA.

Trust, Reliability, Information retrieval.

Extracting Diagnoses and Drug-Abuse Patterns from Italian Clinical Reports of Patients with Headache Disorders

Matteo Gabetta[a], Cristiana Larizza[a], Lina Rojas Barahona[a], Elena Guaschino[b], Grazia Sances[b], Cristina Cereda[b], Riccardo Bellazzi[a]

[a] *Dipartimento di Informatica e Sistemistica, Università di Pavia, Italy*
[b] *Headache Unit, IRCCS C. Mondino Foundation, Institute of Neurology, Pavia, Italy*

The ever increasing interest in extracting valuable information from heterogeneous unstructured biomedical texts has yielded important contributions. However, most of the advances concern processing English reports and literature; this growth has not been equal for other languages, including Italian. This work is focused on processing discharge summaries, written in narrative Italian, related to patients admitted into a Headache Unit with the aim of extracting the type of discharge headache and, in case of a diagnosis of Medication Overuse Headache, also the original headache type leading to it. The evaluation of the system has given satisfactory results encouraging the application of these techniques for extracting automatically other relevant clinical information not available in structured form.

Improving Access to Medical Literature Using Multilingual Search Interfaces

Steven Bedrick

Department of Biomedical Informatics & Clinical Epidemiology, Oregon Health and Science University, Portland, OR, USA

The vast majority of the internationally-published medical and scientific literature is published in English. However, most of the world's population speaks English as a non-native language, if at all. This linguistic situation creates a barrier to access for clinicians and scientists throughout the non-Anglophone world, and first manifests itself during the literature search process. This poster describes a multilingual search system that seeks to address the linguistic barrier using a combination of machine translation and linguistic support features. The poster also describes user-centered evaluation methods for multilingual interfaces.

Implementing a Census Tracking System to Improve the Real Time Reporting Capability in the Cleveland Clinic Informatics System

Jennie Q. Lou [a], Ricardo Gomez [b]

[a] *Medical Informatics Program, Nova Southeastern University, Ft. Lauderdale, Florida, USA*
[b] *Cleveland Clinic, Weston, Florida, USA*

To improve the real-time census tracking capability in Cleveland Clinic Florida, the Census Tracking System (CTS) was developed and implemented. CTS provides not only the real-time bed usage/status in the hospital, but also data with historical trends, allowing administration to accurately predict demand and capacity on a daily basis, along with current patient flow statistics. CTS improves the overall workflow throughout the hospital by efficiently facilitating inter-departmental communication between physicians, nursing staff, and environmental services.

Keywords:
Census tracking, Real time reporting, Workflow

Utilizing Technology and Collaboration to Improve Patient Throughput and Manage 100+% Capacity

Gerard Colman[a], Frank Tortorella[b], Julianna Moorad[a]

[a] *Clinical Operations, The University of Texas M. D. Anderson Cancer Center, Houston, Texas*
[b] *Clinical Support Services, The University of Texas M. D. Anderson Cancer Center, Houston, Texas*

As demand for services increases, health care organizations must be able to efficiently diagnose and treat more patients utilizing fewer resources. Increasing demand requires faster patient throughput, optimally allowing for more admissions with the same staff and space; this faster throughput provides the hospital with additional "effective" beds. Beginning in 2004, M. D. Anderson Cancer Center faced a critical bed shortage as patients boarded for hours in the Emergency Center, Admissions, and Operating Rooms while beds became available. By focusing on the inpatient discharge process, M. D. Anderson developed short and long-term solutions: 1) formation of housekeeping room turnover teams, 2) creation of an escort-assisted discharge process, 3) assignment of discharge nurses, 4) selection of an electronic bed management system. In combination, all solutions show promise in achieving greater efficiencies and potentially a longer-term reduction in length of stay (LOS) and a capacity gain.

Development and evaluation of the critical pathway for endoscopic submucosal dissection

Eunhye Kim[a], Moonsook Kim[a], Ki Ho Park[a], Sang-Gyun Kim[b], Kyung-Hwan, Kim[c]

[a] *Division of Quality Assurance, Seoul National University Hospital, Seoul, Korea*
[b] *Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea*
[c] *Center for Medical Information, Seoul National University Hospital, Seoul, Korea*

These days, endoscopic submucosal dissection (ESD) is ac-cepted effective alternatives to radical surgery for the treat-ment of UGI superficial neoplasm. The aim of this study is to determine an impact of a standardized critical pathway (CP) and an integrated education program for the early gastric cancer patients.The ESD CP was developed and implemented in Seoul National University Hospital, from June 2007 to December 2008. The CP programs included 1) standardized protocols based in EMR, 2) the integrated education pro-grams provided by doctor, nurse, and nutritionist to the pa-tients and their family members. We have performed ESD procedure on the very admission day in pathway group, while we implemented it on the 2nd day of stay in pre-pathway group. Our standardized critical pathways and integrated education programs for the patients who undergo ESD had an effect on reducing the length of hospitalization (from 4.2 days to 2.9 days) and the hospital cost per day (from 585 USD to 365 USD) with an improved patient's satisfaction.

Development and Implementation of Critical Pathways in Electronic Medical Records Systems for Strabismus surgery in Children

Moon-Sook Kim[a], Hyo-Nam Woo[a], Jung-Hun Kim[b], Ki-Ho Park[b], Kyung-Hwan Kim[c]

[a] *Division of Quality Improvement, Seoul National University Hospital, Seoul, Korea*
[b] *Department of Ophthalmology, Seoul National University Hospital, Seoul, Korea*
[c] *Division of Health Informatics, Seoul National University Hospital, Seoul, Korea*

Objectives: The aim of this study was to decrease length of stay and to improve cost-effectiveness by developing and implementing Critical pathways (CPs) in Electronic medical records systems for strabismus surgery in children. Methods: CPs have been developed and implemented since 2006. The results of average annual length of stay, the number of surgery per month, total hospitalization costs and costs per day were compared between CPs group and total patients from 2006 to 2008. Results: The rate of CPs implemented was 97.1%, and the results of CPs group were nearly same as those of total patients in 2008. Average length of stay was reduced from 3.0 days to 1.7 days, and the number of surgery increased 1.9 times, costs per day increased twice as much while total hospitalization costs has not changed in both CPs group and total patients.

[a] *Health Informatics Department, Hospital Authority,*
[b] *Information Technology Department, Hospital Authority*

The scope and structure of health information is complex; so as the management of it. Since 1995, the Hospital Authority (HA) has accumulated 8.9 million patient's records in her Clinical Management System (CMS). There is an increasing demand for sharing clinical data across various CMS modules. HA has developed a model to manage her information throughout its lifecycle. The model includes developing standardization principles to ensure the semantics of the captured data is being preserved; establishing a trio-party governance structure being led by clinicians, health informaticians and information technologists; building generic services, defining roles and workflow to facilitate data capturing, retrieving, transferring, and reporting. With this model, the HA has successfully developed an efficient and effective mechanism to manage her valuable asset and support meaningful reuse of her clinical data.

[b] *Hospital District of South-West Finland, Turku, Finland*
[c] *Turku Centre for Computer Science (TUCS) and Department of Information Technology, University of Turku, Turku, Finland*

In intensive care units, the shift leaders spend substantial amount of time in selecting and combining different kind of data to support their decision making during the coordination of patient care. Most of information systems for intensive care are focused on individual patients and provide detailed information only related to direct patient care. The systems should be more process-oriented in order to serve their multiprofessional users. Based on our previous study, we developed a questionnaire to define process-oriented information needs of intensive care charge nurses and intensivists for immediate decisions (ad hoc). In this paper, we describe the administration of our survey, report preliminary results of our study and evaluate the necessity of information for ad hoc decisions of shift leaders at intensive care.

Situated Coordination Through Communication: A Field Study of Operating Room Personnel

Børge Lillebo[a], Andreas Seim[b], Arild Faxvaag[a]

[a] *Norwegian EHR Research Centre, Faculty of Medicine, Norwegian University of Science and Technology (NTNU), Trondheim, Norway*
[b] *Department of Computer and Information Science, Faculty of Information Technology, Mathematics and Electrical Engineering, NTNU, Trondheim, Norway*

Operating rooms and other parts of the perioperative environment are among the costliest resources in a modern hospital, and the coordination of perioperative processes can be a challenge. Situated coordination – i.e. mutual adjustment during the course of action – is an important means of ad hoc coordination in hospitals, and our main objective was to understand how well communication between perioperative healthcare professionals supported situated coordination. We used a qualitative approach conducting interviews with and observations of domain experts. We found that verbal, one-to-one and just-in-time communication was widely used to notify each other about progress of important perioperative processes.

The use and management of information and technology in maternal healthcare: A case study in the Western Cape, South Africa

Vania Banze[a], Bobby Moeng[a], Cornell Stofberg[a], Retha de la Harpe[a], Mikko Korpela[a,b]

[a] *Department of Information Technology, Cape Peninsula University of Technology, Cape Town, South Africa*
[b] *Healthcare Information Systems Research and Development Unit, University of Eastern Finland, Finland*

Maternal healthcare is one of the Millennium Development Goal areas. In maternal healthcare, expecting mothers tend to visit a number of healthcare institutions and interact with the healthcare information systems throughout their pregnancy period. The interaction with different systems makes the management of patients and their data challenging. We present the first results of a study that aims at in-depth understanding of the use and management of information and technology in maternal healthcare in South Africa through a case study in Vredenburg, Western Cape.

In a competitive health-care market, hospitals must deliver high quality care while reducing costs. To accomplish this goal, hospital managers need a thorough understanding of the actual Care Processes (CPs). Diffusion of ICT tools within hospitals, provide huge collections of data, useful for process analysis. Process Mining (PM), describing a family of a-posteriori analysis techniques, can be used to extract process-related information from data. We applied PM to data from hospitals in the Lombardia region, to analyze differences and performance of their CPs.

The Department of Knowledge Informatics and Translation: A Case Study with Implications for Academic Medicine

Julie J McGowan[a,b], Shaun J Grannis[a,b], Brian E Dixon[b], Osman Gurdal[a]

[a] *Department of Knowledge Informatics and Translation, Indiana University School of Medicine, Indianapolis, Indiana, USA*
[b] *Regenstrief Institute, Inc., Indianapolis, Indiana, USA*

This poster presents the development of a new department in the Indiana University School of Medicine (IUSM), one that addresses a number of contemporary challenges and introduces a new construct for knowledge management. Academic medicine is faced with many opportunities that could drastically change the face of medical practice. However, few medical schools are equipped to insure that researchers and clinicians have access to the tailored knowledge they need, when and where they need it, nor can they create knowledge relationships that could lead to new research and clinical practice. This department builds on medical school strengths, requirements and a theoretical framework of knowledge dimensions to establish a new hybrid discipline that utilizes the best precepts of knowledge management and medical informatics within an academic department designed to foster future research and manage two critical cores, the library and educational technology.

