Space constraints are a consideration in all health facilities, and it is in general not possible to allocate a dedicated space to host a server. As a solution, we install a self contained system in a compact (approx 50 cm tall) rack-mount cabinet. The cabinet ensures basic physical security and effectively provides a "server room in a box" (see Figure 1). The cabinet is wall mounted, and raised to conserve floor space. For any site, the cabinet is grounded for electrical safety, and in addition to the equipment mentioned above also contains a basic unmanaged switch to create the local area network (LAN) for the data entry terminals. For sites with internet access the cabinet further contains the broadband modem, which is paired with a Cisco router.

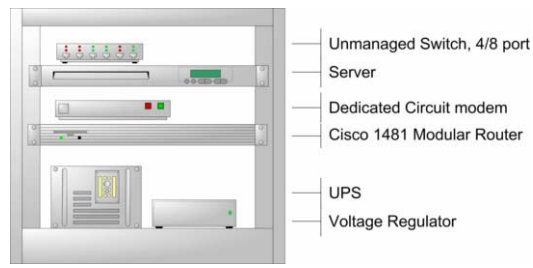

Figure 1 - "Server room in a box." A compact rack-mount system holds the OpenMRS server, and peripheral equipment for networking and power conditioning.

For data entry, standard configuration laptops are used but they rely on their own batteries for backup power as opposed to the UPS. In all current setups the LAN is a wired configuration, although wireless connectivity has also been tested when the LAN switch is extended with a wireless access point.

Management

In a distributed setting with facility based servers, the ability to reduce technical support overhead of the operational systems is critical. A web based server administration tool is configured with simple modules so that facility staff can handle database backups and basic server management. For networked facilities, it is also possible to remotely monitor the installed systems with a network resource monitoring application[3]. The application registers network resources that support the Simple Network Monitoring Protocol (SNMP). The status of the server, managed networking hardware, the UPS equipment, and the status of the OpenMRS database can be monitored centrally, and continuous link monitoring indicates when connectivity is lost.

Using the system

Data management

The quality of the information in an EMR has been shown to have real impact on the use of the data, and training of the data

[3] We employ the Zenoss product: www.zenoss.org

management staff has been identified as a critical factor in maintaining good data quality [14]. In the FGH program each health facility is supported by two data entry staff. A regional supervisor oversees data entry in three districts, and a centrally located coordinator oversees the complete team and process. We consider the data entry staff as an integral part of a comprehensive approach to data quality. Prospective candidates for data entry staff positions are screened on problem solving ability. If accepted, a two week training program follows. The first week is primarily classroom based, with an introduction to the entire patient monitoring and tracking process. This includes training in location of missing information and resolution of anomalies in the paper chart by directly contacting the health care providers. This is followed by classroom training on using the actual data entry tools. The second week occurs in the field, where they are immersed in the actual environment of the health care facility, with close supervision from trainers, more experienced data entry staff, and supervisors. During the first weeks of actual field work new staff are monitored by supervisors until considered experienced.

A data quality assurance process is implemented using a data quality assessment instrument. For a group of measurements critical to the current reporting requirements, we compare the electronic and paper based data. Errors are categorized according to missing data elements on the paper record or in the electronic record, or actual mismatch in values between the paper and electronic record. Early sample runs of the tool have already allowed us to use the results to improve training for those fields where common errors occurred. We do not employ a double data entry scheme.

Reporting

The FGH program generates reports in three formats, reports for the MOH each month, reports for PEPFAR, and reports for the US based HIVQUAL quality improvement program. For the MOH, any discrepancies between the reports generated from the EMR, and a corresponding report using only the paper based system must be adequately explained. In a recent audit of the patient monitoring system for multiple sites a formal process was followed to resolve discrepancies. Here the power of the EMR presented a clear advantage because most discrepancies were found to be the result of a lack of analysis on the paper record data to correctly identify patients in lost-to-follow-up status, and the report generated from the electronic system proved more accurate.

Use by the program clinical and technical teams

The main use of the data outside of reporting is by the district and regional community health teams which use the data to find patients who do not appear at the health facility in time to obtain their medication. The “active follow-up” teams use custom reports to identify patients that should be tracked down and reminded or encouraged to return to the clinic for treatment. In some locations, clinicians with an active (volunteer) interest in health information technology are using the system for ad-hoc analysis of patients in their care. There is no institutionalized use of the data for direct patient care at the moment.

Current Status

The first OpenMRS installation for FGH was put in use in November 2008, only weeks after the first dedicated health information systems staff member joined FGH in Mozambique. The initial OpenMRS sites were in districts where the legacy database was never used, and at the time of writing some legacy sites remain to be migrated. Per July 2009, the number of patients ever in care in all districts is 26893, ranging from 567 to 4469 patients for individual facilities.

Conclusions and Discussion

The current work represents the (near) completion of the first phase in adopting OpenMRS for the FGH program in Zambézia. Throughout the process we have been able to take a long term perspective, focusing on building capacity in Zambézia province to ensure our continued ability to evolve the application.

To determine the actual impact of timely and accurate data, the data will ideally be used in routine clinical practice which can be used to evaluate real improvements in health care delivery and, ultimately, improved patient outcomes as a result of improved care. Several installations of OpenMRS described in the literature have illustrated how this can be done, and we intend to follow these examples to demonstrate utility. Initially we will be providing patient specific alerts or reports at the time of a patient visit.

There is also an increasing focus on building sustainable health information systems. As metrics for determining sustainability emerge, we will be evaluating our approach by comparing against these metrics [15]. The emerging capacity within FGH will be applied to engage the regional health officials in defining a strategy to improve the access to and use of health information for decision and policy making within Zambézia, and to use this strategy to guide ongoing development efforts.

In the development of regional capacity in Zambézia new opportunities are also emerging. In recent years, health information systems have been of great interest at national planning levels of the Mozambique MOH. The department of health information systems within the MOH is evolving a national policy for building a health information infrastructure and an e-health strategy. Key aspect of the strategy is to balance the adoption of health information technology with the capacity to use it within all levels of a health care system [16]. There is also a deeper understanding on the reasons why information systems may fail in a given context [17]. In Mozambique, there are no large scale implementations of commercial enterprise solutions for facility-based health information systems. However, for some applications for aggregate level information, in-country developed systems have been deployed.

Recent changes to national policy include a restructuring of the interaction with partner organizations. An organization that wants to develop a data collection or analysis instrument (paper or electronic), is required to describe and document the instrument, as well as disclose findings resulting from its use

to the MOH. This process will improve transparency on informatics related activities in the country, while at the same time encouraging innovation in the context of specific regional constraints. The other key element is the development of national expertise on health system strengthening through linkages between the MOH and academia in Mozambique that are also considering OpenMRS and other open source technologies for health information systems.

As an implementing partner for the PEPFAR program in Mozambique tasked with the provision of technical assistance to the MOH both at the national level and at the local level, we are faced with an opportunity to investigate solutions that benefit the HIV services in particular, and the health system as a whole. The current work represents in-country capacity development, harmonization with emerging e-health policies at a national level, and creation of a system that fits the needs of Zambézia province. In turn, a successful demonstration of health information technology in Zambézia may benefit others seeking to follow a similar approach.

Abstract

This paper describes the process of implementing a low-cost 'real-time' vital registration and verbal autopsy system integrated within an electronic medical record within the Millennium Village cluster in rural Ghana. Using MGV-Net, an open source health information architecture built around the OpenMRS platform, a total of 2378 births were registered between January 2007 and June 2009. The percentage of births registered in the health facility under supervision of a skilled attendant increased substantially over the course of the project from median of 35% in 2007 to 64% in 2008 and 85% midway through 2009. Building additional clinics to reduce distance to facility and using the CHEWs to refer women for delivery in the clinics are possible explanations for the success in the vital registration. The integration of vital registration and verbal autopsies with the MGV-Net information system makes it possible for rapid assessment of effectiveness and provides important feedback to local providers and the Millennium Villages Project.

Introduction

A global agenda to address the overlapping vulnerabilities of poverty, underdevelopment and ill-health has recently been articulated in the United Nations Millennium Development Goal (MDG) framework [1]. Reducing premature death among children and among women during childbirth have been identified as urgent priorities, with specific time-bound MDG targets. The Millennium Villages Project (MVP) has been previously described and involves the systematic delivery of a package of proven health and development interventions, with the aim of accelerating progress towards the Millennium Development Goals [2].

The MVP is among the first applications of a multi-sector community health and development intervention. Interventions in agriculture, infrastructure, economics, education and health are being simultaneously introduced to village units of 1,000-10,000 households. This intensity and scale, combined with the diversity of MVP contexts, provide an unprecedented opportunity for better understanding the contribution of economics, infrastructure and health to human development. Lessons learned from the project have enormous potential to inform policy and program development in Africa and elsewhere for the coming decades.

In parallel to enhancing access to proven interventions, global health gains require the generation of high quality health information that can be used to guide program delivery [3].

Recent calls for 'information reform' to improve bottom-up approaches to the generation and use of information has the potential to revitalize locally-based health information systems and provide data on access of care, and critical health outcomes that can be used directly to improve local practice and reduce deaths [4].

While addressing maternal and child death rates are overriding concerns of two of the MDG targets, tools for the systematic measurement of mortality have evolved relatively recently. Currently more than half of deaths in developing countries go unregistered. With vital registration data often missing, incomplete and inaccurate, informed decisions regarding how and where to best intervene are often difficult to make [5].

Vital registration (monitoring of births and deaths) and verbal autopsies have been put forth as a potential strategy to address the need for real-time information to inform the targeting and improve coverage with essential public health interventions. Verbal autopsies (VAs) are "a procedure to exploit the information provided by the relatives of a deceased person to reconstruct the events and symptoms that preceded the death so as to deduce a medically acceptable cause, or causes, of death" [6, 7].

Despite the potential for vital events monitoring and VAs to inform intervention strategies, there has been much less inter-

national experience in this regard [8]. VA data has limited use, because of long time delay between vital event identification, VA data collection, cause of death determination, and data aggregation/analysis. However, some important preliminary work has been undertaken in a diversity of settings including the use of VAs to inform programs to address diabetes in the Ukraine [9], assess care seeking for malaria in Tanzania [10], understanding health seeking behavior, to guide the targeting health system interventions to improve TB diagnosis and treatment initiation in South Africa [11], and to guide improvements in the quality of community and hospital care to reduce infant mortality in India [12].

Medical records are often a key source of information to obtain the complete picture about births and deaths. [13] Integration of vital registration with clinical systems such as hospital records has been suggested using linkage software. [14] However, the work required to implement vital registration systems in low resource, rural communities with historically low access and/or utilization of health delivery systems should not be underestimated. [15] Capturing the complete picture of vital events often requires integration of multiple sources including the community, health facilities and other sources. [16]

When viewed holistically, the importance of vital events information, the existence of multiple primary data sources, the resources required to implement the system, and the value in reusing the data to assist with program management and patient care, it is likely that integrating vital registration and verbal autopsies with electronic medical records close to the communities will be beneficial.

This paper describes the process of implementing a low-cost 'real-time' vital registration and VA system within the Millennium Village cluster in rural Ghana. Implementation is currently in progress; however, we present preliminary data from the system and underscore ways in which these data can be used to inform and strengthen health systems and service delivery.

Materials and Methods

MVP Bonsasso, Ghana

Bonsaaso Millennium Village is located in the Amansie West District in the Ashanti Region of Ghana. The village is an agglomeration of 30 communities with 5769 households and has an estimated population of 30,000 people, of which 23% are women with reproductive age (15-49 years). When the project started in 2006 there were only three health centers within the cluster. The nearest hospital where surgery could be performed is the Agroyesum Catholic Mission Hospital which is about 27 km away from the village. In Bonsaaso, the nurse-population ratio in 2006 was 1:5,452. At the Regional level, nurse-population ratio was 1:3,082 and the doctor-population ratio was 1: 31,477. Due to the dispersed nature of the communities, coupled with poor condition of roads, inadequate transport services, access to the health facility posed enormous challenge to the people at the beginning of the project.

Currently there are 7 clinics and a medical store operating in the village that have reduced the distances people have to travel to access health care (see Table 1). Other changes between 2006 and 2009 are also shown.

Table 1 – Comparison of infrastructure between 2006-2009

Infrastructure/Human Resources	2006	2009
Number of Clinics in Cluster	3	7 + store
Average Distance to Reach Clinic	8.5 km	3.5 km
Health Clinic Staff	3	71
Midwives	2	7
Community Health Ext. Workers	0	28

Overview of the MGV-Net Vital Registration and Verbal Autopsy (VRVA) System

The Millennium Global Village-Network (MGV-Net) has been described previously and is an open source health information architecture built around the OpenMRS platform. [17] In the Ghana MVP site, vital registration and verbal autopsies are being integrated into MGV-Net to provide this critical information at the community level to facilitate decision-making and assist in the delivery of care. The VRVA system has a number of components that will be highlighted briefly below:

- **Community Health Extension Workers (CHEWs):** In all MVP sites, CHWs or CHEWs have been introduced to maximize the delivery of health information and services to households in the project clusters. There currently a ratio of 1 CHW to every 100-200 households, with household visits taking place every 1-2 months. CHWs are supported by an MVP Health Coordinator (doctors or allied health professionals), and provide a spectrum of health interventions to target households. Furthermore, CHWs are aware of vital events in households (births and deaths) very quickly.
- **Verbal autopsy specialist:** the VA specialist is non-clinical health worker specially trained in the VA methodology. VA specialists have the primary responsibility for conducting VAs.
- **VRVA tools:** have been developed for adults/maternal deaths and child deaths with two main components:
  - *Birth registration form:* questions to evaluate the circumstances of child birth, including location, attendance of skilled professional, and condition of the child.
  - *Cause of death module:* questions to assess signs and symptoms experienced by the deceased in the time preceding death. The module was derived from previously validated VA tools and consists of both close and open-ended sections as per best-practice guidelines.

- *Social autopsy module:* a specific module has been developed to include details regarding the social circumstances surrounding death. It includes information on health seeking behavior, access barriers to health care, communication, transport, and economics.

- **Data entry and algorithmic assessment of cause of death/social autopsy diagnosis:** All VRVA forms are entered into an OpenMRS database monthly. In order to facilitate a rapid generation of critical information for targeting interventions, a series of algorithms has been employed. These are established, valid techniques for determining the probable cause of death [18-24]. Selection criteria for algorithm were sensitivity and specificity greater than 50% and 75%, respectively as well as an estimated cause specific mortality rates (given sensitivity and specificity) within 40% of prevailing rates. Additionally, algorithms to assess the social circumstances leading up to death are also employed. This innovation eliminates the need for dual physician-based assessments, which can be both expensive and create a long time delay in generating 'real time' information for program managers.

- **Community Morbidity & Mortality Rounds:** the broad aim of the system is to generate information on the cause and social circumstances surrounding death to inform the delivery of health and development interventions on the ground, in real-time. Data collected on cause of death will be compiled and form the basis of a community 'morbidity and mortality rounds' – conducted by clinic staff, VAS, and the CHWs. These meetings will provide a forum for engaging with the medical and social autopsy data with appropriate recommendations being made regarding the introductions of new health programs, modifications in the delivery or targeting of existing health programs, or the need to liaise with other sectors such as infrastructure, education or nutrition to address other remediable concerns.

Status of Implementation in Ghana

Prior to 2008, data on births and deaths were collected by community volunteers. In January 2008, data collection responsibilities were transferred to the CHWs. This data is currently collected on paper and transferred to OpenMRS using retrospective data entry. MVP has recently tested entry via forms submitted from a Java-enabled mobile phone using an application based on the JavaROSA platform. In addition, we are in the process of rolling out data entry via ChildCount+, based on RapidSMS, a UNICEF-sponsored, SMS-based client on mobile phones. Mobile-based data collection will hasten the transfer of data from the community to the clinic. In particular, mobile technologies will lessen the lag time between death identification and the verbal autopsy interview, which further promotes the 'real-time' utilization of community-based health information.

Clinical Integration

At the time of this article, vital registration information has been reviewed by MVP office and clinic staff in Ghana. It has yet to be integrated clinically with daily operations of MVP clinics. However, plans are already underway to use the newly available information to create alerts and reminders for childhood immunizations and for the care and follow-up of newly delivered mothers. Registration of pregnant women in the medical record will also allow for improved antenatal care as well as identification and referral at the time of delivery if necessary. The MGV-Net infrastructure, involving OpenMRS, SMS and other mHealth technologies, is also consistent with work being done elsewhere in Ghana by the Mailman School of Public Health, the Grameen Foundation and the Bill and Melinda Gates Foundation.

Results

Birth Registration

Our initial analysis of the Bonsasso data focused on birth registration. A total of 2378 births occurred in the project area between January 2007 and June 2009. These are shown in Figure 1. The sharp decrease in total births at the end of 2008 was thought to be due to increased family planning efforts earlier in the year.

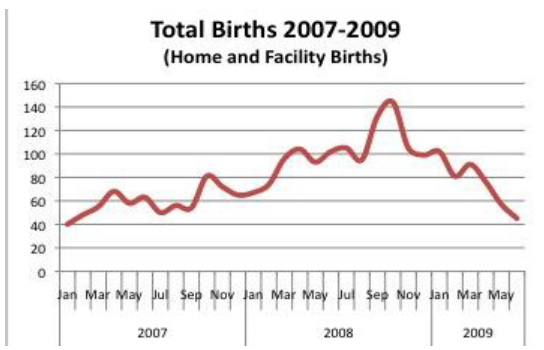

Figure 1- Total Births within the Bonsasso MVP cluster from 2007 through 2009.

According to community-based interviews administered to each new mother, the percentage of births within the project area that took place in a health facility increased substantially over the course of the project as shown in Figure 2 from a median of 35% in 2007 to 64% in 2008 and 85% midway through 2009.

Figure 2 - Percentage of all births occurring in a health facility versus home from 2007 through 2009.

In addition to MVP sponsored clients, the MVP clinics services patients from outside the intervention area. Seventy percent of facility-based births were to woman who resided within the MVP site and 30% were to woman who lived outside the cluster of villages as shown in Figure 3.

Figure 3 - Proportion of woman who gave birth in MVP facilities who lived in the MVP site at the time of birth.

Death Registration and Verbal Autopsies

At the time of this article, piloting of the death registration and verbal autopsy program is still ongoing while an external validation of mortality rates is undertaken. The likelihood of underreporting is very high given the emotional and social sensitivities of death within a household; therefore, a cross-sectional validation is recommended. Reporting of mortality and cause of death trends will be reported once implementation is completed and the results are validated.

Discussion

We present a novel application of a 'real-time' vital registration and VA system integrated within an open source electronic medical record in rural Ghana. This paper demonstrates the design and feasibility of the system as well as highlights its potential relevance as a tool to assist in monitoring intervention effects and facilitating improved coverage with essential maternal–child health services.

During implementation several challenges and limitations of the system were evident. Registration of births appears to be accurate and easy to implement given the modest cultural sensitivity; however, high community mobilization and awareness efforts of the CHEWs is required. Like many other community-based monitoring systems, CHEWs may underestimate deaths, particularly newborns, if families refuse to disclose them. Facility-based deaths that are included in the medical record will be more accurately reported, but most rural deaths happen at home. Home-based verbal autopsies may not provide a less complete picture of cause of death as clinic-based diagnoses, particularly pediatric deaths, which are often complex to assess. Further research and local validation of algorithms is needed. However, this VRVA system, including mobile death reporting, is valuable for quickly identifying patterns in the medical and social circumstances surrounding death.

In relation to the preliminary results presented, dramatic increase in skilled birth attendance can be attributed to several possible explanations. The construction and staffing of additional clinics in the MVP site and reducing the distance to the facility both seemed to contribute towards ensuring reliable supply of high quality care. It is also likely that training the CHEWs to refer women for delivery may have also had an effect on accelerating the demand for safe delivery services..

It is still too early to fully interrogate the potential of having detailed birth and death data available to MVP at the community level. The initial analyses of birth information have provided important detail about the numbers of births within the MVP site and the relative contribution of those living outside the cluster of villages. The marked reduction in overall births and the shifting of births from the home to skilled attendant deliveries in the clinics over the period of the project is encouraging. The impact of higher skilled birth attendance on child survival within the MVP site is currently under study. The integration of vital registration and verbal autopsies with the MGV-Net information system makes it possible for rapid assessment of effectiveness and provides important feedback to local providers and MVP. We hope that such timely and practical information will lead to improved quality of programming and of local delivery of care.

Adopting the National Structure of Nursing Documentation is Consequential in the Development of Care

Tapio Ala-Hiiro, Kaisa Lemmetty, Satu Pitkänen and Eija Häyrinen

MediKes Information Management, Central Finland Health Care District, Finland

Abstract

When healthcare units adopt the national structure of electronic nursing documentation, the process requires managerial support in nursing development as well as theoretical education arranged prior to the implementation. According to the experiences of the pilot units in the Central Finland Health Care District, nursing core data documentation in accordance with the national structure promotes care planning, clarifies and constructs documentation and furthermore unifies the documentation system. The change process gives rise to juridical aspects of documentation as well as a critical evaluation of the documentation contents. The early period of implementing the new theoretical aspect and proceeding from paper-based to electronic documentation required learning, training and agreement on common policy. In health care practice, there is at present one collective structure and model for nursing documentation based on national guidelines. A documented nursing plan is available when a patient is transferred between units or even into extended care. The structured care plan is also helpful when new nurses are introduced to praxis. The continuity of care is at stake when employees are transferred between units to meet the demands of resource allocation.

Core data, Nursing, Information systems, User training

Introduction

The law on using electronic social and healthcare client data in Finland was passed on July 1, 2007. Accordingly, the information in electronic health records (EHR) must be structured in order to support decision making in patient care as part of health management and the acquisition of health policy information. [1, 2]

According to the legislation, every electronic patient record must follow core data structures. The core data structures consist of essential health and care documentation that must be coded as defined so that it can be archived nationally. [3, 4]

The Nursing Minimum Data Set (NMDS) is a part of the EHR core data set. The Finnish Ministry of Health and Social Affairs has set the core data structure as a national goal for nursing documentation. The core data in nursing includes nursing diagnoses, nursing interventions, intensity of care and summary on discharge. [4] Nursing documentation is done by choosing headlines under different phases of the nursing process that can be complemented with free text. The documentation is based on the nursing core data that comply with the Finnish Care Classification (FinCC). [5]

Structured Nursing Documentation – a Pilot Study in the Central Finland Health Care District

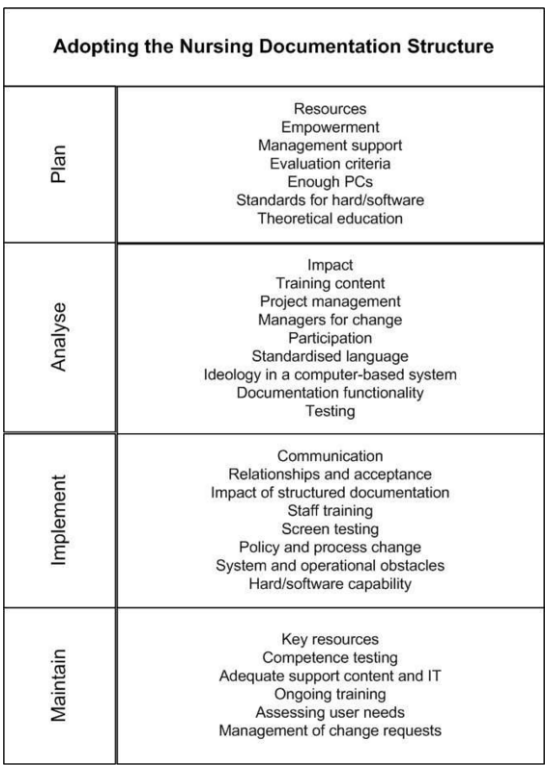
The Central Finland Health Care District participated in a national electronic nursing documentation project titled *HoiDok* in 2005–2007 and in the national development of structured nursing core data. The goal of this development was to unify and standardise nursing documentation and to connect it with interdisciplinary core documentation of patient history, the national code server and the national archive. [6, 7] Finnish nursing documentation is based on the nursing decision making process, the nursing core data (NMDS) and the Finnish Care Classification (FinCC). The FinCC includes the Finnish Classification of Nursing Diagnosis/Needs (FiCND), Nursing Interventions (FiCNI) and Nursing Outcomes (FiCNO). [5, 7] The participants of the pilot study were nine hospital units of different specialties. These represented psychiatric and somatic care, and both wards and outpatient departments. In addition, a technical application of nursing documentation titled *WHOIKE* was utilised as part of patient data recording. [7]

Both theoretical education and case-based training were arranged at the hospital while the electronic application of nursing documentation was prepared for implementation. Nursing documentation will generate an interdisciplinary document that consists of daily notes done by several professionals engaged in patient care. During the training sessions, nurses and care providers received theoretical education of the nursing process. The training focused on structured data models following the national guidelines as well as on the legal aspects of documentation. A theoretical model of the nursing process was also introduced and its use rehearsed. The FinCC was explored with the help of case studies and examples. The training content was tailored to the units' needs and expectations. Every unit had one person engaging with the manager to plan and enable the personnel's participation in the training sessions.

The units also appointed one or two super users to support the implementation and utilisation. The documentation training was arranged immediately before the implementation. [9, 10]

The implementation of nursing documentation was accomplished in phases in the nine units during a two–month period from December 2006 to February 2007. The units made accurate plans describing the implementation date, volume of users, the final date of completion and plans for user support. (*Fig 1).*

The assessment of the implementation revealed that seven units achieved their goals well. In two units, the preparation for electronic documentation was insufficient. In the wards, every patient had a structured nursing document within two months. In the outpatient departments the transfer phase took over six months.



.

Figure 1- The adoption model for structured nursing documentation [9, 10]

The evaluation from the units shows that successful implementation of structured nursing documentation requires managerial support, commitment to development and intense co-operation with managers and super users. Implementation must be executed with a careful design, realistic schedule and organised support. [10] It is important to immerse profoundly in the nursing process, classifications and the ideological significance. All professionals participating in patient care must determine both the meaning and relevance of documentation. Learning a new method of documentation takes time and is dependent on a well-operating application.

In May 2007, a survey was carried out in two of the pilot units after five months' use of electronic nursing documentation. Based on the results, some amendments were made in both the classifications and the application. A renewed application was implemented in February 2009. The pilot projects in structured documentation continued until September 2007. Based on some critical issues raised in user comments and requests, both operational and user interface usability alterations were implemented in January 2008. [9, 10]

Increasing the Use of Structured Nursing Documentation

Before increasing the use of structured nursing documentation, several information events were arranged for nursing managers and leaders. The units also received general directions on how to prepare for the implementation. During the lessons in the wards, theoretical studies were organised for both the super users and support persons. The actual training sessions for the application use were held from February 2008 to April 2008. Two training facilities with PCs were in constant use. Over 2000 nurses attended the training sessions.

Every unit made their own implementation plan that was executed immediately after the training. At present, structured nursing documentation has been adopted in all the psychiatric and other hospital wards as well as in the outpatient departments. A regional training program and implementation are under process. For example in the health care in Jyväskylä, a gradual switch is being made to structured nursing documentation.

The Impact of Structured Nursing Documentation

The impact of documentation in nursing has increased considerably in recent years. In previous years it was enough to record some of the interventions to be made, and nursing documentation lacked a legal function. Nowadays the demand for precise documentation is increasing, and the central function of documentation is to serve patient care planning, intervention and assessment and promote the continuity of care. Documentation also provides information to patients and establishes legal protection for both the patients and the personnel. With daily documentation, it is possible to explain and estimate how appropriate the treatment a patient receives is.

Developing structured nursing documentation has clarified and firmed the content of documentation. Some outpatient departments have considerably increased the volume of their documentation following the nursing process. Structured nursing documentation has enabled the units to also develop other functions. Through nursing documentation, change-of-shift reporting has taken the form of silent reporting. Orders can be prescribed in EPR by doctors, and the information is forwarded to the nursing documentation.

Nursing intensity is measured by a national system called *Rafaela*. Nursing documentation notes about ward intensity are available when workload is measured. A search engine enables patient information to be available to all users. Information can be retrieved according to the nursing sector, nursing process or the nursing period.

The implementation of structured nursing documentation increases the time consumed in storing data. However, it is obvious that in the long run, when the personnel have become familiar with the structure and the classification, documentation becomes precise and quality ameliorates. Structured nursing documentation accumulates significant patient data.

Discussion

The application of nursing documentation (*WHOIKE*) does not yet fulfil the structured nursing documentation standards completely. The structure of documentation is efficient but the user interface requires improvements to the usability. Some doctors are not satisfied with the use of the components and the terminology in the classifications. The documentation following the nursing process can appear abstract when implemented, and it takes time to visualise the new way of updating patient care.

Now it is time to confer, further develop patient care and make records to serve interdisciplinary documentation. It is important to find a common understanding of the consequential information documented into the nursing care plan. This means specific demands for the software application, user interface and usability.

Nowadays nurses read or retrieve doctors' documentation from different forms. At the same time, doctors inspect nursing data from a Nursing View frame or Nursing Plan frame. In the future, all information can be retrieved by similar search methods. The new nursing application includes a Daily Monitoring frame as well as a Medication frame; this will additionally enhance the significance of integrated software. Adopting a single recording principle for the patient records will improve visibility and usefulness and benefit patients in nursing planning, intervention and assessment. During the care period, the nursing document is vital for an individual patient's care.

A national study revealed that it takes about 3–6 months to learn the nursing documentation structure. When structured nursing documentation is carried out for a few months, it speeds up the recording and also guides documentation. Overlapping documentation has decreased, and documentation is more specific. The quality of the nursing documentation content has improved, and it has become more uniform and patient-orientated. Information is up to date, and the continuity and security of nursing care have improved. [7]

Symptoms from Patients as the Primary Information Source for Real-time Surveillance

Monika Alise Johansen[a], Jan-Are Kolset Johnsen[a], Neema Shrestha[b], Johan Gustav Bellika[a,c]

Abstract

The aim of this study was to identify whether patients could become the primary data source for symptom based real-time surveillance. The study investigated people's attitude towards providing symptom information electronically before a consultation, and how they preferred to carry out the reporting. Data was collected by distributing questionnaires to 83 respondents. The results show that 96 percent of the respondents had a positive attitude towards providing information about their symptoms to the GP's office as soon as possible after falling ill. Over half of the respondents preferred to use e-mail or a web-interface to perform this task. Eighty four percent were willing to have their symptom data stored in their EPR and 76 percent agreed that the GP might access and present the symptoms together with the prevalence of matching diseases in order to assist the diagnostic process during the next consultation. This study indicates that patients could become the primary data source for symptom based surveillance in countries with high e-readiness.

Doctor patient communication, Electronic symptom reporting, Disease surveillance, Syndromic surveillance, Social networks

Introduction

The importance and relevance of disease surveillance and management is emphasized through the recent swine-flu pandemic, and through the facts that infectious diseases account for around 25 percent of all deaths in the world [1]. However, studies show that traditional disease surveillance systems struggle with a considerable reporting lag that limits early detection and timely response to outbreaks [2, 3]. Consequently, there is a demand for new electronic surveillance systems capable of eliminating unnecessary delays, and reducing the risk of data corruption [3].

Methods exploiting clinical data that exist at a stage before a confirmed diagnosis, e.g. symptoms, are commonly referred to as syndromic surveillance [4], or symptom based surveillance. Typically, in syndromic surveillance the frequency of illnesses is monitored using a specified set of clinical features (e.g., fever and respiratory complaints, skin rashes, diarrhoea) in a given population of a given geographic region, regardless of specific diagnoses [5]. It is the real time nature of the syndromic systems that makes them valuable for outbreak monitoring and detection [4]. Syndromic surveillance is considered useful for general public health, quality improvement, epidemiology, patient safety and research [4]. However, perhaps most important is its usefulness in clinical medicine [4], where it can make clinicians aware of community trends and enable them to issue the right tests and improve their diagnostic assessment [6].

Ideally, information should be entered once and used often [6]. Secondary use of clinical data, for instance structured documentation from the electronic patient record (EPR), unstructured narrative text, or laboratory results, is expected to have an enormous potential [7]. Today the necessary technologies are available to extract and present surveillance data from EPRs, laboratories, and hospitals [8]. However, the validity of a syndromic surveillance system depends on the quality of the collected and presented data, both in terms of representativeness and completeness [9]. One of the most challenging steps in utilizing such systems and technologies is to define the optimal data sources [10]. Unfortunately, data sources such as ICPC codes, free-text fields in the EPR, and data generated in conjunction with laboratory orders and results might have serious limitations [11]. One explanation is that the data entered into the EPR by the general practitioner (GP) is intended for other purposes than disease and/or syndromic surveillance, and produced in a different context. In general, use of data for secondary purposes influences data quality [12]. Consequently, the information must be disentangled from the context in which it was produced [12], and transformed into the new context of disease or syndromic surveillance. This process is particularly challenging with regards to real time data.

The Patient as the Primary Information Source

Thus, at the present, the challenge is to collect real time data of proper quality that is produced also for the purpose of disease or syndromic surveillance. Since patients could be seen as the GP's primary source of information on the current prevalence of infectious diseases [13], it seems appropriate to exploit this primary source further by collecting symptom information directly from the patients. In countries with high e-readiness, such as Norway where at least 80 percent of the population (15 years and older) are Internet users [14], this information could be reported electronically. This represents a new approach to syndromic surveillance that might provide

more data of better quality than what is available today, and at an earlier stage. One of the core questions is, however, if patients would be willing to provide this symptom data.

This paper presents an investigation of people's attitudes towards providing symptom information electronically before a medical consultation and how they prefer to carry out this type of reporting. Further, the study investigates to which degree people acquire information prior to the medical consultation.