Breach Notification Laws and the American Patient

Tyrone Grandison

Health Informatics, IBM Almaden Research Center, San Jose, CA

Since California's pioneering Breath Notification Law (CA SB 1386 Senate Bill) came into effect on July 1, 2003, there has been a significant number of states that have crafted their own breach notification laws. The intent of these activities is to notify people whose information was compromised by the companies holding their data. In this work, we study the current Federal breach notification initiative and the impact on the American patient

[c] *National Institute for Health and Welfare, Helsinki, Finland,* [d] *Datawell Ltd and the University of Helsinki, Finland*
[e] *Hospital District of Helsinki and Uusimaa, HUS ICT, Finland,* [f]*Consulting Researcher, Tampere, Finland*

There is universal usage of EHRs among public primary and secondary care providers in the Hospital District. Integration of care between these providers has been supported by healthcare information exchange (HIE) that has been refined from point-to-point messaging to wide-area networks. The aim of this paper was to assess progress achieved by HIE in information access and care management with shared EHRs. This was done by clustering results from both reported and unpublished studies [1]. Initially, eReferral and eConsultation messaging decreased the demand for secondary care services reducing first visits to the outpatient clinic with more patients treated at less cost. Advancing interoperability of federated repositories with a regional locator system (RLS) improved information access and shared EHRs. A usability interview of 30 physicians indicated that HIE benefited 85 % of the patients in one of several ways. Finally, aggregating data from four feeder data and EHR sources into a regional diabetes register (T2DR) allowed monitoring of clinical outcomes and quality of care.

eHealth Readiness and Needs Assessment Framework for Low Resource Communities in Developing Nations

Kendall Ho, Kleber Araujo

eHealth Strategy Office, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada

The study of successes and failures in eHealth initiatives has led to publications on good practices in eHealth implementation. Unfortunately, not many controlled studies able to provide strong evidence have been conducted, especially in developing countries and even less commonly involving underserved communities. Based on the level of evidence currently available in the peer reviewed literature and in previous experience in the field, the authors propose a framework on readiness and needs assessment for underserved communities in developing countries. With the expectation of raising attention of stakeholders to critical factors that need to be analyzed even during the early stages of considering eHealth as a potential solution to minimize health challenges of underserved communities in developing countries.

Keywords:

Can It-governance make a difference in Healthcare implementation?

Sue Bech[a], Pia Kopke[b], Jan Kold[c]

[a] *Customer Relations, Corporate IT, Capital Region of Denmark*
[b] *Customer Relations, Corporate IT, Capital Region of Denmark*
[c] *CIO, Corporate IT, Capital Region of Denmark*

Business involvement in IT decision making is crucial for successful IT implementation and ownership. The Capital Region of Denmark (Region H) established IT Governance with business executive managers as committee chairmen. The result after 2 years with this ITG model is consolidation of 6 central EHCR modules and distribution to 30.000 users. The conclusion: IT governance with business executive managers as committee chairmen ensures focus and creates foundation for clinicians' accept of new IT-implementation projects.

Hospital Information Systems: are they sufficiently helpful for the management of patient safety? Valuable lessons from the Japanese experience

Minoru Ikeuchi[a], Kiyomu Ishikawa[a,b], Takeshi Tanaka[a], Hidehiko Tsukuma[a], Hideo Kusuoka[b], Etsuko Ito[b], Hiroyuki Sugawara[b], Makoto Oohara[b], Shinji Kishi[b], Yoshimasa Umesato[b]

[a] *Healthcare Informatics and Hospital Systems Management, Hiroshima University Hospital, Hiroshima, Japan*
[b] *Health IT Safety management, Project, Japan Council for Quality Health Care, Tokyo, Japan*

The authors examined how electronic health record systems improved healthcare safety. According to the survey of 503 hospitals in Japan, there was a gap between the system function and the operation of medical staffs. For the aim of the effective availability of EHR systems, the authors conclude that appropriate education for medical staffs is required to improve their accuracy and secure management. The Electronic Health Record (EHR) is a crucial means for establishing collaborative healthcare processes across multiple clinical specialties. The EHR depends on integrated hospital information systems that are designed to secure patient safety whilst fulfilling crucial information disclosure demands. This poster will draw out key lessons for the development of the next generation of EHRs based upon the practical experiences of Japanese health institutions.

Management of Electronic Medical Records and Images

Soo-Yong Shin, Young-Ah Kim, Min-A Hwang, Wan-Suk Kim, Jong Hyo Kim, Kyung Hwan Kim, Chun Kee Chung

Medical Information Center, Seoul National University Hospital, Seoul, South Korea

Seoul National University Hospital (SNUH) in Korea has utilized the electronic medical records (EMR) system since 2004 and the picture archiving and communication system (PACS) since 2002 in all hospital units. Therefore, all data such as medical records and images at SNUH have been stored in the digital storages. In addition, we have been scanning all the previous paper charts for easy access. However, the standard guideline or protocol to handle digital data and storages has not established yet. In this paper, we examined all digital storages at SNUH which contain medical records and images, and then discovered that the information lifecycle management strategy (ILM) would be beneficial to improve the efficiency of hospital information system. Based on the findings, we also developed the standard guidelines for EMR and PACS data.

Innovative collaborations to improve data flow in Community Nursing

Jenny Lee, Judith Barr, Fiona Hearn

Royal District Nursing Service, Melbourne, Australia

This poster will explain a community nursing service project that successfully used a blend of skills and experiences in nursing informatics, project management, human resource management and a firsthand understanding of contemporary clinical practice. An innovative interface between clinical activities and financial functions ensured availability of information and data flow. The key to this interface was the development of collaborative relationships between internal departments and external funding partners.

Trustworthy e-Health Services facilitating effective cooperation

Martin Staemmler, Christian Schmidt, Heino Ehricke, Jürgen Dräger

University of Applied Sciences, Stralsund, Germany

Effective e-Health Services have to take the business perspective into account. This is achieved by deriving a four layer structure, thereby combining IT-related and business related layers. This structure is used for designing an e-Health service leading to distributed responsibilities and allowing for mutual cooperation in a state-wide approach. The reference implementation comprises a highly reliable central infrastructure providing second opinion, emergency consultation and remotely supervised examination in radiology. The implementation includes extended means to guarantee trustworthiness on multiple levels: (i) actively controlled network and application availability, (ii) automated routine performance tests fulfilling regulatory requirements and (iii) hub-to spoke and an end-to-end authentication. As a result, about half of the hospitals of the state have signed up to the services provided.

Qualitative Issues Influencing the Electronic Integration of Medical and Dental Data

Miguel Humberto Torres-Urquidy[a], Franklin Din[b], Valerie Powell[c]

[a]*Center for Dental Informatics, Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA, USA.*
[b]*Medical Informatics Center of Excellence, HP Enterprise Services, Camp Hill, PA, USA.*
[c]*Robert Morris University, Pittsburgh, PA, USA.*

Limited electronic information exchange between dentists and other health professionals arises not only from technical aspects but also from cultural, financial and historical issues. We report on the assessment of these issues by identifying and modeling:1) influencing factors; 2) relations between factors. The resulting model highlights the preponderance of limiting factors, which partially explain current lack of electronic data integration.

Mapping a Local Drug Interface Terminology to SNOMED CT

Daniel Luna[a], Antonio Arias[a], Hernan Navas[a], Cintia Budalich[a], Marcela Martínez[a], Laura Gambarte[a], Alejandro Lopez Osornio[b], Fernán González Bernaldo de Quirós[a]

[a] *Medical Information Department, Hospital Italiano de Buenos Aires, Argentina*
[b] *TermMed IT, Buenos Aires, Argentina*

The use of standard terminologies is one of the requirements of interoperability among different clinical information systems. In healthcare, particularly with pharmaceutical products, controlled terminology is necessary. Pharmaceuticals have multiple components and controlled terminology plays a vital role in the exchange of information among different actors in the creation of a system of electronic prescriptions. The Hospital Italiano de Buenos Aires maintains an institutional database of pharmaceutical products at a national level. This work describes the process of mapping this knowledge base to SNOMED CT. This work is intended to describe the challenges encountered during the process of mapping of a reference terminology (SNOMEDCT) to an institutional database of pharmaceutical products (local drug interface terminology), who were created for the electronic prescription functionality in a large Healthcare Information System.

SNOMED CT, Interface terminology, Electronic prescription system.

Implementing rules to the control modeling with SNOMED CT

Hernan Navas[a], Alejandro Lopez Osornio[b], Laura Gambarte[a], Adrian Gomez[a], Analía Baum[a], Daniel Luna[a], Fernan Gonzalez Bernaldo de Quirós[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*
[b] *TermMed, Buenos Aires, Argentina*

SNOMED CT utilization as the reference standard terminology makes interoperability between clinical systems. SNOMED CT provides the creation of post-coordinated terms by the users, according to each local need. Even though the creation of these terms is free, there are a number of rules defined in the User Manual of SNOMED CT that must be performed. The Hospital Italiano of Buenos Aires (HIBA) has a Terminology Server for encoding medical terms using SNOMED CT as the reference vocabulary. The Hospital Italiano of Buenos Aires performed an interoperability test with the Nebraska Medical Center and found a high error rate in the post-coordinated terms (26%). Then it was decided to implement an automatic system of rules within the agreed Terminology Server defined in the User Manual of SNOMED CT. After the rules implementation, the error rate decreased from 26% to 2%. The aim of this paper is to describe the effectiveness of the control rules modeling to the post-coordination of terms.

Concept Group Design For An Effective Medical Vocabulary Utilization

Pierre-Yves Vandenbussche[a, b], Jean Charlet[a,c]

[a] *INSERM UMRS 872, éq.20, Paris, France*
[b] *MONDECA, Paris, France*
[c] *DSI AP-HP, Paris, France*

The aim of the present work is to design a model pattern for controlled vocabularies subset representation (see its UML representation below). Vocabularies utilization in informatics system faces some obstacles: their model representation heterogeneity; their size and organization. The pattern we present intends to address this last problem by including artifacts for subset representation in an existing unified model for vocabularies description. This subset, composed by vocabulary concepts (also called 'concept group'), stems from and complies with actual standards and projects for vocabulary description.

Electronic Thesaurus to Recover Information on Mammography

Paulo Roberto Barbosa Serapião, Paulo Mazzoncini de Azevedo Marques

Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo - Brazil

The goal of this study is to propose, investigate and develop a system which can represent electronic knowledge –thesaurus- in Portuguese in order to facilitate mammography report reading for the specialist and also to improve the recovery of existing information in them. In order to do so, the technique of finding out information in databases, the thesaurus structure and development, and web language were employed.