Methods

Data collection was performed by distributing 83 questionnaires among the population of the city of Tromsø in Northern Norway during March 2009. A convenience sample was drawn by approaching people directly, and having them fill out the questionnaire immediately after agreeing to participate. Data was collected at diverse public locations, including a student hostel, the university library, a research centre, the airport, and various social venues (cafés). However, attitudes towards health and information technology could be envisioned to vary based on age, gender, and level of education. In this regard the sampling procedure aimed to approximate a representative distribution of these demographic variables in the sample. The respondents were at least 16 years old as this is the requirement to consent to participation in health related research projects in Norway. Foreigners received the questionnaires in English. The questionnaires were piloted on a small sample.

The questionnaire consisted of 13 items, which represented a combination of multiple choice and free text (comments), and prioritization of alternatives. In addition to demographics (age, gender, nationality, and level of education) participants were asked several questions aimed at assessing their attitudes towards providing their GP with symptom information using electronic media. This also included items concerning medical visits (last 12 months) and whether or not they acquired information about symptoms and problems prior to the medical consultation. The questionnaires contained no information identifying a person or questions regarding personal health status. Respondents spent 5-10 minutes completing the questionnaire. Three questionnaires were excluded from the analysis due to incomplete answers. Selections of free-text responses were subject to a content analysis identifying dominant themes related to the specific questions. SPSS 16.0 was used for the statistical analysis.

Results

Demographics

A total of 80 questionnaires were included in the survey. The sample characteristics are show in Table 1. The youngest participant was aged 16 years, the oldest 70 years, and the age mean was 36.7 years. A higher proportion of females (81 %) than males (58 %) reported having visited the GP in the last twelve months.

Nationality	Norwegian: 77			Foreign: 3	
Gender	Female: 36			Male: 44	
Age	[16-22]	[23-32]	[33-42]	[43-52]	[53-70]
n	20	15	16	13	16
Education	Primary and lower secondary school: 5			Upper secondary school: 30	
	Undergraduate: 16			Bachelor/Master: 29	

Acquiring information prior to the medical consultation

The majority of the respondents (68 percent) had visited their GP during the last 12 months, while 31 percent had not. Also, the majority (78 percent) of the respondents usually had a clear opinion about their diagnosis before they visited the GP, while 14 percent answered "seldom" and 5 percent "never". An independent samples t-test was used to show that there was a significant difference between those who had visited their GP in the last 12 months (mean = 1.16), and those who had not (mean = 1.44) with regard to "having a clear opinion about the diagnosis" prior to the medical consultation (scale, 1 = "often", 2 = "seldom", 3 = "never"), $t = -2.18$, $df = 74$, $p < .05$. Respondents were asked to select up to four sources for their "opinion about the diagnosis". Sixty nine percent answered that they made use of previous experience, 55 percent discussion with family, friends, and colleagues, 41 percent searched the Internet, and 19 percent medical books. Four respondents commented that they had some level of medical education. Information based on, partly or mainly, newspapers represented only nine percent, TV/radio eight percent, and information from pharmacies eight percent.

The respondents were asked if they used the Internet to check out or "Google" their symptoms prior to a consultation. Sixty one percent did, 41 percent frequently, 20 percent more infrequently, while 35 percent never did. Of those who used the Internet, 16 respondents commented by free-text that they conducted this kind of search because the information on the Internet is available and easy to access. Sixteen respondents commented that they conducted this search to clarify their symptoms, and to get a preliminary idea about the nature of their problems. Nine respondents commented that they used the Internet to diagnose themselves, where six of these nine emphasized that they did not intend to consult a GP if they were successful. Of those who never used the Internet, 10 respondents commented that they had not needed that due to not having been ill, or not having symptoms they did not recognize. The remaining eight respondents expressed a lack of interest in symptoms and uncertainty with regard to quality of information on the Internet.

Providing information prior to the medical consultation

Nearly all of the respondents, 96 percent, had a positive attitude towards providing information about their symptoms to the GP's office as soon as possible after falling ill (61 percent "yes", 35 "maybe"). Only one of the positive respondents commented on why, and that was because "this is the future - it has to be done like this", while two sceptical respondents found this approach too time consuming.

The positive respondents preferred to provide the GP with this symptom information as soon as possible after becoming ill, 39 percent by e-mail, 25 percent by web-interface, and 13 percent by the mobile phone Internet service (WAP). Thirteen percent preferred to provide this information by a computer or PDA at the GP's waiting room.

A linear multiple regression analysis was performed to investigate which variables could predict the respondents "attitude towards providing symptom information prior to a medical consultation using electronic media". Variables were selected based on a correlation analysis and theoretical assumptions (Table 2). Model 1 accounted for approximately eight percent of the variance of the dependent variable. The analysis showed that the attitude towards providing symptom information prior to a medical consultation was predicted by "medical visits in the last twelve months (yes/no)".

Table 2 - Summary of multiple regression analysis for Age, Gender, Level of Education, and Medical visits, and Pre-consultation use of the Internet predicting Respondents' attitudes towards providing symptom information electronically. Tromsø, Norway, March 2009.

Model	Variable	B	SE B	β
1	(Constant)	.98	.19	
	Medical visits	.33	.13	.28**
2	(Constant)	.92	.39	
	Medical visits	.27	.15	.23
	Age	-.00	.00	-.09
	Gender	.02	.13	.02
	Level of Education	-.02	.07	-.03
	Pre-consult Internet	.21	.14	.18

Note. **p < .05; **p < .01; R^2 = .08 for Model 1 (p < .05).*

The respondents were asked for their opinion regarding possible re-use of the reported symptoms. Eighty four percent of the respondents were willing to have their reported symptom data stored in the EPR at the GP office. In addition, 76 percent accepted that the GP might access and present the symptoms alongside the prevalence of matching diseases in order to assist the diagnostic process during the next consultation.

Regarding the storage of reported symptoms in the electronic journal system, four respondents commented that this would provide better documentation related to their problems, and would be a good way to update their personal health record. Further, four respondents commented that the fact that the GPs would be able to repeatedly access the reported symptoms could play a positive role in having their case thoroughly investigated. This, in turn, would be beneficial for them as patients, and maybe also save time. One person had the opposite view, worrying that "the info would lead the GP to be 'sloppy' ". On the other hand four commented that privacy and security had to be guaranteed. Two respondents were unhappy with electronic storage in general and afraid that unauthorized people (e.g., insurance companies) could get access to the data.
As to presenting the symptoms alongside the prevalence of the diseases matching the symptoms, two respondents commented that this might help the GP to identify the patient's problem and contribute to a more effective and time-saving consultation, while two commented that this is a tool that must be used with extreme caution not to scare people.

When asked if they would be willing to report the symptoms directly into a surveillance system without going through the GP's office/system, 43 percent were positive, 49 percent were negative, while nine percent did not reply to this question. Five sceptical respondents worried about the quality and would like the GP to confirm their symptoms before using them for surveillance. Of the positive respondents, two answered that they would report the symptoms since it would help early detection of diseases, four commented on the importance of anonymity, and one expressed concern whether the quality would be sufficient.

The respondents were asked for suggestions and user requirements with regard to how they wanted to provide information to such a system, the output they would like to receive, and other functional requirements. Security was highly prioritized by six respondents. For a surveillance system without GP's involved, the respondents suggested that the patients should be kept anonymous. Further, six respondents commented that it is most important that such a system is extremely easy to use (e.g., easily accessed, no need to set a lot of parameters, easily comprehensible information and questions). If possible, visual guidance should accompany the questions. Three respondents wished to have a response from the system with regard to diagnosis and possible treatment.

Respondents were asked to select up to three sources that they would trust when presenting them surveillance information. Eighty nine percent answered that they would trust their GP, 70 percent the Norwegian Institute of Public Health, and 60 percent the local university. Only 10 percent would trust the Internet, six percent the TV, three percent Google Flu trend, and between one and three percent would trust the local or national newspapers.

Discussion

The results show that the respondents are predominantly positive with regard to providing symptom information electronically to their GP. Ninety-six percent of respondents indicated that they would be willing to do this immediately after feeling ill. Over half of the respondents indicated that they would prefer to use e-mail or a web-interface to perform this task, rather than WAP-interface or technology in the GP-office's waiting room. This implies that people are motivated to use the most readily available technologies, and the technologies with which they are accustomed. Also, it points to a preference towards home-based solutions. Further, the respondents accepted that their symptoms could be stored in the EPR system. This will enable the GP to access these data at future consultations and present these alongside the prevalence of local diseases matching these symptoms, in order to assist in the diagnosing process.

In general, it appears that "medical visits (last twelve months)" is a central variable in this context. First, the variable is included in the regression model (Table 2, Model 1) as a significant predictor of respondents' attitudes towards providing symptom information. However, this model only ex-

plains 8 percent of the variance in the dependent variables. Thus, several other variables, not included in this study, are also relevant in explaining people's attitudes towards providing symptom data electronically. Second, having visited the doctor during the last twelve months is associated with being more likely to form an opinion about one's own diagnosis. However, the meaning of this variable is somewhat ambivalent, as it might both reflect a respondent's attitude towards health (i.e., being preoccupied with health issues) and indirectly, health status (i.e., visits equals poorer health). Inclusion of other variables (health status and other health-related attitudes) would be necessary to understand this relationship better.

The majority of the respondents were sceptical regarding reporting symptoms directly to a surveillance system without going through the GP's office. However, this still might be a possible approach since the 43 percent expressing a positive attitude could be sufficient to provide a representative outbreak picture.

Research on computer-mediated communication (CMC) has indicated that mediated communication is often associated with higher levels of self-disclosure [15]. These findings have been replicated for medically relevant communication, in both pre-clinical and clinical settings [16-21] and in anonymous, peer-support settings [22]. In sum, people appear more willing to disclose socially sensitive health information using CMC. They report more and/or more serious symptoms, and they comment that it feels easier disclosing their health problems in an anonymous setting. It seems worth mentioning that this is apparently irrespective of whether the information will be seen by health professionals at a later stage [e.g., 17], thus rendering the patient non-anonymous for all practical purposes. Our findings related to this published evidence support the viability of a patient-centric symptom-reporting tool.

The presented study utilizes a non-probabilistic sampling technique, and this limits the generalizations that can be drawn from the data. However, we believe that the care taken to ensure approximate representation with regard to gender and age allows for generalization to a certain extent. The fact that more females than males in our sample reported having visited the GP during the last twelve months underlines this viewpoint by reflecting the general population's behaviour regarding the use of health services. The sample is probably unrepresentative in terms of older age groups (50+), and the group with low level of education (only five participants).

Based on this survey we know the respondents say that they would report symptoms. However, we also know that there is a considerable gap between people's intentions/attitudes and their behaviour. Consequently, there is a need for studies that investigate if people/patients actually are able to report symptoms electronically. As to the willingness to report symptoms, encouraging experiences have been gained from large-scale volunteer efforts. This includes free and open source software development, distributed computing, and the Wikipedia project [23]. Evidence directly relevant to syndromic surveillance has also been published. Epidemiological data has been gathered from patients using web based questionnaires [24], and websites like "whoissick.org or sicklike.me, which ask users to enter their symptoms, demonstrate that consumers are willing to actively participate in surveillance" [25], (p. 8). The Great Influenza Survey in Netherland and Belgium (www.degrotegriepmeting.nl), which is based on weekly voluntary online participation of the population, supports this impression. We believe that future disease surveillance systems will be a combination of patient-centred symptom reporting systems, and surveillance systems utilizing other both formal and informally sources.

Conclusion

This study supports the hypothesis that patients could become the primary data source for symptom based real-time surveillance. In a patient-centred symptom reporting system the data would be produced for the purpose of surveillance, which would simplify the production of surveillance information of proper quality, provided that the symptoms are reported with sufficient quality. However, in order to draw a final conclusion, larger studies are needed.

Acknowledgments

This study has been partly funded by grants from the Health North Authorities (TFP-661-07), Norwegian Research Council grants (1749349), and The Norwegian Centre for Integrated Care and Telemedicine (NST). We want to express our thanks to colleagues and the participants for their contributions, Gro Berntsen, NST, for useful feedback on the outline, Gunnar Ellingsen for his involvement in the preparation of the study and Alexander Horsch for useful feedback on the outline, both from the Department of Telemedicine and e-Health, University of Tromsø.

Abstract

Surveillance of clinical entities such as healthcare-associated infections (HCAI) by conventional techniques is a time-consuming task for highly trained experts. Such are neither available nor affordable in sufficient numbers on a permanent basis. Nevertheless, expert surveillance is a key parameter for good clinical practice, especially in intensive care medicine. MONI-ICU (monitoring of nosocomial infections in intensive care units) has been developed methodically and practically in a stepwise manner over the last 20 years and is now a reliable tool for clinical experts. It provides an almost real-time view of clinical indicators for HCAI—at the cost of almost no additional time on the part of surveillance staff or clinicians. We describe the use of this system in clinical routine and compare the results generated automatically by MONI-ICU with those generated in parallel by trained surveillance staff using patient chart reviews and other available information ("gold standard"). A total of 99 ICU patient admissions representing 1007 patient days were analyzed. MONI-ICU identified correctly the presence of an HCAI condition in 28/31 cases (sensitivity, 90.3%) and their absence in 68/68 of the non-HCAI cases (specificity, 100%), the latter meaning that MONI-ICU produced no "false alarms". The time taken for conventional surveillance at the 52 ward visits was 82.5 hours. MONI-ICU analysis of the same patient cases, including careful review of the generated results required only 12.5 hours (15.2%).

Introduction

Surveillance of clinical entities such as healthcare-associated infections (HCAI) by conventional techniques is a time-consuming task for highly trained experts who, in clinical settings, neither are available nor affordable in sufficient numbers on a permanent basis. Many published surveillance studies have been performed with either additionally budgeted (scientific) staff or with information technology (IT) tools specifically developed for the studies and not used later. Nevertheless, continuous expert surveillance is a key parameter for good clinical practice (GCP), especially in intensive care medicine [1,2]. Furthermore, healthcare authorities increasingly demand the installation and regular use of HCAI surveillance by healthcare institutions [3] as a part of quality management (QM). However, this sound demand is often overruled by financial constraints or simply by the unavailability of a suitable workforce at the local or regional level.

For a long time now, we have been attempting to bridge these gaps by establishing a fully automated computer-based system for early recognition and continuous monitoring of HCAIs [4–6]. The foremost challenge was to obtain reliable surveillance data from intensive care units (ICUs) without the need to employ additional documentation staff and statisticians.

When developing MONI-ICU, our main clinical concerns were the following:

- Its reliability and accuracy in clinical terms and its acceptance and adoption by clinical experts; possibly lowering infection rates and costs through (almost) real-time monitoring.
- Compliance with international standards and HCAI case definitions such as those issued by the Centers for Disease Control and Prevention (CDC) in Atlanta, USA [7], the European HELICS criteria [8], or the German KISS definitions [9].
- Timeliness of the obtained results for early identification of infection: both in the individual patient and in the patient population of the healthcare institution.
- Full technical and organizational feasibility with no need for additional staff for documentation or analysis.

Technically, MONI-ICU possesses the following components and characteristics to enable its fully automated mode of operation and wide acceptance by clinical users:

- Data import interfaces to the intensive care medical information or patient data management systems (PDMSs), the laboratory information system of the mi-

crobiology department and, last but not least, to the respective hospital information system.

- "Raw" measured and observed medical data coming from these information systems are entered into a stepwise pipeline of aggregation and interpretation, eventually to draw conclusions with regard to the presence or absence of HCAI conditions according to their definitions (cf., [6,10]).
- Extensive adoption of fuzzy set theory and fuzzy logic methodologies to allow for graded intermediate and final results [10]; this permits immediate identification of borderline cases and trends.
- Deployment of MONI-ICU as modern web-based, Java-programmed system with routine operation within the intranet of the healthcare institution [11]; it is based on a service-oriented architecture.
- Representation of the necessary medical knowledge and processing steps in Arden Syntax [11–13], a standard programming language fostered by Health Level Seven (HL7) and adopted as an American National Standards Institute (ANSI) standard.
- Presentation of explanations that describe how and why the intermediate and final results were calculated.

Technical Background

MONI-ICU relies on the following three components in terms of both method and practice: (1) Data sources that provide the respective structured medical data; (2) a medical knowledge base with computerized knowledge about all relevant clinical entities in the system; and (3) a processing algorithm that evaluates, aggregates, and interprets medical data in a stepwise manner until they can be mapped into the given HCAI definitions.

Additionally, graphical user interfaces display the daily results while reporting tools summarize the patient-oriented outcome.

Specifically, MONI-ICU's systems consist of the following:

Data sources: MONI-ICU is connected to 12 ICUs at the Vienna General Hospital where adult intensive care patients are treated. These ICUs are all equipped with Philips Care Vue PDM systems that collect clinical, laboratory, and nursing data over time. The patients' administrative data is transferred from the hospital's information system into the PDMSs and is thus available for MONI-ICU. However, a separate data interface was established between the laboratory information system (LIS) of the microbiology department (the LIS there was developed by the municipal authorities of Vienna) and MONI-ICU.

Furthermore, all PDMS data are restored daily and made available for further software systems, such as MONI-ICU, in a so-called information support mart (ISM). ISM is a relational data base containing a number of MONI-ICU specific tables, and is filled at night. In the morning about 5–6,000 data items are waiting to be processed by MONI-ICU.

Medical knowledge base. MONI-ICU contains an extended number of algorithm- and rule-based knowledge to recognize and interpret relevant data constellations that finally contribute to the decision as to whether a certain HCAI is present or not. By the use of fuzzy set theory and fuzzy logic, presence of HCAI is tagged with its calculated certainty. The required medical knowledge was defined by a small team consisting of an infection control specialist and a knowledge engineer. It was a difficult task, which was facilitated by the availability of standards [7–9]. For more details the reader is referred to [6,10].

Processing algorithm. The inference process is started daily at 5 am. For each patient (a maximum of 96 in the 12 ICUs), the entire knowledge base is applied. Processing is done in a stepwise manner: first, medical data are checked for plausibility and algorithms are applied to calculate intermediate numerical values such as means and scores; second, the patients' measured, observed, and calculated data are interpreted and classified into normal or the respective pathological classes (increased, decreased, …). Then, the abstracted and intermediate results are aggregated by the use of clinically meaningful rules. Finally, all included HCAI definitions are evaluated. As a result the (definitions of) HCAIs are fulfilled, not fulfilled, or fulfilled to a certain degree by the respective patient data. Quite often, patient data from the last few days are also taken into account.

A surveillance screen allows the infection control user to obtain an overview about all 12 ICUs, the patients, and the HCAI results. Moreover, detailed explanations containing the intermediate clinical results, and—if requested—the "raw" measured and observed patient data can be demanded by simple mouse clicks.

The results of MONI-ICU on the surveillance screen (we call it cockpit surveillance) are accessed from the rooms of the infection control unit at the Vienna General Hospital. Clinicians at the ICUs are directly contacted by the infection control staff when necessary.

Aims of the Clinical Evaluation

The objective of the clinical evaluation presented here is to perform the following two comparisons:

- Surveillance results generated automatically by MONI-ICU and those generated in parallel by trained surveillance staff and attending clinical experts using patient chart reviews and other available information. The data collected by human staff were taken as a clinical "gold standard" and then compared with the Moni-ICU results.
- Objective comparison of the time period taken to manually analyze patient charts on the one hand, and applying MONI-ICU as well as reviewing the results presented on screen on the other.

Methods

The clinical "gold standard"

From November 2006 to February 2007, trained surveillance staff together with attending clinical experts reviewed patient charts and other available information twice weekly, thus collecting data from 1007 patient days (two ICUs with together 16 beds, for adult patients, 99 admissions of > 48 h duration; refer to Table 1). All data were collected at the Vienna General Hospital, a 2,200-bed teaching and tertiary-care hospital.

The European HELICS [8] definitions for HCAIs (which are to a large extent identical with US-based CDC [7] definitions) were applied for the identification of HCAI episodes. The top-level main episodes are (with onset > 48 h after admission):

- septicemia (blood stream infection, BSI),
- central venous catheter-related infection (CRI),
- central venous catheter contamination (CCO – no infection!),
- pneumonia (PN), and
- urinary tract infection (UTI).

For more details on these entities and several variants of them, we refer the reader to [8].

Table 1 – Patient Data

	ICU 1	ICU 2	total
# Admissions > 48 h	56	43	99
Patient days	471	536	1007
Average duration of stay (days)	8.4	12.5	10.2

In addition, the time taken by the surveillance staff to review patient charts was recorded and summed up. The recording was performed in 6-minute units.

MONI-ICU surveillance

The above selection of patient data was again analyzed. This time the analysis was performed by automatically accessing the respective PDMS data, the data from the microbiology laboratory, and data from the admission department of the Vienna General Hospital. The complete analysis of the selected cases was done with MONI-ICU [actually, a programmed prototype of the present system].

Again, the time taken to load the results on the screen, select patient data and review the results, including the backward-chained inference and calculation path to the "raw" patient data, was measured and recorded for comparison.

Both, the results of infection surveillance and the time taken for two independent cycles were then compared.

Results

The following results were obtained:

MONI-ICU correctly identified the presence of one of the above-listed HCAI conditions in 28/31 cases (sensitivity 90.3%) and their absence in 68/68 of the non-HCAI cases (specificity 100%). Thus, an overall accuracy of 97% was achieved (cf., Table 2). Of the three undetected cases, two were due to missing microbiological data in the MONI-ICU database (a transfer error in data input) while one was due to a missing parameter in one rule definition.

Table 2 – HCAI Conditions Correctly / Falsely Identified or Missed by MONI-ICU

	Condition present "gold standard"	Condition absent "gold standard"
Condition present "MONI-ICU"	28/31 (90.3%)	0/68 (0%)
Condition absent "MONI-ICU"	3/31 (9.7%)	68/68 (100%)

The time taken for conventional surveillance was 52 ward visits comprising 82.5 hours (incl. 7.2 hours of walking) for human data collection and analysis. MONI-ICU analysis of the same 99 admissions took 12.5 hours at the MONI cockpit, which was roughly 15% of the time taken for conventional surveillance (cf., Table 3).

Table 3 – Time Expenditure for Conventional (Human) and MONI-ICU Surveillance

	Conventional surveillance	MONI-ICU surveillance
Time spent	82.5 h (100%)	12.5 h (15.2%)

Discussion

Automated surveillance by MONI-ICU is much faster and less dependent on human factors than conventional (manually operated) surveillance. High specificity of the results of surveillance is of paramount importance, as false alarms would rapidly and strongly discourage clinicians from accepting such a tool.

As the missing cases in MONI-ICU surveillance were due to rectifiable technical errors, a sensitivity of 100% can be achieved.

Investing resources in the development and programming of MONI-ICU is meaningful, as it provides reliable surveillance data rapidly. In general and also for the future, time and know-how must be invested so that MONI-ICU can keep pace with

advancing clinical expertise and adapted to the users' specific needs. The users, in turn, benefit from this time investment because their daily surveillance becomes rapid and precise.

Requirements for MONI-ICU and challenges:

- Availability of a suitable electronic PDMS; any additional manual data entries is counterproductive!
- Sufficient data of adequate quality must be stored and be accessible in PDMS. Its functionality is hindered or blocked by improper use or changes in interfaces to other clinical and institutional data systems. Similarly, sudden software and/or hardware changes in remote components of the healthcare institution's IT network may cause unexpected breakdowns. MONI-ICU requires a smoothly functioning IT environment.
- Clinical experts must be available and willing to cooperate in tuning and updating the system. Continuous cooperation between the MONI-ICU provider, the local IT management, the surveillance team, and clinical experts is indispensible.
- Funding the development and installation as well as continuing support of the system to keep in pace with advancing clinical expertise and case definitions are also necessary.
- Being understood and accepted by intended users. The reluctance of medical and other experts to entrust knowledge to an electronic system, the fear of being replaced by it in the long run and similar prejudices may prevent potential users from getting acquainted with its qualities.

Conclusions and Perspectives

MONI-ICU generated no "false alarms", thus demonstrating high specificity. Its sensitivity was reasonable even with the applied MONI-ICU prototype, the data of which are shown here. After having modified the rule definition and corrected the data input, its sensitivity has now been optimized, and re-evaluation of the presented data is under way. Regular updating is a basic feature of MONI-ICU in order to keep pace with advancing clinical expertise. In fact, MONI-ICU may be used as a tool for challenging current definitions for HCAIs and for investigating their validity.

With MONI-ICU as an add-on to PDMSs, regular and continuous surveillance of HCAIs is feasible even with a small workforce. This opens great possibilities for GCP, QM, and benchmarking routines in healthcare institutions. Likewise, MONI-ICU may be used as a tool for clinical science. Although it was primarily developed for continuous surveillance, its features offer clinical decision support directly at the ICUs in the form of alerts and reminders.

Acknowledgements

The MONI-ICU program used in this study was programmed by Software Unlimited, Vienna, Austria. The authors are indebted to the AKH-EDV (IT Department of the Vienna General Hospital) for their continued assistance in putting the MONI-ICU systems into routine operation at this hospital.

Using ProMED-Mail and MedWorm Blogs for Cross-Domain Pattern Analysis in Epidemic Intelligence

Avaré Stewart, Kerstin Denecke

L3S Research Center, Hannover, Germany

Abstract

In this work we motivate the use of medical blog user generated content for gathering facts about disease reporting events to support biosurveillance investigation. Given the characteristics of blogs, the extraction of such events is made more difficult due to noise and data abundance. We address the problem of automatically inferring disease reporting event extraction patterns in this more noisy setting. The sublanguage used in outbreak reports is exploited to align with the sequences of disease reporting sentences in blogs. Based our Cross Domain Pattern Analysis Framework, experimental results show that Phase-Level sequences tend to produce more overlap across the domains than Word-Level sequences. The cross domain alignment process is effective at filtering noisy sequences from blogs and extracting good candidate sequence patterns from an abundance of text.

Keywords:

Biosurveillance, Automatic data processing, Medical informatics applications, Investigative techniques

Introduction

Many factors in today's changing societies contribute towards the continuous emergence of infectious diseases. In response, Epidemic Intelligence (EI) has emerged as a type of intelligence gathering which aims to detect events of interest to the public health, from the unstructured text of news and outbreak report.

In a typical Epidemic Intelligence scenario (Figure1), disease reporting events (i.e. victim, location, time, disease) are extracted from raw text. The events which are considered to be relevant for detecting an emerging disease are annotated with additional information (such as threat or severity level) and then aggregated to produce signals. The signals are intended to be an early warning against potential public health threats, and the epidemiologist uses them to assess risk; or corroborate and verify the information locally and with international agencies.

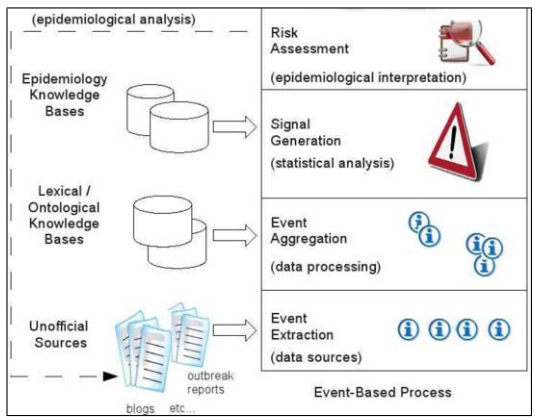

Figure 1- Epidemic Intelligence Scenario

In such a scenario, the diversity of the sources plays an important role in the intelligence gathering process. Medicine 2.0, social medical blogs and other forms of user generated content can be seen as an additional source. These sources are of significance, since those who experience as well as treat disease first hand, and describe their experiences in blogs and other forms of social media.

These present-day systems use news and outbreak reports as sources of information to support intelligence gathering. Moderated systems, (GPHIN, ProMED-Mail [5] ARGUS [9]) rely upon the interpretive and analytical expertise of analysts to filter and extract information about health threats. In automatic approaches such as MedISys [7], HealthMap [2], and BioCaster [1], all stages of the document collection, filtering and processing is done with little or no human intervention. Disproportionately, these systems do not take user-generated content, such as blogs, videos and twitters into account.

In order to fully realize the value of using Medicine 2.0, several challenges must be considered. First, acquiring information relevant to public health events from blogs requires filtering a huge number of irrelevant sentences. Those sentences which are irrelevant, or of poor quality need to be filtered out before any events can be extracted. Second, since natural language is inherently ambiguous, there are many ways to express

the same meaning. Particularly for social media, the complexity is increased given its volume, variety, evolution and informal nature (i.e. interspersing of subjective and factual information, many contributing authors with different styles, topic drifting prose and special lingo) [6]. Finally, abundant well labeled corpora, suitable for supporting many of the tasks in epidemic intelligence – is scarce or non existent.

In this work we seek to overcome these shortcomings, by demonstrating the underlying premise that if two sources discuss the same things - disease outbreak victims – then the languages have common linguistic structures. Thus, the symbols in one corpus can be used to identify them in another one.

In order to better understand which structures are potentially useful for extracting events from the sentences of blogs, we investigate how to transfer sentence structures acquired from a moderated data source (ProMED-Mail), and how this can be leveraged for the structures detection process within a new and less amenable one (MedWorm blogs), based on the commonality of the two used languages.

In this exploratory analysis we seek to understand the following questions with regard to a cross-corpora alignment:

- When do corpora align?
- What type of features (linguistic structures) best characterize such an alignment?

Methods

We cast the problem of Cross Domain Pattern Analysis as a alignment problem where the alignment sought is among the sentences of ProMED-Mail and MedWorm (see ***Figure 2***). In this approach we compare the sentence structures acquired from an auxiliary source (ProMED-Mail), to see if sentences relevant to outbreak reporting can be detected in a target domain (MedWorm blogs).

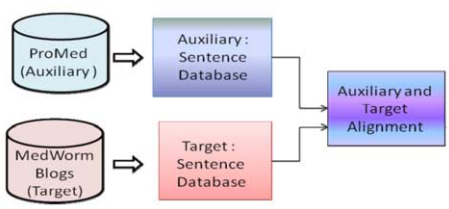

Figure 2- Cross Domain Pattern Analysis Overview

Structural Representations for Sentences

The sentences from each domain can have different levels of structuring (see Table 1). At the token level, the order of the individual words is considered unimportant; and can consist of (1a) the original word of the sentence (1b) a word's stem or (1c) a word's named entity. At the next structural level, one or more tokens can be sequenced lexically. For example, the named entity tokens derived from the Unified Medical Language System[1] (UMLS) concept identifiers (CUI) or the semantic classes (TUI) can be used to define a token sequence based on named entities (2a). An example sequence constructed from named entities using CUI and TUI is shown in ***Figure 3***. Finally, at the highest structural level, the sentence can be represented as a parse or dependency tree; respectively capturing the structure and semantics of the sentence.

Table 1-Structural Representations for Sentences

Structural Level	Example Representation
1. Token	a) Word b) Stem c) Named-Entity
2. Sequence	a) Token Sequence b) Phrase (i.e.: noun, verb)
3. Hierarchical	a) Parse tree b) Dependency tree

Sentence Database

Given a structural representation applied to all the sentences, in both the auxiliary and target domains, we construct a **Sentence Database.** An example sentence from a sentence database using the UMLS concept identifiers and semantic classes is shown in ***Figure 3***.

A 23 **year old** (C0419638, T061) **woman** (C0043209, T098) from Thanh **Hao** (C1435591, T116) **Providence** (C1227418, T005) died of **bird flu** (C0016627, T047) on **Wednesday** (C0585027, T079)[22 **April** (C1332090, T028) 2009]	
UMLS CUI Sequence	<C0419638,C0043209,C1435591, C1227418, C0016627, C0585027, C1332090>
UMLS TUI Sequence	<T061,T098,T116,T005, T047, T079, T028>

Figure 3-Example Sentence with Sequences Constructed from Named Entities using CUI and TUI

Definition: Cross-Domain Pattern Analysis

Given: a) a Sentence Database for an auxiliary domain, b) a second Sentence Database for a target domain and c) a comparison metric; Cross Domain Pattern Analysis is defined as follows:

Find an alignment between sentences having the same structural representation, of the form X -> Y, where X is a structure from the auxiliary domain; Y is a structure from the target domain and X is aligned with Y when the value of the comparison metric used is above a threshold value.

Results

Experimental Goals

In order to automatically determine suitable sentences for extracting events from the sentences of blogs, we align sentence structures acquired from ProMED-Mail and MedWorm blogs. The goal of these experiments it to understand: 1) when corpora align and 2) the type of linguistic sentence structures best characterize such an alignment.

Data Collection

ProMED-Mail data was collected directly from the website[2], and MedWorm blogs via RSS. The blog data was collected by We used the blog urls from the RSS feed to get the full content of each blog post. The data for the outbreak reports was collected during an eight month period from January 1, 2009 through August 12, 2009. This coincided with the known outbreak period of the Swine Flu influenza, which reached pandemic status in June, 2009 [3]. The total amount of data used is shown in *Table 2*.

Sentence Structures

To construct the Sentence Databases for the auxiliary and target domains, the documents were first split into sentences using the Stanford Parser[4]. Next, several structural representations for each sentence were produced, this included: a) stems; b) TUI sequences, c) phrase sequences and d) parse tree (see ***Table 1***) . Stems were created using the Porter Stemmer available with Apache Lucene[5], the phrases were obtained by using MetaMap and both the parse and dependency trees were constructed using the Stanford Parser.

Table 2-Summary of the Amount of Data Used

	ProMED Mail	MedWorm Blogs
Documents	1,129	2,171
Sentences	32,518	130,487
Tokens	542,229	1,489,686

Pre-Filtering and Alignment

Pre-Filtering: Not all sentences were used in the Cross Pattern Alignment process. We exploited the characteristic style of ProMED-Mail, where the information about an outbreak is typically expressed in the first sentences of the text. We experimentally used the top-3 sentences. For blogs, we used the top-10. Documents below a 300 Kb size were not included in the experiments.

A*lignment:* To align the structures across the domains, sentence structures of the same type from the target and auxiliary domains were compared using three similarity metrics; one for each structural level; the range of values for all scores were bounded by 0 (not similar) and 1 (equal).

Experiment I: Token Level Alignment

In this section, we present a token level alignment for terms in appearing in both corpora. The metric used for comparing tokens was based on the use of wildcards concatenated with stems. For example , the stem "outbreak" was concatenated with a wildcard to allowing matching morphological variations of the token. The salient terms are visible in the word clouds for MedWorm (***Figure 4***) and ProMED-Mail (***Figure 5***)

Figure 4-MedWorm Stemmed-Word Cloud

[5] http://lucene.apache.org

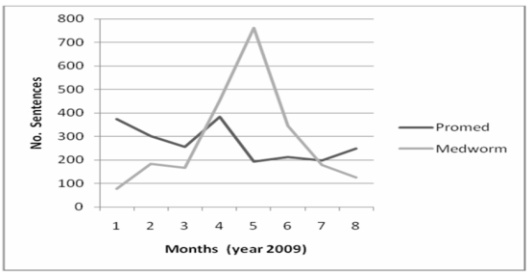

Figure 7-Total Sentences per Month for "outbreak"

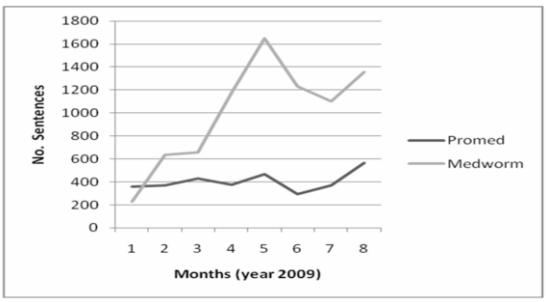

Figure 8-Total Sentences per Month for "virus"

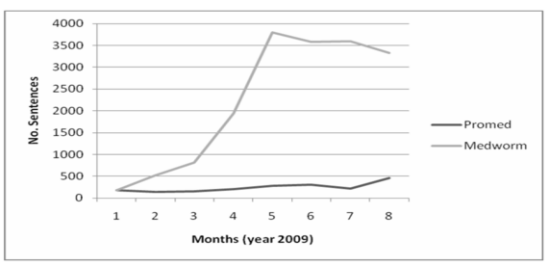

Figure 9-Total Sentences per Month for "flu"

Experiment II: Sequence Level Alignment

In this section, we present a sequence level alignment. The similarity metric used was based on our implementation of a string comparison algorithm which computes the longest overlapping contiguous subsequence of named-entity tokens. The score was normalized by the length of the longest sequence. Pairs with no named entity tokens in common received a score of 0. If all named-entity tokens in the sequence matched, one-for-one, then the pairs received a similarity score of 1.0.

Alignment of Token Sequences

Table 3 depicts the overlap between the sentences in ProMED-Mail and MedWorm for TUI and CUI Word-Level annotations varying the sequence lengths. The overlap between TUI annotated ProMED is far greater in number than the CUI annotations since several CUIs map to the same TUI semantic class. However, we notice that when the length of the sequences exceeds three, the proportion of overlap between ProMED and MedWorm for both types of annotations remains relatively the same.

Table 3-TUI and CUI Sturcture vs. Sequence Length

Number of Aligned Sentences Between ProMED-Mail and MedWorm Using TUI and CUI		
Sequence Length	TUI	CUI
3	6,105	422
4	130	136
5	30	20
6	15	16
7	10	9
8	8	6

Alignment of Phase Sequences

For the Phrase level structures were constructed by using the sentence chunks produced by the MetaMap parser. These chunks were then sequenced together to form the phrase sequences used in the experiments. Pairs of Phrase sequences were considered similar if there was and exact match.

Table 4-Phrase Sturctures vs. Sequence Length

Number of Aligned Sentences Between ProMED-Mail and MedWorm Using Phrases	
Sequence Length	Phase Structure
3	1,180
4	202
5	2

Experiment III: Hierarchical Level

For the hierarchal level, the parse tree for each sentence was used; to compute similarity for this structure, a tree kernel was used (http://dit.unitn.it/~moschitt/Tree-Kernel.htm). The results for tree alignments proved to be much less effective than the above methods, as no scores above .5 were obtained.

Experiment IV: Sequence Quality

In Experiment IV we examine the quality of the sequences with respect to the disease reporting task. ***Table 5*** shows the percentage of overlapping sequences which contain the semantic classes Population Group, Geographical Location, Temporal Concept or Disease. As can be seen, the percentage of sequences containing mentions to population groups and diseases are roughly the same for low support (10 % – 20%). Notably, as the support increases, the proportions change significantly and more overlapping sequences contain mentions to groups (30% support) and geographical location (%40 support).

In addition, we made a human assessment of the cases with a very small number of overlapping sequences. We find that these patterns contain interesting subsequences from which good candidate patterns can be built. One such subsequence

contains the location, disease and public health agency involved in responding to the event: e.g.:

TUI: Vietnam (Geographic Area), **from the disease** (Disease or Syndrome), **Health Ministry (**Health Care Related Organization)

Table 5-Sequence Quality Based on Entity Types

Sequence Quality Bases on Outbreak Report Named Entity Types				
Support Percent	Group	Geographical	Temporal	Disease
10	306	73	150	178
20	31	7	2	82
30	18	2	1	2
40	4	82	0	3

Discussion

The experimental goals of this work were to determine if an increasing level of abstractions in representing sentence sequences play a role in characterizing the sentential patterns between moderated and blog information sources.

In our analysis, we have seen that Phase-Level sequences tend to overlap more than Word-Level sequences. This can be explained by the fact that phases aggregate words and thus there is less variation across domains for these aggregations.
When aligning mined frequent sequences, the support played less of a role than the sequence lengths. Although very small numbers for higher sequence lengths were obtained, we believe this to be encouraging and demonstrate the ability of our approach to filter noise from large amounts of blogs data which a relative small about of human interpreted data.
We also experimented with other types of annotation such as POS and mined rare sequences instead of just frequent ones. Although not presented, these results showed less promise.
A notable limitation of the match phase used in these experiments is that the absence of a „sliding window" to align subsequences with a sequence. More rigorous matching could be used and is considered as future work.

Conclusion

In this work we motivate the use of medical blog user generated content for gathering facts about disease reporting events to support biosurveillance investigation. Given the characteristics of blogs, the extraction of such events is made more difficult due to noise and data abundance.

We address the problem of automatically inferring disease reporting event extraction patterns in this more noisy setting based our Cross Domain Pattern Analysis Framework.

The experimental results show that Phase-Level sequences tend to produce more overlap across the domains than Word-Level sequences and that the cross domain alignment process is effective at filtering noisy sequences and the extracting good candidate sequence patterns from an abundance of text.

As future work, we would like to take into account the significance of the errors associated with the annotation process itself. Also for the future work, we intend to examine how rules can be applied across the domains. Finally, we also intend to compare how the quality of the learnt patterns compares with patterns which are induced from predefined entity pairs in a greedy approach.

Abstract

Introduction: Web-based applications are a choice tool for general practice based epidemiological surveillance; however their use may disrupt the general practitioners (GPs) work process. In this article, we propose an alternative approach based on a desktop client application. This was developed for use in the French General Practitioners Sentinel Network. Methods: We developed a java application running as a client on the local GP computer. It allows reporting cases to a central server and provides feedback to the participating GPs. XML was used to describe surveillance protocols and questionnaires as well as instances of case descriptions. An evaluation of the users' feelings was carried out and the impact on the timeliness and completeness of surveillance data was measured. Results: Better integration in the work process was reported, especially when the software was used at the time of consultation. Reports were received more frequently with less missing data. This study highlights the potential of allowing multiple ways of interaction with the surveillance system to increase participation of GPs and the quality of surveillance.

Keywords:
Sentinel surveillance, Software, Communicable diseases

Introduction

The use of computerized information systems is increasingly common in General Practitioners (GP) practices [1]. Such systems may run as local applications on desktop computers and guarantee very quick response time and good integration in the clinical process. This is for example the case with most electronic patient record software. By contrast, other systems are based on interaction with distant servers through web browsers with typical larger response time that may limit integration in everyday's practice.

In the French Sentinel Network (FSN), an electronic epidemiologic surveillance system operating in France since 1984, a web based interface has been the preferred way of interaction since 1996 [2]. The FSN is based on a nationwide network of voluntary GPs who report cases of several conditions, mostly childhood and acute infectious diseases. Estimates of disease incidence are computed from GPs reports and used for public health decision making.

The satisfaction surveys of GPs participating in the surveillance alerted us to the fact that interaction with the website could be a limitation to the doctors' persistence in surveillance. Indeed, with this system, GPs must periodically log in to a secure web site and report cases using a dedicated interface (see Figure 1). This process is difficult to perform during consultation, and leads to delays in reporting. As public health decision makers are increasingly expecting near real time reporting and analysis of data [3-4], it is relevant to try and integrate the surveillance process more directly in the GP clinical process, so that cases may be reported almost in real time.

In this article, we describe how we redesigned the electronic web based surveillance system for better integration into the GPs work process, using a java-coded application run as a client on the local GP computer. While making case reporting easier to the GP, the solution also allows for real time data collection (on a daily basis). Furthermore it allows deployment of new surveillance items in real time. Finally, we report how this software was received by participating GPs.

Materials and Methods

Surveillance information model

The surveillance information model is split in two abstract models. The metadata model describes the surveillance protocol and the report data model describes the structure of the reported data. The implementation of the above model is presented using Unified Modeling Language (UML) in Figure 2.

Metadata model

The metadata model describes the surveillance protocol for a disease (or a medical condition). It consists of the definition of a **Disease** class holding the case definition in plain text, a unique identifier and a flag indicating whether reportable items, used to collect individual data about reported cases have been defined.

These reportable items are described by a set of combined classes. A first class (**Form**) acts as a container for **Item**

classes which specify the labels and types of data (text, numeric). Presentation and validation information is linked with the list of reportable items via classes **Group** (grouping items for display), **Choice** (set of acceptable values), **Parameter**, (named parameters like limits, validation pattern) and **Dependency** (dependencies between fields).

Report Data model

Cases of disease are observed by an Agent (here a GP) during a given observation period. Reports to the surveillance system are described by the **Declaration** class and is composed of an **ObservationPeriod** holding start/end dates and activity during the period (full time or not) with a set of **DiseaseCases** (for each disease included in the protocol). This last class is a set, possibly empty, of **Cases**, observed for the disease. A Case may hold individual data according to the **Items** in the form model associated with the disease. Each **Declaration** instance also includes references to the version number of the surveillance protocol, an agent identifier and the count of cases by disease.

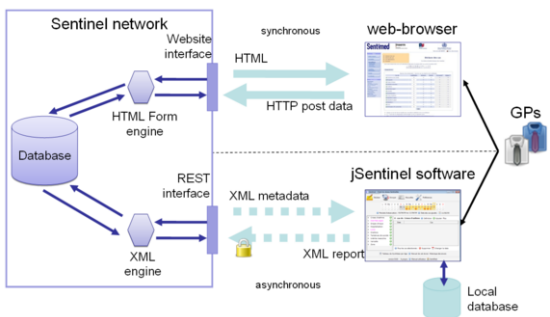

Figure 1-Overall architecture of the French Sentinel Network for epidemiologic surveillance. GPs may report data using a web based interface or a desktop client.

Client/Server model implementation

Two packages were defined and used to generate the set of XML schema files used in validation process (Figure 1 & 2). Files conforming to the **Metadata** model package are deployed from a central server to client applications to update surveillance protocol, while data sent from client application to the central server are expected to conform to the **Report** package description.

Available operations (authentication, push data to server, etc) are handled using a REST (Representational State Transfer) service interface: HTTP operations (GET, POST) are used to make an operation on a resource identified by an URL (Uniform Resource Locator), for example, the GET request to the URL https://[server]/metadata is used as the endpoint to get last metadata version. All exchanges use HTTPS protocol.

Metadata package XML files are instantiated on the server side from protocol descriptions stored in a database. Getting a file from the server is split in two operations: first, the server send an XML manifest file containing the version number available requested file and then the requested file is sent if it is new to the client.

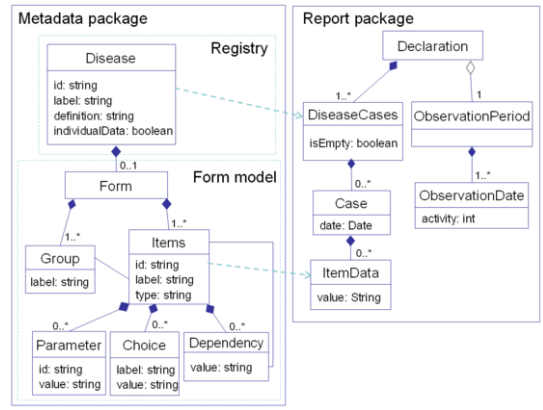

Figure 2- Surveillance information model. This model is used to generate XML files structure and XSD files

Desktop client implementation

We developed "JSentinel", a lightweight desktop Java application for surveillance and report. The application uses a modular architecture: a core component provides the basic functions like networking (http client), version management and updates, XML and Graphical User Interface (GUI) support.

A graphical library was developed using Java Swing components to display forms. This library transforms reportable items (conforming to the Form model) described in the metadata package (Figure 2) into a graphical form for data entry. It also handles data validation according to constraints defined in Dependency and Parameter class in the model, and displays an alert when an error is detected.

Main functionalities are packaged into "modules" which are interfaced with the core component and graphical user interface library. The four available modules (surveillance, news, update and preference) are described below.

Modules description

The Surveillance module allows data collection according to the surveillance protocol. It provides a GUI to collect case descriptions conforming to the **Metadata** XML package. If individual reportable items are required, the corresponding XML file containing the reportable items description according to the form model (Figure 2) in the Metadata package is passed to the GUI library to dynamically create a form and return the data entered. Data corresponding to reported cases are stored locally in an XML file conforming to the report package.

The Update module handles the synchronization of data with the server, downloading and inserting new files as required.

The News module provides a news reader user interface using Really Simple Syndication (RSS) and can be configured to

read several RSS sources and this source definition could be deployed within synchronization.

The Preferences module provides a user interface to define options and connection parameters.

Using the client

The client software is a point & click / menu driven application. The surveillance module user interface, presented in Figure 3, shows the list of diseases created from the downloaded metadata XML file, and the reported number of cases for each disease. If required, reportable items for the selected disease are listed in the right panel and may be filled in by clicking on the panel. A top bar shows a calendar displaying the observation period and activity level (half-time or full-time on a daily basis). Help and documentation is available, as well as summary displays of past reports for each GP.

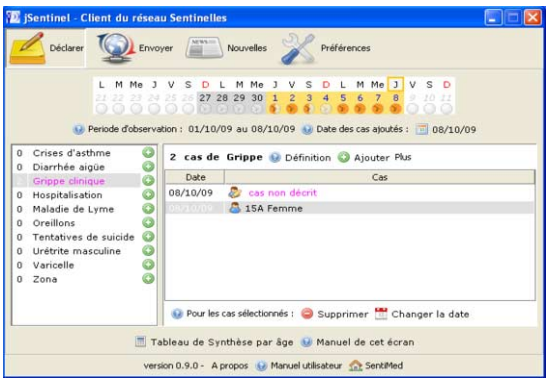

Figure 3-Screenshot of the jSentinel software. Diseases are listed in the left column. Two Influenza Like Illnesses (=Grippe) are currently being reported with one individually described Results

Deployment of the software

The software was developed and tested with 20 voluntary GPs, it was then made available for download and use for all GPs in the network. Two months after deployment, we invited all GPs who had used the client at least once to participate in a short survey. This survey explored GPs satisfaction with the new client software on several dimensions: time spent collecting and reporting cases, access to information about the network. Objective indicators related to the use of the system were also computed: frequency of connection, number of reported cases, completeness of reports (% cases with individual data) and persistence of use. When possible, we compared these indicators between GPs using JSentinel client and those using the web based interface.

Results

Software Utilization

209 GPs (out of 415 providing data) used JSentinel at least once over the first 9 months of availability (January - September 2009). During this period, 133 GPs used JSentinel more regularly than the web interface (those will be referred as JSentinel users) and 279 used the web interface (referred further as Web users). 3 GPs used both equally (but had very few connections) and were excluded from comparisons. Among JSentinel users, 60% used only the JSentinel software to report their cases. Proportion of weeks with at least one report for each GP was not significantly different during the evaluation period (median 63% inter-quartile range (IQR) [25%; 83%]) from the previous year (median 70% IQR [27%; 90%]) for JSentinel users.

Impact on surveillance data

The median time lag between 2 successive declarations for GPs using the website was 6 days with an inter-quartile range (IQR) of [3;8], but it was 0 days ([0;2]) for JSentinel users ($p < 0.001$) showing that daily declarations were common for the client software users. From January to September 2009, the median number of cases by week of observation was 5.13 cases for web users and 5.50 for client's users (not significant). These results are presented in Table 1.

Age and sex (common reportable items for all conditions included in the surveillance protocol during the year 2009) were fulfilled for 96% of reports from JSentinel and 91% from website declarations ($p < 0.001$).

Qualitative evaluation

107 GPs (out of 168 who used the client at least once during the 2 months following the deployment) responded to the evaluation survey. 95% reported spending less time reporting cases using the client, 59% agreed to say the client helped them to provide exhaustive reports and 83% agreed to say the client helped them not to forget reporting. Reasons most frequently mentioned to explain the client's help were the ability to report cases during consultation and desktop availability.

Table 1- Characteristics of participating GPs and changes in surveillance according to Web / JSentinel use.

	Web	JSentinel	p value
Use of Electronic Medical Record *% (N)* [1]	95.5% (233)	99% (126)	0.06
Days between consecutive reports, *median [IQR]*	6 [3;7]	0 [0;2]	< .001
Reported cases per week, *mean ± sd*	5.5 ± 5	5.1 ± 3	0.5
Report completion	91 %	96 %	< .001

[1] *data available for 89% of GPs*

Discussion

Making GPs persistent in reporting cases is a continuing challenge in voluntary based epidemiological surveillance systems [5]. Our users' survey confirmed that better integration of surveillance within the GP clinical process was a key element for participation. Indeed, desktop availability made it possible to describe cases quickly, allowing the additional work required for surveillance to fit in the consultation time. Another positive effect of the better integration of surveillance in the clinical process was the reduction in reporting delays. Indeed, most GPs sent data the day they were input, when the delays could be larger using the web based interface. However, some GPs preferred the web interface over JSentinel: these included GPs with a non computerized practice, as well as those who felt that using JSentinel took more time than reporting cases only once a week. Loss of time is often reported as an obstacle to adopt eHealth solutions [1].

In designing JSentinel, we aimed at developing a content management system for epidemiologic surveillance rather than a closed software for the FSN. For example, JSentinel includes an automatic newsreader functionality using a RSS stream reader. This function is used to provide rapid feedback to the GPs, and to deploy epidemiological alerts, as well as to maintain motivation in surveillance data collection. It has been suggested that making this information available may improve clinical decision rules, for example in the presence of epidemics [6].

The content management system approach of our architecture is further illustrated by the way the surveillance details are described. Indeed, these were all packaged (details on surveillance data presentation, capture and transmission) in XML files that are dynamically interpreted within the JSentinel software. Thus, the system is easily extendable to include new diseases. For example, modification of the influenza-like illness surveillance protocol to include influenza pandemic specific questions (risk perception, specific vaccine, etc) could be achieved in a few hours. JSentinel may also serve as a platform for data collection outside the routine surveillance protocol.

We developed our own data description using XML based on an abstract but simple model for continuous disease surveillance. There is indeed no well adopted standard for epidemiological surveillance, with most systems using ad hoc descriptions [7]. Contrary to clinical epidemiology, where Operational Data Modeling CDISC standards [8] has been put forward due to requirements by the Food and Drug Administration, initiatives for public health data standardization are still in their infancy. Our set of XML files may serve as a first step for allowing integration of heterogeneous systems in a unique framework.

Electronic data collection methods have become increasingly common for epidemiologic surveillance. Terminal based solutions were rare but existed before the internet [9]. Web based solution are now broadly used in surveillance system. Thanks to the web architecture based on W3C standards, web forms provide simple and flexible way to collect data since web browsers are only in charge of presentation and all data treatment could be done on the server side (forms definition, validation of data and storage). In our experience this data collection method has some limitations when especially when the working process of the users is not fully web-oriented and/or when permanent internet connection is not available or acceptable (for security reason or patient's home visits).

Another promising solution is the use of existing EMR software for surveillance purpose [10-12] . This solution has for example been implemented for syndromic surveillance to collect data (sex, age, chief complains, etc...) in existing software from Emergency Department or General Practice.

The real extent of the overlap between data required for public health surveillance and that entered in the Electronic Medical Record (EMR) content is an debate [13]. In case of emerging health issues and research the actual overlap is not clear cut.

In such cases, some specific data may be valuable which are of little use for the care of the patient: these would include for example contacts for a transmissible disease, detailed data on exposure or the environment, and so on. This type of data would be difficult to extract from the EMR, as the GP is unlikely to request them unless it is in a well defined surveillance protocol.

For surveillance of common diseases, one may expect that most of the data required may be in the EMR although it may be entered with little structure so that automated extraction is difficult.

Better integration of surveillance in the GP work process is therefore likely to pass by direct interaction with the EMR. This calls for standardizing the way data is stored in the EMR, so that automated extraction is possible; this also requires standardizing interaction between EMRs and surveillance systems to guarantee interoperability. Some solutions have been tested using the Clinical Document Architecture [14] or Archetype-based models [15] but they are generally based on a unique or few type existing software.

We did not pursue this goal here because there is a very large diversity in EMRs used in France by GPs; these have no capabilities for interoperability; and proprietary formats for data storage are common. Implementing a dedicated tool to extract from each EMR is clearly a dead-end, as it is not maintainable.

A further issue is that privacy of medical data is a stronghold in French regulations, so that third party software may not be allowed to perform automated scanning of EMRs. Pushing information from the EMR to the surveillance system would be better in this respect, although an authorization would still be required.

Implementing a standalone software was therefore the only viable solution that could be used by every Sentinel GPs regardless their choice of EMR. Our XML files may be a first step to base interoperability of such EMRs with surveillance system. Example files and schemas could be found at http://www.sentiweb.fr/xml/jsentinel

Future developments will proceed along two lines: 1 - industrial data standard to represent metadata considering specific (CDISC) or generic solutions (XForms) [16] as recommended by Retrieve Form for Data Capture published

by Integrating Healthcare Enterprise initiative [17] ; 2 - improve integration or communication with existing EMR.

Attempting to predict the fate of an ongoing epidemic. Lessons from A(H1N1) influenza in USA

José Luis Hernández Cáceres

Center for Cybernetics Applications to Medicine, Havana Higher Institute of Medical Sciences, Cubanacan, Playa, Ciudad de La Habana, Cuba

Abstract

A simple method is proposed for predicting the fate of an epidemic outburst from early data. The method is based on the Richards model, and linearizations are proposed for obtaining preliminary values. A second step with nonlinear estimation fed with preliminary values as initial guess values may be attempted if field conditions allow the computation. The method was tested on data from 2001 dengue outbursts in both Havana and Winward Islands (French Polynesia). Predictions were satisfactory and an attempt of true prediction based on daily data for the 2009 H1N1 influenza outburst in the USA was undertaken. Comparison of early predictions with actual values obtained 3 months later suggests that some of the discrepancies are not due to method's inacuracy, but to real improvement of infection rate as the H1N1 outburst proceeded. The method can be applied in any setting where cumulative number of cases is properly recorded.

Mathematical Model, Epidemic prediction, Dengue, Influenza A(H1N1)

Introduction

In 2001 both the Cuban capital and French Polynesia were affected by dengue epidemics. Both places belong to the high dengue risk tropical belt, and dengue was known to both populations. In Cuba half a million persons (more than 5% of the country's population) suffered from Dengue-1 in 1977, whereas 300 000 were affected by dengue-2 in 1982 [1]. In French Polynesia, 17% of the population caught the disease during the 1989 dengue-1 epidemic [2]. An epidemic of Dengue-2 affected Santiago de Cuba in 1997, but was succesfully controled [3].

The 2001 Havana dengue-3 epidemic lasted for almost 9 months[1]. Dengue-1 was flagellating French Polynesia for 10 months. In spite of similar time course, one epidemic affected less than 0.6% of the population of Havana, whereas the other involved 16% of French Polynesians [2].

The paid prizes, however, were similarly high: In Cuba , huge human and financial resources were diverted to curb the epidemic. In French Polynesia, pediatric health infrastructure almost collapsed [2].

These two examples may illustrate the spoil caused by epidemics worldwide. Fighting them is a major public health challenge, and no country can proclaim to be completely safe [4]. Public opinion apparently sees the solution to most of epidemics in the development of vaccines as well as in their availability [4-5].

It seems reasonable to assume that the success of public health response to an epidemic also depends on the possibility to early predict its time evolution [6].

Here, we maintain the viewpoint that early prediction of an ongoing epidemic is a task approachable in a medical informatics framework. We recognize that only the first steps are being made in that direction. Thus, deeper theoretical work is needed together with closer collaboration with public health authorities. At the same time the task is not very appealing for theoreticians. For data miners relevant information appears when huge data sets are analyzed and sophisticated methods are applied. In the case of early prediction of an ongoing epidemic, computations are based on rather coarse approximations to small sets containing between 2 and 10 data points. The soundness of such a task can be negligible mathematically. However, when figures have deal not with abstract numbers, but with human beings under threat the motivation may find a proper space.

As an illustration, the method described in this paper predicted, based on early data available on weeks from 3rd to 10th of the outburst that the cumulative incidence of dengue hemorrhagic fever (DHF) for Windward Islands in French Polynesia would be between 6 and 11 cases/1000 inhabitants. Real cumulative incidence, determined after week 40, totaled, 3.07. Closer to this figure were estimates obtained with standard nonlinear approximation methods, but only available after the 10th week. Standard methods failed for the early stage, and our early forecasts, though relatively rough, could be very valuable as a guidance for preparing public health response during the most critical stage of epidemic fighting. For Havana, on the basis of data available from weeks 3rd till 5th, the total number of cases was predicted between 2 700 and 7 000, 45% of the actual number of cases: 12 889.

During the preparation of this manuscript, an attempt of "true" prediction was undertaken for H1N1 epidemic in the USA. A very important step is model selection [7-9].

A very useful expression for incidence rate was derived theoretically from the classical SIR model developed by Kendrick and McCormick 70 years ago[10]:

$$Incidence=A*4/(\exp(b*t-c)+\exp(c-b*t))^2 \quad (1),$$

where A corresponds to the maximum incidence and Tau=c/b is the time from the beginning until the peak of the outburst . For realistic conditions, this approximation is satisfactory, in particular, it fits nicely to a more complicated model for dengue fever conveyed by the mosquito[11].

As an illustration, in figure 1 incidence data for Winward Islands DHF are fitted to model 1.

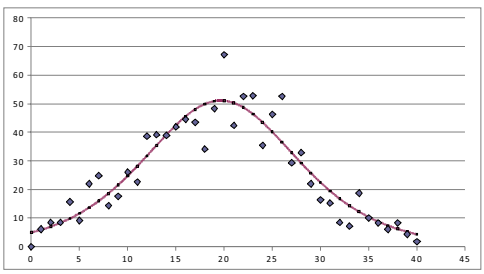

Figure 1-Theoretical bed occupancy with DHF patients in Leeward Islands[2]. Abscissa: Week since the starting of the epidemic; Ordinates: Percentage of theoretical bed capacity. Solid line was estimated from equation (1) using the Hooke Jeeves method.

Incidence data tend to be noisy, but cumulative incidence combine the advantages of a smooth filtering with faithfulness to original data; when little is known about the mechanisms of the ongoing disease, it is advisable to select the simplest models being capable of adapting to different possible variants. For cumulative data S(t), the Richards model can be valid [12-14]:

$$S(t)=K/(1+\exp(R(Tau-t))) \quad (2)$$

K corresponds to the total number of cases and equals

$$K= (S(0)*(1+\exp(R*Tau)) \quad (3)$$

Tau has the meaning of the peak time for incidence; the basic reproductive number R_0 (defined as the average number of secondary cases generated by one primary case) can be estimated as

$$R_0=\exp(T_g*r) \quad (4)$$

Where T_g is the transmission time, or the mean time between the appearance of symptoms in the primary case and the appearance of symptoms in a secondary case [12]. For dengue fever a value of T_g=2.71 weeks has been accepted [14].

There are several approximation methods to fit data into nonlinear models, such as Simplex, Hooke-Jeeves, Gauss-Newton, that have been implemented in different commercial statistical packages. These allow, in principle to simultaneously estimate several parameters from a data set. However, straightforward estimation beyond the domain of observed values with a highly nonlinear function, is not always reliable. As an example, Hooke Jeeves approximation for DHF in Windward Islands yielded cumulative incidence estimates surpassing 40 000, obviously a senseless value. In other words, data are behaving as those typical for ill-posed inverse problems. A practical way to try to deal with this kind of drawbacks is via limiting the space of possible solutions, and imposing to the them certain plausible requirements. In this case, the use of linearizations and manual stepwise estimation of values seems to be recommended. The rationale of our method is based on this philosophy.

Materials and Methods

General Description of the Prediction Method

The first step to linearize the Richards model is as follows. If R(Tau-t)>>1, the expression for S(t) (2) can be seen as S(t)≈ exp (R(t-Tau)), thus the value of R can be obtained from the slope of the curve log(S) vs time.

The next attempt to linearize is via a Taylor expansion of the exponential function. Expanding it, and having deal with realistic numerical values, we found that a good approximation for inverse values of expression can be:

$$(1/S(t))^{(1/4)} \approx -(R(t-Tau)) \quad (5)$$

The right side becomes equal to zero when t=Tau; thus from the relationship between the 4th root of the inverse of the cumulative data and elapsed time, it is possible to obtain a good guess for the time to the peak of the outburst (or "turning point" in the terminology of Richards model [14]) .

From the determination of Tau and R, the value of parameter K can be found from (2) for any value of time t. These estimates obtained "by hand" are subsequently entered as initial guess values for a Hooke Jeeves estimation of data into function (2). Two parameters are fixed an the third one is estimated. After several iterations a refined set of parameters is obtained. In some practical situations, the computer demanding nonlinear estimation step can be omitted.

Results

Dengue hemorrhagic fever in Leeward Islands, French Polynesia

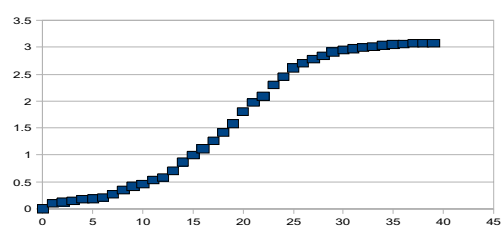

Figure 2-- Cumulative incidence of DHF in Leeward Islands [2]. Axes: Week since the star vs Cumulative incidence.

Hooke Jeeves estimation from the whole data set yielded: K=3.16, R=0.22, and T(weeks)=18.59.

The basic reproduction number (R_0) can be calculated as R_0=1.82 based on a 2.71-weeks transmission time (T_g) [14].

The application of the our method for early prediction based on data from weeks 3rd to 6th, yielded the following values (Table 1):

Table 1-- Early predictions for the Richards model parameters. DHF. Leeward Islands

Week	T	R	K
3	19.6	0.22	6.22
4	21.7	0.20	6.45
5	24.1	0.19	7.17
6	28.1	0.16	7.37
Geometric Mean	23.2	0.19	6.79

Assuming a transmission time of 2.71 weeks, a value of R_0=1.67 is obtained. As appreciable, predictions for T and R are satisfactory whereas for parameter K early estimates roughly doubled the final outcome. We regard that, in practical terms this information is valuable, especially considering that they were given 8 months before the end of the outburst. This value of R_0 is in agreement with other reports using the Richards model for its estimation [14].

Havana dengue-3 epidemic, 2001

The model estimated focumulative numbers for dengue fever cases reported for Havana [1] yielded:
R=0.31
Tau=18
K=12900
(R_0=2.31)
Early estimates for weeks from 3rd to 5th are shown in Table 2.

Table 2 -- Early predictions for the Richards model parameters. Dengue Fever, Havana.

Week	T	R	K
3	11.5	0.42	2661
4	15.33	0.38	6904
5	14.38	0.36	3786
Geometric Mean	13.64	0.39	4113

(R_0=2.88)

In this case the prediction for cumulative number of cases are below 50% of the actual value.

This discrepancy respect to parameter K might reflect our previous finding that Havana Dengue epidemic behaved as several independent outbursts. Curiously, this value is concordant with the predicted size of the early outbreak [11].

An attempt of true prediction: H1N1 in the US.

The possibility for real a priori predictions about an ongoing epidemic came with the advent of H1N1 flu epidemic in the US. Since the first notification of two H1N1 cases in April 2009, the Centers for Disease Control (CDC) were informing, on a daily basis, all the confirmed cases of H1N1 [15]. The information was freely available for any Internet user.

From the beginning of the outburst, predictions were based on a combination of estimates based on the linearizations described above, and then using these estimates as initial guess values for a Hooke Jeeves estimation.

Figure 4 is showing the cumulative cases numbers for the US H1N1 Flu outbreak.

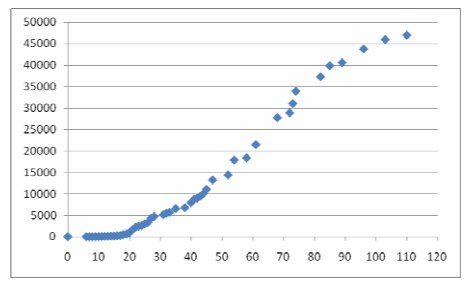

Figure 3-- Cumulative cases of H1N1 in USA(2009). Legend: Abscissa: Day since the starting of the epidemic; Ordinates: Cumulative cases. Redrawn from daily CDC reports [15]

A Hooke Jeeves estimation yielded the following "final" estimates, K=48234.3, R=0.070, and T(days)=63,67.