Enhanced Mapping Method for Medical Terminology

Seung-Jae Song, Sungin Lee, Senator Jeong, Myeng-Ki Kim, Hong-Gee Kim

Biomedical Knowledge Engineering Laboratory, School of Dentistry, Seoul National University, Seoul, South Korea

Medical terminology mapping imposes tremendous challenges in ensuring healthcare information sharing and developing structured physician-patient encounter documentation. Each hospital at present uses its own collection of mapping guidelines created by different departments. Though some mapping assistance programs are available, most of them focus on providing a 'suggestion list' of candidate concepts, lacking in objectivity needed for decision making, resulting in discordance in mapping results. We here propose a novel mapping method, which aims to increase trust for mapping results, and to facilitate ease of use. The method uses collective intelligence, which translates into collecting mapping results of terminology specialists, which subsequently are used as mapping guidelines for other mapping activities. The collected knowledge is housed at a remote server for efficient sharing of knowledge related mapping. The method has been implemented as an add-on module of a national terminology server called LexCare Suite.

Health Professionals' Choice of Keywords in an EHR System

Annika Terner[a], Helena Lindstedt[b], Karin Sonnander[b]

[a]*Occupational Therapy Department, Uppsala University Hospital, Sweden*
[b]*Department of Public Health and Caring Sciences, Uppsala University, Sweden*

The aim with the present study was to describe how different health professions use different kind of terms when recording health care information. The Electronic Health Record (EHR) was introduced and implemented in order to improve patient safety and care quality. The EHR requires a uniform structure that includes established and shared terminologies for handling and exchanging information efficiently. Therefore it is of interest to investigate how different professions use the terminology e.g. keywords in the EHR. Eight professions' use of keywords in an EHR-system during a period of one year was investigated. The main finding is that different professions use different kind of keywords when recording health care information. The result indicates that the EHR system in the present study do not handle and exchange information efficiently.

Can a hole be inflamed? On the handling of anatomical cavities in SNOMED CT

J. Niggemann[a], S. Schulz[b], H.R. Straub[c], H. Herre[d]

[a] *CompuGroup Software GmbH, Koblenz, Germany,*
[b] *University Medical Center Freiburg, Germany,*
[c] *Semfinder AG, Kreuzlingen, Switzerland,*
[d] *OntoMed Research Group, University of Leipzig*

"Sinusitis" is, despite its name, not the inflammation of a nasal sinus cavity, but of the mucosa that delineates that cavity. In SNOMED CT this should be reflected, and all body cavities should be handled alike and in an ontologically well-founded way. A few basic theorems from the upper ontology GFO lead to a consistent handling of the problem. As a side effect, SNOMED CT would also have to improve the precision of its relations, replacing "finding-site" by "has-object" and "has-location" respectively.

SNOMED CT, Ontology, Anatomical cavities.

Multi-professional Terminology - a Common Language – for Needs Assessment in Social Services for Elderly in Sweden

Ann-Helene Almborg[a,b], Ann-Kristin Granberg[a]

[a] *National Board of Health and Welfare, Stockholm, Sweden*
[b] *School of Health Sciences, Jönköping University, Sweden*

The objective was to develop a multi-professional terminology for needs assessment in social services for elderly persons in Sweden. Qualitative content analyses of such social services acts and focus-groups were used to create meaningful concepts. These have been linked to the International Classification of Functioning, Disability and Health (ICF) and mapped to the Systematized Nomen-clature of Medicine – Clinical Terms (SNOMED CT). The results showed ten needs areas for needs assessment of social services. The needs areas are structured in a hierarchical structure according to the ICF. The conclusion is that ICF and SNOMED CT could be used for developing a multi-professional terminology to describe the elderly persons' needs of social services.

Alignment between domain ontologies and SNOMED: three case studies

L. Mazuel, J. Charlet

AP-HP, STIM, Paris, France; INSERM, UMR S 872, eq. 20, Paris, France.

Experiments on ontologies show increasingly clearly that the latter are only capable of representing small domains correctly and consensually. Hence, domain ontologies have been developed for particular applications, whereas reference ontologies tend to be used to draw together the results of specific applications. Here, we present the analysis and discussion of an alignment between three domain ontologies created by the I NS E R M UMR_S 872, Éq. 20 (OntoPneumo, OntoHTA and OntoReaChir) and the French translation of SNOMED v3.5. We propose a categorization of non-adherent decisions.

A method for automatic content classification in health informatics based on specialized thesaurus

Fabio O. Teixeira[a], Alex J. Falcão[a], Anderson D. Hummel[a], Felipe Mancini[a], Thiago M. Costa[a], Fernando S. Sousa[a], Domingos Alves[b], Ivan T. Pisa[c]

[a] *Postgraduate program in Health Informatics, Federal University of São Paulo (UNIFESP), São Paulo - SP*
[b] *Social Medicine Department, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto – SP*
[c] *Health Informatics Department, UNIFESP, São Paulo - SP*

The purpose of this study is to present the results of a procedure for automatic classification of scientific articles in Health Informatics using a specific thesaurus. Statistical, vectorial, and artificial intelligence methods were applied to classify HI-related content. Statistical procedures and measures of accuracy, precision, recall, area under the ROC curve, and F1 measures were performed to measure the degree of similarity between terms of the specialized Health Informatics thesaurus and the selected articles. The percentage of accuracy achieved was 0.87, F1 measure was 0.88 and the area under the ROC curve was 0.94. The study results were positive showing a remarkable difference in the classification patterns, based on a specialized HI thesaurus, between specialized HI articles and those from Health.

Representation of Patient Terms for Symptoms and Health-Related Problems Using SNOMED CT(R)

Dean Wantland[a], Cornelia Ruland[b,c], Stein Jakob Nordberg[b] , Suzanne Bakken[a,c]

[a] *School of Nursing, Columbia University, New York, New York, USA,*
[b] *Center for Shared Decision Making and Nursing Research, Rikshospitalet University Hospital, Oslo, Norway and Department of Medicine, University of Oslo, Oslo, Norway,*
[c] *Department of Biomedical Informatics Columbia University, New York, New York, USA*

Given the increase in consumer-facing health-related systems, there is a need to link the interface terms used in such systems with formal representations of healthcare terms to facilitate communication with clinician-facing systems. Seven expert practicing oncology nurses used a Web-based terminology assessment and mapping application to evaluate 53-54 of 107 symptoms or problems on the "patient-friendliness" of the term and to determine the quality of match between the source terms and SNOMED CT concepts. Of 104 terms rated as user-friendly, 24 mapped to a single concept with a match quality of ≥6 for 19; 80 patient- reported multiple-term concepts mapped to SNOMED CT concepts with varying levels of match quality and; 23 terms had no appropriate matches. Single terms often present only a partial representation of a patient symptom/problem term. Reference terminology models provide a structure for concatenating concepts for complex patient terms that require multiple concepts for representation.

Generating a Disease Ontology using specialization and combinatory restriction rules

Ihssen Belhadj[a,b], Christian Jacquelinet[a,b]

[a] *Laboratoire d'informatique médicale et de bioinformatique, Faculté de médecine de l'université Paris 13, Bobigny, France*
[b] *Agence de la biomédecine, Saint-Denis La Plaine, France*

This paper reports on the design of a method to generate a wide coverage disease ontology starting from a root concept: here Disease and using its related semantic structure we refer to as its description knowledge model as a seed to generate Disease subtypes by a stepwise specialization and controlled combination of the knowledge model's constituents organized within a primitive pre-existing domain ontology. The core algorithm was developed in Java using Eclipse. The generating module was related to Protégé as the support for the initial and generated ontologies and a connection to the DL toolbox. The generating module was also linked to ConExp used for the examination and validation of the generated ontology with the FCA toolbox. Experimental results showed us that the explicit statement of Principles of opposition of siblings in the primitive ontology provides an efficient mean to restrict the combinatory explosion and to enhance the human readability of generated hierarchy.

Implementation of Interinstitutional and Transnational Remote Terminology Services

Laura Gambarte[a], Daniel Luna[a], Gastón Lopez[a], Hernan Navas[a], Alejandro Mauro[b], Claudio Torres Casanelli[b], Pelayo Navarro[b], Adrián Gomez[a], Fernán González Bernaldo de Quirós[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*
[b] *Megasalud, Chile*

Hospital Italiano de Buenos Aires (HIBA) implemented all the necessary changes in order to offer such services to other healthcare institutions, using the Internet as communication vehicle. The most integrated healthcare network of Chile, Megasalud decided to change their legacy system, to develop their own Healthcare Information System (HIS) and started to use Remote Terminology Services (RTS). After the implementation of these Terminology Services we tested the high performance for identifying free text added in their electronic health record, between 78% to 89% of text entered was recognized. The task of creating an institutional interface terminology provides an excellent service to the users, as they have liberty to enter information in free-text style. The aim of this study is to quantify the use of Remote Terminology Services (RTS) provided by the HIBA through a transnational and interinstitutional implementation.

e-Publishing of Healthcare Code Systems

Ivan Emelin, Igor Gubin, Dmitry Tashkinov

RINTECH, Ltd., Moscow, Russian Federation

A solution of electronic publishing of healthcare code systems is discussed. This solution supports official publication of code system content, documentations and instructions authorized by publishing authorities using digital signatures. All the code systems have both the human readable and machine processable format. Users may download code system content manually and applications may access this content through web-services. The solution is based on uniform data model of the code systems and on web-services specifications defined in ISO/HL7 FDIS 27951. Code system content and metadata are prepared using ISO/IEC 29500 workbook format. So this solution may be used internationally and may be considered as a source for ISO technical report.

The aim of the present work was: 1) to design a terminology meta-model (see its UML representation below) into which all terminology models can be integrated, 2) to design and to implement a process capable of integrating terminologies into a French-language health multi-terminology server, and 3) to map these terminologies.

The Development and Application of a Korean Clinical Data Dictionary

Hyeong-Yun Choi[a], Mi-Hyun Kim[a], Jae-Il Lee[a,b], Yoon Kim[a,c], Hong-Ki Kim[d]

[a] *R&D Center for Interoperable EHR, Seoul, Republic of Korea*
[b] *Department of Oral Pathology and Dental Research Institute, College of Dentistry, Seoul National University*
[c] *Seoul National University College of Medicine, Seoul, Republic of Korea*
[d] *Biomedical Knowledge Engineering Laboratory, Seoul National University, Seoul, Republic of Korea*

Several English-speaking countries have already been developing concept-based clinical data dictionaries for effective data integration and management that guarantees interoperability in EMR environment, but such dictionaries are hardly usable in non-English-speaking countries, and this cannot be resolved simply through translation. In mixture environment Korean and English, we are in need of a clinical data dictionary for overcoming the problem. For that reason, we developed a Korean-type clinical data dictionary and proved its usefulness with EMR. As a result, we confirmed that our Clinical Data Dictionary has structure and contents that can effectively support the integration of data in different clinical environments.