A value for T_g=2.3 is plausible for influenza A(H1N1) [15-16], corresponding to R_0=1.17, which is in agreement for the first early report in the range of R_0=1.4-1.6 for H1N1 in Mexico [17].

For days from 7th to 20th the following predictions were obtained (Table 3)

Table 3-- Early predictions for the Richards model parameters. H1N1 flu outbreak, US (2009).

Days	Tau	R	K
7	43.98	0.19	9197
8	37.68	0,228	9477
9	22.26	0.577	43541
10	20.9	0.575	20584
11	19.68	0.566	8108
12	28.07	0.30	9990
13	30.07	0.34	38919
14	28.76	0.336	21442
15	31.94	0.331	47121
16	31.97	0.327	44800
17	32.20	0.317	38013
18	29.35	0.328	20252
19	30.89	0.328	32863
20	30.78	0.328	31685

Geometrical mean values were:

Tau	*R*	*K*
29.3	***0.345***	***22576***

(R_0=2.11)

Discussion

Predictions in all the three examples differed from the "true" values obtained from complete data sets. In order to assess the reliability of the method, it is necessary to explore possible sources of disagreement.

Total number of cases (K). At early stages of the epidemic the parameter K is estimated as a nonlinear function of the estimates of Tau, R, and the number of cases at time zero (expression 2). Small errors in either Tau or R can lead to large differences in the estimated value of K. Moreover, the incidence reported at time zero can easily vary in a large relative quantity as it can be the difference between 1 and 2 cases, a situation very likely in everyday practice of data reporting. Thus early estimates for K between 50% and 150% of the "actual" value can be regarded as "acceptable". We expect that this range expected cases, predicted several months before the end of the outburst may be a useful figure for decision makers.

In data for Havana and French Polynesia, early predictions for Tau were between 70% and 130% of the final values. This was not the case for H1N1 in the US where the early estimate for Tau was 45% of the "final" value.

Similarly, estimates for parameter R were similar to "final" values for dengue outbursts in both French Polynesia and Havana (at least 75% of final values), but very divergent for H1N1 in US (almost 500%).

These differences between early predictions and final values can be due either to inaccuracies of the method or to specific features of the data.

We tried to explore method's predictions for parameters Tau and R using simulated data with two different parameters sets. One set corresponds to early estimations for H1N1 and the other set containing the final values. If the accuracy of early prediction is poor, it is to expect that no differences will be found between predictions for each data set.

These results are summarized in Table 4. Predictions reflect the geometrical mean from 19 estimations (from day 2 till day 20). As obtained, estimations in this range of values were clearly different between data sets. The largest difference was for parameter Tau and was 65% of the actual value (19 vs 29.6). For parameter R early predictions were very accurate, better than 97% of actual values.

Table 4-- Early Predictions for model parameters for two simulated data sets. Geometrical means for the first 20 days are shown.

Week	T	R
real	29.26	0.345
estimate	19	0.344
%	65%	100%
real	60	0.07
estimate	65.6	0.068
%	109%	97%

Thus simulation results suggest that differences in the estimates for parameter r are not due to inaccuracies of early prediction. An additional reason for this conclusion might be the dependence of estimates for r as the epidemic proceeded.

Data fitted to an exponential decay curve(r^2 =0.84), and might reflect a real reduction in parameter r, and, subsequently of the basic reproductive number as the epidemic proceeded. Given the nature of this epidemic with an unknown virus and the subsequent strong response by health authorities it is to expect a sharp reduction of infectivity after the initial days of the outburst.

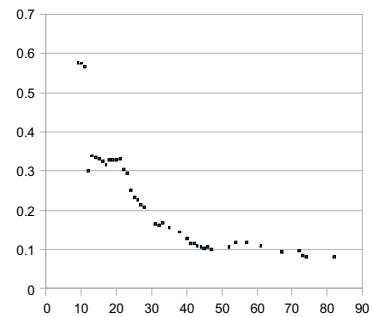

Figure 4-- Time evolution of estimates for parameter R estimated for reported H1N1 cases in USA(2009). Legend: Abscissa: Week since the starting of the epidemic; Ordinates: estimate for parameter R until the given day.

For parameter Tau , a trend towards the increase was also appreciated (r^2=0.91).

Taken together, the reduction in parameter R with increases in parameter Tau can be interpreted as a positive impact of public health decisions to fight the epidemic in the US. As it is known, reducing transmission rate without a reduction of a number of susceptibles leads to an elongation of Tau [8].

Limitations of the present study.

As any research with modeling of real data, the present study is limited by reporting accuracy and under-reporting. In the case of H1N1 in the US, only CDC confirmed cases were studied, these numbers reflect only a small fraction of real H1N1 cases. However, our results might be regarded as a good reflection of the real dynamics of the epidemic.

Limitations related to the method include model selection, limitations of theoretical approximations assumed, as well as those related to assumption abiding under real circumstances. Richards model has been applied for the description of SARS as well as dengue fever and seems to be a good first choice model for different outbreaks. To approximate nonlinear functions with coarse linearizations is always accuracy-costly, and randomness, can additionally hinder theoretical predictions. Simulations suggest that for realistic sets of parameters, excelent accuracy is chieved for R; acceptable predictions can be obtained for Tau and 50-200% or real K-values, based on early estimates from the first 3-5 weeks of an outburst lasting for almost 20 weeks. Assumptions are necessary for getting nice models, but they are not always congruent to reality [17].

Richards model is good for a spatially homogeneous population with parameters unchanged with time. We showed earlier that the 2001 dengue epidemic in Havana corresponds to several independent isolated foci (a nice result from spread prevention measures [11]). It is to expect that for the US, the outbreak can be represented as well as several relatively independent clusters. By actively fighting the spread of the disease, infection parameters change. This is not assumed in the model. The proposed method apparently detects changes associated to intervention measures. The main advantage of the method, is that it can be applied in any setting where an epidemic outbreak appears. A table of logarithms a pencil and a sheet of paper are the only requirements.

Thus a simple method has been proposed for early prediction of the fate of an ongoing epidemic. Its application to real data suggest that some of the discrepancies between early predictions and values obtained at the end of the outburst are not necessarily due to the poor accuracy, but to spatial heterogeneity of the outbreak, or to the impact of prevention measures taken during the time of the outbreak.

Abstract

Public health organizations in different nations face similar needs for gathering and analyzing population health data to detect and manage infectious disease outbreaks, including outbreaks of the 2009 Novel H1N1 Influenza A virus or "swine flu." This paper presents our progress to date on the design and assessment of a multi-national public health informatics infrastructure for data collection and disease surveillance. This initial work, under the aegis of an open health tools collaborative, lays the foundation for best practices in patient care and public health preparedness in the national health IT sector. This multinational collaboration is the first to identify essential electronic health record (EHR) data sets as well as standard public health informatics indicators to electronically monitor a notifiable public health condition internationally.

Introduction

With advent of a severe *Novel H1N1 Influenza A* pandemic in the 2009-2010 season, there is a need for improved awareness and response in national public health efforts. As a result of increased cases globally of H1N1 Influenza A, the need is both emergent and evident for increased and integrated multi-national surveillance and tracking for the pandemic.

Comprehensive large-scale surveillance requires the integration of health IT data streams including point-of-care electronic medical record data into national and international influenza surveillance systems [1, 2]. At present, there is minimal or no integration between the clinical delivery systems and public health organizations in the organizations and national settings studied, a gap targeted in the focus of this work.

Recognizing this gap, this study sought to address the following problems: (i) identifying what are the known national-level data information sources within countries (ii) coordinating overlapping public health informatics efforts across nations in the face of limited budgets for response; (iii) the feasibility of analyzing public health data in a cross-national manner. This paper is designed to help provide an insight into the international e-health information streams and data sets available to allow consistent world-wide surveillance and assist in bridging this identified gap between clinical delivery and public health contexts.

This collaborative endeavor identified the existing national data streams that can be used to answer surveillance questions as well as identify indicators of importance to public health management of influenza. The multinational collaboration is comprised of individuals from various United States institutions and worldwide public health systems, including the [US] Centers for Disease Control and Prevention (CDC), the [US] Indian Health Service (IHS), and the Office of Health Protection (OHP), Australian Government Department of Health and Ageing Canberra, Australia, in all case bridging both informatics and epidemiology divisions of each organization.

The objective of the multinational collaboration is to foster sharing among major e-health programs globally to promulgate common knowledge for health information technology best-practices in patient care and public health preparedness. The initial focus of this study has been centered on the determination of de-identified health IT data streams contained within point-of-care electronic medical records. These data streams provide a content source of rich medical information that the authors are asserting can be a critical asset for use in national influenza surveillance systems to prepare for and respond to the worldwide pandemic. Moreover, our findings are that sufficient commonalities exist

among existing health IT data streams in different organizations so as to allow for their use in cross-national pandemic influenza surveillance. This information is a necessary foundation for the dynamic sharing of information across the different institutions and countries involved. Based on the feasibility analysis presented here, further work will continue in order to develop a set of common data specifications for e-health-based large-scale multi-national surveillance systems.

Methods

The design and assessment method used in the study consisted of four main steps. First, a set of three test cases of national-level public health systems were chosen through which to conduct the assessment. These were the US Indian Health Service, the Australian National Influenza Surveillance Systems, and the United Kingdom Health Protection Agency.

Second, an exercise to evaluate the existing e-health data streams available in the context of each health system was undertaken. Third, a consensus set of key Novel H1N1 pandemic surveillance indicators was selected for the underlying multi-national surveillance system design. Fourth, each indicator in the consensus set was cross-walked against the e-health data streams to evaluate the feasibility of integrating these streams for multi-national pandemic surveillance.

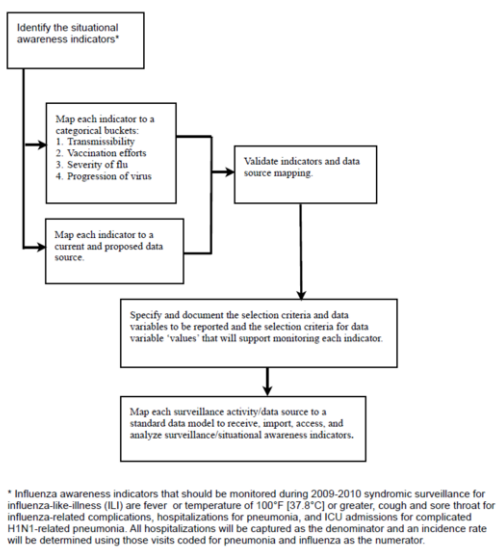

Figure 1 - Design and assessment process for an e-health-based pandemic surveillance system

Results

Each of the three health systems chosen were comparatively evaluated against the coupling of population based and individual-patient based health data streams used for surveillance. This relationship spanned from very tight coupling at the US Indian Health Service, to indirect coupling in the UK NHS, to traditional parallel data streams in the Australian health system (see Table 1).

Table 1 - National Health System Data Streams

Health System	Integration Level	Representative Data Streams
Indian Health Service (United States)	Tightly integrated population and patient based data streams with record-linked aggregates	Resource and Patient Management System (RPMS) and Point of Care (POC) EHR – Electronic Health record with integrated public health functions including syndromic and case-based surveillance
Department of Health and Ageing (Australia)	Traditional hybrid system with sentinel, case-based, and population-based surveillance without row-level case reporting	- Laboratory confirmed influenza surveillance - GP sentinel surveillance - ED sentinel surveillance - Laboratory surveillance - ICU surveillance - Community absenteeism - National syndromic call centre surveillance - Online syndromic survey
National Health Service (United Kingdom)	Patient-based national identifier-linked case reporting with de-indentified aggregates	- NHS Care Record Service ["Spine"] for case-based and sentinel provider surveillance - Call Center for Syndromic Surveillance

The varied level of coupling between the population aggregate and the individual patient level has implications for the ability to effectively integrate large-scale surveillance systems with traditional case-based and sentinel provider surveillance. For instance, the US Indian Health Service Resource and Patient Management System (RPMS) is an integrated health IT solution in use nationwide within the entire health system for native Americans. The RPMS provides the ability to capture individual patient- specific data at point-of-care that can then be used for public and population health management and surveillance. This allows direct and seamless "drill-down" from population aggregates and the automated linkage of syndromic surveillance with case notification of confirmed cases.

On the other hand, the Australian Department of Health and Ageing (Canberra) utilizes a traditional hybrid approach with multiple systems as data stream sources for their national influenza surveillance system. The case-specific streams include laboratory confirmed notifications from the National Notifiable Diseases Surveillance System (NNDSS), and a national online web-enabled outbreak case reporting system (NetEpi). The de-identified aggregate surveillance systems include a general practitioner sentinel surveillance system, Emergency Department presentations of ILI at sentinel

hospital sites, sentinel community absenteeism, national call centre data [4] and an online self-reporting syndromic influenza surveillance system, FluTracking [5]. The integration of de-identified aggregate data with case-specific data on a national level requires a record linkage algorithm whose ultimate validity is constrained by the levels of de-identification and aggregation.

This variation in the coupling characteristics of the health IT data streams provided an objective constraint against which to design the indicator set for a multi-national pandemic surveillance system. The indicators had to be specific enough to be valid and general enough to be stable and reportable from both tightly-coupled as well as hybrid data streams. For this step, an iterative process was used to identify a set of Influenza-like Illnesses (ILI) and H1N1 indicators that used appropriate standards and which would be reportable across the range of health IT data steams.

The indicators were also chosen to reflect a range of epidemiologically important categories including ILI symptomology, transmissibility/progression, severity, vaccine effectiveness, and healthcare utilization. Indicators considered in the study included both natural language processing (NLP) and formal terminologies such as ICD9 and, ICD10. The group first identified situational awareness indicators that could be monitored for syndromic surveillance of influenza-like-illness (ILI). The indicators identified for pandemic multi-national surveillance of ILI were: (i) fever or temperature of 100°F [37.8°C] or greater, (ii) cough and sore throat for influenza-related complications, (iii) self-report of fever and other ILI symptoms. For transmissibility/progression, indicators were (iv) disposition from outpatient to inpatient when hospitalization occurs with (v) specific indication of hospitalizations for pneumonia. For severity, indicators chosen were (vi) mortality rates associated with H1N1/ILI cases and (vii) ICU admissions for complicated H1N1-related pneumonia. Lastly for utilization and vaccinations, indicators were (viii) health care utilization (number of beds utilized and intensive care units-ICUs), and (ix) adverse events associated with the H1N1 vaccines.

Lastly, a collective cross-walk of these consensus data indicators was carried out against the national health system data streams to assess the feasibility of multi-national pandemic surveillance. Of the set of 27 indicator-data-stream combinations, the three different national health IT systems were able to satisfy 24 reporting streams, for a score of 89% for the eight indicators chosen. Secondly, the data collection and evaluation for the indicator selection resulted in the identification of common data elements and alignment of data sets to candidate disease indicators to foster semantic interoperability for H1N1 electronic multi-national surveillance.

Discussion

One central challenge for the design of national surveillance systems in the medium term is to reconcile (a) the specificity of older, established surveillance data streams based on clinician-diagnosed case reports or sentinel provider syndromic surveillance with (b) large-scale, higher-throughput, timelier but less specific automated surveillance data based on national health IT infrastructure [6].

During a significant epidemic the sensitivity and specificity of these laboratory based and syndromic influenza surveillance systems may need to be optimized. Each type of system has advantages. For example, the timeliness of syndromic surveillance may outweigh its lower specificity than clinical confirmed or laboratory confirmed surveillance systems in certain situations, such as during an emerging outbreak. Once significant clusters are identified during these syndromic systems it then may be necessary to confirm laboratory evidence for each cluster. During a pandemic, it may not be necessary to gather laboratory evidence on every case.

Recognition of differences among international surveillance systems offers the possibility to change the case definition based upon the sensitivity and specificity of early data from countries initially involved in an epidemic situation. Preparation for an epidemic or pandemic from a novel subtype, international cooperation to identify data elements and proposed data monitoring may help increase sentinel awareness and more timely interventions. A further evaluation has begun on refining the indicators to the best level of granularity in terms of case definitions and geographic reporting segments to find the optimal trade-off between specificity and generalizability across the different health IT systems.

Conclusion

This work includes input from participating countries, but is limited to participants from the respective national e-health and surveillance authorities. Future work would benefit from involvement of additional countries. This work also points to the need for integration of public health surveillance within the point of care HIT solutions. Development of meaningful use criteria internationally that encourage the addition of public health functionality within electronic health records may be a critical path for long term improvements in public health surveillance. Similarly, future work such as the development of open-source software components to facilitate the extraction and transformation of identified indicators may promote multinational participation and involvement in pandemic influenza surveillance. This multinational collaboration around surveillance and health IT infrastructure may initiate a more widespread conversation on the critical need for integration of public health programs and health information technology infrastructure development.

Table 2 - The table summarizes the flu specifications where the empirical data set of influenza indicators are cross walked and validated.

Indicator		Population under surveillance	Common Indicator Definition	Indian Health Service – Integrated Health System	Office of Health Protection, Australian Nat'l Influenza Surveillance Systems	United Kingdom Health Protection Agency
Monitor Transmissibility of Flu	Syndromic	Primary Care	▪ ILI - specific symptomology – fever, throat pain or sore throat, cough	▪ ICD 9 Code definitions: fever 780.6, 780.60, 780.61; pain, throat 784.1, 462; cough 786.2 ▪ 100% of charts reviewed electronically on a daily basis and exported to national epi center each day	▪ GP Sentinel Surveillance, ILI = fever, cough and fatigue	▪ Sentinel Primary Care Surveillance, Royal College of General Practitioners, ILI, pneumonia, acute bronchitis
		Community Based Self Reporting			▪ National Call Ctr Hotline; FluTracking (syndromic survey, self-reported illness); ▪ Sentinel absenteeism data from national employer ▪ Sentinel childcare absenteeism	▪ National Health Service nurse-led call centers, Community Syndromic Surveillance, colds, flu, fever
	Lab Confirmed	Public health notifiable disease surveillance system	▪ Laboratory confirmation of influenza	▪ Laboratory results at point of care in RPMS HIT system	▪ National Notifiable Diseases Surveillance System	▪ First few hundred surveillance system and enhanced surveillance system
		Sentinel School-based syndromic surveillance	▪ILI	▪ ILI with swabs at point of care in reservation based schools using RPMS HT system	▪Not available at national level	▪ Boarding schools in Medical Officers of Schools Association and HPA Scheme
		Primary care	▪ Sentinel primary care surveillance with virilogical monitoring	ILI with swabs when indicated clinically	▪ILI with swabs from a sample of patients in some regional areas	▪ ILI with swabs from a sample of patients
		Hospitals	▪ Disposition from outpatient to inpatient (hospitalizations)	▪ Incidence rate: hospitalizations (as the denominator) and visits coded for pneumonia / influenza (numerator)	▪ Emergency Department sentinel hospital surveillance	▪ All patients admitted to hospital with severe respiratory illness, with virological monitoring
Vaccination	Vaccine effective-		▪ Adverse events - to the H1N1 vaccine	▪ Adverse events instructed by the Food and Drug Administration	▪ Adverse Events Following Immunization Surveillance ▪ Adverse Drug Reactions Reporting	
Severity Measure	Mortality Rates - Virulence	Laboratory surveillance networks	▪ Mortality rates-electronic death reporting ▪ Subtyping, antigenic characterization, sensitivity / susceptibility to anti-virals	▪ Death reporting not utilized due to loss to follow-up. ▪ Delayed monitoring via Death Certificate Data	▪ Deaths data from sentinel hospital surveillance; ▪ ICU admissions and clinical severity; ▪ Drug resistance, antigenic characterization, shift and drift	▪ Death registrations, total respiratory deaths, mortality excess estimation; ▪ HPA Regional Microbiology Network and National Laboratory Reporting Scheme Antiviral Resistance Monitoring and Viral Sequencing
Healthcare Utilization			▪ Utilization of hospital beds, ICUs, and respiratory ventilators	▪ RPMS – Resource and Patient Management System collects this data, but it is not utilized.	▪ Hospital bed capacity, ventilator usage and extracorporeal membrane oxygenators

Towards A Multi-Level Game Model for Influenza Epidemics

Qiongyu Chen, Tze-Yun Leong

Medical Computing Laboratory, School of Computing, National University of Singapore

Abstract

Although game theory has been first invented to reason with economic scenarios with rational agents, it has since been extended into many other fields including biological and medical sciences. In this paper we propose to model the interactions between virus and human in an influenza epidemic in a two player, adversarial game scenario with multiple levels of abstraction. As conventional game representations are inadequate in this complex problem domain, we propose Object Oriented Multi-Agent Influence Diagrams (OO-MAID), a novel graphical representation for multi-level games, which takes advantage of both organizational information and probabilistic independence in the problem domain. The OO-MAID representation can be readily applied in similar medical situations exhibiting hierarchical and probabilistic independent characteristics. We demonstrate the feasibility of this novel approach with sample models in the domain.

Game theory, Influenza, Knowledge representation

Introduction

Influenza or "flu" is one of the most common diseases found in both developed and developing countries, causing tens of thousands of deaths and huge financial losses each year. The damages are even greater in the case of a flu epidemic, e.g., the recent spread of H1N1 virus. While it is one of the most studied diseases, we have yet to be able to effectively deploy various management strategies to control the spread of seasonal or epidemic influenza.

The current modeling techniques for influenza can be classified into three categories: deterministic dynamics functions [1,2], complex network theory [3,4], and stimulation based on mathematical spreading models and population distribution [5]. Most of these approaches assume fixed virus characteristics, known consequences of policies, and/or unbound resources, which are often unrealistic. In addition, most of the research emphasizes on the epidemiological impact, without details on lower level interactions, such as clinical and microscopic interactions. In this paper, we propose to model the holistic interactions between influenza viruses and human populations in a game theoretic framework.

Game theory provides a mathematical framework for determining what strategies are, according to pre-defined utilities, most beneficial for agents interacting with each other in a partially observed environment. While it was first proposed to analyze rational behavior in economics, its adaptation in the biological domains, i.e., evolutionary game theory [6], enables reasoning with populations under revolutionary pressure, instead of rational agents. In this context, players are individuals in a large population engaging in a series of independent game play. Strategies may be any phenotypic characteristics, such as tail length in certain bird species; or behaviors, such as the instinct of defending territory. Payoffs, or utilities, for the players are additional or reduced "fitness" a player receives after each game play, using some set of strategies. The concept of Nash Equilibrium is replaced by a similar concept of revolutionary stability, and the associated concept Evolutionary Stable Strategies, defined as the set of strategies that, under the current circumstances, cannot be "invaded" by mutant strategies [6].

Modeling Influenza as a Game Scenario

In any game, there are three essential components: players, strategies and payoffs. In addition, there may exist random variables in the problem domain that are beyond the control of the players, who may however observe some of their values. In this section we identify the three components as well as possible random factors in the proposed influenza game scenario, and examine potential challenges and issues in modeling and reasoning in the game.

As the interactions between influenza virus and human society is a complicated process involving a large number of random variables in multiple levels of abstraction, we divide the possible factors and interactions into three levels of different granularities: microscopic, clinical, and epidemiological. In all three levels, the players would be influenza virus and human. The strategies, utilities and other factors, however, may differ.

At the microscopic level, the infection of influenza in a human host is the interactions between influenza virus and human body cells. In general, systematic infection of a host by influenza virus depends on factors [7,8] such as: matching hemagglutinin receptors on the host cell surfaces, availability of protease for virus post-entry cleavage, cleavage properties of virus surface protein precursor (the above three factors facilitate the entry of virus into a host cell, in a process called

endocytosis), suitability of the host cell for viral replication, and release of replicated viruses into bloodstream for further infection, which is related to virus neuraminidase surface protein. The immune system responds to virus infection by two mechanisms: innate response, which respond to infections in general; and adaptive immune response, which keys specifically to some particular virus strain after an infection. The acquired adaptive immune response against a specific influenza virus strain is temporary, waning with time. In response to immune anti-viral mechanisms, influenza virus may evolve to acquire mutant genes that can suppress the immune response [9].

In a game model for the microscopic level, strategies for player virus are characteristics such as HA and NA configurations, while strategies for human player are characteristics such as immune responses. The payoff at this level is the extent of the infections, which can be modeled as average virus count in the infected host.

At the clinical level, we consider medical intervention in influencing infection cases. Treatments for infected cases usually aim for symptom relief and do not directly target viruses, although anti-viral treatments may be necessary in immno-compromised patients. Therefore, for the population at large, the most important step taken during a flu season is prevention. Clinical prevention of influenza can be divided into two categories: vaccination and prophylactic use of anti-viral drugs. Vaccination is highly effective when the vaccine matches with the circulating virus strand. However, the fast mutation of influenza virus means that there is usually a genetic drift of the circulating virus strand. Prophylaxis with anti-viral drugs is less sensitive to genetic drift; still, drug resistance may arise from its usage. We show a sample game models the interaction in Table 1.

Table 1- Sample game model in the clinical level

	Drug-resistant	Non-resistant
Anti-viral	$c\,\beta$	$(1 - \theta)\,\beta$
Vaccination	$c\,(1 - \lambda)\,\beta$	$(1 - \lambda)\,\beta$

Let β be the baseline transmissibility of influenza virus, c be the factor of change in transmissibility after drug-resistant mutation, λ be the efficacy of the vaccine, and θ be the efficacy of prophylaxis. The human player may choose using anti-viral prophylaxis or vaccination. And virus may mutate to become drug-resistant. The four possible scenarios are:

1) Anti-viral prophylaxis is chosen; virus strain mutates to become drug-resistant. In this case, the prophylaxis would be ineffective. However, studies also show that mutated drug-resistant virus strains have lower transmissibility than wild-type virus strains [5]. Therefore, the transmissibility in this case is reduced to $c\,\beta$. c may be as low as 10% [5].

2) Anti-viral prophylaxis is chosen and virus strain does not mutate. In this case the transmissibility is reduced by effective prophylaxis measure. The payoff in terms of transmissibility is $(1 - \theta)\,\beta$. Currently θ (for neuraminidase inhibitors) is around 70% [10].

3) Vaccination is chosen; virus strain mutates to become drug-resistant. The payoff as transmissibility is $c\,(1 - \lambda)\,\beta$.

4) Vaccination is chosen and virus strain does not mutate. The payoff in this case is $(1 - \lambda)\,\beta$.

This simple model may help to explain the low level of emerging drug-resistant strains <1% [11], as strategy "non-resistant" dominates "drug-resistant" for virus player. A complete model would include many more factors and provide a clearer picture of the interactions.

At the epidemiological level, the factors relevant to the extent and severity of an influenza epidemic are well studied. Some of these factors are: transmissibility, a characteristic of the virus strain, which determines how easily the virus can spread in a population; infectious period, the duration that an infected case continues virus shedding (Combined, transmissibility and infectious period can be modeled as a function of infectiousness over time.); regeneration number, which is defined as the number of secondary infections generated from a primary infection case; contact rate, the number of people a person gets into contact in a fixed time unit; quarantine efficacy, which can be defined as either the portion of infected people being quarantined, or the degree that their infectiousness is reduced.

At this level, payoff for the human player may be defined as a cost function consisting of disease management cost and extent of virus infection in the population. For the virus player, the payoff may be a similar function of the extent of infection.

From the proposed modeling approach, we observe that a complete game model consisting of all three levels and all the important factors is a very complex scenario. Therefore, neither of the traditional game representations, including the normal form, which is a table listing payoffs according to different combination of strategies; and the extensive form, which is a game tree with payoffs at the leaf nodes, is feasible. They both suffer from the curse of dimensionality and omit potentially important structural information in the problem domain. A new game representation is needed to address the characteristics in this specific problem domain.

Graphic Representation for Multi-Level Games

A related work that addresses part of the complexity is the Multi-Level Games representation proposed by Hausken [12]. It provides a framework for analyzing game situations where there are different levels of organization. However, at each level, the strategies and payoffs in the sub-game are still represented in either normal or extensive forms. Therefore it is unable to take advantage of any locality features that often exist in complex game domain such as the proposed influenza game scenario.

A representation that does utilize potential probabilistic independencies in the problem domain is the Multi-Agent Influence Diagram (MAID) [13], a probabilistic graphical game representations. It takes advantages of the Influence

Diagrams' ability to represent structural dependencies in the problem domain. However, when dealing with problem domains with multiple levels of organization, the MAID approach requires all hierarchies to be flattened into a single level structure. While this is theoretically possible, it is often inefficient or even intractable when the number of players or levels of organizations are large.

While neither approach alone can satisfy the requirements for the proposed influenza game scenario, a combination of the two addresses both organization and probabilistic independencies issues. Therefore, we propose the Object-oriented Multi-Agent Influence Diagrams (OO-MAID), which is based on the multi-level game concept and the MAID formulation. An OO-MAID is probabilistic graph segment that models an uncertain game situation with multiple levels and multiple agents. Each segment has a set of well defined input and output, which appear as chance nodes in other graphs. In the next section, we formally describe the syntax and semantics of OO-MAID.

Definitions and Semantics

We base our definition of multi-level games on an adaptation of Hausken's work [12]. In this formalism, a multi-level game consists of three components – multi-Level game structure, multi-level game form and finally, multi-level game. All three components are extended in the OO-MAID representation as follows:

Multi-Level game structure, which is a recursively defined directed graph $G = (N, A)$, where N is a set of nodes and A is a set of arcs. Three types of nodes are allowed in set N - chance nodes, decision nodes and utility nodes. We assume that there exists one and only one utility node for each player at each level. The outermost graph (level 0) is labeled G^0, which organizes players. Player A^{L}_{i} at level L plays the game with other players at the same level. In the proposed influenza game scenario, the game structure represents the factors in the whole problem domain, with decision nodes denoting strategies, chance nodes denoting random variables and utility nodes denoting payoffs. The arcs between the nodes share the established semantic meaning in the Influence Diagrams, namely, an arc pointing into a chance node or utility node represents conditional dependence, while an arc point to a decision node represents information availability.

***Multi-Level game form*,** which is a combination of multi-game structure and feasible (pure) strategies S. Therefore, player A^{L}_{i} has strategy domain S^{L}_{i}. This corresponds to the set of possible values for the decision nodes at level L. A decision rule for node D is a function that maps each instantiation pa of Pa(D) (set of parents of D) into a probability distribution. For agent A^{L}_{i} at level L, the assignment of a decision rule to each decision node is called a strategy. In the influenza game scenario, S denotes the possible "strategies" that the virus or the human player may use in the game play in a certain level. Each player may choose to use single strategy or a set of different strategies with different probabilities.

***Multi-Level game*,** which is a multi-game form together with defined payoff structure. In Hausken's definition, each player's (at any arbitrary level) payoff consists of two components: a "within-group" payoff, coming from the sub-game at the player's level, and a fraction of payoff distributed downwards from higher level games. Here, we adopt a simplified case where only "within-group" payoffs are considered. Payoff in the influenza game scenario differs between levels, e.g., for the human player, the payoff in the clinical level may be an individual's well-being after being infected with flu virus, but the in the epidemiological level, the payoff could be a cost function involving the studied population.

With our definition, the basis of modeling a multi-level game starts with building the game structure, which is a directed acyclic graph consisting of basic nodes and complex nodes. There are three types of basic nodes, the chance nodes, decision nodes, and utility nodes, with conditional probabilistic table (CPT), decision rule and utility function, respectively. A complex node is a self-contained OO-MAID segment that models a sub-game in the problem domain and has a set of input nodes and output nodes. Each agent is represented by its corresponding decision nodes in the graph, and may have multiple utility nodes. The overall utility for the agent is simply the summation of all his utility nodes U_{a}^{L} at level L.

An example of a simple multi-level game segment is given in Figure 1, which shows a simplified influenza game model at the clinical level. M denotes the game play in microscopic level, which is an OO-MAID segment contained in the graph. The output of M is observed by both players at the clinical level and has an effect on their utilities. We further define the "output" of

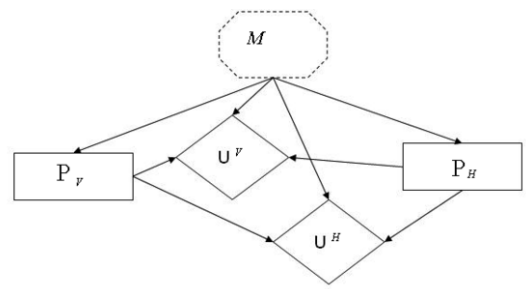

Figure 1- A sample OO-MAID model

an OO-MAID segment below.

We consider an OO-MAID segment to be a stochastic function that converts a set of input to a set of output variables. It is recursively defined as follows: for each complex OO-MAID node X^L at game level L, it consists of

Input: a set of chance nodes or decision nodes in(X^L) defined in X^{L-1}, i.e. for node v in in(X^L), Pa(v) are in graph X^{L-1}. However, they may have children nodes in graph X^L. In addition, v is considered chance nodes in graph X^L.

Output: strategy profile σ, expected payoff EU(X), output chance nodes Out(X^L). The output nodes are defined in X^L, and may be decision nodes or utility nodes in X^L. But they are treated as chance nodes in X^{L-1}.

To map the distribution of input node set to distributions of output nodes, a complex OO-MAID node is itself a complete OO-MAID which may contain basic nodes and complex nodes.

A complex OO-MAID node that contains only basic nodes is simply a MAID. Its correctness is established from the work on Multi-Agent Inference Diagrams. Between levels, we show below that nodes inside a complex are independent of nodes outside, give the input and output nodes set.

Let X^{L-1} be a complex OO-MAID node containing complex node X^L, we prove that node set N^L in X^L are independent of node set $N^{L-1} - N^L$, given the input/output set of X^L.