An attempt to develop a fast and intuitive user interface for searching, identifying and comparing LOINC® Codes – The LOST (LOINC Search Tool)

Jakob Hatzl[a], Stefan Sabutsch[a], Alexander Mense[b]

[a] *Department of Health Care Engineering, University of applied sciences "FH Joanneum", Graz, Austria*
[b] *University of Applied Sciences "Technikum Wien", Vienna*

The increasing application of information and communication technology in healthcare delivery makes the utilization of domain specific languages necessary to ensure semantic interoperability between information systems. Although the basics for implementing interoperable systems already exist, there is a lack of simple aiding tools for working with these domain specific languages. The available tools for working with the current version of LOINC do not support efficient and simple functions for browsing or comparing terms. Therefore a simple user interface for searching, identifying and comparing LOINC terms has been developed. After deciding upon the technologies to use, the LOINC Search Tool (LOST) has been implemented as a Java™ application. The user interface has been designed using the paper based prototyping approach. The result of the implementation is a simple graphical tool for searching, identifying and comparing terms from the current version of the LOINC nomenclature. The practical value of the application has to be validated by analyzing user feedback, but the LOINC Search Tool has the potential to facilitate development of semantic interoperable communication in healthcare networks.

[c] *eHealth Services Research Group, School of Computing & Information Systems, University of Tasmania*
[d] *Royal Hobart Hospital, Tasmania*
[e] *School of Nursing and Midwifery, University of Tasmania*

Dementia imposes a significant challenge for healthcare systems, and can be under-coded in hospital patients. A review of coding in an Australian setting identified deficiencies which could impact on funding for dementia care, and for research. Further work is needed to clarify the impact of coding on decisions about funding for dementia care and research.

Evaluation of a program for identifying patients with diabetes from electronic health records in the information system

Leandro Biagini[a] , Alejandro Mauro[a], Claudio Torres Casanelli[a], Luisa Legorburu[a], Lisette Lucic[a], Marcela Pezzani[a], Pelayo Navarro[a], Daniel Luna[b] , Fernán González Bernaldo de Quirós[b], Marcelo Maira[a]

[a] Megasalud, Chile
[b]Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Diabetes is a major cause of morbidity and mortality. Multiple strategies have been tried for managing populations that suffer from this disease; they all identified the need for correct patient identification. The objective was to assess the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of HIBA's Terminology Server (TSHIBA) for detection of diabetic patients in the Megasalud legacy health system.

Diabetes, Problem-oriented health record, Sensitivity and specificity, Clinical terminology.

What are the Barriers to the Submission of Good Quality Diagnosis Codes by Medical Practitioners in South Africa?

Luisa Whitelaw

Clinical Risk Management, Discovery Health, Sandton, South Africa – paper prepared by the author as a student of the University of Bath/Royal College of Surgeons of Edinburgh, as a research component towards the degree of MSc Health Informatics

While the use of ICD-10 codes in South Africa is legislated, various unofficial studies have shown the quality to be poor, in that there is little correlation of codes across sources. This study undertook to identify the barriers to the submission of accurate diagnosis codes by medical practitioners. A mixed methodology was used; one-on-one interviews were conducted with representatives of 6 doctor societies to identify the main quality barriers. The level of agreement with the identified barriers was measured through an on-line survey distributed to the doctors within these societies. There was no split between responses from the different specialist societies or between private and public doctors. The combined interview and survey results revealed the main barriers to be: mistrust of Medical Schemes' use of the ICD-10 codes, a lack of co-ordination and linking between different sources of coding and a fear of inadequate legal protection in the event that the use of an ICD-10 code(s) by a doctor causes a breech in patient confidentiality.

Implementation and Validation of a Tool for the Automatic Calculation of DRG

Gastón Lopez, Hernan Navas, Nancy Orrego, Santiago Wassermann, Guadalupe Elías Leguizamón, Daniel Luna, Fernán González Bernaldo de Quirós

Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Standards application for coding the medical information stored in Information Systems offers a series of advantages at the time of making management analysis. DRG (diagnosis related groups) code for calculation of the DRG code for each admission episode makes it possible to estimate costs as well as the consumption of hospital resources. With the purpose of running management processes to the information generated during admission episodes, the discharge summary was structured in several fields so that it could be then coded with ICD 9 CM and assigned a DRG code. The objective of this study is to compare an automatic coding tool for the discharge summary with DRG against a web tool (IRP). As the assignment of a DRG code was a manual process, the institution decided to develop a tool which would make those calculations automatically. Comparing the result from the newly developed tool to a web tool in 6566 clinical records were tested later the concordance of the system. Concordance was 98.43%, with a standard deviation of 98.1-98.7%.

Impact of Barcode Medication Administration on Nursing Activity Patterns in Taiwan

Huang Hsiu-Ya[a], Lee Ting-Ting[b]

[a]*Nursing Department ,Taipei Veterans General Hospital, Taiwan*
[b]*Nursing Department, National Taipei College of Nursing, Taipei, Taiwan*

The purpose of this study was to explore the impact of BCMA on nursing activity patterns and nurses' usage experience in Taiwan. A total of 4,940 observation items were collected by work sampling method on nurses who used BCMA and those who did not use, and interviewed were conducted to explore users' experiences.. The results of this study were as followed. First, nurses who used BCMA spent more time on indirect care and unit-related activities but less on medication-related activities. Second, nurses' direct care, indirect care, medication-related activities and personal time were significantly different on the day and night shifts. Finally, nurses commented that BCMA could enhance workflow and patient safety, however, hardware insufficiency and system functions needed further improvement. The study results could be a reference for BCMA outcome evaluation.

[e] *Iwate Prefectural University, Japan,* [f] *Nagano College of Nursing, Japan,* [g] *University of Shizuoka, Japan*

Patient information is shared widely among medical teams through EHR systems to improve quality and safety of care in Japan. However, in fact, medical personnel often and unnecessarily share patients' information with other personnel and professionals in daily care. Recently, the awareness of patients' privacy protection is growing in Japan. It is important to consider how to protect their privacy. A self-administered survey was conducted on 772 hospitalized patients. Questions on 4 core items on medical records regarding information privacy were asked. As a result, out of the 4 items, the last thing they wanted to be disclosed was "their family history." The closer relationship patients had with medical service personnel, the less they tended to hesitate to allow medical service personnel see their medical records.

Measuring the level of acceptance of the Electronic Health Record

Ybranda Koster – de Jong, William Goossen

There is a need to measure the acceptance of the electronic health record (EHR). The purpose of this study is to gain insight in the relation between level of adoption, computer use, and acceptance of the EHR. This is a Quantitative non-experimental research in two pilot units in an academic hospital. Results: Employees with the same degree of adoption of the EHR score significantly the same on the acceptation of the EHR and the computer in general. There is no significant difference between the degree of acceptation of the computer in general and the degree of acceptation of the EHR between the units. The conclusion is that the questionnaires for acceptation of computers and the acceptation of EHR and the questions on adoption are found to be valid en reliable and can be used for further research.

Evaluation of Telehealth use in Home Care: A Proposed Study

Ting-Ting Lee

Department of Nursing, National Taipei College of Nursing, Taipei, Taiwan

As chronic diseases have become prevalent and care resources are still limited, telehealth has been proposed as an alternative in addition to traditional treatments in the aging population. Although the benefits of technology use have been studied in recent years, the evaluation of teleheath has not been explored extensively. This study proposed a framework to evaluate the impact of telehealth use from different perspectives. Clients and care professionals from a long term care facility where telehealth has been implemented will be invited for this study. Individual interviews will be conducted to explore the impact of this technology use. Data of emergency visits and medical appointments will be obtained prior to and after the technology use to compare the differences. It is hoped that the technology use could benefit the client, their families, the care provider and the organization.

Data Mining in Self-Management

Sunmoo Yoon[a], Suzanne Bakken[a,b]

[a]*School of Nursing, Columbia University, New York, N, USA*
[b]*Department of Biomedical Informatics, Columbia University, New York, NY,USA*

Self-management is recognized as a key component of strategies for health promotion, disease prevention, and acute and chronic disease management. Self-management data are increasingly available in digital form. Our objective was to explore the data mining literature to determine the extent to which data mining techniques had been applied to the domain of self-management. We searched multiple databases and manually reviewed and summarized studies according to the types and methods of data mining. Few studies have applied data mining to the topic of self-management and the range of methods applied is limited. Data mining techniques have the potential to improve our understanding of self-management.

The nursing documentation system in the Tyrolean federal hospitals produces an enormous amount of highly structured nursing data. We built an extensible data mart aggregating these data in combination with information on the patients' medical history and current living conditions. Using the workflow-based application KD^3 it is possible to easily explore, visualize and evaluate the data in order to reach our goal: finding new knowledge supporting evidence based, quality assured patient care.

Evaluation of a fall-risk assessment tool implemented in an EMR System

InSook Cho[a], IhnSook Park[b], EunMan Kim[c]

[a] *Department of Nursing, Inha University, Incheon, South Korea,*
[b] *Department of Nursing, Seoul National University Hospital, Seoul, South Korea,*
[c] *Department of Nursng, SunMoon University, Chung-nam, South Korea*

This paper examines the routine clinical use and the validity of a built-in fall-risk assessment tool to identify patients at high risk for falls, which has implemented in the enterprise electronic medical record (EMR) system of a tertiary teaching hospital in Korea. The tool was developed using an evidence-based approach as a fall safety initiative. It is consisted of nine items with dichotomous score and the sum score ranges from 0 to 9. The cutoff score is six. A retrospective analysis of 1,934 inpatient admissions in 2007 was conducted. Falls status was ascertained from the hospital's accident self-report system and the review of electronic nursing records in the EMR system. This validity study assessed the sensitivity, specificity, positive predictive values and negative predictive values with the associated 95% CI. The results showed much low sensitivity at the current cutoff score. We found many weaknesses of the tool and great opportunities to improve our fall prevention practice.

Discharging the patient from Hospital to Home-Care: An application attempting to combine E 2369 (CCR), ISO 13606-1, and prEN 13940 Standards

Basile Spyropoulos, Maria Botsivaly

Medical Instrumentation Technology Department, Technological Education Institute of Athens, Athens, Greece

The aim of this project was the development of an application attempting to combine E2369 (CCR), ISO 13606-1, and prEN 13940 Standards and to comply with them by adopting all crucial features, and the most innovative functional solutions, according to the requirements of those standards. The developed system consists of a first module that is responsible for the creation of a typical CCR that contains the appropriate demographic and administrative data, as well as the relevant clinical information, while a second module is responsible for the creation of a homecare plan which will be included in the Care Plan section of the CCR. Finally the system comprises of a prototype ontology based upon the HL7 – Clinical Document Architecture (CDA), and an application that converts the referral documents into a CDA–compliant format and the contents of the CDA–compliant documents into ontology instances.

Development of a Computerized Material Management System in a University Hospital

Maria Lúcia Habib Paschoal[a] Valéria Castilho[b]

[a] *Nursing School of the University of São Paulo, Hospital Universitário at the University of São Paulo.*
[b] *Administration Department of the Nursing School at the University of São Paulo*

The aim of this study is to present the implementation of computerized management of materials system (CMS) of the University Hospital at the University of São Paulo (UH-USP). The UH has an expense with consumables which represent 49% of the cost of the hospital, a value above the reports found in the literature [1]. In the hospital, the materials were distributed to users, according to predetermined material quotas, being replaced at fixed dates. This traditional system, with manual control, had some problems, such as: monthly prevision with poorly programmed quotas, loss of inventory control, total lack of knowledge on consumption, waste and lack of material. Based on the facts above mentioned, it was planned to develop a computerized system for materials management with an interface with other existing programs in the hospital.

How Did We Show the IT People What We Nurses Want about the System? The Case of Self-developed Ostomy Skin Assessment Tool with VBA

Ming Chuan Kuo[a,b], Polun Chang[a]

[a] *Institute of BioMedical Informatics, National Yang-Ming University, Taipei, Taiwan/ROC*
[b] *Cathay General Hospital, Taipei, Taiwan/ROC*

The home-made Nursing Information Systems (NIS) have long been known to be done by IT people trained with using "Window-based" Interface building tools and a database-oriented thinking. However, for the healthcare professionals, we need to have an easy IT tool fitting into our workflow and thinking process. In this study, we used the VBA to design an Ostomy Skin Assessment Application to communicate to our IT people. The results support the positive value of using VBA as a communication tool for the system design.

VP-Based Final Examination – a model to reach advanced level standards for the degree of Paediatric Nursing in Sweden

Elenita Forsberg[a], Uno Fors[b], Kristina Ziegert[a]

[a]*School of Health and Social Sciences, Halmstad University, Sweden*
[b]*Department of Learning ,Informatics, Management & Ethics, Karolinska Institutet, Sweden*

Web-SP is a system for virtual patient, developed at Karolinska Institutet (KI) in Sweden. In this study, we examine Web-SP cases for assessing paediatric nursing students. To investigate the possibility of using Web-SP for assessing clinical reasoning skills and to study students acceptance and to determine whether the skills required of experienced paediatric registered nurses could be adequately assessed by the system. The intervention included a two-part of exams. The results show high levels of acceptance of the Web-SP as an examination method. Students also thought it was a good way to practice their clinical skills. Findings have relevance in the development of clinical information systems where clinical decision making is important.

Development and Evaluation of Website about Nursing Care in Post Anesthesia Care Unit

Thaís Honório Lins[a], Heimar de Fátima Marin[b]

[a] *University of São Paulo (UNIFESP), São Paulo, Brazil, BR*
[b] *Federal University of São Paulo (UNIFESP), São Paulo, Brazil, BR*

Introduction: The Post Anesthesia Care Unit (PACU) is the unit where patients under an anesthetic and surgical procedures must be kept to receive specialized nursing care. It is important for nurses to have access to the updated information to deliver care to the patients. Objectives: To develop a website about Post Anesthesia Care Unit related to the nursing care and evaluate its content. Methods: Research based on the DADI methodology. The evaluation was performed by practice nurses in the criteria of authority, general content, presentation and information reliability. Results: The website comprises 82 pages of information, photos and illustrations. The content was separated into stages to facilitate organization and subject understanding. Seventeen nurses evaluated it as excellent. Conclusion: The information available about the nursing care at PACU is reliable and valid.

Informatics Competencies Study in Iberoamerican Nursing Population

Erika Caballero[a], Carol Hullin Lucay Cossio[b], Veronica Rojas[c]

[a] *National Director of University of San Sebastian Nursing School, Santiago, Chile. Director & Co Founder of eHealth System.*
[b] *Senior Business Analyst Department of Health & Co Founder of eHealth Systems, Santiago Chile &Melbourne, Australia* [c]*General Manager & Co Founder of eHealth Systems, Santiago Chile*

Nowadays, many hospitals and health center of the Latino-American region have adopted information technology (IT), to help nurses in their practice. Less study has focused in computer literacy of Latino American nurses. The purpose of this study was to determine computer literacy and use of systems and technologies of the information amongst nurses. The on line survey was the instrument for data collection. The respondents were 435 Chilean and Latina-American nurses. The results of this study revealed that 99.7% of nurses to possess knowledge and abilities in the computer use, but not of tools of informatics science in health nurse practice. They demonstrate to discharge motivation and interest to use nursing informatics and consider necessary to become qualified.

Design and Development of Tailored Interactive Education Program for Safe Medication of the Elderly

Myonghwa Park

College of Nursing, Keimyung University, Republic of Korea

Safe medication is one of major health issues in the elderly population who has chronic multiple diseases. The purpose of this paper was to describe a research in progress which purpose is to develop a tailored interactive education program using age friendly interface to prevent medication misuse and abuse of the elderly in the community settings. A program for safe medication is being developed using the following five processes: 1) Analysis stage 2) Designing stage 3) Content Framing and development stage 4) Program application stage 5) Evaluation stage. The completed program would be applied to the elderly in the community and tailored interactive education could be an effective teaching media of safe medication for the elderly in the information age.

E-learning in the Undergraduate Nursing Course

Cláudia Prado[a], Eloá Otrenti[a], Heloísa Helena Ciqueto Peres[a], Irene Mari Pereira[b], Jaqueline Alcântara Marcelino da Silva[b], Luis Carlos Santiago[c], Maria Madalena Januário Leite[a], Valéria Leonelloa[a]

[a] School of Nursing, University of São Paulo;
[b] School of Nursing, Vocational Guidance Department, University of Sao Paulo
[c] Alfredo Pinto Nursing School, University of Rio de Janeiro State

This study aimed to show validity of the experience of e-learning in a discipline with students in 4th semester of the Undergraduate Nursing Program of Nursing School, Sao Paulo University. The Nursing Education: Trends and Challenges discipline, intends to demonstrate that the educational process is inherent in nursing work in all its aspects. The workload is composed of 60 hours, with 30 hours devoted to classroom teaching and the other 30 hours to e-learning. The platform chosen for structuring the discipline was Moodle, because it has online open access. At the end of the course, students performed a simulation of educational action for evaluation purposes. Participation in virtual activities was also evaluated. This strategy enabled the collective construction of knowledge through discussions, studies and richer conclusions.

Alert information sharing – a proposed model

Rikard Lövström[a], Rong Chen[b], Gunnar O Klein[c]

[a] *The Swedish Medical Association, Stockholm, Sweden*
[b] *Department of Biomedical Engineering, Linköping University, Linköping, Sweden*
[c] *Dept of Microbiology, Tumour and Cell Biology, Karolinska Institutet, Stockholm, Sweden*

Some types of information in Electronic Health Records can have a particular significance to ensure patient safety e.g. notes on severe hypersensitivity to medicines. In order to ensure that all health professionals take note of this, it is important that Alert Information is structured and can be shared between providers and systems. A defined structure is also a prerequisite for the use of such information for automatic decision support. This paper presents an analysis of requirements and describes a conceptual model and a visual symbol for presentation. This paper also discusses how alert signals can be generated. The first implementation of this has been made in the context of the Swedish National Patient Summary project and it is the basis for ongoing formal standardization in CEN and ISO.

[c] *University of Toronto Medical School, Toronto, Ontario, Canada*
[d] *ClickDiagnostics, Boston, Massachusetts, USA*
[e] *University of Botswana, Gabarone, Botswana*

Currently clinicians in rural sub-Saharan Africa have limited access to the Internet, which may impede the practice of evidence-based medicine. However, wireless mobile phone access and use is extensive. The University of Pennsylvania in collaboration with the National Library of Medicine (NLM) launched txt2MEDLINE and a Short Messaging Service (SMS) optimized, searchable clinical guidelines in Botswana. This pilot project will enable clinicians to query and receive PubMed abstract summaries and country-specific clinical guidelines using mobile phones. The objective of this project is to evaluate the utility of these tools for clinicians in Botswana. It will be an added resource to a pre-existing telemedicine network. Establishing the usefulness of these resources may provide an effective working model for other countries where limited Internet access impedes upon patient care.

[d] *Department of Obstetrics and Gynecology, University of Pennsylvania Medical Center, Philadelphia, PA*
[e] *Botswana-UPenn Partnership, Women's Health Initiative, Gaborone, Botswana*
[f] *Department of Dermatology, University of Pennsylvania Medical Center, Philadelphia, PA*

Throughout the developing world, delivery of women's health care, specifically cervical cancer screening, is limited by cost and access to trained personnel. Visual inspection with application of 4% acetic acid (VIA) is a practical, inexpensive alternative to cytology-based screening in areas where women's health resources are limited. We present results of a prospective case control study evaluating the accuracy of off-site (remote) expert diagnosis using photographic images of the cervix with VIA (PIA) in HIV-positive women in Gaborone, Botswana. Mobile telemedicine using the 5 Megapixel camera-enabled Samsung Soul U900 cell phone to photograph the cervix after VIA allows clinicians in "see and treat" cervical cancer screening clinics to capture high quality images of the cervix. Photos can then be transmitted via the mobile phone to a gynecology specialist located remotely, in order to provide accurate diagnosis of precursor lesions, and appropriate triaging and implementation of therapy.

How integrated health IT systems improve efficiency of MRSA Surveillance in hospitals

Tong YH[a], Tsui CH[b], Sin H[b], Choi HY[b], Cheng M[b], Chung A[b], Cheung NT[a], Fung V[a], Wong WN[a], Sek A[a]

[a] *Health Informatics Section, Hospital Authority of Hong Kong*
[b] *Information Technology Department, Hospital Authority of Hong Kong*

MRSA infection poses great health problem in the community. For decreasing MRSA nosocomial infection, hospitals have great resource to collect relevant clinical data related to MRSA infections to monitor the trends in hospitals and community and to develop protocol and guidelines of its control for infection management improvement. A clinical IT system, named MRSA Surveillance System, with integration of different clinical IT systems has been developed and implemented in hospitals of Hospital Authority of Hong Kong in 2007, in order to facilitate the originally labor-intensive data capture by frontline infection control teams related to MRSA surveillance and to provide updated and quality management reports for prompt MRSA infection identification and control. This integrated system improves efficiency of MRSA surveillance in hospitals.

Mutual Isolation and the Fight for Care: Exploring Home-based Healthcare in two South African Communities

Izak van Zyl, Anton Delen, Siphokazi Tswane

Home-based Healthcare Research Unit, Faculty of Informatics and Design, Cape Peninsula University of Technology, Cape Town, South Africa

The 'duty' of home-based care is often imparted on non-government institutions that employ nurses and caregivers to provide care. These organisations are hampered by a capital barrier in that they rely on grants and donations. Therefore they are often not financially sustainable. This generally results in caregivers and nurses being underpaid and –resourced. A lack of resources translates into fractured coordination and systems when administering care. It has become crucial to redirect these systems so as to be more practical and effective. Yet this process cannot commence without understanding the many dynamics that shape the home-based healthcare context. A bottom-up ethnographic approach is therefore necessary to inform a proper care 'solution'. For this analysis, two communities in the Western and Eastern Cape of South Africa were assessed in their home-based healthcare endeavours. It was found that the care context is volatile and that caregivers require more resources to guarantee continued service. These findings are significant for understanding the 'grassroots' of home-based healthcare in South Africa for the possibility of developing a (technological) solution to care.