Proof: First we consider node types in the input/output set of X^L. In the previous section, we have defined the decision rule to be a function that maps each instantiation of D's parents into a probability distribution for node D, therefore it has the same form as a conditional probability distribution. For utility nodes, the utility function also may be considered conditional probability distribution with probabilities of 1 and 0. Therefore, we may treat both decision nodes and utility nodes in similar ways to chance nodes.

Now, consider any path between X^L and $X^{L-1} - X^L$, which contains adjacent nodes n_1 in X^L and n_2 in $X^{L-1} - X^L$. There are two possibilities for the arc direction between n_1 and n_2. If there is an edge from n_1 to n_2, then n_1 is in the output set of X^L. And n_1 does not have converging arrows centered on itself. Applying Baye's Balls rule [15], the path is blocked when conditioning on n_1.

If there is an edge from n_2 to n_1, then n_2 is in the input set of X^L. And n_2 does not have converging arrows. The path is blocked when conditioning on n_2.

With the definition we may now extend the complex node in Figure 1. An example is shown in Figure 2. This is a segment that has one input node and two output nodes.

Computing Nash Equilibrium

The main computation task in any game form is the calculation of the Nash equilibrium. In multi-level games, the definition of the Nash equilibrium can be tricky considering the players and payoffs in all the sub-games. A definition of multilevel Nash Equilibrium is given in [12]. In our proposal, because of the simplification of the "within group" payoff structure and the probabilistic independence proved in previous section, we can use the conventional definition of a single player achieving no benefit from changing strategy, given the strategy of the other players being fixed.

In the single level representation of MAID, the concept of strategy relevance and *s-reachability* is central in the computation of Nash equilibrium [13]. These two concepts both hold for the OO-MAID framework. By definition of the OO-MAID complex node, which maps each instantiated set of pa for Pa(X), the mapping then has the same form of conditional probabilistic distribution. Therefore a complex node can be collapsed into the output node set, with pre-computed distribution function. In addition, as the output nodes are all considered chance nodes in higher level graph, they do not change the topological order of the decision nodes in the higher level.

For games consisting of only basic nodes, e.g., the microscopic level, we may break up the problem domain according to

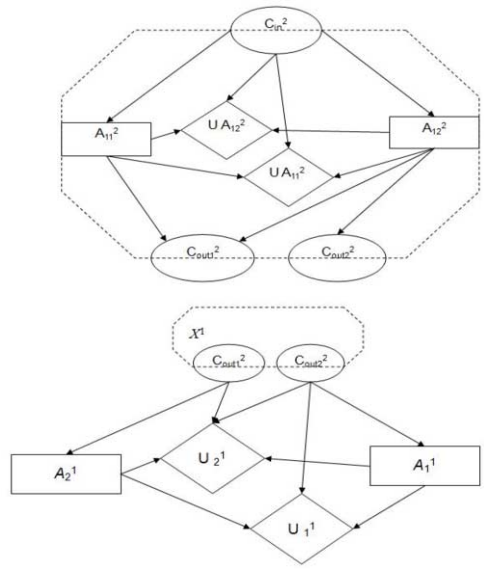

Figure 2- The expanded graph for X' in Figure 1, and an encapsulated X' viewed from the higher level.

strategic relevance, the sub-graph, consisting of decision nodes that are strategically relevant (denoted as a component graph), is then converted to a regular game tree and standard game solver may be applied [13]. As finding a Nash Equilibrium for a game tree is super-linear, this reduces the computational time. A straightforward "divide and conquer" algorithm and an approximate algorithm have been proposed [14].

For games consisting of both basic and complex nodes, we propose a recursive inference algorithm, enabled by probabilistic independence of a complex OO-MAID node given its input and output node set. The algorithm below makes use of the algorithm proposed for MAID [14], denoted as ComputeMAID. An extra step at the end of ComputeMAID is added to return updated probability distribution of the nodes defined in the output node set of a complex OO-MAID node, after applying the strategy profile calculated from ComputeMAID.

Algorithm

```
ComputeOO-MAID (OO-MAID X)
    If X contains only basic nodes
        ComputeMAID (X)
    Else
        For each complex node Xi' in X
            ComputeOO-MAID (Xi')
            Update distributions of output node in Xi'
        // X now contains only basic nodes
        ComputeMAID (X)
```

Comparing OO-MAID with MAID, while both take advantage of the "divide and conquer" concept, the built-in conditional independent complex nodes in OO-MAID simplify the topological ordering process by encapsulating decision nodes from sub-games, and also enables pre-computation.

Towards A Complete Influenza Game Scenario

With the introduction of OO-MAID, each level in the proposed influenza game can be modeled in one or more OO-MAID segments, with the graphical representation at each level able to utilize any structural independencies among the random variables at that level.

A complete model with all three levels and most of the relevant factors is currently in progress. Firstly the three different levels will be constructed separately, each with its own in-level strategy set, random variable set and payoff function. The connection between levels will be made possible with relevant input/output nodes. For example, a "strategy" chosen by the virus in the microscopic level, the extent of mutation, or deviation from prevailing strain, will be reflected as averaged virulence in the general population in the clinical level. Further domain knowledge will be elicited in later stages of the model construction.

Conclusion

In this paper we show the potential and feasibility of modeling an influenza epidemic as a game situation involving influenza virus and human society. As the problem domain is highly complex with multiple levels of granularities and large number of random variables in each level, the conventional game representations are inadequate in this situation. To address both the "multiple levels" and "potential structural independency" nature of the scenario, we propose OO-MAID, a novel probabilistic graphical representation for multi-level games. This framework has the potential of taking advantages of possible conditional independences as well as organizational hierarchies in a problem domain. It is based on single level probabilistic graphical game representations, with extensions to allow modeling of a game scenario in different levels of abstraction. Although it's motivated from the influenza game scenario, it is a general game representation that may be applied to other program domains exhibiting both characteristics.

To complete the proposed game model, further domain knowledge on influenza epidemics must be solicited from healthcare experts.

Future work also includes extension of the payoff definition. Currently we only consider localized payoff (or utility) for each agent within his own game level. While this greatly simplifies computation and probabilistic independence analysis, it is a very restricted assumption that may not be satisfied in many real life complex game scenarios. In the influenza game scenario, for example, an individual's payoff is also associated with the payoff in the general population, as one of the factors, percentage of the population infected, greatly influences an individual's chance of being infected.

Is population-oriented IT supported preventive care in general practice feasible? A database study

Jacobus T van Wyk, B. Mosseveld, J. van der Lei

Department of Medical Informatics, ErasmusMC University Medical Centre Rotterdam, PO Box 2040, 3000 CA Rotterdam, The Netherlands

Abstract

Background: Introducing a clinical decision support system (CDSS) in general practice that provides broad support based on all available guidelines for preventive care might dramatically increase the workload of a general practitioner. Aim: We evaluated the potential effect on workload of a CDSS that aims to support the whole breadth of preventive guidelines currently used in The Netherlands. Methods: We analysed the guidelines of the Dutch college of General Practitioners (DCGP) for preventive activities, developed a CDSS based on the guidelines and studied the behaviour of the system on real patient data. Results: 20 of the 87 DCGP guidelines contained data on preventive activities which was incorporated in the system. Out of 485 793 patients, the system indicated that for 138 885 (28.6%) a preventive action was needed. Conclusion: A CDSS that aims to support the whole breadth of preventive activities in general practice will have a substantial effect on workload. Further tailoring of the support will be needed.

Clinical decision support, Electronic patient records, Prevention.

Introduction

Prevention is often positioned as a disease-oriented activity (prevention of cardiovascular diseases, prevention of diabetes, etc.). Guidelines are disease or risk specific, resulting in overlapping or sometimes even conflicting recommendations. Disease-oriented organizations typically target a limited set of diseases reflecting their own focus. Continuous medical education is often also characterized by disease orientation when preventive care is discussed. In day-to-day care, health-care workers and even the target populations themselves have to integrate (or select between) the separate preventive activities for the different risks or diseases, and, in the context of what is locally feasible, and merge these preventive activities with other activities (such as curative care). Faced with limited resources, a general practitioner, for example, may have to decide whether preventive activities in the context of diabetes should take priority over prevention of cardiovascular diseases.

Research in the past years has shown that Information and Communication Technology (IT) is able to support practitioners and changes physicians' behaviour [1, 2] Already in 1989, the first review paper that also included IT-based interventions suggested that of all known interventions, computer-supported interventions were most effective and costs efficient [3]. In subsequent years, randomized trials studied the impact of IT-based interventions. As a result, most researchers will now accept that IT can play an important role in the implementation of guidelines[4]. IT has also been successfully used to support prevention [1, 4].

The use of IT in the context of prevention has been characterized by a disease-oriented approach. The resulting software modules are aimed at supporting a practitioner in an individual disease domain - resulting in separate, individual software applications. In the Netherlands [5], for example, the general practitioner is confronted with a range of separate modules: a software module for cardiovascular screening, another module for diabetes, yet another for influenza vaccinations, still another for cervical smears, etc.. The general practitioner often decides to focus on just a few diseases (for example, cardiovascular disease), and uses the software available for that disease. That choice for a given domain, however, may have as consequence that another disease or risk will receive less attention. Ideally, the practitioner should tailor, within the constraints of available time and possibilities, preventive activities to the local population. This process of tailoring to the local population needs to be informed by both the total set of possible preventive activities and the specific characteristics of the local population [5]. In a resource-limited setting, allocation of resources should be a careful and explicit decision based on local circumstances. At present, IT tools typically do not aid the practitioner in selecting, from all the possible preventive activities, the most suitable to his or her population. The need to develop an intervention strategy that enables an individual practitioner to tailor preventive activities to his or her local population and local circumstances is often ignored.

Our objective is to assist the practitioner with the whole range of possible preventive activities and subsequently aid him or her in tailoring these activities to his or her own local circum-

stances. The first step in this approach is to confront the practitioner with the consequences of all the available guidelines. That is, not until the physicians has realised what it would mean to actually conduct all these activities will he or she be confronted with the limitations posed by their own environment (e.g. financial constraints, limited time available, or patient compliance). Guidelines are often developed as individual guidelines, but the consequences of a collection of guidelines with the resulting possibly exponential growth of activities are typically not studied. In order to gauge the consequences of implementing a collection of guidelines, we need to gain insight in the actions that will need to be performed once the IT intervention is implemented.

Various authors have described critical success factors when introducing any computerized decision support system (CDSS) into daily practice[1, 6]. These include integration of the software with the electronic patient record, performance and enabling general practitioner workflow. It is, however, interesting to observe that the consequences of a CDSS on workload are often not addressed. The fact that the introduction of decision support carefully tailored to workflow might have as a consequence a prohibitive increase in workload is of ten not considered.

In this paper we evaluate the potential effect on workload of a CDSS that aims to support the whole breadth of preventive guidelines currently used in The Netherlands.

To understand the consequences of a CDSS supporting all the available preventive actions in guidelines, we first need to analyse the guidelines, secondly need to develop a system based on the guidelines, and, finally, based on actual medical records, study the behaviour of that system based on real patient data.

The objective of this study is to understand the practical consequences the CDSS would entail if physicians would introduce the system in daily care.

Materials and Methods

Design overview

Our study analyzed the guidelines of the Dutch College of General Practitioners (DCGP) on preventative activities, formalized the recommendations into a CDSS framework, and studied the recommendations of the CDSS based on the electronic patient records of general practitioners.

CDSS knowledge base

In the Netherlands the DCGP publish and maintain evidence based guidelines for use in the Dutch setting [7]. The guidelines have a high acceptance and penetration amongst Dutch general practitioners. The guidelines advise on actions that a GP should undertake in the presence of a trigger factor. A trigger factor can be previous diagnosis, physical exam results, measurement values, or more difficult, a combination of any of the above.

If a trigger factor is present, the guideline suggests any of a number of actions to perform; Table 1 lists the possible actions.

Table 1- Definition of activities needed in prevention

Type of action	Definition of action
Diagnosis	Capture a specific diagnosis in the presence of absolute values
Medical History	Capture a value needed to complete a risk profile or set a diagnosis
Physical exam	Capture a value related to the physical examination a of a patient
Laboratory investigation	Request a laboratory investigation
Medicine	Prescribe or change medication
Referral	Refer the patient to a specialist
Patient action	Advise patient on actions that can be objectively measured

A limiting factor of electronic patient records is that not all patient data will be available in a coded, structured format. Data, for example, may be available only in free text. That is, a guideline might refer to a medical condition that can only be recorded in text. In order to integrate the CDSS with the commercially available electronic patient records and existing workflows, we focus on data that is available in a coded (e.g., diagnosis, laboratory values or prescriptions) or structured (e.g., system-specific defined coding schemes) fashion. That is, we did not include free text analysis to mine for data not available in a coded or structured fashion. As a result, sections of guidelines that refer to data not available in a coded fashion were ignored.

Patient data, setting

To study the consequences of the CDSS, we conducted a retrospective cohort study in the Integrated Primary Care Information (IPCI) database. IPCI is a longitudinal GP research database, which contains information from computer-based patient records of GPs in The Netherlands. Within The Netherlands, patients are registered at single GP and the record for each individual patient contains all medical information on that patient [8, 9]. The database contains information on approximately 500,000 patients.

The computer records contain information on patient demographics, symptoms (including free text), diagnoses (using the International Classification for Primary Care (ICPC)), episodes, referrals, laboratory values, measurements (e.g. BP, cholesterol levels), drug prescriptions with their ICPC-coded indications, and hospitalizations [10, 11]. Summaries of the hospital discharge letters or information from specialists are available in a free text format. To maximize completeness of the data, GPs who participate in the IPCI project are not allowed to use paper-based records. The system complies with

European Union guidelines on the use of medical data for medical research and has been proven valid for research [12].

Participants

The sample date in IPCI was July 1st 2008. The source population comprised all living patients, with at least one year of valid history (that is, the patient had to be alive on July 1st 2008, and registered in that practice prior to July 1st 2007). All subjects were evaluated from the earliest of the following dates: one year of valid history, or birth.

Outcome measure: Recommended Preventative actions

Data from IPCI were submitted to the CDSS. We established whether any patient in our cohort had any of the identified trigger values available that should lead to a preventative action by a GP. When a trigger value was present we evaluated if the action had been performed. We thus counted the total number of actions needed as an indicator of the clinical workload needed to perform preventative activities recommended by the guidelines.

RESULTS

Knowledge Base

We analyzed all of the guidelines of the DCGP up to 31 March 2007 [7]. Of the 87 guidelines, 20 contained trigger factors and related recommendations relevant to preventative activities that could be determined based on coded or structured data. The recommendations in the guidelines could not be translated to coded or structured data were ignored. For example, the guideline on asthma for adults contains a reference to the patient feeling a shortness of breath over the last month. This information, however, cannot be captured in a coded or structured fashion in the available Dutch systems. As a result, such instances in guideline were not included.

Preventative Activities

The electronic patient records of 103 GP practices with a total valid population of 485 793 patients (females 247 557, males 238 087) were submitted to the CDSS.

Of these 485 793 patients, the CDSS generated for 138 885 patients (28.6%) recommendations to perform one or more preventive action(s). Of the 247 557 females, the CDSS generated for 71 944 patients (29.1%) one or more recommendations. Of the 238 087 males, the CDSS generated for 66 941 one or more recommendation (28.1%).

For an individual patient, the CDSS could recommend a range of preventive action to be taken (see Table 1). Table 2 shows the number of patients requiring actions recommended by the CDSS.

As shown in Table 2, a total of 1092 patients had sufficient information in the electronic patient record to assign a diagnosis whereas 138 885 required the inclusion of the results of a physical examination. It is interesting to observe that in total 40 113 patient needed some form of modification of the drug prescription, whereas 64 006 needed laboratory tests.

Discussion

We built a CDSS that support preventive care in general practice, and we studied the potential impact on the workload by submitting electronic patient record to that CDSS.

We observe that approximately one third of all registered patient in the GP practices required some form of preventive actions to be undertaken. The percentage of preventive actions to be undertaken varied slightly between males and female (28.1% versus 29.1%). Our first conclusion is that if a GP was to use the CDSS it would have a significant impact on the workload that that physician. We would argue that our finding that so many patients would be eligible for additional preventive care highlights the need to tailor the workload the locally available resources.

In the design of the CDSS we limited ourselves to those recommendations that could be firmly concluded based on coded or structured information. That is, we ignored a number of recommendations that could not be reliably concluded from the data available in the medical record. As a result, our estimate of the workload might be an underestimate; if we were to include the currently ignored section of the guidelines, a further increase in workload would ensue.

It is important to underscore that our finding that the workload to GP increases significantly does not constitute a value judgement on the medical content of those guidelines. We merely argue that the designer of a CDSS faces the issue of the practical consequences of implementing of a collection of guidelines when these guidelines were never considered as a whole. The collective impact of the different guidelines may result in a situation that the CDSS is destined to fail because the consequences of translating the guidelines into actions cannot be dealt with within in the constraints of day-to-day care. We also propose that designers of CDSS should include in their endeavours to introduce decisions support in daily care some form of impact analysis that would aid in gauging the practical consequences of their system without having to decide on the medical content of the guidelines involved.

Limitations

Our study suffers from a number of fundamental limitations that need to be stressed in order to avoid misinterpretation.

Firstly, the general practitioner is not the sole provider of care. It is quite possible that some of the preventive care is proved by secondary or tertiary care providers. That is, the absence of a preventive action in the GP record does not necessarily mean that the action has not been conducted. It is important to stress, however, that if the CDSS would be introduced in the GP practice, the recommendation would be given to the GP. Although the actions might be supervised by some else, the GP would be confronted with the need to determine whether the activity had been performed. Secondly, although the CDSS requires coded or structured data, the GP might have recorded data in free text. If the GP records data in free text, we will not have identified that data. As a result, we could have overestimated the workload proposed by the system.

Table 2- The number and type of actions identified by the CDSS by gender

	Male		Female		Total	
	n	(%)	n	(%)	n	(%)
Total number of patients with actions	66941		71944		138885	
Actions by type						
Diagnosis	532	(0.8)	560	(0.8)	1092	(0.8)
History	43017	(64.3)	45919	(63.8)	88936	(64.0)
Physical Exam	66941	(100.0)	71944	(100.0)	138885	(100.0)
Laboratory investigation	31509	(47.1)	32497	(45.2)	64006	(46.1)
Medicine	21552	(32.2)	18561	(25.8)	40113	(28.9)
Referral	1137	(1.7)	1092	(1.5)	2229	(1.6)
Patient action	7046	(10.5)	5969	(8.3)	13015	(9.4)

Conclusion

We believe that out study is the first that address workload that will result from implementing a set of guidelines focusing on preventive activities in general practice. The workload that will result from the preventive activities, even in the most optimistic scenario, is substantial. We propose that further tailoring is needed in the activities, for example by disease profile. We aim to pursue this tailoring in the SUNRISE trial.

Funding

The study was funded by a non-specific grant from ZonMW (grant no 6100.0011-1). ZonMW in no way interfered with the design or execution or reporting of the study.

Abstract

The main objective of this paper is to report our achievements in investigating new directions in the disease surveillance field. Targeting the vulnerable group of people with diabetes, we explored the possibility of early detection of infections using an electronic disease surveillance system (eDSS); this system could collect data for certain physiology indicators, e.g. blood glucose and white blood cell count, by incorporating specific point-of-care (POC) devices. We performed an analysis using the data of two large-scale clinical studies that involved people with type-1 and type-2 diabetes correspondingly; also, we conducted a feasibility study to examine the available POC technology. Even though the analyses provided us with some evidence for further investigation, the available technological solutions appeared to have significant limitations, mainly in terms of usability. Based on our first-hand findings we defined the next steps of our research, i.e. the data collection in a controlled study and the subsequent development of the eDSS. Furthermore, the lessons learned in our project could facilitate the related research for other vulnerable population groups.

Keywords:

Infection, Surveillance, Diabetes, Point-of-care systems

Introduction

The utilization of reliable and accurate means for the timely detection of infections may prevent contagious disease outbreaks or even pandemics. Biological threats still exist, such as the avian influenza that, according to World Health Organization (WHO) reports, has caused almost 60% deaths among the total number of cases reported from 2003 to September 2009 [1]. The recent influenza virus threat (H1N1 – swine flu), has alerted the health authorities and governments over the globe, and increased the pandemic fear. Such pathogens can spread over and affect the general population but, primarily, the most vulnerable individuals.

The 2005 International Health Regulations articulated surveillance as 'the systematic ongoing collection and analysis of data for public health purposes and the timely dissemination of public health information for assessment and public health response as necessary' [2]. The existing disease surveillance systems collect data after the onset of the first symptoms and eliminate the incubation period[1] from their processes; thus, a significant delay from the actual onset of the infection threat occurs. Beyond that, they mainly target the general population and work less on vulnerable groups, such as people suffering from chronic diseases (diabetes, chronic heart failure etc.) and elderly; these groups are likely to be at heightened risk even in non-outbreak settings, such as in the case of cryptosporidiosis and other waterborne diseases [3]. Indicatively, the National Center for Chronic Disease Prevention and Health Promotion (Atlanta, GA, U.S.A.) has recently announced special guidelines for H1N1 flu and diabetes [4].

To address these needs we explored some new directions in the field of disease surveillance under the umbrella of an ongoing project, which investigates the automatic detection of infections; this project is supported by the Tromsø Telemedicine Laboratory (TTL). The core of our approach is the identification of an infection before people even know, through the onset of the symptoms, that they have been infected; specific physiology indicators and other personal health data could be used for that. Also, we are particularly interested in investigating this idea in people with diabetes and, furthermore, in exploring the possibility of building a dedicated electronic Disease Surveillance System (eDSS) for them.

The starting point for our study was based on the hypothesis that blood glucose (BG) and white blood cell (WBC) count could be the potential indicators for the early detection of infections in people with diabetes: BG may increase at a very early stage of infestation, immediately after the infection manifestation [5]; also, WBCs play a key role in the body's defense against infections and in most of the cases their count is increased at the early stages of incubation period [6]. Hypothetically, an eDSS could collect the appropriate data for these parameters incorporating monitoring devices and, subsequently, process this input in combination with other personal data; early indications for infection threats, i.e. quite before the onset of the symptoms, could be the system output.

[1] The subjects have no symptoms during the incubation period but have already been infected and become contagious.

In order to investigate these assumptions we defined the specific study objectives and attempted to meet them following a certain plan, which is presented below. This plan has been implemented over a period of 3 years (March 2007 – March 2010) and most of our findings have been already published (references are provided accordingly). The current paper attempts to give an overview of our efforts to explore novel approaches in the disease surveillance of people with diabetes, the main tasks that we have accomplished and the lessons that we have learned. Based on our experience we further discuss the potential future directions in the field.

Materials and Methods

In the beginning of our study the potential use of the suggested physiology indicators for disease surveillance purposes was investigated. This was highly prioritized considering that there are no solid findings for the BG elevation during the incubation period as well as for the exact timing of this alteration. The technological aspects had to be examined as well; for example, even though there are various BG monitors available that could be used as part of the eDSS, it is questionable whether similar devices for WBC count can be found in the market.

External Data Sources

In order to study the physiology response to infections for people with diabetes, we should either run a clinical study to collect the appropriate data for thorough analysis and model development or use external data sources to further investigate our ideas. The latter option was explored considering that diabetes is a condition that has been studied extensively in randomized controlled trials (RCTs); thus, we assumed that the huge data collection in a RCT might contain information both for infection incidents and continuous blood glucose monitoring. Subsequently, we gained access to the data collection of two RCTs:

- *Diabetes Control and Complications Trial (DCCT)*. DCCT was a full-scale multi-centre clinical trial, which recruited 1441 people with type-1 diabetes and was conducted by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) [7]. The participants were randomized into two arms (conventional vs. intensive therapy arm) and data was collected every three months, i.e. during the follow-up visit. Among the numerous parameters of this study, glycosylated haemoglobin (HBA_{1c}) and disease-related parameters were further assessed. Adult males and females were studied separately. The null hypothesis that the diseased HBA_{1c} values were equal to the non-diseased values was tested for both sexes and arms [8].
- *Informatics for Diabetes Education and Telemedicine (IDEATel)*. The population of IDEATel study consisted of 1665 people with type-2 diabetes who were enrolled through the primary care practices in the New York City [9]. With the enrolment hub at the NewYork-Presbyterian Hospital/Columbia University Medical Centre (NYP/CUMC), the study participants either received a set of telemedicine services (intervention group) or remained under the usual care of their primary care providers (control group). The intervention group measured and uploaded their BG values into the NYP/CUMC Clinical Information System Repository and used the inpatient and outpatient health services in the same hospital as well. Consequently, it was possible to access and analyze inpatient and outpatient healthcare data (related to infection incidents) as well as glycemic control data (BG and time of measurement) for a certain number of people with diabetes.

Electronic Disease Surveillance System – Feasibility study

In order to incorporate a set of physiology indicators into a disease surveillance system and support patients' monitoring, it should be primarily checked whether the existing technology could support the development of this system. For example, our approach to use WBC count required the existence of a point-of-care (POC) device that could accurately measure this parameter at the user's location and not at the healthcare facility; even though such a device existed, it had to be examined whether it fitted our purposes. Furthermore, the cost-effect relationship could not be otherwise evaluated but in the context of a feasibility study. This study was performed in the city of Tromsø, using four POC devices that could monitor temperature, blood pressure, blood glucose level and certain hematological variables. It should be also mentioned that we selected validated and approved devices, which were shown to produce results equivalent to laboratory equipment [10].

Results

Table 1 shows the results of the DCCT data processing. Paired comparisons of diseased HBA_{1c} values (during the infection incident) vs. average HBA_{1c} values (before or after the infection incident) were performed using t-test statistics; the values for the intensively treated females were normalized to correct the skew and normalize the distribution. In almost all cases (excluding the intensively treated females case) HBA_{1c} values rose after infection despite the tight BG control held in the DCCT study, and returned to the non-diseased levels when the initial infection cause ceased; the complete analysis and results have already been published and presented at MIE 2008 conference (Göteborg, Sweden) [8].

Regarding the processing of IDEATel data we could briefly mention that glycemic control (blood glucose values and time of measurement) was shown to be altered when a person with type-2 diabetes was exposed to a pathogen. The complete analysis and results are fully presented in another paper, which is still under review; thus, it is not possible to discuss the findings of this work here.

Table 1- The results of testing the null hypothesis using the DCCT data; the mean paired difference (Mean), the standard deviation of the difference (SDev), the 95% confidence interval of the difference (95% CI) and the p-values of the t-test statistics [8].

		HBA_{1c}	Mean	SDev	95% CI		P
Conventional Arm	Female	Diseased – Average Before	0.288	0.719	0.163	0.412	<0.001
		Diseased – Average After	0.273	0.851	0.126	0.421	<0.001
	Male	Diseased – Average Before	0.267	0.722	0.151	0.384	<0.001
		Diseased – Average After	0.225	0.681	0.115	0.335	<0.001
Intensive Arm	Female *	Diseased – Average Before	0.007	0.081	-0.009	0.023	0.342
		Diseased – Average After	0.016	0.076	0.001	0.031	0.021
	Male	Diseased – Average Before	0.169	0.450	0.077	0.261	<0.001
		Diseased – Average After	0.115	0.563	0.001	0.230	0.049

* normalized values

The findings of the feasibility study suggested that it is not possible to use the available devices for our purposes, even if they are really promising. Particularly, the POC device measuring certain hematological variables appeared to be the most problematic due to the repeated failures during the feasibility study; moreover, the thermometer accuracy was questioned as well as the blood pressure measurements. The blood glucose monitor operation was quite acceptable; however, it caused dissatisfaction among the users because it required manual quality control. An overall limitation factor was the excessive time needed for the measurements (prepare consumables, perform tests, wait for results), with the average time for performing all measurements being 20 minutes. It should be also mentioned that the total cost of the four devices per subject was approximately $5,200, while the appropriate consumable costs were approximately $350 per subject for performing daily measurements in a one month period. These costs were further split per subject, device and daily measurement (Table 2).

Table 2- Equipment costs; all prices are calculated in USD (no taxes included) [10]

Devices	Price	Consumables*	Accessories**
Haematologic Analyzer	4,000.00	8.00	500.00
Blood Glucose Monitor	400.00	3.50	40.00
Blood pressure Monitor	167.00	N/A	25.00
Thermometer	55.00	0.40	N/A

*N/A: Not Applicable, * Cost per measurement, ** Cables, software, printer*

Specific details for the devices (vendors, trade names etc.) as well as the complete results of the feasibility study can be found in the manuscript that has been already published [10].

Discussion

The main scope of this project was to work on new directions in the disease surveillance field targeting the early detection of infections. Particularly, in the context of the existing disease surveillance systems that have been studying mainly the general population [11-13], our disease surveillance approach for vulnerable population groups with special physical needs is novel. For completeness, we should refer to Mohtashemi et al. [14] who described a system for the early (still after the onset of the symptoms) detection of tuberculosis outbreaks among the San Francisco homeless population; however, homeless individuals should be considered vulnerable mainly due to social and not physiology reasons. As a first approach to our idea we considered that diabetes could be the ideal research area since:

- People with diabetes are highly motivated to monitor their infection status;
- Diabetes is a condition that has been extensively studied before and, thus, we expected to:
  - get access to external data sources with numerous variables and complete data,
  - attract the interest of other researchers in the field, and
  - disseminate our ideas rapidly;
- The diabetes monitoring technology has advanced more than the technology in other chronic conditions;
- Our team has years of experience in the field [15-16].

One of our primary mid-term goals was to build the theoretical background of our approach. Thus, it was necessary to investigate our claims regarding the early detection of infections and, mainly, the possibility of using certain physiology indicators for accomplishing this task. Normally, a dedicated clinical study is required to fulfill this demanding task. However, it is often risky to allocate a considerable amount of resources before examining the solidity of a novel idea. In this context, the solution of getting access to external data sources was the most appropriate.

Subsequently, we have managed to access the archives of two large-scale RCTs, the DCCT and the IDEATel studies that involved people with type-1 and type-2 diabetes correspondingly [7, 9]. This allowed not only the processing of two large data sets but also the investigation of our approach in both types of diabetes condition. The idea of blood glucose elevation and the alteration of glycemic control during the incubation period were supported by the results of the analyses in both cases [8]. It was not possible though to investigate either the contribution of other parameters (e.g. WBC count, insulin intake) or the detailed physiology mechanisms.

Unambiguously, the methodology that was followed in the first phase of our project had some limitations. First of all, both studies were not specific for our purposes and, thus, it could be argued that the results are inadequate to base any further research. Nevertheless, it should be mentioned that our main intention was to seek for evidence and reserve our resources for a dedicated clinical study. The same strategy was followed in the feasibility study where approved devices were tested in a low-budget schema.

Additionally, the study of devices that measure symptomatic (i.e. temperature) and non-infection-related (i.e. blood pressure) parameters could be considered as irrelevant to our purposes. However, our disease surveillance approach should be viewed as an effort towards personalized medicine; otherwise users might not see the potential benefits and be skeptical on such systems. Subsequently, the examination of other 'pieces of the puzzle' is important; this is further discussed below.

Considering that the end point of our project was the development of an eDSS that would incorporate specific devices for the continuous monitoring of physiology parameters, it was important to test the available technology. As aforementioned this was the reason for conducting the feasibility study, which showed that technology is still immature both in terms of accuracy and usability [10]. On the other hand, a successful eDSS requires the collection of accurate data in order to fulfill its purposes. Consequently, the idea of performing continuous monitoring for multiple physiology indicators should be abandoned, especially in the case of diabetes where only blood glucose can be measured in a reliable manner.

Based on our up to date progress, we are able to define our next step that is the conduction of a dedicated clinical study to collect the appropriate data. Taking into account the results of the feasibility study and, particularly, the high cost of the POC equipment, the main characteristics of the proposed study should mainly include:

- A cohort of 100 people with diabetes, either type-1 or type-2;
- Continuous data collection (BG values, insulin, physical activity, food intake, infection-related data, temperature, diagnosis of infections);
- A study period of one year to be able to accurately define the participants' profile and maximize the possibility of observing infection incidents.

The tools that should be used in this study are also important; the selection should be based both on the conclusions drawn from the feasibility study and on the characteristics of the existing equipment solutions. Keeping in mind that users' involvement is critical for the success of any system (before, during and after system development), the following criteria should be considered:

- A simple device for continuous BG monitoring is definitely more usable and should be part of the clinical study; however, more accurate devices should be used as part of the final eDSS. The BG monitor that was used in the feasibility study was comparable to laboratory equipment in terms of accuracy and should be examined prior to building the final product [17];
- A mobile device carrying a dedicated software for data input should be used, like the one that has been developed by Arsand et al [16];
- The secure communication infrastructure should support the data collection in a central repository for further processing;
- An important component of the eDSS is the mathematical model that will process the incoming data, send feedback to people with diabetes/physicians and trigger alarms if necessary. The potential modeling approach should be examined before the initiation of the clinical study and then adjust its parameters at predefined time points.

Our approach could also empower the development of personalized health care systems that involve portable devices, sensors and wireless networks [18]. In this context a personalized eDSS could adjust its parameters to support each subject, e.g. by alerting them for an infection threat in a region. Systems of the kind could also interoperate with Electronic Health Record (EHR) systems and provide health care professionals with adequate information to take the necessary actions and support the information sharing between vulnerable individuals. For example, a threat raised by monitoring one person with diabetes could be used in evaluating the relevant threats for the community of people with diabetes living in the same area. This would also consist an excellent opportunity to build a social network with special interest and a huge impact on the infection control.

The project objectives were decided upon but not limited to the initial selection of people with diabetes; our approach is broader and we aim to study other vulnerable populations, too. Among our intentions was to form the basis for a further exploitation of our findings in the general population or otherwise healthy groups that are very interested in getting early

alerts for their condition, such high-competition athletes. The related research might initially target individual surveillance and then move up to the population level (bottom-up approach). Beyond the study that is required to determine the exact physiology alterations after infection, the role of medical informatics regarding the eDSS conceptual, organizational, architectural and technological aspects is crucial.

Conclusion

The development of strategies for the detection of infections before the onset of the symptoms is critical, especially given the limitations of the current disease surveillance systems that are based only on people's awareness of their health status. This is particularly important for vulnerable population groups, such as people with diabetes, that their health status is altered significantly when they are infected. Here, we highlighted the lessons learned in our project, the difficulties of this approach as well as our future plans. We hope that this work will provoke the thoughts for new directions within the disease surveillance field.

A 3-step eHealth approach to transfer knowledge on HIV and sexual violence in developing countries

Hendra van Zyl[a], Liz Dartnall[b]

[a] *Web and Media Technologies, eHealth Research and Innovation Platform, Medical Research Council, South Africa*
[b] *Sexual Violence Research Initiative, Gender and Health Research Unit, Medical Research Council, South Africa*

Abstract

This paper discusses an innovative 3-step eHealth approach to translate research for target audiences' knowledge uptake in developing countries. The first step uses a knowledge transfer model for the identification and packaging of health content as well as the selection of appropriate Information and Communication Technologies (ICT) platforms; followed by consumer health informatics studies to evaluate the efficacy of addressing health consumers' information needs; and the final step recommends forming of strategic partnerships to strengthen and support knowledge transfer and sharing. The 3-step eHealth approach is based on a convergence of ICTs, and application of the practices and principles of informatics and knowledge management. It was refined during the development of AfroAIDSinfo, an AIDS information portal of the SA Medical Research Council (MRC). The approach was evaluated during the forming of a strategic partnership between the AfroAIDSinfo project of the MRC's Web and Media Technologies Platform and the Sexual Violence Research Initiative. The successful outcome of the eHealth approach served to collect evidence for good practice in informatics and knowledge management.

Introduction

The developing world and Africa in particular is facing the dual epidemic of sexual violence and HIV. In the AIDS Epidemic Update for sub-Saharan Africa [1] South Africa is still singled out as the country in this region where an estimated 1.8 million people have died of AIDS-related disease since the epidemic began.

The linkages between HIV and Sexual Violence are well established [2]. With a rate of reported rapes at 194 per 100,000 women, South Africa is said to be the "rape capital" of the world [3]. Education has been highlighted as fundamental to overcoming both HIV/AIDS and sexual violence in the sixth millennium development goals [4].

In response to the AIDS epidemic, the high prevalence rate of HIV in sub-Saharan Africa, and the call for education interventions, AfroAIDSinfo™ was launched in 2001 on World AIDS Day. Developed by the Web and Media Technologies Platform (WMTP) of the SA Medical Research Council (MRC), it is an online HIV and AIDS project[1] supported by community outreach programmes.

AfroAIDSinfo aims to provide reliable information on HIV and AIDS to its consumer groups, with emphasis on the needs of sub-Saharan Africa. The AfroAIDSinfo consumer groups are researchers, health professionals, educators, policy makers and the public.

Using portal technology and community based educational interventions AfroAIDinfo meets its objectives by:

- **educating** its audiences on HIV;
- **updating** audiences on current issues and developments;
- **facilitating** decision-making;
- **improving** peer interaction, and;
- **stimulating** innovative knowledge transfer, with the latter focusing on innovative online as well as community outreach projects.

Sexual violence is the least understood and researched form of violence against women. Research is critical in highlighting the extent of the problem, and strengthening public health services and prevention programmes dealing with this problem. Lack of evidence hampers the development of good quality, evidenced based policies, services and programmes for women and girl survivors of sexual violence [5]. To address this gap, the Sexual Violence Research Initiative (SVRI)[2] was established in 2002, with the support of the World Health Organisation as an initiative of the Global Forum for Health research and is currently hosted by the Gender and Health Research Unit, Medical Research Council of South Africa.

The SVRI consists of a network of experienced researchers, policy-makers, activists, donors and others committed to the promotion of research on sexual violence and to generating empirical data to ensure that sexual violence is recognised as a priority public health issue.

---

[1] AfroAIDSinfo is available online at www.afroaidsinfo.org

[2] SVRI is available online at www.svri.org

Against the background of the WMTP's work in eHealth to address HIV through a Web portal and its partnership with the SVRI to address sexual violence, this paper discusses an approach to address public health problems in the developing world.

The WMTP implements eHealth solutions in the context described by the World Health Organisation that refers to it as "*The cost-effective and secure use of information and communication technologies (ICTs) in support of health and health-related fields, including health-care services, health surveillance, health literature and health education, knowledge and research* [6].

The aim with this approach is to collect evidence for good practice eHealth approaches in public health interventions in developing countries. Good practice in eHealth is interpreted as those sets of processes and activities that are consistent with eHealth values, theories and models, understanding of the environment, and are most likely to achieve eHealth goals. Using a Consumer Health Informatics theoretical framework proposed by Lewis & Friedman [7], the health consumer is placed at the centre. Information technology becomes a mode to transfer health information to the consumer, as well as acting as a feedback catalyst. Health consumers' interaction with health providers empowers them to make healthy lifestyle decisions.

Based on this theoretical framework, this paper outlines a 3-step informatics and knowledge management approach with the following objectives:

- To implement a knowledge transfer (KT) model for the initial identification of consumer groups' information needs and selection of suitable Information and Communication Technologies (ICTs) platforms;
- To conduct Consumer Health Informatics (CHI) studies evaluating the extent to which consumer groups' information needs and format preferences have been met, addressed and integrated into the ICT platforms and
- To form strategic alliances between two developing country initiatives to address their public health problems.

The objectives of the 3-step eHealth approach aims to strengthen and support the effective translation of research into practice.

Materials and methods

A Web to Public Knowledge Transfer Model (WPKTM) was developed as an intended standard for Web development at the MRC. It was applied for the development of the AfroAIDSinfo AIDS information Web portal. Over time this model was extended into a 3-step eHealth approach to address specific areas of public health in developing countries.

Step 1 of the eHealth approach

This step consists of two phases, where the WPKTM's generic principles were applied during the first phase of development to establish the information needs of the AfroAIDSInfo consumer groups.

The generic principles included processes to:

- *Identify the target audiences;*
- *Ascertain whether the knowledge intended for the audience is required by them;*
- *Classify content according to the health literacy of the audience;*
- *Show the relevance of new knowledge;*
- *Avoid an information overload;*
- *Strive for utilisation of knowledge by the audience;*
- *Address the issues relevant to the audience.*

The WPKTM is further put into practice according to Snowden's [8] definition of knowledge management as "*the identification, optimisation and active management of intellectual assets, in the form of explicit knowledge either held in artefacts or as tacit knowledge possessed by individuals or communities. The optimisation of explicit knowledge is achieved by the consolidating and making available of artefacts. The optimisation of tacit knowledge is achieved through the creation of communities to hold, share, and grow the tacit knowledge. The active management of intellectual assets is the creation of management processes and infrastructure to bring together artefacts and communities in a common ecology that will sustain the creation, utilisation and retention of intellectual capital*."

With this definition in mind, health information was transformed into technology based on good practices for knowledge transfer on the Web. These practices formed the second phase of the WPKTM and included:

- *Selection of appropriate push and pull technologies to transfer and share knowledge;*
- *Packaging content with cultural understanding;*
- *Classifying content for different audiences;*
- *Packaging content according to Web Accessibility standards;*
- *Applying a convergence of ICTs to address the information needs of consumers;*
- *Implementing methodologies to measure health consumers' knowledge levels and packaging content accordingly;*
- *Implementing content to prevent an information overload;*
- *Implementing intuitive and easy navigation;*
- *Implementing quality assurance methodologies such as the HON principles[3], workflow processes, and an editorial process;*
- *Implementing policies, terms of reference for use, explanations and assistance.*

ICTs that further facilitated the knowledge sharing process for the AfroAIDSinfo consumer groups included a Discussion Forum along with technology to distribute a monthly eNewsletter to registered members. In the monthly eNewsletter; and at the end of articles specific questions are

[3] The Health On the Net Foundation (HON) developed an ethical Code of Conduct to guide consumers on the Web to reliable health information.

posed to each consumer group to be discussed in the forum in order to stimulate discussions among its members. The main purpose of the discussion forum is to capture tacit knowledge of members' expertise in a format that could benefit all the consumer groups.

Step 2 of the eHealth approach

The next step is underpinned by Consumer Health Informatics as described by Eysenbach [9]: "*the branch of health informatics that analyses consumers' needs for information, studies and implements methods of making information accessible to consumers and models and integrates consumers' preferences into health information systems.*"

Cognisant of the theoretical framework, regular CHI eSurveys are conducted among AfroAIDSinfo consumer groups to investigate if the deployed ICTs were successful in transferring research knowledge to consumer groups. It would imply effectively responding to information needs and identifying new requirements, based on the CHI model referred to earlier.

As an example, the AfroAIDSinfo CHI study revealed a need by the health profession and public consumer groups for more information on women and HIV. As part of an overall strategy to address this information request, the AfroAIDSinfo entered into a partnership with the Sexual Violence Research Initiative (SVRI).

Step 3 of the eHealth approach

The notion to form partnerships is seen as a strategy for improved public understanding of health and science [10]. Both the SVRI and AfroAIDSinfo view partnership as a key strategy to advance innovation and to extend their reach. The partnership included technology development for the SVRI; collaborative content development and CHI studies to evaluate the deployed ICTs to translate research and knowledge effectively to benefit health consumers.

The Sexual Violence Research Initiative has been providing materials and resources on sexual violence to its members since 2003. Based on the successful 3-step eHealth approach followed for the development of AfroAIDSinfo, the same approach was pursued for the expansion of the SVRI ICTs.

Through this partnership, members of both networks were able to share knowledge and insights into HIV and Sexual Violence; and to learn more about the increasing feminisation of the HIV epidemic and the complex interactions between rape and HIV. Examples of the outputs of this partnership were the collaborative development of a fact sheet on the link between HIV and sexual violence. News items based on the linkages between these areas are exchanged and disseminated to each initiative's consumer groups.

Two years after the partnership between the SVRI and AfroAIDSinfo was formed, the WMTP and the SVRI undertook a CHI study to evaluate whether the core ICTs as implemented for the SVRI were successful in addressing the information and research needs of the SVRI members.

Results

AfroAIDSinfo CHI study results

At the time of this study, the AfroAIDSinfo Web portal was recently re-engineered and registered users requested to resubmit subscriptions. Of the 491 new subscribers, the AfroAIDSinfo eSurvey received 124 (25%) responses where the majority of consumers registered in the *scientist* group 74.19% (n=92) followed by *public* 11.29% (n=14), *health professionals* 6.45% (n=8), *educators* 5.65% (n=7) and *policy makers* 2.42% (n=3). As previously alluded to, efforts were focused on providing reliable and useful information on HIV and AIDS to the AfroAIDSinfo consumer groups. Figure 1 is a summary of the collective feedback from respondents in the main areas on which all audiences were questioned.

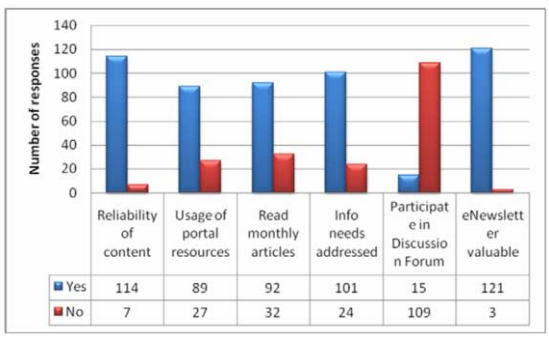

Figure 1- High level summary of eSurvey responses

These results showed that the aim of AfroAIDSinfo to be a reliable resource on HIV information was achieved as its members rated reliability of content at 91.94% (n=114).

Linked to the above, 71.77% (n=89) of the respondents indicated that they used the resources on AfroAIDSinfo. A respondent from the public category said he/she considered the AfroAIDSinfo content reliable and thus felt confident in using it in community events. 74.19% (n=92) of the respondents read the monthly articles. The value of the eNewsletter to transfer HIV knowledge was rated at 97.58% (n=121). This result was very encouraging as the eNewsletter acts as a pull technology, including links to the latest articles on the AfroAIDSinfo portal. On the other hand, only 11.29% (n=15) usage was reported for the Discussion Forum.

Finally, 81.45% (n=101) of the respondents indicated that their information needs were addressed as described in the first step of the eHealth approach. They were further given the opportunity to identify "new" topics and areas on which they needed information and resources. A community worker in the public category requested "*case studies in handling a community project*" and "*basic HIV information in indigenous languages*"; while a health professional required guidance on "*Different forms of support - for the patient as well as the family*." Results of the CHI eSurvey were communicated to the AfroAIDSinfo members through the monthly eNewsletter. In the months following the CHI eSurvey, articles addressing these identified topics were highlighted in the eNewsletter.

The same 3-step eHealth approach was implemented for the partnership between the WMTP's AfroAIDSinfo project and SVRI to develop their ICT platforms (step 1) and was later followed by a CHI study (step 2) to evaluate the SVRI members' perceptions how their information and research needs were addressed.

SVRI CHI study results

The SVRI originally set various objectives to be met with information distributed to their members via the Web site and listserv[4]. Respondents overwhelmingly indicated that their expectations were mostly met or were exceeded. As shown in Figure 2, the objective to *Promote informed research practices* was *Mostly met* receiving the highest rating (n=80) followed by *Bridging research and practice* (n=73). The objective that exceeded expectations was *Promoting reliable, valuable information* (n=56), followed closely by *Raising awareness of SV as a public health priority* (n=53).

New information needs were addressed, for example a number of key changes to the SVRI ICT platform have been made. The SVRI initiated a number of region-specific activities to increase its membership and interest in work on sexual violence in the Latin American and the Caribbean regions. Taking the feedback forward and using the technology available, the SVRI plans to create a policy portal to promote research based policy analysis and expert commentary in the field of sexual violence, with emphasis on research from developing countries. Through the proposed SVRI Policy Portal the SVRI will endeavour to raise the level of debate by providing a space for researchers to draw out the policy implications of their research, and to make their work more accessible to professionals working in the field.

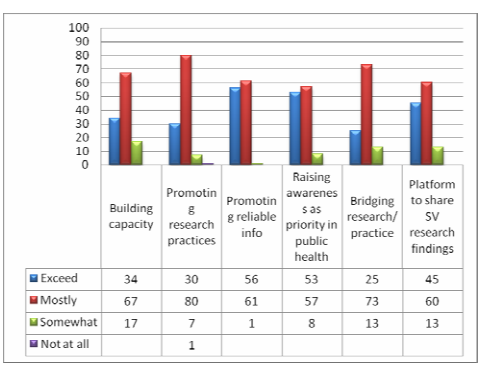

Figure 2- Information needs of SVRI member met

Discussion

As the results indicated, each of the three steps proved to be beneficial to the respective initiatives and their consumer groups. The eHealth approach assisted both AfroAIDSinfo and the SVRI from inception, to become aware of the specific information needs of their consumer groups.

Following the eHealth approach enabled both partners to select the most appropriate ICTs and to develop the appropriate resources to address the information needs of their specific consumers. Examples include the additional portal desktops integrated into AfroAIDSinfo with basic information on HIV in two indigenous languages.

Both sites have been reviewed and carry HON accreditation as reliable sources of health information on the Web. These actions were specifically taken during the first step to meet the aim of the approach – to translate research into a practice.

The CHI studies conducted during the second step was used to further inform both AfroAIDSinfo and the SVRI of extent to successfully implement the Web to Public Knowledge Transfer Model. It also gave the consumer groups an opportunity to highlight new information needs that subsequently arose, initiating interaction with communities as advised by the CHI theoretical framework.

The high rate of satisfaction reported by both CHI surveys indicated the importance of unpacking research into different formats according to the information needs of those who seek it.

The CHI studies further highlighted areas for improvement, such as the low participation rate in the AfroAIDSinfo discussion forum.

Robertson [11] believes that a *clear purpose* should exist for people to use online collaborating ICTs, i.e. they should see that their contributions make a direct impact on their group or they should see tangible effects from their contribution. He further suggested that an online collaborating ICT should draw upon *a common sense of community*. A success criterion is thus that there should be an existing community or network.

Although the "community" does exist in AfroAIDSinfo in the form of its five consumer groups, it does not mean that the consumers have a sense of being a community and therefore make time to participate with "strangers" in the forum. This calls for innovative approaches to unlock experts' knowledge. If this could be achieved, the spiral effect of learning predicted by Nonaka [12] would take place. He suggests that knowledge sharing leads to knowledge uptake which in turn leads to production of new knowledge practices, and beneficial usage.

In communicating the results of the CHI studies to consumer groups the gap between knowledge provider and consumer was decreased. It laid the foundation for future responsive relationships as both sites received increased member registrations and interaction in their collaborative ICTs.

The final step of the eHealth approach, to develop a strategic partnership, acted as a catalyst for a strategic alliance between two eHealth initiatives. It opened up opportunities for consumer groups to share in knowledge across both platforms, meeting the objectives of each step of the eHealth approach.

Conclusion

The successful implementation of the 3-step eHealth approach has provided knowledge for good practice in informatics and knowledge management. Moving forward, the SVRI and

[4] Listserv is an application that maintains lists of e-mail addresses in order that users can participate in an electronic discussion or conference.

AfroAIDSinfo will continue with regular CHI studies to collect evidence ensuring that the aims and objectives of both partners are met. Continuous adaption of efforts and activities will promote the use of best evidence in the prevention and responses to sexual violence and HIV. From a public health perspective, the 3-step eHealth approach is presented for replication in other fields of health.

Acknowledgements

The AfroAIDSinfo Project Team wishes to thank the SA Medical Research Council as its hosting organisation for its continued support as well as its initial funders, Bristol Myers Squibb and the Irish-based Protea Education Development Project for current funding.

The SVRI would like to thank the Global Forum for Health Research, the SA Medical Research Council, along with our Coordinating Group for their invaluable support for and feedback on the SVRI eSurvey.

Using a File Audit to Evaluate Retention in Care and Patient Outcomes in a Programme to Decentralise Antiretroviral Treatment to Primary Health Care Facilities in a High Prevalence Setting in KwaZulu-Natal, South Africa

Catherine Searle, Arthi Ramkissoon, Thamandrie Govender

Reproductive Health & HIV Research Unit, University of Witwatersrand, Johannesburg, South Africa.

Abstract

HIV care and antiretroviral treatment (ART) provision is largely hospital-based with an over-reliance on doctors. Existing ART sites are reaching capacity and are increasingly unable to initiate new patients and also see follow up patients. In response, the Reproductive Health and HIV Research Unit (RHRU), has supported the KwaZulu-Natal provincial Department of Health with developing a model to decentralise services to primary health care (PHC) level. The programme has been in operation since 2006, and currently nine ART initiation sites down refer stable patients to 24 PHC clinics. Data on patient numbers, treatment outcomes and patient retention rates were collected through a file audit of 2071 adult patient files and analyzed. Results indicate that a file audit is a feasible mechanism to provide this data and can be used to identify gaps and improve quality of care. PHC sites in resource-constrained settings are able to manage stable patients on ART; however, sites need support with monitoring and evaluation and with tracking patients that have been down referred. In terms of quality of care, PHC sites need to ensure that clients receive CD4 count tests and viral load monitoring at six monthly intervals to ensure that treatment failure does not go undetected. Patients suspected of experiencing adverse events or treatment failure appear to be managed according to standard operating procedures, but there is a need to ensure that adverse events are clearly documented in patient files.

Keywords:

Antiretroviral treatment, Primary health care, Retention.

Introduction

eThekwini district in KwaZulu-Natal has an estimated 1.5 million individuals infected with HIV; 12-15% of whom require antiretroviral treatment (ART). HIV care and ART provision is largely hospital-based with an over-reliance on doctors. Existing ARV sites are reaching capacity and are increasingly unable to initiate new patients and also see follow up patients. In response, the Reproductive Health and HIV Research Unit (RHRU), has supported the KwaZulu-Natal provincial Department of Health with developing a model to decentralise services to primary health care (PHC) level. The rationale for shifting the care of stable patients to PHC level is two fold. Firstly, it will allow for stable patients to access care closer to their homes saving them time and resources and ensure that waiting times for services are minimized. Secondly, it would allow more new patients to be initiated on ART, reduce waiting times for treatment initiation and result in more efficient use of human resources if doctors are freed up to focus on new patients and follow up patients are managed by nurses. This approach has been used in countries such as Malawi [1], Rwanda [2] and Lesotho [3, 4] and is promoted by the World Health Organisation [5]. The HIV and AIDS and STI Strategic Plan for South Africa 2007-2011 mandates decentralised care and nurse-driven services [6] and there is widespread recognition for the need for decentralised care and task shifting/sharing in the South African context [7, 8].

RHRU has developed a comprehensive model for decentralising care. The model starts at PHC level, where clients are prepared for ART (all services prior to ART initiation are conducted at PHC level) and then referred for ART. Once clients are stable on ART (at least 6 months), they are down referred to be managed at PHC level. In order to support implementation, RHRU has developed standard operating procedures for the up and down referral process [9]. This includes documenting the procedures for up referral of adults (including pregnant women) and children; management of patients at initiating sites; down referral of stable patients; dispensing ARVs to PHC; and the management of side effects. Standardized data collection forms and a two-way referral form were developed in consultation with the provincial department of health to track patients up and down referred. RHRU conducts a three day training programme for nurses and provides follow-up mentoring & coaching on-site in order to implement the model. RHRU has implemented the programme since 2006. However, no formal assessment of the programme has been conducted. In order to assess patient retention in care and how well patients, who are down referred are being managed, RHRU conducted a file audit of patients down referred to RHRU supported PHC sites. Currently nine ART initiation sites down refer patients to 24 PHC clinics.

Research Objectives

The objectives of this study were to:

1. Collect information on the numbers of patients currently accessing care at PHC level
2. Collect information on treatment outcomes and inconsistencies in patient management to inform improvements in quality of care
3. Identify areas requiring follow-up interventions, quality improvement projects and to improve the quality of routine data collected.

Methods

RHRU has developed a file audit process for the collection of valid and reliable data in hospitals and clinics using paper-based record keeping systems. The file audit methodology allows for the collection of valid and reliable data in a way that keeps disruption of normal clinic operations to a minimum and makes use of all available clinic staff at various levels of training and expertise. The process has been found to be useful to establish the need for specific follow-up interventions, such as introducing staff for defaulter-tracing and identifying improvements to existing data collection systems. RHRU has used this method in numerous facilities in KwaZulu-Natal, Gauteng and North West Province [10].

RHRU has subsequently adapted the tool to collect similar data on patients who have been down referred to primary health care facilities. Two audit tools designed by RHRU were utilized in this study, a Client File Audit Form and a Clinic Register Audit Form. The tools allow for data collection on the following variables:

- patient demographics;
- CD4 count & viral load at time of down referral and during the course of treatment;
- ART regimens used;
- Incidence and timing of side effects and adverse events;
- numbers of patients falling pregnant on treatment;
- prevalence of co-morbidities;
- number of patients and timing of defaulting including patients not reaching down referral sites and those defaulting after down referral;
- number of patients up-referred to ART sites;
- number and timing of deaths.

A total of 14 individuals were trained on the tools and participated in the audit including 11 of RHRU's monitoring and evaluation team and three visiting students. The team visited 9 initiation sites and 24 primary health clinics over a one month period in October 2008 and reviewed a total of 2071 files. Data on the above variables were extracted from patient files, registers, two-way referral forms and other sources of data at each site and entered on a file audit form for each patient. Data were captured in EpiData and analyzed with SPSS Version 17.

Results

A total of 2071 adult patients were identified as down referred from files opened at PHC sites. The nine initiating sites referred patients to a number of PHC clinics. Table 1 below illustrates the sites and numbers of patients down referred. The number of patients down referred by initiating sites ranged from one to 275, with the average number of patients being 122. As a result of several sites with small numbers of patients and several with large numbers, the median is likely to be a more accurate reflection, at 45 patients per PHC.

Table 2 presents demographic and patient information for the down referred patients. 72% of the down referred patients were female. Data on gender were missing for 2% of patients. Most patients were on regimen 1A or 1B (94%), while this information was missing for 1% of patients. Most patients (56%) had been down referred for a period of 0-5 months, the primary reason being that the programme has rapidly expanded in recent months. Only 4% of patients had been down referred for 12 months or more. Poor record keeping and the non- completion of the two-way referral form meant that the date of down referral was not available for 20% of the files. At the time of down referral 99.6% of patients had undetectable viral loads and the median CD4 count was 264. Three patients were down referred with detectable viral loads. This is not in line with the standard operating procedures for down referral, but may reflect a transcription error of the results. 164 patients (8%) had no information on CD4 count at down referral in their files, while 37% of patients had no viral load documented.

As shown in Table 3, of the 2071 patients identified as down referred, PHC sites received 78% of these patients, 3% did not ever arrive at the PHC site and there was no data on any visit available for 18% of the patients. One possible reason for the lack of data in the files is that some sites reported preparing patient files in advance before patients arrive and therefore may reflect patients yet to arrive at the site. As a result of this finding, measures to prevent this will be implemented on site.

Table 2- Demographic Data

Patients down referred	**Number (n)**	**Proportion (%)**

Table 3- Number of Patients Received at PHC Sites

Number of patients received at down referral clinic	**Number (n=)**	**Proportion (%)**
Received	1624	78
Not received	65	3
No data available	382	18

Patients showed increasing CD4 counts at 6, 12 and 24 months indicating that management at PHC level is effective. However, of concern is that not all patients were receiving regular follow up CD4 counts at PHC or these were not being documented in their files. Most patients continued to have undetectable viral loads at 6 and 12 months after down referral, with 90% and 97% of patients having undetectable viral loads respectively. As for CD4 counts, few patients had these test results documented in their files, which may hamper the effective monitoring of treatment.

Table 4- CD4 & Viral Load Results

Median CD4	**Number of individuals (n)**	**CD4**
@ down referral	1922	264
6 months	223	339
12 months	49	395
% of patients with undetectable VL	**Number of individuals (n)**	**%**
Baseline	1298	99.6
6 months	224	97
12 months	43	93

Files were also reviewed to identify patients lost to follow up after being received at PHC sites. The review found 13% of patients received on site were lost to follow up (13%). Data on 4% of patients were missing or there was no information on last appointment attended in the file. As only stable patients are down referred, the retention rates at PHC level should be higher than at initiating sites [11]. Without a more sophisticated patient information system, it is not possible to identify whether the patients lost to follow up have returned to the initiating site or another site for treatment. Data on patient deaths were not found in any patient files.

Table 5- Loss to follow up

Patients lost to follow up after down referral	**Number (n)**	**Proportion (%)**
Lost to follow up	263	13
Active patients	1737	84
Not documented	38	2
Missing	33	2

The file review also collected data on patient outcomes. In total only 3% of client files indicated adverse events (AE) and 3% opportunistic infections (OI). This data is presented in table 6. Most common OIs were flu, shingles and other minor ailments. In terms of AE, peripheral neuropathy, lipodystrophy and fungal infections were most common.

Table 6- Adverse Events

Numbers of clients who presented with Adverse events	**Number (n)**	**Proportion (%)**
Clients with adverse events	59	3
Clients with opportunistic infections	68	3

Table 7 shows the number of patients and the reason for up referral. Only 1% of patients were up referred back to the initiating site. Reasons for up referral included pregnancy (16%), medication not being available (12%), side effects (12%) and patients wanting to return to the initiating site (8%). Logistics for the delivery of medication may need to be strengthened at some sites. In 40% of the cases, no reason was documented on file. Without accurate and complete documentation, it is difficult to assess the outcomes of programmes. Sites will need to be supported to improve record keeping if that data are to be used for evaluation purposes. Also of concern is the up referral of pregnant women to secondary level care. Pregnant women should be managed at PHC level and not up referred.

Table 7- Patients Up Referred

Clients Up Referred	**Number (n)**	**Proportion (%)**
Number of clients	25	1
Reasons for Up Referral	**Number (n)**	**Proportion (%)**
No reason stated	10	40
Medication out of stock/not available	3	12
Pregnant	4	16
Lactate levels raised	1	4
Side effects	4	16
Non adherence	1	4
Missing prescription card	1	4
Returned to initiating site	2	8

Conclusions & Recommendations

While PHC sites report that down referral programmes are feasible and effective, programmes may lack accurate data on key variables such as patient numbers, treatment outcomes and patient retention rates. A file audit is a feasible mechanism to provide this data and can be used to identify gaps and improve quality of care. The results of the file audit indicate that PHC sites in resource-constrained settings are able to manage stable patients on ART. However, sites need support with monitoring and evaluation and both the initiating and PHC site should track patients down referred and accessing services to prevent loss to follow up. Systems to track patients not attending appointments need to be introduced at PHC sites. This includes the need to ensure accurate and updated contact details are recorded for patients at each visit. On-going mentoring and support for monitoring and evaluation is required at PHC level and RHRU has introduced regular audits and data quality reviews at PHC to address these gaps. Other gaps identified during the audit included two way referral forms not being completed and no standardised tools being used at PHC sites. The planned introduction of a new ART register should go some way to address this concern. In terms of quality of care, PHC sites need to ensure that clients receive their CD4 count tests and viral load monitoring at six monthly intervals to ensure that treatment failure does not go undetected. Patients suspected of experiencing adverse events or treatment failure appear to be managed according to standard operating procedures, but there is a need that this management is clearly documented in patient files.

Abstract

Rare diseases cover a group of conditions characterized by a low prevalence, affecting less than 1 in 2,000 people; 5000 to 7000 rare diseases have been currently identified in Europe. Most diseases do not have any curative treatment. They represent thus an important public health concern. CEMARA is based on a n-tier architecture. Its main objective is to collect continuous and complete records of patients with rare diseases, and their follow-up through a web-based Information System, and to analyse the epidemiological patterns. In France, 41 out of 131 labelled Reference Centres (RC) are sharing CEMARA. Presently 56,593 cases have been registered by more than 850 health care professionals belonging to 171 clinical sites. The national demand of care was explored in relation with the offer of care in order to reach an improved match. Within 2 years, CEMARA stimulated sharing a common platform, a common ontology with Orphanet and initiating new cohorts of rare diseases for improving patient care and research.

Keywords:

Introduction

Rare diseases cover a group of conditions characterized by a low prevalence, affecting less than 1 in 2,000 people. According to this criterion, 5000 to 7000 rare diseases have been currently identified. Three to 4% of children and 6% of the population in Europe are affected. Rare diseases are often chronic, progressive, degenerative, life-threatening and disabling. It is thus a true public health concern since most diseases do not have any curative treatment. In France, the Ministry of Health has initiated in 2004 a National Rare Diseases Plan; 131 Reference Centres (RCs) were then labelled for a given disease or group of diseases. Among their missions, the RCs lead the management networks and are involved in the epidemiological monitoring of pathologies they are in charge of, in order to better assess the distribution of rare conditions on the territory, as well as their social, educational and familial repercussions. To support RCs networking, an information system named CEMARA (CEntres MAladies RAres), was developed.

The main objective of CEMARA is to contribute to the missions of the RCs regarding the registration and description of their activities, collecting continuous and complete records of all patients presenting with a rare disease in France and their follow-up, coordinating the network of correspondents, and analyzing the epidemiological patterns.

Material and Methods

Professional network

Thirty three centres are presently active members of the CEMARA network in France (Figure 1) and 16 additional centres joined CEMARA in 2009. Each centre is composed of one or more clinical units, managed by a coordinator. The RCs have been described elsewhere [1].

Ontology for rare diseases: Orphanet classification

Orphanet[1] [2] is member of the European Rare Disease Task Force[2] and in charge of the topical advisory group for rare diseases for the World Health Organization. Orphanet database provides an ontological support to experts for each field of CEMARA. Thus, specific thesauri were designed. The specificity of our collaboration provided a shared ontology for each thesaurus of CEMARA. A grammatical and lexical uniqueness for labelling each disease includes the management of synonyms and eponyms. The associated nosography helps health professionals to share common terms.

[1] Orphanet : http://www.orpha.net
[2] Rare Disease Task Force : http://www.rdtf.org/

Regarding gene mutations we use GENATLAS[3], which contains relevant information with respect to gene mapping and genetic diseases. A specific link was also developed with this database. OMIM codes are also provided.

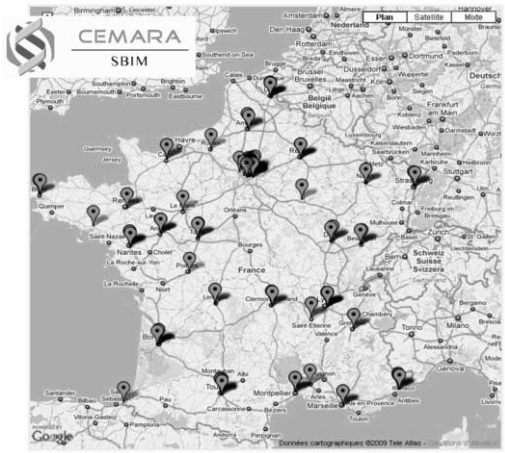

Figure 1- CEMARA network of the first 33 centres for rare diseases

Information System (IS): Design and Implementation

The IS of CEMARA has been described elsewhere [1]. Briefly, it collates in a standardized representation a minimal patient record. CEMARA IS has been based on a n-tier architecture. At the client side, CEMARA relies on existing local Internet networking facilities and on a widely spread computer configuration in medical settings. Via a web browser, the client tier connects to the middle tier, which is connected to several databases: the production database, the geographical dictionary database, and the thesaurus database. The data warehouse and the geographical information system are not yet connected [3]. Their framework is close to an already available application for end-stage renal disease [4]. The middle tier supports client services through Web containers and business logic services through component containers. Business logic components in the middle ware support transactions toward the databases.