CHRONIOUS: A Multinational and Interdisciplinary European Project for Innovative E-Health Management of Chronic Patients at Home

R. Farré[a], A. Papadopoulos[b], V. Isetta[a], G. Munaro[c], R. Rosso[c], on behalf of CHRONIOUS

[a]*Biophysics & Bioengineering Lab, School of Medicine, University of Barcelona-IDIBAPS and CIBERES, Spain*
[b] *FORTH-BRI, Greece*
[c]*TESAN, Italy*

CHRONIOUS is a highly innovative Information and Com-munication Technologies (ICT) research initiative that aspires to implement its vision for ubiquitous health and lifestyle monitoring of people with chronic diseases. CHRONIOUS is funded by the European Union (ICT-2007.5.1: Personal health systems for monitoring and point-of-care diagnostics). CHRONIOUS, with a budget of 10.59 million €, is a multidisciplinary consortium composed by 19 partners - including industry, academia and hospitals - from 12 European countries. The CHRONIOUS project works on an innovative wearable system with intelligent sensors which can monitor patients' vital body parameters, context and environmental variables, patient motion and other activities such as drug and food intake. The system will assist both patients and physicians by providing tools for health status monitoring and decision support**.** In particular CHRONIOUS focuses on chronic kidney and pulmonary diseases.

LexCare Suite: Korean National Terminology Server for Interoperable EHR

Sungin Lee, Senator Jeong, Soo Kyoung Lee, Seung-Jae Song, Hong-gee Kim

Biomedical Information Knowledge Engineering Laboratory, School of Dentistry, Seoul National University, Seoul, Korea

This poster describes our ongoing efforts spanning more than 5 year, in which a terminology server, comprising a centrally-managed terminology repository and terminology management applications, has been developed as part of a government-funded initiative to develop core technologies necessary to implement lifetime EHR. The server called LexCare Suite houses core standard reference terminologies such as International Classification of Disease (ICD-10), International Classification for Nursing Practice(ICNP), Systematized Nomenclature of Medicine(SNOMED-CT), Logical Observation Identifiers Names and Codes(LOINC), Korean Standard Terminology of Medicine(KOSTOM, a Korean equivalent of UMLS), and RxNORM. The server comprising LexCare Editor (a localized and customized LexGrid editor) and auxiliary modules is developed to meet the terminology needs of primary to tertiary hospitals in Korea. This paper introduces LexCare Suite in detail.

Indicators of Success for Clinical Engagement in Scotland's National eHealth Programme

Heather Strachan[a] and Caroline Vance[b]

[a] *eHealth Directorate, Scottish Government, Edinburgh, United Kingdom*
[b] *Director, Synchroni Consulting Ltd., Ayr, United Kingdom*

A survey of Nursing, Midwifery and Allied Health Professions (NMAHP) capability and capacity was undertaken to assess clinical engagement in Scotland's National eHealth Programme. The survey explored four themes; leadership and engagement; eHealth tools; eHealth skills; and knowledge management. The results were shared via a Clinical eHealth Toolkit in the form of" indicators of success" and linked with working examples of good practice to support engagement of all clinicians in eHealth.

Keyword:
Nurses, Midwives, Allied health professionals, Clinical engagement, eHealth

Medical Informatics Efforts in Turkey

Osman Saka[a,b], Neşe Zayim[b], Kemal Hakan Gülkesen[a,b]

[a]*Board Member, Turkish Medical Informatics Association*
[b]*Akdeniz University, Faculty of Medicine, Department of Biostatistics and Medical Informatics, Antalya/TURKEY*

Parallel to the developments in the world, health informatics field is experiencing a continuous growth in Turkey. Health informatics efforts in Turkey initiated in 1992 with the establishment of postgraduate Medical Informatics Education Program in Akdeniz University, Antalya. Today, six institutions provide postgraduate health informatics education in Turkey. In 1999, Turkish Medical Informatics Association (TURKMIA) was founded. Until today, TURKMIA organized several activities in order to fulfil its guiding role in health informatics in Turkey. In order to improve healthcare services in Turkey, "National Health Information System" project was initiated under the authority of Ministry of Health in 2003. In this study, a review of developments in the field of health informatics in Turkey will be presented.

[e] *Institute for Medical Informatics, University of Applied Sciences Mannheim, Germany*
[f] *Department for Information Technology and Business Development, Medical Centre Braunschweig, Germany*

Secure electronic documentation has become increasingly important in healthcare. However appropriate IT-infrastructures develop slowly in healthcare settings. This leads to uncertainties in healthcare industries and to tremendous costs caused by duplicate archiving of health records. We established a Competence Centre for Electronic Signatures in Healthcare (CCESigG) to support implementation and provide information services for electronic signatures. Our objective is to report about CCESigG and first experiences with its services. Institutions like CCESigG may accelerate the introduction of electronic signatures, particularly in those countries, which rely on these signatures regarding legal management and archiving of electronic health records.

Towards the Standardization and Promotion of Interoperability in eHealth

Marta Ortega-Portillo, María de las Mercedes Fernández-Rodríguez, María Fernanda Cabrera-Umpiérrez, María Teresa Arredondo

Life Supporting Technologies, E.T.S.I. Telecomunicación. Universidad Politécnica de Madrid, Spain

Interoperability and solutions based on global clinical and administrative standards are considered a basic strategy to improve medical care. In this sense, several networked initia-tives in the development and promotion of Open-Source Soft-ware (OSS) are ongoing. However, these initiatives are not specifically conceived to function as collaborative resources for the multidisciplinary set of stakeholders involved in the different aspects of eHealth. In this context, SHARE project enhances this situation by means of a web platform for current and future actions in research, development and technology transfer in the field of OSS applied in the eHealth sector.

Selecting Clinical Computing Hardware Devices for Hospital Wards: The Role of IT Vendors

Mirela Prgomet, Joanne Callen, Johanna Westbrook

Health Informatics Research and Evaluation Unit, Faculty of Health Sciences, The University of Sydney, Australia

There is limited evidence available to inform decision making processes for selecting clinical computing hardware devices for implementation on hospital wards. We undertook a study to determine the role of IT vendors in this decision making process and to ascertain the factors that vendors deem important to consider in the selection of computing devices. Interviews were conducted with twelve vendors who provide hardware and/or software products to hospitals. Interviews were recorded and the transcripts were analyzed by coding of key concepts. The results highlight the need to assess information about a number of technology, workflow and environmental factors. The study provides a basis for developing a framework to assist decision makers in identifying the ideal devices to adequately support clinical work practices.

eHealth for all: Territory wide electronic health records in Hong Kong

ACH Sek, NT Cheung

Department of Health Informatics, Hong Kong Hospital Authority

Electronic health records (eHR) definition varies across different countries. With the global push for eHR adoptions, only a few has achieved a longitudinal records at the point of care and there is no territory-wide eHR in the world yet. Since 2008, Hong Kong has embarked on an eHR journey to allow "records follow patients". This paper will detail the methods for building partnerships across the health sectors (both private and public) to achieve a common objective of HIE to support improved patient care, building on incremental extensions of core functionality and new pilot platforms and demonstrating adoption strategies and key principles (clinical, technical, policy) to support a territory wide next-gen EHR.

Electronic health records (eHR), Hong Kong, Medical records systems, Implementation.

Mapping to SNOMED CT in Sweden – a matter of quality

Ulla Gerdin[a], Bengt Kron[a], Lars Berg[a], Daniel Karlsson[b], Roland Morgell[c], Anna Vikström[cd]

[a] *The National Board of Health and Welfare, Stockholm, Sweden,*
[b] *Division of Medical Informatics, University of Linköping, Sweden,*
[c] *Stockholm County Council, Sweden,*
[d] *Karolinska Institutet, Stockholm, Sweden.*

A key objective of the Swedish IT strategy for health care is to ensure that all health records share a common terminology [1]. The national health organisations in Sweden have decided to use SNOMED CT and a clinical information model in adherence to EN 13606 and openEHR. Mapping clinical data to controlled terminologies is an important step towards achieving standardisation of data [2]. The reliability of SNOMED CT mapping is imperfect [3]. Thus, measures which lead to a high level of semantic agreement between mappers are of great importance when aiming at high quality. We have elaborated guiding principles and rules for the mapping activities and qualification requirements for mappers. An outline of the semantic boundary between the terminology and the clinical information model has been elaborated. Training has been carried out in order to obtain a common attitude to mapping. This poster describes the lessons learned.

Keywords:
SNOMED CT, Semantic mapping, Guiding principles, Clinical information model

Governing quality in translation of SNOMED CT

Karin Ahlzén, Ulla Gerdin, Erika Ericsson

National Board of Health and Welfare, Sweden

Translation of SNOMED CT is part of the national IT-strategy for health and welfare. The strategy identifies the Swedish special language for health and welfare as interdisciplinary and including of meta concepts with definitions, classifications and SNOMED CT. The special language is also a vital part of the national information structure and should be reliable and safe to use. The European effort to make it possible for the patient to share health data with a physician in another country is yet another aspect of quality in translation. The translation of concepts from one language to another is therefore of big importance. This poster points out one of the quality issues: the choice of and the qualification of recommended terms. The framework and process are vital to the outcome and the question we want the answer to is: will the recommended term be accepted by the professionals? This poster discusses used methods and lessons learned.

Keywords:
Terminology, SNOMED CT, Translation

The National information structure for eHealth in Sweden

Åsa Schwieler, Lotta Holm Sjögren

National Board of Health & Welfare, Stockholm, Sweden

The National Board of Health and Welfare has been commissioned by the Swedish government to develop a generic National Information Structure. The Information Structure consists of three models: The generic Process-, Concept- and Information models. The National Information Structure will form the foundation for development of ICT solutions that support process oriented care and will also be used as a basis for forming a regulatory framework specifying the content, form and structure of information. It is our view that the specialisation and implementation of the generic models in eHealth solutions will contribute to improvements of the quality of the services delivered to patients. The foreseen benefits include better cooperation in the clinical work, systematic follow up, clinical decision support and enhanced patient safety. It will provide and enable effective use of secondary data to perform management and evaluation of patient outcomes.

Keywords:
Information structure, process model, concept model, information model, semantic interoperability.

ALIAS: Alpine Hospital Networking for Improved Access to Telemedicine Services

Frédérique Laforest[a], Salma Sassi[a], Marian Scuturici[a], André Flory[a]
Thierry Durand[b], Emmanuel Eyraud[b]
Natalia Allegretti[c], Claudio Beretta[c], Roberto Nardi[c], Roberto Zuffada[c]

[a] *Université de Lyon, CNRS - INSA-Lyon, LIRIS, UMR5205, F-69621, France*
[b] *GCS SISRA, Centre Léon Bérard, Lyon, France*
[c] *Lombardy Region, General Directorate for Health, Milano, Italy*

The ALIAS project is a European project funded by the Alpine Space programme started in August 2009. ALIAS addresses medical services and information inadequacy to ensure health care provisions in the Alpine Space where telemedicine services are not widely exploited. Alpine space touristic vocation during some periods of the year makes its healthcare structures "periodically" inadequate to face a widened request of services supply. On the other hand, a major receptivity of those structures during the rest of the year is unnecessary due to the low density of Alpine space local residents. ALIAS is aimed at linking together a number of Alpine space hospitals enabling the creation of a Network shaping the ALIAS Virtual Hospital Network (VHN) for sharing medical information, adopting telemedicine and best clinical practices, to improve the efficiency of hospitals in that area.