CEMARA fulfils several requirements: scalability, portability, reliability, accessibility and cost effectiveness oriented toward non-proprietary software [1].

Maintenance and evolutions are made centrally, which reduce deployment costs and delays. The structure of the production database was built according to a "beehive-like" structure.

The implementation began as of May 2007, initiated by fifteen centres. Coordinators were trained and on-site trainings were also provided for the rare diseases professionals. A technical assistance was also available.

Data entry sheets

All centres share a common core data set. It comprises identification data for the index case and family members, diagnosis, context and medical activity. According to the European Directives and French protection Act, permission was obtained from the "Commission Nationale de l'Informatique et des Libertés"[4] to identify patients on the basis of: name, surname, birth date, date of death, place of birth and municipality of residence. The respect of privacy, confidentiality and security [5] was ensured. An identification module warrants identity doubles using a double-entry prevention function [6].

Figure 2- CEMARA data entry sheet: patient identification.

Medical activities and mode of recruitment are recorded. Optional information is related to antenatal or neonatal data. Diagnosis is recorded using Orphanet classification cited above, as well as the circumstances of the diagnosis. A description of chromosomal abnormalities is also possible. Additional keywords are available for describing atypical signs and symptoms, or for patients presenting with a still unknown diagnosis. Several diagnoses may be provided for a given patient, if need be. Complementary information for specific diseases are described in the so called "petals", attached to the core data set, and focused on specific data collection. Petals are dedicated to follow-up specific diseases such as ichthyosis, nephronophtisis, nephrotic syndromes, cystinosis, juvenile chronic arthritis, rhombencephalosynapsis, rare congenital deafness, Turner syndrome, or neonatal diabetes.

Results

Demand of care

As of September 23rd 2009, the data set included 56.593 records comprising 29,241 male patients (1,605 foetuses) and 25,900 females (1,431 foetuses). Gender was indeterminate in 1452 foetuses. Median age of patients born alive was 9.2 years, (range: from birth to 87 years). Patients were mainly

[3] GENATLAS http://www.dsi.univ-paris5.fr/genatlas/

[4] CNIL : http://www.cnil.fr/english/the-cnil/

enrolled via outpatient clinics (39,402) or hospital wards (3,460). They were predominantly referred to CRs by paediatricians (20,646) and medical specialists (13,084). For foetuses, their mothers were mainly referred by gynaecologists (3,074) and by centres for prenatal diagnosis (1,012). Foetal cases were described during pregnancy (3,162), or after spontaneous miscarriage or termination of pregnancy (1,619). Figure 3 shows the heterogeneous distribution of patients with rare diseases according to departments per 10^5 inhabitants; in mean, 86 patients / 10^5.

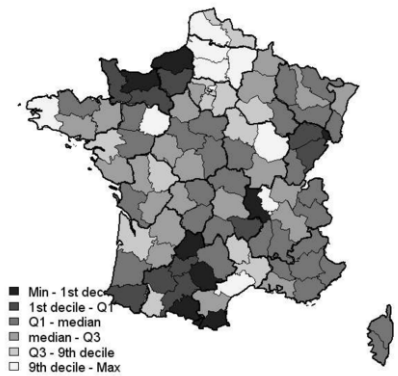

Figure 3- Distribution of patients with rare diseases according to French departments per 100,000 inhabitants

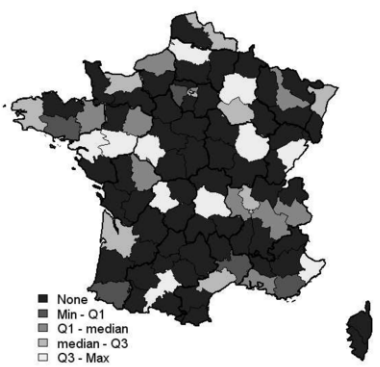

Figure 4- Distribution of CEMARA clinical sites in the French departments, according to departments'population

Table 1 and table 2 summarize the 10 most frequent diagnoses for the 4 centres of rare renal diseases (5,789 patients) and the 8 centres of rare developmental defects during embryogenesis (3,938 foetuses and 28,636 patients), respectively. They cover a broad spectrum of developmental anomalies[5].

[5] http://www.feclad.org/anomalies.html

Offer of care

Close to 850 members are presently registered in 171 clinical units of the 33 active registered RCs. All gave their consent and signed the confidentiality charter of the network. Figure 4 represents the distribution of CEMARA RCs offer of care. The offer of care is present in 35 departments out of 95. A median of 2 clinical units by region cater for patients except in Paris where there are 50 clinical units.

Table 1 – Ten most currently registered diagnoses by the 4 centres for rare renal diseases (879 unknown diagnoses).

Diagnoses *(n)*
Nephrotic syndrome, steroid-sensitive (*534*)
Polycystic kidney disease, autosomal dominant (*306*)
Posterior urethral valve (*285*)
Renal agenesis, unilateral (*244*)
Renal dysplasia, multicystic, unilateral (*228*)
Renal hypoplasia, bilateral (*208*)
Berger disease (*172*)
Renal dysplasia (*152*)
Hydronephrosis congenital (*138*)
Henoch-Schoenlein purpura (*135*)

Table 2 – Ten most currently registered diagnoses by the 8 centres for rare developmental defects during embryogenesis (1,552 "unknown diagnoses" for foetuses and 6,582 for patients).

Diagnoses *(n)*
For foetuses
Trisomy 21 (*153*)
Spina bifida (*84*)
Trisomy 18 (*80*)
Anencephaly (*44*)
Turner syndrome (*42*)
Osteogenesis imperfecta (*40*)
Holoprosencephaly (*36*)
Isolated corpus callosum agenesis (*36*)
Trisomy 13 (*35*)
Cleft lip with or without cleft palate (*30*)
For patients
Neurofibromatosis type 1 (*575*)
Marfan syndrome (*509*)
Trisomy 21 (*444*)
Noonan syndrome (*416*)
Osteogenesis imperfecta (*373*)
Intellectual deficiency with developmental anomaly, rare (*336*)
Fragile X syndrome (*307*)
Steinert myotonic dystrophy (*203*)
Beckwith-Wiedemann syndrome (*200*)
Cleft lip with or without cleft palate (*200*)

Institutional collaborations were developed with the Ministry of Health, the National Institute for Health Surveillance for epidemiological survey, with the French National Authority for Health[6] and the National Health Insurance Fund concerning the design of national protocols for diagnoses, treatment and follow-up, as well as for cost analyses, with associations of patients, university hospitals, for the coordination and networking of clinical correspondents.

Discussion

As of June 9, 2009, a recommendation of the European Council called for concerted action at EU and national levels in order to:

- Ensure that rare diseases are adequately coded and classified;
- Enhance research in the field of rare diseases;
- Identify Centres of Expertise by the end of 2013 and foster their participation into European Reference Networks;
- Support the pooling of expertise at European level;
- Share assessments on the clinical added value of orphan drugs;
- Foster patient empowerment by involving patients and their representatives at all stages of the decision-making process;
- Ensure the sustainability of infrastructures developed for rare diseases.

This recommendation was welcome since many patients with rare disease continue to advocate their need to overcome common obstacles.

An important challenge is thus to collect pertinent information on rare diseases in order to better assess the demand of care and adapt the offer of care.

CEMARA: networking rare disease reference centres

In this perspective, CEMARA offers a secured web-based information system via Internet for rare diseases dedicated to professionals of RCs. The platform is shared by 33 rare diseases centres in France, and recently 16 added centres joined the network in 2009. It helped networking 850 health care professionals belonging to 171 clinical sites who recorded 56,593 cases since 2 years. During this period, it stimulated sharing a common platform, a common ontology with Orphanet and initiating new cohorts of rare diseases for improving patient care and research. We developed a simple core data set to enable registering easily all patients presenting with a rare disease. A pattern of the demand of care could thus be initiated.

As expected, the number of patients per diagnosis is limited, even for the most prevalent diagnoses (tables 1 and 2). Moreover, for rare developmental defects during embryogenesis, nearly 1 out of 4 records are classified as “unknown diagnosis”. It means that no diagnosis has been reached, which is a common occurrence for patients with multiple malformations, whose syndrome do not fit with currently delineated entities. It is less frequent for rare renal diseases where 1 out of 6 records remained however with a not yet identified diagnosis.

Other networks for rare diseases have been proposed. For instance, the European Society for ImmunoDeficiencies (ESID[7]) promotes research on causes, mechanisms and treatment of primary immunodeficiencies (PID) [7]. ESID developed an Online Database network for PID. The French National Immunodeficiency Centre, CEREDIH[8], belongs to this network.

RAMEDIS [8] enables reporting cases of rare metabolic diseases. It is a platform independent, web-based information system. Developed in close cooperation with clinical partners, it allows collecting symptoms, laboratory findings, therapy and molecular data. Comparing and analyzing data was made possible by the use of standardized medical terms and conditions.

The British Paediatric Orphan Lung Disease[9] (BPOLD) [9] was dedicated to nine rare lung diseases in children in the UK. This registry is oriented toward describing epidemiological data, prevalence and incidence of these rare lung diseases. It also informs on research projects in order to improve treatment strategies.

The Tumori Rari in Età Pediatrica (TREP) project [10] was launched in 2000. It is an Italian cooperative project focusing on rare pediatric tumors. It is oriented towards improving clinical management, networking professionals and stimulating basic research on very rare solid malignancies in childhood (annual incidence < 2/million). Though an electronic web-based data management system is not yet available, in the near future it will support this multidisciplinary experience, a network of professionals sharing a common structured framework including practical management schemes and research project.

Demand of care for rare diseases: patients’ expectations

The demand of care is multiple and complex as illustrated by two recent EurordisCare surveys which investigated patients’ experiences and expectations regarding access to diagnosis and to health services [11]. The results of Eurordis Care2 showed that much remains to be done. For instance, 1 patient out of 4 reported a delay of 5 to 30 years to a confirmatory diagnosis of their disease from the time of first symptoms; misdiagnosis was reported in 4 out of 10 cases; 1 out of 4 of patients had to travel to a different region to obtain a diagnosis. Genetic counselling was provided in only 50% of cases which is low since most rare diseases are of genetic origin.

Over the two-year period preceding EurordisCare3, in mean, a patient required more than nine different medical services (from 4 to 12, according to the disease). One patient out of 4 reported difficult or even impossible access to services. The greatest barrier in accessing essential medical services was a lack of referral. Three out of 10 respondents required the assistance of a social worker in the 12 months preceding the survey. More than one-third experienced difficulty or even failed

[9] http://www.bpold.co.uk/

to find such assistance. Twenty-nine percent of respondents reported a patient in their family had to reduce or stop professional activity as a result of their disease and an additional 30% of respondents reported one member in the family had to reduce or stop professional activities to take care of a relative with a rare disease. The majority of patients reported a reluctance of professionals to treat them due to the complexity of their disease.

Federating Reference centres

These two studies confirmed that a lot remained to be done. The offer of care has to be organized in order to match the demand. CEMARA faced this major goal. It appeared as an efficient platform to gather useful information to aid promoting a better identification of the demand of care, a necessary step to better adapting the offer of care. To date, the offer of care described by CEMARA shows that it covers 1 out of 3 departments for a demand for care which covers the whole French territory. Thus, much remains to be done to allow each patient to have an appropriate access to care.

Federating RCs in France is also an important challenge for reinforcing European Reference Networks. The Rare Disease Task Force[10] (RDTF) at the European level contributes to networking professionals through its two main goals:

- advise and assist the European Commission Public Health Directorate in promoting the optimal prevention, diagnosis and treatment of rare diseases in Europe, in recognition of the unique added value to be gained for rare diseases through European co-ordination,
- provide a forum for discussion and exchange of views and experience on all issues related to rare diseases.

The Alliance Maladies Rares[11], the Association Française contre les Myopathies[12] (AFM) or EURORDIS[13] strongly stimulate a better knowledge for rare diseases and attaining the most appropriate offer of care.

Conclusion

An information system shared by professionals appeared a valuable support to better matching the offer of care to the demand. In this perspective, CEMARA proposed a secured information system via Internet for rare diseases centres. The platform is now shared by 49 rare diseases centres in France. It helped networking health care professionals. They share a web-based secured beehive-like platform and a common ontology with Orphanet. It also helped initiating new cohorts of rare diseases for improving patient care and research.

Acknowledgments

The coordinators of the 49 centres who chose CEMARA for their information support are warmly acknowledged for their participation to the program as well as the members of all the centres. This work was granted by Paris Descartes University.

Abstract

Populations are under-served by local health policies and management of resources, partly because of a lack of realistically complex models to enable a wide range of potential options to be appraised. Rising computing power coupled with advances in machine learning and healthcare information now enables such models to be constructed and executed. However, such models are not generally accessible to public health practitioners because they do not have the requisite technical knowledge or skills. This paper presents a system for creating, executing and analyzing the results of simulated public health and healthcare policy interventions, which is more accessible and usable by modellers and policy-makers alike.

Keywords:

Computer simulation, Graphical models, Epidemiology, Medical economics, Public health, Decision modelling

Introduction

Long-term conditions, such as Coronary Heart Disease (CHD), consume the largest proportion of healthcare budgets, and are a major target for public health initiatives. Moving interventions up-stream to earlier stages of the natural histories of diseases would delay or prevent subsequent events, thereby reducing the amount of suffering over the average lifetime, and saving money. Health policy-makers and those planning and managing local health services are poorly served by over-simple estimates of the potential public health impacts of making changes to the pathways of care or taking preventive public health measures. These estimates are often unreliable [1], because the models do not adequately represent the complexity of the disease, population or care over time.

Population health impact estimation is usually done by a small group of analysts synthesizing evidence and producing a report for a decision-making team. For example, how should the balance be struck between investments in statins vs. smoking cessation vs. physical activity promotion in respect of health impact for a defined population over five years? There are three problems with this approach: a) there are not enough analysts to support current decision-making needs, yet the available data and literature to consider is increasing - it is unlikely that health systems could afford to employ more analysts, and furthermore they are in short supply; b) a static report does not enable 'what if' scenario planning, so the options that are appraised are inflexible; c) most healthcare commissioning groups do not have the skills or time to build realistically complex models which take all reasonable factors into consideration, so decisions may be biased by where a narrowly defined model focuses –this may reflect the interests of service providers more than the needs of the population served. It is possible to construct graphical models of disease and healthcare pathways, and to use the resulting probabilistic networks to simulate outcomes for populations. Such a simulation system would enable the user to compare different intervention scenarios, with the ability to modify both clinical and public health interventions, and measure both the effectiveness based on clinical outcomes and costs. Such a system could bring together public health professionals, clinicians and service commissioners in interactive scenario planning activities to inform policy decisions. The ideal system would enable users to construct and share models around 'what if scenarios' easily; to execute individual simulations quickly; and to interpret simulation results collectively. Larger simulations, in terms of the population size, provide greater accuracy but consume more computational resources. The construction of models requires collaboration between health economists, epidemiologists, biostatisticians and typical decision-makers/leaders (public health professionals, healthcare managers, and clinicians).

In this paper we report on the IMPACT system that has been designed to enable this approach, by bringing together model builders, model users and computational resources to participate in shared decision-making.

Background

CHD is one of the most extensively modelled diseases, so we chose it as the focus for designing a generic system for modelling health impacts in defined populations.

A recent systematic review [2] of cardiovascular disease policy models concluded that models vary widely in their depth, breadth, quality utility and versatility, with few models ade-

quately validated or replicated in different settings. Moreover, few were available for inspection or transparent enough to fully understand model methods and assumptions. As such, the strengths and limitations of most models could not properly be defined, therefore few were acceptable for use in policy making. Most recently, a model published by the English Department of Health to support cardiovascular screening is both over-simple and not transparent [3]. Out of 70 modelling attempts identified in this area fewer than 10% published a paper and almost none have survived for a decade or more.

The first IMPACT model [4], typical of those used in Health Economics, was based on simple Markov propagation and implemented in a spreadsheet with over 44,000 cells – it required extensive training of users and was difficult to deconstruct for validation. Here we report a new approach to IMPACT, separating the generic modelling challenge from its application to CHD. Furthermore we separate the computation of the model from interaction with users, and address the generic problem of simulating public health impact.

Research Aim & Objectives

The mathematical methods and computing technologies required to unify model building, and use are available [5]. The aim of this work was to harness the unified modelling methods for health policy making. The main objectives were: to develop a versatile, flexible, valid and credible quantitative system for executing population disease models; to provide a single framework for domain experts to collaborate on model design and validation; and to provide a decision support capability that enables health professionals to interact with the models.

Method

System Requirements and Analysis

Taylor-Robinson et al conducted a consultation exercise with policy-makers on their attitudes to modelling and simulation [6]. The findings of that research were used to inform our requirements for the system.

Versatile and flexible

Our principal objective is to provide a generic system for simulating public health interventions, enabling users to to ask, find and reuse 'what-if' questions about options for preventive and clinical interventions in a population's health. This can be contrasted with the prevailing use of bespoke models often implemented with spreadsheet applications. Consequently, the system must contain a generic execution engine, that can instantiate a given *model* and perform the simulation. To create models, a model design tool is required that guides the end user through model creation and ensures valid models are created. What constitutes a valid model is intrinsically linked to the design and implementation of the model execution engine. The model alone cannot be executed; it must be configured with additional parameters that define a *simulation*. Thus a simulation is the combination of the model and the data that characterises the population, the environment, and the interventions being considered. Therefore the system must provide a tool that enables users to define simulations for a given model. We must also consider what the system will be used for. The IMPACT system is intended for answering five types of question:

- How will the burden of disease change over time?
- What will be the impact of specific treatment interventions/technologies?
- What will be the impact of population level/public health interventions?
- In terms of life expectancy is prevention more effective than treatment?
- Are interventions targeted at high-risk groups more effective than whole population level interventions?

The system must provide a tool that enables the results of a simulation to be analysed and visualised, and for comparisons to be made between simulations.

Transparent

Transparency was identified as a key requirement for users to be able to trust and subsequently act on the result of simulations. By transparency we mean that the system must be open to inspection at all levels. Consequently:

- The system software must be open source. We have chosen the Artistic Licence 2.0. The source code must have companion documentation that describes its architecture, algorithms and implementation that is accessible from the system.
- The mathematics underpinning the models and their execution must be formally documented and accessible.
- For each model, the model builders are required to supply descriptive meta-data that describes the risk factors and disease groups; data sources and main assumptions; the relative risk reductions of interventions; the uptake (availability and adherence) of interventions; the nodes of the graphical model; the edges of the graphical model, defining transition probabilities between health states; the observable outputs of the model; and terminology.
- For each simulation, the system must enable users to inspect the configuration that defines the population & environment, and the interventions.

Accessible

To achieve wide spread adoption, access to the system must be as easy as possible for the end user. Thus we are delivering the IMPACT model as a web application that requires no end user installation, configuration or maintenance.

The user interface must be simple and intuitive to use. In order to achieve this different classes of user are defined in terms of their intended use of the system, such that the functions and features available in each user class provides a different view of the system. This enables the complexity of the system to be hidden from the user interface if it is not required. Basic users can execute simulations, compare simulations, and edit simulations (restricted to modifying population demographics and

interventions). In addition, intermediate users can create new simulations. In further addition, advanced users can edit models.

Usable for collaborative model creation and decision making

The development and validation of models requires collaboration between statisticians/modellers, epidemiologists and health economists. Health policy-making is also a multi-disciplinary process. Web-based social computing technologies are widely deployed and used across many different disciplines [7] for collaborative working. This again favours a web application such that a shared workspace can be created and technologies for storage, retrieval and search of work products can be leveraged. In essence the system must bring people, data and methods together if it is to meet our objectives.

Model and Execution Engine

In the IMPACT system a population is modelled and simulated through the use of a number of graphical models. A population model is used to generate incident patients from the general population; the patients are then consumed by the patient model that models the life course in the presence of specific disease(s) and treatments. The priorities for the population and patient side models are different, so different types of model are used. As the patient side is concerned with the healthy life years gained from treatment vs. cost, and as clinical trials study treatments in isolation from one another, strong emphasis is placed on modelling the combined effects of different treatments.

The population model employs a Bayesian network [8] and is restricted to categorical variables for tractability of computation. There is a single node for the general health state, reflecting different levels of health, and one for each of the disease states considered. There is a time period associated with these states, producing a probability distribution over the health state of an individual at a given time point.

The posterior distribution over the general health and the various disease state variables in the patient model, together with the population size, are used to sample incident cases for the subsequent time period. Any variables relevant to the disease course are included in the generated cases.

Interventions are added as variables. In the simplest case they will have just two states, 'yes' and 'no', indicating compliance (or not). The associated probability mass function will describe the probability of compliance. But as they are variables like any other, they can also be made children of variables, which are believed to influence compliance. Children of interventions need to have their conditional mass functions updated to reflect the presence of the intervention. In the simple case this means retaining the existing probabilities for the 'no' state of the intervention, and specifying a corresponding set of probabilities for the 'yes' state. It is a very flexible approach, with the graph structure implying exactly what information needs to be supplied with an added intervention. More importantly, the effects of multiple interventions are handled naturally by the causal structure, with no need to resort to simplifying assumptions.

The patient model is governed by another graph where nodes represent variables. Generally, there should be a node for each variable where a change in state will influence the likelihood of a change in state of another modelled variable. Thus it will generally contain a node for general health, and a node for each possible intervention. Interventions will generally have some influence on disease progression.

It is possible to adjust the parameters of the models to reflect external factors such as changes in the population (migration) or in prescribing/availability of treatments. Migration can be modelled by adjusting the population size of a model at, say, annual intervals, and/or by adjusting ancillary variables such as ethnicity. Non-prescription/unavailability of an intervention can be accommodated by making a suitable adjustment to the relevant survival densities for a simulated case (such that a transition from 'yes' to 'no' is made immediately, or a transition from 'no' to 'yes' is scheduled for some time well beyond death). Thus the various components can be part of a larger simulation environment. New interventions can be added easily, and the structures of the models dictate what accompanying information is required.

System Architecture

The system was designed around a number of architectural principles. In the interests of transparency open source technologies were used and the IMPACT system has Service Oriented Architecture to provide a clean separation between components with a view to minimizing the impact of future development and to enable scaling through flexible deployment across a range of hardware platforms.

The system architecture is composed of four components that work together to provide the capability to create and edit models, to create, store and retrieve simulations, to execute simulations and to analyze results. The presentation layer is a web application that provides the interface for users to interact with the system. Views are provided for model editing and for configuring individual simulations through intervention editors, adherence and availability editors, region editors and cohort simulation type that specifies whether the simulation is limited by population size or epoch over which the simulation should run. Users can therefore select an existing simulation to run, modify an existing simulation by changing its parameters, modify and existing model. User accounts and role-based access control is managed through the presentation layer component. Because the user interface requires a high degree of graphical interaction, the lack of consistent support for a common standard in web browsers resulted in both VML and SVG implementations to ensure the system works across the full range of modern web browsers. The *data management* component provides storage and retrieval services for models, simulations and results. The system domain model is defined via entities, each of which provides the definition of a domain object and, where applicable, mapping attributes that specify how it will be persisted within the database; therefore providing an abstraction of the logical data model from the physical one. The Hibernate framework is used to perform the object-relational mapping. Users can therefore select an existing simulation to run or modify an existing simulation by changing

its parameters or modify an existing model by retrieving them from the data management component.

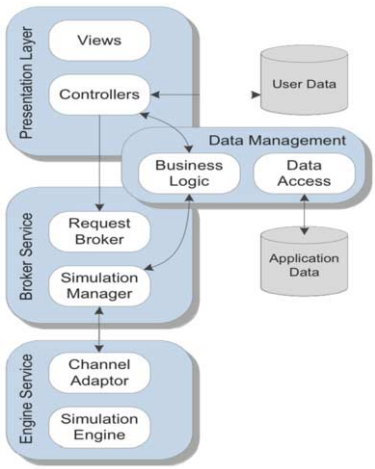

Figure 1-The IMPACT system architecture

The presentation layer interacts with the Request Broker Service (RBS) to execute a simulation. It uses the Data Management component to retrieve information required to configure simulations and to persist the results. The RBS is a client of the Engine Service, which it uses to set-up simulations, start execution and retrieve the results. The RBS is a web service and each RBS client is required to identify itself using an X509 certificate, which is validated by comparing it to existing client certificates held on the host. The use of X509 certificates enables the RBS to guarantee the integrity of the transferred data by including a digital signature in the request message. The Engine Service component is another web service that executes simulations and returns the results under the direction of the RBS. The engine service is composed of two sub-components. The Simulation Engine actually performs the simulation. Given a simulation configuration it instantiates and configures the model according to the simulation definition that it is passed. Once execution is complete, it returns the results. The simulation was developed primarily in Python with some mathematical functions written in FORTRAN. As the other components are developed in C# on Microsoft .NET technology this led to the decision to allow the Engine Service to execute on a different server from the Request Broker Service; it was therefore necessary to be able to configure a simulation and obtain results across a network. To support this, a *channel adapter* was developed for the Simulation Engine that exposes a web service interface to support both the configuration of a simulation, execution and the return of results based on the exchange of SOAP messages over HTTP. This architecture allows multiple Engine Services to be deployed to execute simulations, ensuring the future scalability of the system to many concurrent simulations and improving the tolerance of the software to problems such as hardware failures and network faults.

Results

The IMPACT simulator is deployed and available on the Internet at http://www.impactsimulator.org.uk.

Validation

The system has been tested by using it to implement and validate the IMPACT model of coronary heart disease.

The validation process is an integral part of model development. It helps in identifying issues with model implementation, data and assumptions. More important, it is a key element towards increasing the model value for policy makers. However, this aspect of model development has been frequently overlooked in cardiovascular disease modelling [2].

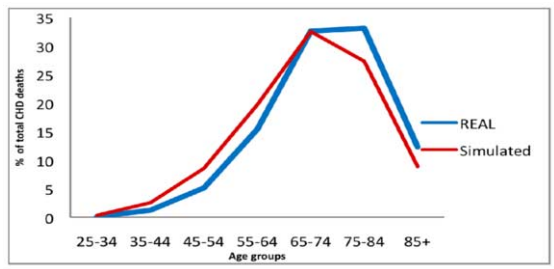

Figure 2 -Distribution of CHD deaths by age, simulated vs real

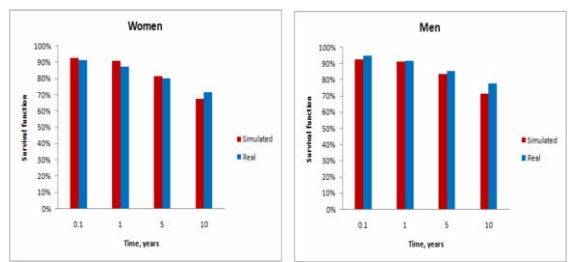

Figure 3 -Comparison of simulated and real survival functions at selected time in years, men and women.

We validated the model by simulating the SLIDE cohort, a cohort of survivors of acute coronary syndromes in Scotland [9]. Our aim was to reproduce with the model CHD mortality experience of the acute myocardial infarction sub-cohort. (n=80241). For this, we simulated a population with the same age and gender structure of the real sub-cohort, and enabling the simulation to take into account historically plausible treatments effects.

The model produces an age distribution of CHD deaths that resembles the real cohort (Figure 2), although it tends to overestimate the absolute number of events. This is probably related to the fact that the model cannot replicate the actual censoring that happened in the real cohort. Mortality calibration issues related to this particular population might be also relevant, as well as an underestimation of treatment effects, due to

lack of Scottish specific treatment uptake data for the period. The Kaplan-Meier survival functions generated by the model were similar to the observed ones (Figure 3). These preliminary results are encouraging. They demonstrate that the system is usable for model creation and execution and that the predictions of such models match observations. More validation work is needed, specifically regarding comparisons with different cohorts and populations. In addition, the validation process will offer valuable insights towards improving the model ability to produce more accurate estimates of the number of CHD deaths, data visualization and model functionality.

Figures 2 and 3 show close concordance between death rates simulated by IMPACT and those observed in a well-studied case cohort.

Discussion and Conclusion

The next phase in the evaluation will be to return to the community of planners and policy makers [6] to assess the usability, accessibility and utility of the system and the IMPACT CHD model. The usage and uptake of the system will be monitored, as this will be the key measure of success.

Future work is planned to parallelise the simulation engine to take advantage of multi-core and cluster computing. This will dramatically reduce the simulation run-time making the system more usable for complex models and large populations. The modular nature of the architecture enables the use of cloud computing infrastructure in the future.

The IMPACT simulator will be integrated into the nascent e-Lab population health information system [10]. This will leverage electronic health record data to refine, extend and localise models. The e-Lab platform provides the Work Object mechanism as a way of exchanging knowledge between federated e-Labs in different localities. The IMPACT Simulator already has the capability to export IMPACT Simulation Work Objects (ISWO) for a specific simulation, including information used to configure the simulation and the outputs from the simulation. As each simulation is configured based on evidence gathered from range of sources (including clinical trials and literary reviews) and makes use of specific statistical methods, the outcomes of each simulation can only be fully understood in the context of these methods and evidence. The ISWO provides a semantically unambiguous way to explicitly relate components of a simulation together along with statistical methods, decisions and evidence.

Unified modelling frameworks such as IMPACT may encourage epidemiologists, health economists and public health practitioners to contribute to open, accessible policy models rather than creating a blizzard of niche models.

Acknowledgments

This work was supported in part by the UK MRC IMPACT project and the NIHR CLAHRC programme.

A full-text information retrieval system for an epidemiological registry

Marc Cuggia[a], Sahar Bayat[a], Nicolas Garcelon[a], Lauren Sanders[a], Florence Rouget[c], Arnaud Coursin[b], Patrick Pladys[c]

Abstract

Case finding for epidemiologic registries still relies mainly on a manual process. In this paper, we show that retrieval information tools could be a complementary way to identify cases for a pediatric malformation registry. We developed a full-text and metadata search engine plugged to a clinical documents repository and used it to identify Epi/Hypospadia and Spina bifida cases. The queries were enriched with Snomed terminologies. We compared the performances of this prototype versus the hospital DRG database (classical method). The best precisions of prototype for identification of Spina bifida and Epi/Hypospadia were respectively 73% and 87%. The prototype overlap with the DRG system was 83% and 97%. Compared to DRG, 13 new not referenced and 2 miscoded cases were detected. This free full-text retrieval system prototype allows efficiently reusing clinical documents for case finding for an epidemiologic purpose.

Keywords:
Registries, Epidemiology, Information Storage and Retrieval

Introduction

The conventional method of case finding used by many institutions to feed an epidemiologic registry is still largely to manually scan and read printed reports or manuscript notes generated during the health care process. These documents are most of the time archived in the paper patient record. This task aims to identify cases in a comprehensive way. It is a painstaking, time consuming and costly work [1]. With the development of Electronic Medical Records (EMR), patient data are more accessible as ever, however these data remain widely coded as free text. Clinicians either dictate or type relevant patient data into the EMR without formal structure or a controlled medical vocabulary.

Coding information is difficult and the reasons why clinicians are so reluctant to do it are well identified [2]. So, clinicians still code little information, either because it's mandatory (e.g. for the billing process), or because they derive a direct benefit (e.g. in term of scientific research or patient safety). Hence, electronic free text medical reports are a mine of information for the registry feeding or cohort enabling, but they are also difficult to exploit. Numerous works have been carried out to develop NLP methods for automatically extracting information from patient data but they are still rarely applied outside of the laboratory [3]. An alternative way to achieve this goal is to provide to clinicians, information retrieval tools (that rely on methods of indexing, searching, and recalling data, particularly text or other unstructured forms). These tools, derived from the web technologies are today broadly used for searching accurate information amongst terabytes of data for personal information management as well as on the Internet (e.g. Google Desktop or Apache Lucene). Hence, "Finding a needle in a haystack" becomes a reality.

For example Schulz & al. [4] have developed a retrieval system to support search across patient discharge letters. They used a linguistic transformation method to deal with the morpho-semantic wealth of German language. They have shown the very good acceptance among the physicians of a WWW-like querying. Few works using these technologies have been carried out in the epidemiologic field. For example, Hanauer & al [5] have defined a custom-made list of terms, phrases and Snomed codes intended to build free text query. Their system was designed to populate a cancer registry database.

Rosier & al [6] applied regular expressions to extract relevant information from surgical reports in order to populate a cardiologic registry.

In this paper, we describe an information retrieval platform combining a searching engine "plugged" to a clinical documents repository automatically fed by our Hospital Information System (HIS). We study the performance of this retrieval system in order to identify cases for an epidemiological pediatric registry. We compare our searching method using free-text clinical documents and their related metadata versus a classical query method, based on the DRG (Diagnosis related group) coded database. We study also the interest in our system of using SNOMED (versions 3.5 and CT) terminologies for a semantic enrichment of the full text queries. As the coverage of the DRG coded database is structurally lower than our EMR repository (as it concerns only inpatients) we measure the added value of our system to identify cases that are not reachable through the DRG coded system.

Materials and Methods

The pathologies studied:

This work fits within a broader feasibility study for the future neonatal malformations registry of Brittany (France). This study focuses on Epi/Hypospadia, Spina bifida malformations.

According to the MeSH definitions, Epi and hypospadia *are* birth defects due to malformation of the urethra in which the urethral opening is below its normal location. Spina bifida is a congenital defect of closure of one or more vertebral arches, which may be associated with other malformations.

Population of interest:

We searched cases amongst children aged 1 year old or lower, born between 11/1/2006 and 11/1/2008, and who had a contact with the University Hospital of Rennes until March 1rd 2009.

System design:

We developed a repository containing the medical reports corpus extracted from our HIS (see Figure 1). The repository is automatically fed by an Extract Transform and Load (ETL) process. ETL is a process in database usage and especially in data warehousing that involves: Extracting data from outside sources; transforming it to fit operational needs (which can include quality levels); loading it into the end target. Each document extracted from the EMR is associated with a XML notice containing all the relevant metadata available from the EMR such as patient information (birth date, sex, weight) or administrative information (such as ward id, dates of admission and discharge). Then the documents and the XML notices have been indexed. We used Apache Lucene [7] as the indexing and search engine tool.