Productivity and management tools in the Chilean hospital market

Luis Osorio[a], Sandra de la Fuente[b]

[a] *Hospital Cínico Universidad de Chile, Chile*
[b] *Facultad de Ciencias Físicas y Matemáticas, Universidad de Chile, Chile*

The Project called "Productivity and Management Tools in the Chilean Hospital Market" being developed by the "Hospital Clínicc Universidad de Chile" (HCUCH), and the Inter-American Development Bank (IADB) aims to promote competitiveness in Chilean healthcare industry, so that there is a healthcare market with diverse companies offering healthcare services for public and private insurances companies. The specific goal is to increase the productivity of HCUCH and of small and medium size private hospitals, to facilitate the access to AUGE plan. This objective will be achieved by using new tools based on information and communication technologies for management and delivery of healthcare services. The Project is structured into four components: 1) To prepare the private sector of healthcare providers for management innovation, 2) To prepare the HCUCH for management innovation, 3) Technology transfer from HCUCH to private hospitals and 4) Monitoring, evaluation, communication of results and experience.

Countrywide implementation of Patient Appointment Reservation System in Lithuania

Romualdas Jonas Kizlaitis

Informatics and Development Centre, Vilnius University Hospital Santariskiu klinikos, Vilnius, Lithuania
Systems Analysis Department, Institute of Mathematics and Informatics, Vilnius, Lithuania

20 project partners – the major Lithuanian Hospitals and Primary Care Centers - implemented European Union Structural Funds supported Electronic Patient Appointment Reservation Project (budget of 2.1 million EURO). The EU support was used for developing and adding new features to the Patient Appointment Reservation System of Vilnius University Hospital and spreading it nationwide. The System is based on modern Mobile and Information technologies, such as SMS, Mobile Sync, web services etc. The main objective was achieved - the System enables Patient to reserve an appointment to the GP and all level specialists. GP or any specialist can assist Patient and choose the best suitable consultant and book an appointment for his Patient at any participating institution.

OpenXdata aides in monitoring and evaluating a National Dog bite and Rabies surveillance in a low resource setting of Pakistan

Julia Irani[a], Daniel Kayiwa[b], Owais Uddin Ahmed[c], Aamir Khan[d], Jørn Klungsøyr[e]

[a] *Center for Health Informatics, Interactive Research & Development & Indus Hospital, Karachi, Pakistan*
[b] *Makerere University Faculty of Computing & IT, Kampala, Uganda; OpenXData.org, Global*
[c] *Center for International Health, University of Bergen, Norway*
[d] *Interactive Research & Development & Indus Hospital, Karachi, Pakistan*
[e] *Center for International Health, University of Bergen, Norway; OpenXData.org Global Consortium*

National epidemiological surveys to estimate the burden of disease can become difficult to monitor with limited resources. When the project coordinator is located in one city, and surveillance is being carried out in several urban and rural sites, monitoring the field site becomes very difficult. With the use of cell phones as data collection tools, project coordinators can quickly get feedback on their fieldworkers and their data, which has proved invaluable in managing the study. The patient data captured by the cell phone is then transmitted via GPRS to a central server where it is stored in a database and integrated with Google Earth for later use in epidemiological research. Our implementation required field workers to sign in and sign out daily along with collecting relevant surveillance information. This data is then extracted from the database and presented visually within a google earth web portal.

Information Technology based process model for Health Insurance – Adoption and Implementation

Sushil Kumar Meher[a], B.K.Ratha[b]

[a] *All India Institute of Medical Sciences, Ansari Nagar, New Delhi – 110029 INDIA*
[b] *Utkal University, Bhubaneswar, ORISSA India*

The scope of discussion involves an overview of the industry forces, policies that are responsible for the poor penetration of health insurance in India. This subsequently has an impact on the rate of adoption of IT amongst healthcare providers since, from the example of the US industry, health insurance companies are key influencers for adoption of IT for process stream lining and standardization. Various facets of technology that are discussed result in reduction of errors, process and data standardization, process turn-around time improvement, reduction of working capital etc. Technologies like ICD codes, electronic data interchange, electronic data entry methods, authorizations, centralized databases etc. have a strong role to play in this evolution. Coupled with this is the fact that government policies should stipulate minimum norms for IT technology compliance like HIPAA in the US, that can ensure the adoption and success of the technology model presented

Digital Libraries and Health Information Access in Lusaka, Zambia

Mary White[a], Heather Lee[b], Craig Wilson[b], Lynda Wilson[c], Heather White[b], Cliff Missen[a], Francina Makondo[d]

[a] *WiderNet Project, University of Iowa, Iowa City,*
[b] *Sparkman Center for Global Health, University of Alabama at Birmingham, Birmingham, AL*
[c] *School of Nursing, University of Alabama at Birmingham, Birmingham, AL*
[d] *Medical Library, University of Zambia-University Teaching Hospital, Lusaka, Zambia*

The goal of the Zambian Health Information Project is to enhance access to health information through customized health information portals on the eGranary Digital Library. Over the past year, a partnership between the University of Alabama at Birmingham's Sparkman Center for Global Health, the University of Iowa's WiderNet Project, and Zambian health institutions has been working to create portals of Medical, Nursing, and Public Health specific information for health faculty and students in Lusaka, Zambia. The eGranary offers an offline mechanism to access digital information, over an institution's local area network (LAN). This approach is especially appropriate to areas of the world where access to the Internet is limited. This poster will discuss the experience of portal creation and implementation of the digital library at health institutions in Lusaka, Zambia.

Examining PACS Impacts in the Malaysian Context: Its Utilization and Potential Work Interruptions in Radiology Work Practices

Rohaya Mohd Nor

Faculty of Economics and Business, Universiti Malaysia Sarawak, Malaysia

Utilization of a large-scale PACS has resulted in substantial changes in radiology work practice of a hospital-based radiology department in Malaysia. Based on a three-month period undertaking field work with this organization, this study found that PACS application has contributed to systematic radiology work processes as compared to the traditional-based radiology work practice that centered around the usage of x-ray film and paper-based medical record. Radiologists and radiographers were generally satisfied with the existing PACS infrastructure. However, this study also found that the radiologists and the radiographers have also experienced disruptions in their routine work practice. This paper reports evidence of the nature of interruptions linked with a large-scale PACS utilization in the radiology work practice. Analysis of the data reveals that both human and technical related factors are the root causes of the interruptions.

eSurveillance and eMonitoring for the epidemic of Chikungunya Dengue diseases in capital City New Delhi, INDIA

Ashutosh Biswas[a], Bikram K. Ratha[b], Susil Kumar Meher[a]

[a] *All India Institute of Medical Sciences, Ansari Nagar, New Delhi – 110029 INDIA*
[b] *Utkal University, Bhubaneswar, ORISSA India*

Chikungunya (chik-en-GUN-yah), also called chikungunya virus disease or chikungunya fever, is a viral illness that is spread by the bite of infected mosquitoes. The disease resembles dengue fever, and is characterized by severe, sometimes persistent, joint pain (arthiritis), as well as fever and rash. It is rarely life-threatening. There is no specific treatment for chikungunya. Prevention centers on avoiding mosquito bites in areas where chikungunya virus may be present, and by eliminating mosquito breeding sight. The states affected by chikungunya are Andhra Pradesh, Karnataka, Maharasthra, Tamil Nadu, Madhya Pradesh, Gujarat, Kerala, A&N Island, NCT of Delhi, Rajasthan, Pondicherry, Goa. The number of suspected chikungunya fever cases reported.

Current status of the new Healthcare Advice System that uses e-mail and electronic data exchange for prevention of metabolic syndrome: A study in Japan

Yuko Iwasawa[a], Tetsuo Sakamaki[b]

[a] *Medical Informatics and Decision Sciences, Gunma University Graduate School of Medicine, Gunma, Japan*
[b] *Department of Medical Informatics and Decision Sciences,Gunma University Hospital, Gunma, Japan*

In April 2008, the Japanese government introduced "Health Checkups and Healthcare Advice with a Particular Focus on the Metabolic Syndrome" for all citizens aged between 40 and 74 years. The new system emphasizes on the requirement of an electronic data exchange based on the standardized XML format (HL7) between hospitals and medical insurance providers. All XML data are finally submitted to the government. In addition, it recommends the use of e-mail. The purpose of this study was to evaluate the effectiveness of the new healthcare advice system by analyzing XML data. Our data shows the difficulty encountered by adopting the standardized electronic data exchange owing to many errors in the XML data (error rate = 75%). We observed that for weight loss, intervention for 6 months was more effective than only 1 counseling session (-2.5 [3.3] kg vs. -1.1[2.5] kg; $P < 0.01$). In an intervention for weight loss, e-mail was more frequently used than was telephone. However, there were no significant correlations between the supporting methods and weight loss.

Metabolic syndrome, Weight management, e-mail

Assessment of Hypnotic Prescriptions in Adult Cancer Inpatients Reusing Data in a Clinical Data Warehouse

Qiyan Zhang, Yasushi Matsumura, Taizou Murata, Hiroshi Takeda

Department of Medical Informatics, Osaka University Graduate School of Medicine, Japan

Cancer mortality accounts for one-third of all disease mortalities in Japan. Hypnotics are common medications to treat cancer-related stress and other symptoms. Studies on hypnotic usages were mainly from survey data. In this study, we addressed this issue by reusing data in our clinical data warehouse (DWH). Adult cancer patients who were admitted for at least 7days (2007/4/1-2008/4/1) were defined as eligible study subjects. A multinomial logistic regression model was built to assess relationships between six dichotomous variables with hypnotic prescriptions. We identified 1,947 cases, among which 55.3% (1,076) were prescribed with hypnotics; 49.4% (961) were older than 65 years; 48.5 % (945) were females; 19.2% (374) had operation procedures; 29.6% (576) were admitted for more than 30 days; 47.4% (923) were prescribed with anticancer agents and 22.1 % (431) were prescribed with opioids. The overall model was well-fitted (χ^2=177.518, df=6, p=0.000). The Wald statistic of individual variables indicated that the adopted predictors were significantly related to the hypnotic prescriptions ($P<0.05$).

Development of a web site for information of the general public regarding travel diseases endemic in the Mediterranean basin: the Greek Case

Marianna Diomidous[a], Dimitrios Zikos[b], John Pistolis[c], John Mantas[d]

[a]*Public Health, Laboratory of Epidemiology – Faculty of Nursing, University of Athens*
[b] *Health Informatics- Faculty of Nursing, University of Athens*
[c]*Information and Comm. Systems Enginner, Laboratory of Health Informatics – Faculty of Nursing, University of Athens*
[d] *Health Informatic, Laboratory of Health Informatics – Faculty of Nursing, University of Athens*

Travelers to different countries should be aware of the potential for acquiring diseases and injury which are not common in their own country. Immunizations, preventative medications, and general precautions should be considered prior to trips to different parts of the world. [1] Immunizations against diseases such as rabies, tetanus, diphtheria etc may be recommended or required for travelers to certain countries, as well as preventative medications against traveler's diarrhea, malaria, and tuberculosis may be necessary. Information on Travel Diseases, Vaccination requirements and general Travel Health advice are readily available through the WHO and the Department of Communicable Disease Surveillance and Response (CSR). Additionally, CDC also provides information on current travel medical recommendations and requirements for various countries all over the world.

Evaluating Health Information Exchange for Public Health

Jacqueline Merrill[a], Andrew Phillips[b], George Hripcsak[a], Lisa Kern[c], Rainu Kaushal [c]

[a] *Department of Biomedical Informatics, Columbia University, New York, NY*
[b] *School of Nursing, Columbia University, New York, NY,*
[c]*Weill Cornell Medical College, New York, NY*

We describe an innovative approach to evaluating health information exchange for public health (HIE for PH), representing one project being conducted by the multi-institutional Health Information Technology Evaluation Collaborative (HITEC) in New York State (USA). We use a modified DeLone and McLean framework to conduct a comparative case study of multiple stakeholders involved in HIE for PH applying qualitative and quantitative evaluation methods. We will present preliminary findings from an evaluation of six Regional Health Organizations (RHIOs) that are implementing a PH Use Case to demonstrate HIE within New York's centralized state health information network (SHIN-NY). This study combines existing approaches into a generalizable evaluation methodology that will produce policy relevant conclusions as well as criteria for longitudinal evaluation of state and regional HIE for PH initiatives.

IntegraEpidoso: a web framework to integrate Epidoso data to spread data access for ease data analysis, ease share knowledge, and clusterization

Frederico Molina Cohrs[a], Heitor Gottberg[a], Luiz Roberto Ramos[b], Ivan Torres Pisa[c]

[a] *Public Health Post-graduate Program, Federal University of São Paulo, Brazil*
[b] *Public Health Department, Federal University of São Paulo, Brazil*
[c] *Health Informatics Department, Federal University of São Paulo, Brazil*

Epidoso [1] is a cohort research started in 1991 aimed to understand how people get older, lose some abilities, get sick and die. The first research started with 1500 elders living in São Paulo, in a neighborhood close to and surrounding Hospital São Paulo. One of the biggest difficult to Epidoso was to integrate and distribute data among researchers for analysis and suggestion of new studies. Project Epidoso was finished in 2005 and right after, Project Epidoso II started in 2007, with other 1500 elders. IntegraEpidoso aims to provide a web framework to join Epidoso and Epidoso II data so researchers can find all data in one place, where data are kept safe and available. Some epidemiological calculators will be available. At the end, one clusterization will be done to identify groups of elders with same socioeconomics and epidemiological patterns for better health promotion.

Keywords:
Web framework, Management information system, Epidoso, cluster analysis, Promotion of health.

Supporting Comparative Effectiveness Analysis for Fact Based Policy Development: An End-to-End Solution

April Webster[a], Daniel Gruhl[b], Sarah Knoop[b]

[a] *Department of Computer Science, University of British Columbia, Vancouver, Canada*
[b] *Healthcare Informatics Group, Almaden Research Lab, IBM, San Jose, USA*

Pressure is building to ensure that limited healthcare resources are allocated to provide effective care. Policy decisions need to be made in an evidenced-based manner, a task poorly supported by existing systems. We present our solution, an end-to-end comparative effectiveness analysis (CEA) prototype scoped by a use case on obesity. CEA contrasts two or more competing programs based on clinical outcome and cost. The insight it provides can be used at the population level to guide decision makers. Our system integrates clinical data from multiple sources in a privacy- preserving manner, handles missing data, and uses a data warehouse cube to abstract information critical to policy makers. Knowledge about the relative impact of competing healthcare programs is published in dynamic, online dashboards to facilitate collaboration. Feedback from domain experts demonstrates the utility and usability of our preliminary work.

Propensity Score-Weighted Survival Model for the Benefit of Adjuvant Chemoradiotherapy for Gallbladder Cancer

Jayashree Kalpathy-Cramer[a], Gary V. Walker[b], Daniel T. Chang[c], Jong Sung Kim[d], C. David Fuller[e], Charles R. Thomas, Jr.[f], Samuel J. Wang[f]

[a]Department of Medical Informatics and Clinical Epidemiology, OHSU; [b] Baylor College of Medicine, Houston, TX; [c]Dept of Radiation Oncology, Stanford University; [d]Department of Statistics, Portland State University [e]Department of Radiation Oncology, UTHSCSA; [f]Department of Radiation Medicine, OHSU

The efficacy of adjuvant chemoradiotherapy for biliary tract cancers remains controversial due to the absence of large randomized clinical trials for this rare disease. Survival prediction models created using retrospective data analysis can help clinicians and patients assess the potential benefit of adjuvant chemoradiotherapy based on specific tumor and patient characteristics. In this work, we created a nomogram based on the Surveillance, Epidemiology, and End Results (SEER)-Medicare dataset. As analyses comparing the effectiveness of treatments on non-randomized groups can be subject to treatment-selection bias, we used propensity score weighting to adjust for the imbalance of the covariates between the treatment and control groups. Our nomogram and web-based tool can be used to help make individualized adjuvant treatment recommendations for gallbladder cancer patients.

Keywords:
Survival analysis, Nomograms.

Spatial Decision Support Systems for Optimizing Health Services Delivery

Ajit N. Babu[a], Engelbert Niehaus[b], Gerhard Ackermann[b]

[a]Division of General Internal Medicine, Saint Louis University School of Medicine, St. Louis, MO, USA
[b]University of Koblenz-Landau, Campus Landau, Institute of Mathematics, Germany

Disparities in health services delivery are a world-wide problem. Providing solutions, on the other hand, is a great challenge. Even in the best of circumstances, community needs will outstrip resource availability, not only in developing countries but also in the developed world. Resource optimization is therefore of vital importance. Particularly when considering the problem of infectious diseases, control and response can be greatly enhanced through the creation of an informatics scaffold that would ideally be generalizable and based on open source resources to permit the greatest possible distribution, adoption and sharing of knowledge. This poster will present a description of the methodology and current status of the work on creating a multimodal SDSS which incorporates Geographic Information Systems (GIS), dynamic risk mapping, remote sensing and advanced modeling techniques for addressing mosquito-borne infections in Third World settings. Modeling techniques are currently being refined, variables defined and international collaborative relationships fostered. Pilot sites for data collection have been identified.

A Distributed Healthcare Quality and Outcomes Analysis Architecture

Ed Conley, Andrew Harrison, Matt Shields, Pete Burnap, Ian Taylor, Tim Benson

Distributed Collaborative Computing Research, Cardiff University School of Computer Science & Informatics (COMSCI)

Patient-centred quality monitoring and reporting is needed to improve the cost effectiveness of health services. A multi-vendor and multi-professional accessible layered architecture can meet common requirements of both clinician- and patient-reported outcome measures (PROMs). A distributed modular, layered collaborative standards-based architecture permits ethical information exchange between any set of trusted nodes, leveraging the interoperability, privacy and infrastructure frameworks of the IHE. The approach enables wider reach and cost- effectiveness for large-scale distributed implementations along the entire 'patient path'. The emergent vendor-neutral, internationalised translational computing system supports data aggregation and analysis in EHR-derived healthcare quality improvement and longitudinal outcomes studies.

OpenMRS mobile integration into OpenMRS Multi-drug Resistant Tuberculosis (MDR-TB) module for improved management and monitoring of community based MDR-TB treatment program in a low-resource setting

Daniel Kayiwa[a], Julia Irani[b], Owais Uddin Ahmed[c], Jørn Klungsøyr[d], Aamir Khan[e]

Multidrug-resistant Tuberculosis (MDR-TB) is becoming an increasing problem globally. Drug resistance occurs due to non-compliance of regular Tuberculosis (TB) treatment or via transmission through an MDR-TB patient. Community based treatment is used to improve compliance and generate awareness about prevention and cure. To monitor community care, mobile technology is used to collect data in the field, and monitor validity of the encounter by capturing the GPS location for point of data collection, to ensure that the treatment supporter was entering data at the appropriate location. Data collected on the mobile phone is uploaded via GPRS to the OpenMRS database with the MDR-TB module. This gives program managers a comprehensive database and helps them monitor the patients' progress and the treatment supporter's attendance and data entry at the patient's home. This technology has improved validity of the data collected and project managers have identified problems in their field site quickly and acted upon them accordingly.

Impact of Medicare Part-D and Generic Drugs on Brand Name Competitors: Longterm Care Center Study

Changmi Jung, Rema Padman

The H. John Heinz III College, Carnegie Mellon University, Pittsburgh, USA

On January 1, 2006, Medicare initiated the biggest change in its history by approving the Part D Prescription Drug Plan in an attempt to lower the soaring cost of prescription drugs dispensed to seniors, partly through conversion to generic drugs. Due to their unique characteristics: polypharmacy, homogeneous age structure, and high prevalence of chronic diseases, there are few studies of the impact of this program on long-term care residents, despite being its heaviest users of prescription medications. In this study, we address whether Part-D and generic availability have significant impact on the selection of brand-name drugs in a delivery setting managed through online orders and electronic prescriptions. Using HMG-CoA reductase inhibitor class (Statin, hereafter) as example, our data from an online pharmacy serving multiple long-term care facilities show that, in general, generic drugs substitute for their brand name counterparts and interfere with their brand name competitors.

Georeferencing Swine Flu in Buenos Aires, Argentina

F Campos, M Waldhorn, J Aguilera Diaz, M Soriano, F Plazzotta, A Baum, D Luna, F Gonzalez, Bernardo de Quiros

Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

On July 16th, W.H.O. recommends a weekly report of a qualitative assessment of the geographical spread, trend of cases, intensity of A/H1N1 Influenza and its impact on the health care system. In this study we describe the geographical spread during the onset of the southern winter in 150.000 middle class Argentinean living in Buenos Aires and its surroundings. The process of georeferencing swine flu cases was carried out using our local Geographical Information Systems. This allowed us to understand the swine flu pattern to define the appropriateness of contingency policies adopted at the onset of the epidemic.

National Resource for Infection Control (NRIC) – conveying guidance during the Swine Flu outbreak: an Evaluation Study

Gawesh Jawaheer[a], Ed de Quincey[a], Sue Wiseman[a,b] and Patty Kostkova[a]

[a] *City ehealth Research Centre, City University, London, UK*
[b] *Department of Health, UK*

The National Resource for Infection Control (NRIC) www.nric.org.uk is the one stop shop for infection control guidance, policy documents and evidence based information. Funded by the Department of Health in the UK and content managed by domain experts, this online digital library has became widely established as a source of quality evidence for those seeking IC evidence. This poster will describe our evaluation study investigating user information needs and online behaviour during the swine flu outbreak in spring - summer 2009.