Lucene is an open-source, high-performance, full-featured text search engine library written entirely in Java. It relies on the tri-grams indexing method, allowing phrases, wildcard and proximity queries and returns ranked search results. All the developments were based on web 2.0 technologies (PHP, Ajax). The system provides statistical analysis: e.g. occurrence of expression present in each document, and in the whole corpus. Accessing the document is immediate, and the searched expressions are highlighted in the text to make the reading easier (see Figure 2).

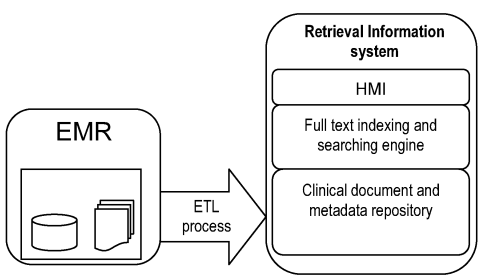

Figure 1-System design

Free Text queries building:

For each pathology, we asked 2 experts (a pediatric surgeon, and a pediatric physician) to provide ten of the most meaningful literal expressions usually employed in clinical notes and that characterize these pathologies. In order to avoid a too high level of noise, a third expert split these expressions in two sets:

The "Major set" consists in expressions relative to the diagnosis and a procedure used in these pathologies (e.g. "neural tube defect" or "myelomeningocel" for *spina bifida* malformation).

The "Context set" corresponds to expressions not directly explicit, but used often with one or more major expressions: for example the anatomical term "penis" or "prepucial" for *Hypospadia* malformation.

As a registry is supposed to be exhaustive, we tried to semantically enrich the expressions given by the experts, by building the "extended major set" containing expressions with synonym and subsumed terms found both in Snomed (version 3.5 and CT). Amongst these candidate terms, we selected only those containing any redundant terms (regarding to the other expressions) e.g: for *spina bifida,* [76916001:Spina bifida occulta] was ruled out, [61819007:Rachischisis] was ruled in.

Then, for the two pathologies, we built 6 queries, combining with Boolean expressions the expressions from respectively the Major set, Context set, and Extended Major Set.

In order to avoid searching in the narrative text different morpho-syntactical forms of a same expression, we transformed them in morphemes. Below is an example of full text query for *spina bifida*. The contextual expressions are underlined.

Expert expressions : *Spina bifida, myéloméningocèle, méningocèle, Fermeture du tube neural, syndrome d'Arnorld Chiari, paraplégie, agrandissement de vessie, cystosomie continente, intervention de Mitranoff, intervention de Malone, sphincter artificial.*

"Major set" query :*(spina) (bifida) (myelomeningocele*) (+fermeture +tube +neural)(meningocele*)*

"Context_set" query:*(+Arnold +chiari) (paraplegie)(+agrandissement +vessie)(cystostomie continente) (mittranoff)(malone)(+sphincter +artificiel)*

"Extended set" query: *(spina) (bifida) (myelomeningocele*) (+fermeture +tube +neural)) (meningocele*) (+rachischisis +aperta) (syringomyelocele*) (meningocele*) (meningomyelocele*) (myelocystocele*) (hydromeningomyelocele*) (+hydromeningocele* +spinal) (+spina +fissure*) (hemimyelocele*) (lipomeningocele*) (rachischisis) (holorachischisis*) (myelocele*) (hydromyelocele*).*

Assessment:

We compared the outcomes of the full text method with the information available in the DRG system (called the PMSI in France). The PMSI aims to provide medico-economic statistics for the hospital budget.

As the PMSI information is supposed to be exhaustive, we used it as a gold standard. It contains the entire coded discharge summaries for all inpatients. Each summary is coded

with ICD10 diagnosis and CCAM procedure classifications. In French hospitals, this coding concerns only inpatients. In our hospital, this coding is centralized and manual. We searched all the patients having a coded discharge report in the DRG System, with ICD10 codes relative to one or more of both pathologies studied.

DRG query building:

For each pathology, a DRG expert selected the codes from ICD10. Two medical experts reviewed these codes. Then we queried the DRG database, using SQL language. For example, the query for spina bifida concerned all the codes starting by *Q05*, which includes of course *spina bifida*, but also codes detailing specific anatomical types e.g : *Q05.1:Thoracic spina bifida with hydrocephalus, etc.*

Comparison method

Two authors reviewed manually each case found by the two searching methods. We searched for the wrongly coded cases and looked at the pertinence of the expressions found with the search engine. For example, for the free text, if the expressions were used with negation, or written in the list of familial histories, the case was considered as False Positive (FP).

For the DRG coded query method, we checked if the DRG were in adequation wih the content of the medical record.

We tried to figure out the reason of non-agreement between the both methods: if for example a case was found by the ICD10 method and there was no track of information of this diagnosis in the medical record, then we considered the case as being "wrongly coded" and false positive.

We also characterized the contributions of the extended set. For each query, we calculated the percentage of added cases owed to the Snomed enrichment.

In France, the coverage of the DRG system only concerns the inpatients. As our clinical documents repository gathers inpatient and out patient's medical reports, it represents a source of information broader than the DRG, and contains potentially precious information about newborns who have been seen only in consultation. Therefore, we measures the number of cases we spotted with our system and amongst them, the number of cases that are true and false positive.

Results

Information sources features:

The clinical reports repository contained 787.000 documents such as surgery reports, clinical notes, or discharge summaries. A subset of these documents, corresponding to the period of study was selected thanks to the "birth" metadata extracted from the HIS. This subset contained 16.512 documents . The full text queries have been applied on this corpus. The run time to queries never exceed 6 seconds.

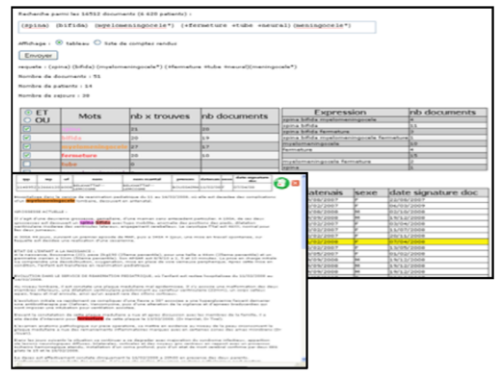

Figure 2-Screenshot of the Retrieval Information System

Cases found with the full-text queries

For the *spina bifida*,
With the "Major set" query, using only the expression given by the two experts, we found 51 documents related to 14 different children and corresponding to 38 contacts in the hospital (in and outpatients). Among them, after checking each document, it turned out that 11 cases were true positives (precision = 73%) i.e. patients for whom there was one or several reports containing an explicit reference to spina bifida. 3 cases have been considered as false positives (FP) and corresponded to the use of related terms in the familial history section of the documents.

The "extended set" query contained 14 supplementary expressions derived from the Snomed terminology but none of these expressions has been found in the reports. So the cases found with the "extended set" query were strictly the same as for the "Major query".

The "context set" query which contained "major" and "contextual" expressions, returned 65 documents related to 20 patients for 47 hospital contacts . Obviously, these results included the cases of the "major set" query. The six new cases were actually five false positive, so the precision was 55%: for example , documents for three cases containing the expression "Malone" which is both the name of a surgery procedure, and the first name of the three patients; one case related to a paraplegia thought it was not caused by a spina bifida. One case corresponded to the maternal familial history, another case was considered by the physicians as a possible spina (a MRI was ordered to confirm the diagnosis), but we didn't consider this case as true positive.

For the epi/hypospadia, with the "Major query", we found 318 documents related to 116 different children and corresponding to 274 contacts in the hospital (in and outpatients). Among them, after checking each document, it turned out that 102 cases were true positives (precision= 87%). 14 cases have been considered as false positives (FP). In 4 cases, we found a negation associated to the expression (e.g : "*no argument for an hypospadia*"), 6 cases were related to an abnormality of the penis with close similarity with an hypospadia (e.g : chordee is a condition strongly associated with hypospadia) but, eventually, the surgeon or the pediatrist did not consider that this

was an actual case of hypospadia. Two cases were related to a penis surgery, but for another problem. Two case contained "hypospadia" in the familial history section. Let's note that we only found one case of epispadia (this pathology is very rare).

The "Context set" query has brought out 45 FP cases, 95 % concerned another diagnosis, 5% a normal clinical exam.

The "Extended set "query (with Snomed) for this pathology was exactly the same as the expert's one. Indeed, after having applied the non-redundancy rule (defined in the method), no new expression was found.

So, for both pathologies, the method using the Major set query (i.e. using only the expressions given by the experts) turned out to be the best one.

The "Extended set" queries gave the same results either because the added expressions were not present in the clinical reports, or because, according to our method of semantic extension, no new expressions were added in the query.

Concerning the "context set" query, for both pathologies, the new generated cases were only FP that is noise.

Comparison with the DRG system

We compare here the best method (i.e. "the major set" using only the expression provided by the experts) versus the DRG query method.

In order to analyze comparable populations, we only consider the hospitalized patients (inpatients).
We calculated the number of patients corresponding to the following sets (Figure 3 illustrates the relationships between these subsets):
Set A =C+D: cases retrieved by the full-text method amongst the inpatients
Set B =C+E: cases retrieved by the DRG methods
Set C: cases retrieved by both DRG and full-text methods
Set D: cases retrieved amongst the inpatients and only by full-text but not by DRG method
Set E: cases retrieved only by the DRG method
Ratio C/B: % of coverage of full-text / DRG method

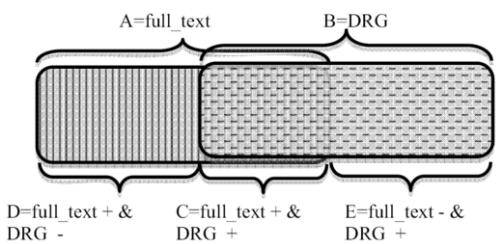

Figure 3-Set definition

The results (in number of patient terms) are presented in the following table for each pathology. The number of true positives and false positives are given for the discordant sets (sets D and E)

Table 1 -Comparison of full text vs DRG searching methods for spina bifida and hypospadia.

Sets	Spina bifida	Hypospadia
A	10	98
B	6	88
C	5	85
D	5 (3TP and 2 FP)	13 (9 TP and 4 FP)
E	1 (1 FP)	3 (2TP and 1FP)
C/B	83%	96,5 %

Concerning the set D *(full text + and DRG -)* and for both pathologies, our system found 12 new true positive cases. These cases weren't retrieved in the DRG database, because they were either not coded, or the DRG summaries didn't contain any code relative to the malformations.
Inversely, our system found 6 false positive cases. The reason was the same as the one quoted above (e.g.: expressions associated with a negation, or found in the familial history, etc).

Concerning the set E *(DRG + and full text -)* and for both pathologies, the DRG method found 2 True Positive cases. It turned out that these cases were coded from manuscript notes, or from the paper-based medical record, so no electronic clinical document about these children was present in the hospital information system.

Inversely, 2 cases were false positives and where clearly due to miscoding.

Added value of the full text method:

Compared to the DRG system, which is focused only on inpatients population, our system, gives in addition access to the outpatient population. The new cases found from this population are summarized in the following Table 2.

Table 2-New cases found with the Full text method from the outpatient population.

	Cases found from outpatients population	TP	FP
Spina bifida	2	2	0
Hypospadia	19	13	6
Total	21	15 (68%)	6 (27%)

Discussion

Our system aims to help researchers retrieve relevant information amongst a huge number of documents. The results are quite good according to the very good overlap between the full-text and the DRG coded sources (83% to 96,5%).

As we dealt with very rare pathologies, we were not able to calculate classical measures of the search engine efficiency (especially recall, Fall-out or F-measure). Indeed, this would have supposed to check a documents sample large enough for containing a significant number of cases, i.e. probably an enormous sample. For this study, we used the same methodology as Li and al. [8] who had carried out a similar study for searching eligible patients for clinical trials.

As the related previous study carried out by Moskovitch and al [9], our outcome tends to show clearly that a combined strategy, using both full text and structured methods, can improve the search of clinical cases for epidemiologic registries. Indeed, the use of the "birth date" metadata for selecting a subset of the clinical reports has clearly helped us to define a context (newborns aged =< 1 year old). This first selection allowed avoiding the adult cases. We plan to include in our system more metadata or structured information in order to reinforce this mechanism.

The noise is the main problem of the full-text searching method. We got a low noise level, probably because the expressions used in the queries were very specific and because we had started by selecting a subset of documents, using the metadata extracted from the HIS.

We assumed that the semantic enrichment of the queries could improve the search of news cases. It seems here that is not the case. The expressions given by the experts were sufficiently comprehensive and specific. Despite this, a terminological system could be useful to help users for designing queries, especially if the user is not a domain expert.

Unlike Moskovitch [9] we didn't find better performance by adding contextual expressions to the queries. On the contrary, these expressions have caused noise.

We were rarely confronted with lexical variations, even if the step of morphemes transforming was manual. Our system could certainly be improved by reusing methods [4] of automatically transforming natural expressions into "sub words" (or lexical units) straightly useable by the search engine.

Finally, from a technical point of view, we were careful to take into account the usability of the system. The system was developed with the Web Ajax technology and so allowed to improve the system accessibility while keeping good ergonomics, as it has been already shown [10].

For example, users could instantly open the reports and check their pertinence at a glance (the keywords were highlighted like Google cached pages [11]). Statistics were also very useful to assess if the query or a document was relevant.

We designed the system in order to be integrated to the HIS but we deliberately chose to build an independent data repository for several reasons.

First, querying such a huge set of documents would be overloading the HIS if the search engine was directly connected to it. This would compromise the health care process in an inacceptable way.

Second, we wanted to control the ETL process, which is a critical step in data warehouse building. Indeed, some information has to be cleaned or corrected before loading (e.g.: outliers, birth date, missing data, incoherent identities).

Third, we can consider extending the repository to other data sources (such as biologic tests or genomic data) and for other purposes such as searching patients eligible for a study.

Conclusion

This prototype allows to efficiently reuse clinical documents for case finding for epidemiologic purposes. As a perspective, we plan to create a regional repository that gathers information from different HIS.

Acknowledgments

We thank Delphine Rossille, Denis Delamarre, Laure-Anne Haumont, and the "Réseau Périnat 35" members for their inestimable help.

Obesity Atlas and Methodbox: Towards an Open Framework for Sharing Public Health Intelligence Workflows

Sarah Thew, Paul Jarvis, John Ainsworth and Iain Buchan

Northwest Institute for Bio-Health Informatics, School of Community Based Medicine, University of Manchester, United Kingdom

Abstract

The large growth in data sources relevant to public health has not been matched by a growth in human resource for producing intelligence to support decisions or generate new insights. There is a need to bring scarce public health expertise into closer alignment with data and data processing methods to support timely public health analysis. The difficulties of developing and sharing this expertise in large organisations such as the UK's National Health Service have long been recognised. We report findings in this area across two projects Obesity Atlas and Methodbox, which are developing and sharing best practice between Public Health Analysts in England, and we address the relevant generic knowledge management problems in the Public Health community.

Keywords:

Public health intelligence, Workflow, e-Lab, Knowledge management

Introduction

Most public health analysis in England takes place in Primary Care Trusts (PCTs), which are responsible for commissioning health services for populations of around 300,000 people. Each PCT employs analysts who collect and analyse local and national health-related data to support local decision-making. Analysts from the different PCTs belong to informal public health intelligence networks which meet regularly to exchange ideas and share expertise. They also communicate by frequent ad hoc telephone and email conversations.

Despite regular communications within and between PCTs' analysts, we identified substantial difficulties in finding information for particular analyses in a timely manner. For example, analysts reported issues such as the difficulty of locating an email sent a year ago which discussed the calculation of an annual statistic, or uncertainty around deciding how and when to apply different versions of a method. All of these difficulties can be characterised as knowledge management problems. The term 'knowledge management' refers to a broad group of activities around the creation, sharing and adoption of expertise and understanding. Knowledge management looks beyond the sharing of information (e.g. the definition of a statistical method) and considers the experience and tacit knowledge required to make use of the information, such as how and when to apply the method, or who is the relevant local expert. Such knowledge, often tacit to individuals or teams, can be difficult to transfer to new staff and is easily lost to an organisation when people move to new jobs. This folk knowledge (making connections, shared learning through problem solving) is often highly contextual and held only in people's minds or reflected in e-mails or informal communication channels such as forums or instant messaging – ideal for supporting the processes of knowledge exchange and problem solving, but poor long term repositories, which cannot be searched and cannot generally provide reliable, accessible context data.

Bate and Robert's review of knowledge management practices in the UK National Health Service (NHS) [1] compared the relative maturity of private sector companies with what they describe as a 'naïveté' around knowledge management within the NHS. In particular, they observed a policy of 'top down' imposition of networks intended to support the sharing of best practice and expertise which was considered unlikely to be successful or self sustaining, and contrast this with a recent change of approach within the private sector to support more organic, grass-roots knowledge sharing activities and naturally-occurring networks

Previous reviews of knowledge management practices in the NHS identified successful approaches as well as pitfalls. The CHAIN (Contact, Help, Advice and Information Networks) project [2] succeeded in fostering the development of a community, and helping users find people with particular areas of expertise. This study highlighted the importance of the social dimensions of knowledge management – whilst there was a technical element (the development of a messaging system), the success of the project depended on vigorous facilitation by an email list administrator, who created new connections between pre-existing groups.

Studies of knowledge management have tended to focus on technologies for storing knowledge [1]; there have been few in-depth case-studies of the human factors and the wider processes of managing knowledge. Storey [3] observes that often, there can be too much focus on the technology, a sense that if only the right technology is in place, people will be able to make use of it, but this has repeatedly been shown not to be the case – successful knowledge management projects build on existing networks. Consequently, we report the engineering of

two pieces of knowledge management software as extensions of a user community, involving users from inception.

Obesity Atlas

Like many western countries, for more than half a century, the UK has recorded the heights and weights of children in order to monitor their growth [4]. More recently these data have been used to produce public health reports for obesity surveillance and local planning [5]. The Obesity Atlas project aimed to develop software to automate the cleaning and analysis of these data.

We identified a number of knowledge management requirements. First and foremost was the need to support a disparate group of Public Health Analysts, from different organisations and backgrounds, to converge on a single workflow for data cleaning & analysis and interpretation of the resulting child obesity profiles for their localities. The analysts work independently in separate geographic areas and are used to determining their preferred analysis approach in isolation. Whilst there were aspects of the workflow on which it was easy to reach a consensus (e.g. which summary statistics to use), other steps were more ambiguous (e.g. handling missing and possibly erroneous data – some analysts may choose to exclude records with any missing data, other analysts may decide to keep those records depending on exactly which fields are missing, or alternatively may choose to go back to the data supplier for clarification). Therefore agreeing a shared workflow for such decisions requires the analysts to negotiate and share their tacit knowledge. In other circumstances, rather than working with the analysts to agree a common workflow, the system has been built to provide some flexibility, for example providing obesity profiles based on different definitions of child obesity.

We used a variety of requirements-gathering techniques to facilitate this negotiation process, including group discussions and meetings, one-to-one formal meetings, informal telephone conversations, and workshops allowing users to interact with prototypes. The use of prototypes was particularly successful, users were able to respond to and interact with simple prototype versions of the software. This interaction encouraged and inspired participants to discuss additional functionality that was incorporated into the system.

The analysts identified two workflow types, data pre-processing and data querying. The data pre-processing workflow included data categorisation, cleaning, standardisation and integration. Once uploaded and pre-processed, the dataset is ready to be queried. There were four functional types of data query: statistical analysis; thematic mapping, charting, and locality profiling. The latter is a context-specific superset of the former three.

The most sophisticated query was the locality profiling in the context of creating a consistent PCT-level profile of child obesity. A profile is a document resulting from a series of data queries. The profiles summarised child obesity statistics for the PCT in a standard format that could be compared with other PCTs. It also compared obesity prevalence by socio-demographic groups and geographical areas within the PCT. Thematic maps showed the spatial distribution of obesity; and charts and accompanying statistical modelling results reflected relations (or not) of obesity with deprivation, ethnicity, or other groups specified by the user. The profile is produced automatically following the upload of a dataset, saving each analyst several days of work, and provided to the user as a downloadable document of approximately 30 A4 pages. Again, the content and format of the document was designed in consultation with the PCT analysts. The document was designed such that components can be extracted and reused in official public health reports. An example component (a thematic map) showing the relative levels of child obesity within Bury PCT sub-regions is shown in Figure 1.

Obesity Atlas V1.0 has been released and is being used by public health decision makers and data analysts across the 10 Greater Manchester PCTs; it is informing their decisions on local public health policy to monitor and reduce childhood obesity[6, 7]. Early feedback is very positive and ongoing improvements and support will be delivered by the Northwest e-Health programme[8], which is set up to sustain health informatics innovations as reliable services for the NHS.

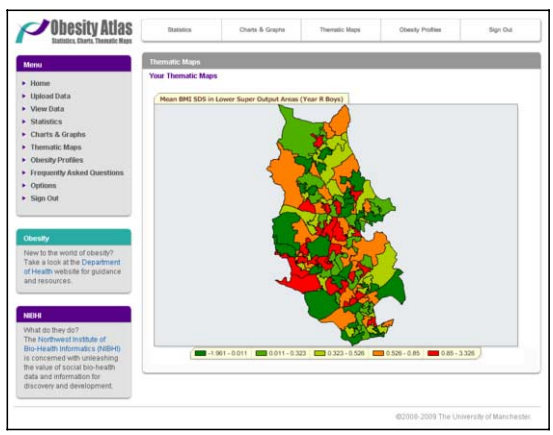

Figure 1- Thematic mapping in Obesity Atlas

The Obesity Atlas project is an example of combining the expertise and knowledge of many public health analysts to converge on an agreed workflow and produce a piece of software that dramatically reduces the burden of analysis on the PCT staff. From a knowledge management viewpoint, the process has enabled a group of experts to work together, sharing their tacit expertise to agree on a set of best practices for this analysis process, which have then been automated. This expertise has now been captured, holding it within the organisation, so that if any of the analysts involved in the project were to leave, the relevant organisational memory would persist.

Methodbox

Our team is now working on a project which takes a wider view of analysts' working practices. Rather than focussing on one single workflow, the Methodbox project [9] looks at supporting PCT analysts and academic researchers in sharing

analysis expertise and methods – applied in the first instance to large health surveys. Methodbox draws on the experience of managing knowledge in e-Science settings, particularly on sharing workflows and using social networking technologies to share expertise [10]. The initial motivation for the project was the recognition that understanding the obesity epidemic at the population level requires expertise from disparate disciplines including medicine, biology and the social sciences, as well as the involvement of academic and NHS researchers – experts who are interested in learning from other disciplines but who find accessing another field challenging for numerous reasons including language, methods, tacit assumptions and background to the work.

The first stage of our project was to interview NHS analysts and academic researchers who either currently use or have expressed an interest in using Health Survey for England (HSE) [11] in order to understand current working practices and barriers to use of the survey. HSE is the largest scale annual health survey in the UK and is intended for both health policy and scientific purposes. Its datasets, although freely available, are complex and perceived to be under-used. We held two workshop sessions at regular meetings of North West England Public Health Analysts, followed by longer interviews with three volunteers. We also interviewed five academic users of HSE, three epidemiologists and two social scientists.

Many of their concerns relate to problems accessing expertise and knowledge about the specifics of how to work with HSE. The most frequently cited reasons for not using existing data were methodological concerns over how to go about using the data, for example understanding the circumstances in which to apply weightings to a survey – tacit expertise that is not easily codified into clear-cut rules. Interviewees also reported being overwhelmed at the size of the dataset, difficulties working with the documentation and a lack of worked examples. Similarly, whilst the expert academic users we interviewed had developed coping strategies for many of these problems, novice academic users also felt the lack of examples and found the size and complexity of the survey and metadata problematic. They were equally unsure of how to access expertise.

These concerns have informed the design of Methodbox. Methodbox provides tools to support the individual in working with HSE data, including improved metadata searching and the ability to download selected slices of a survey rather than entire datasets, but also provides support for collaboration and networking in order to address many of the knowledge management concerns expressed by the analysts. Methodbox allows users to share their expertise with other analysts, whether that be a comment about a variable, a script demonstrating how to harmonise educational variables across several years or a publication they have used, but it does this in a rich context specific way, creating links between the data, for example:

- An analyst's comment about a variable is associated with that variable, so that any search returning the variable will also display the comment to other users. A second user can react to the comment, adding their experiences or suggestions.
- When uploading a harmonisation script the user can link the script to all the survey variables used within that script, providing a rich example for other users. Another analyst who refines the script can upload a new version, linking back to the original script and adding comments to develop the discussion.
- A user can upload details of a publication, perhaps providing evidence in support of a method they have chosen to use, or uploading their own publication, and associating it with a script and a set of variables, used in generating the published results.

Thus Methodbox allows users to interact with each other, in an environment that supports richly contextual information sharing, and allows the searching and indexing of content.

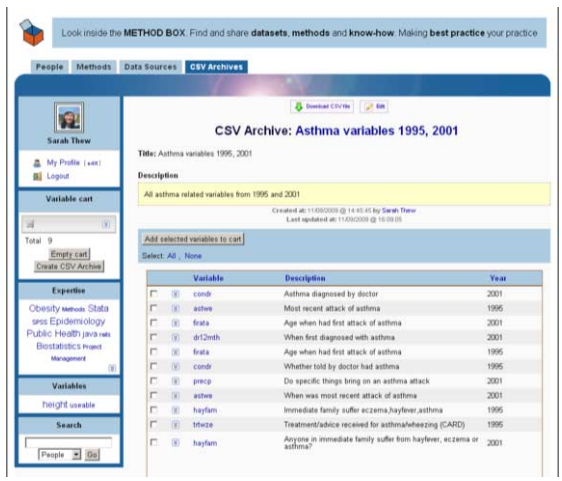

Figure 2- Methodbox Prototype showing a selection of asthma related variables collated by a user from Health Survey for England 1995 and 2001

A prototype system has been developed which is being tested with academic public health researchers and NHS analysts. Based on the experiences of other relevant knowledge management projects we are focusing on building existing communities [12] by working alongside NHS Action Learning groups, PhD supervisors & students, and topic-specific research groups. We believe the system will encourage wider sharing and improved communication between different communities. Whilst a social scientist and an epidemiologist, both interested in public health issues around obesity, may superficially appear to have much common ground, the methods, language and tacit assumptions underlying their analyses can be quite different. Methodbox aims to bridge the division of knowledge that results from this specialisation by providing rich, worked examples of analyses from different disciplines.

e-Labs and Work/Research Objects

The Obesity Atlas and Methodbox activities feed into the general e-Labs initiative, focused on healthcare by NorthWest

e-Health [8]. An e-Lab is a set of integrated components that, used together, form a distributed and collaborative space, enabling in-silico investigations. An e-Lab brings together data, methods and people sharing a currency of Work Objects (digital resources encapsulating the inputs, processes and outputs of an exploration or problem-solving activity). In the e-Science context a Work Object (WO) is known as a Research Object. A WO is an entity that an e-Lab: creates, stores, accesses and manages; exchanges with other e-Labs; publishes to external sites, deposits in external resources; and displays through work- benches. The motivation behind WOs (and the associated services that produce and consume them) is to improve the curation, accessibility and repeatability of research and business intelligence processes. A WO might be:

- A template equity audit containing a collection of workflows with instructions, examples with default input data, a tutorial and links to external learning resources on the methodology;
- A reproducible research article with the workflows and data required to reproduce the results described in the article.
- A reproducible and easily repurposed annual public health report containing: the report and supporting files such as slides, spreadsheets and graphics; commentary around the report such as copies of emails and press releases/articles; pointers to data sources and extracts used in analyses; data extraction, cleaning, derivation and statistical analysis workflows behind the analyses; bibliography; project management resources.

From a knowledge management perspective, WOs address the concerns that: knowledge is heavily context dependent; and knowledge-transfer relies on common ground.

Research/experimental/business intelligence knowledge depends on context, making it's codification and exchange difficult [12]. Some redundancy of knowledge between two parties is necessary for knowledge transfer to take place [13], without any overlap it is almost impossible for anything but the most basic information to be transferred. WOs can provide the rich context and common ground necessary to take, for example, a method beyond a flat set of instructions, to provide worked, interactive, re-playable examples – the learner can interact with the research object, changing parameters, supplying new raw data, and learning by doing.

A case study by Quintas [12] observed that rigid formal reporting and recording of progress, without a social dimension is not an effective way to transfer knowledge. There is a requirement for joint activities - "working together and gaining shared experiential knowledge", WOs provide an alternative way to support collaborative working and, longer term can provide rich examples for teaching.

Conclusion

Obesity Atlas demonstrated the need for combining related public health intelligence tasks into workflows that result in near-complete reports. Methodbox demonstrated the need for a generic framework for finding, sharing and reusing public health intelligence workflows – with an initial focus on the under use of large-scale, general health surveys. The UK NHS is using the NorthWest e-Health programme to harness e-Science activities such as these into a generic framework, e-Lab, for combining data, methods and people more effectively – to produce more health intelligence from the same number of analysts.

WOs and e-Labs, however, are not familiar concepts to most public health analysts. Adoption will require technical and cultural change; change to working practices, as well as assumptions about what it is preferable to share or keep confidential. Obesity Atlas and Methodbox provide steps towards public health e-Labs. Obesity Atlas provides an example of a single packaged reusable workflow, and Methodbox encourages the sharing of methods and expertise.

The next steps include developing knowledge management practices alongside the e-Lab software by embedding e-Lab development in the continuing professional development of public health practice and science. For example, action learning groups in healthcare organisations can produce and use WOs as learning materials as well as operational tools. Continuing professional development credits could be earned by users transforming WOs in ways that demonstrate key competences. The provenance and audit services of e-Labs are easily harnessed for this purpose. These services are essential for the information governance required by healthcare organisations. As WOs contain rich contextual metadata, an e-Lab is a context-specific alternative to (or extension of) a conventional file store – in this respect organisational memory is increased by keeping work as WOs rather than separate files.

e-Lab could also be used to engineer the reward environment for working across organisations and disciplines. For example, a Social Scientist could demonstrate the impact of his/her method for measuring material deprivation by showing the consumption of a WO they produced as a template for this methodology. Given that such environments are increasingly global, e-Lab could be a step towards international interoperability of public health intelligence. Given also that future healthcare is likely to be more model-rich [14], clinical decision-support and public health intelligence may need to interoperate in a similar way.

Acknowledgements

The Obesity Atlas project was jointly funded by the ten Greater Manchester Primary Care Trusts.

The Methodbox project was funded by the *Economic and Social Research Council* under the *National Centre for e-Social Science* programme.

Abstract

Bacterial antimicrobial resistance in both the medical and agricultural fields has become a serious problem worldwide. Antibiotic resistant strains of bacteria are an increasing threat to human health, with resistance mechanisms having been described to all known antimicrobials currently available for clinical use. Monitoring the geotemporal variations of antibiotic resistance pattern is crucial factor in planning a successful therapeutic guidelines preventing further emergence of antibiotic resistance. This study is based on the retrospective spatiotemporal analysis of laboratory results of Antibiotic Sensitivity Tests, time stamped with the date and time of the microbiological specimen dispatched to the laboratory. Geographic location of the isolated bacterial colony is specified with the latitude and the longitude of the patient's location. Agglomerative Hierarchical Clustering was performed on antimicrobial resistance findings based on the geographic locations generating series of Heatmaps to visualize the extent of the resistance pattern. Sequential Hierarchical cluster analysis was proven to be effective in visualization of antibiotic resistance using Heatmaps demonstrating the temporal variations of the antibiotic resistance patterns.

Keywords:

Antibiotic sensitivity test, Antibiotic resistance, Spatiotemporal pattern, Cluster analysis, Agglomerative hierarchical clustering, Geographic information system, Heatmap.

Introduction

The emergence of antimicrobial resistance is neither an unexpected nor a new phenomenon. It is, however, an increasingly problematic situation due to the frequency with which new emerging resistance phenotypes are occurring among many bacterial pathogens.

Over the past 6 decades, the introduction of new classes or modifications of older classes of antimicrobials has been matched slowly but surely by the development of new bacterial resistance mechanisms, [1].

Antibiotic Sensitivity Test is the investigation carried out to determine which antibiotic will be most successful in treating a bacterial infection in vivo. Testing for antibiotic sensitivity is often done by the Kirby-Bauer method, [2] where small wafers containing antibiotics are placed onto a plate upon which bacteria are growing. If the bacteria are sensitive to the antibiotic, a clear ring, or zone of inhibition, is seen around the wafer indicating a poor growth.

Numerous retrospective and prospective studies have demonstrated that increases in antimicrobial resistance occur among both pathogenic and commensal bacteria after introduction of an antimicrobial agent, [3]. Infections caused by resistant bacteria have been shown to be more frequently associated with increased morbidity and mortality than those caused by susceptible pathogens. The emergence and dissemination of bacterial antimicrobial resistance is the result of numerous complex interactions among antimicrobials, microorganisms, and the surrounding environment including geographical location and population dynamics.

There are considerable variations in the antibiotic susceptibility of clinically important bacterial strains based on the geographical distribution of hosts, [4, 5] and exposure to environmental factors over a period of time, [6].

Geographic information systems (GIS) and analysis based on GIS has become widespread and well accepted tool in the field of medicine as well. Geographic information systems are an important way in which to better illuminate how humans interact with their environment to create or deter health, [7]. Recent advancements in the analysis of disease maps have been influenced by and benefited from the adoption of new practices for georeferencing health data and new ways of linking such data geographically to potential sources of environmental exposures, the locations of health resources and the geodemographic characteristics of populations, [8].

It was shown in relation to some bacterial strains that the geographic maps of antibiotic resistance can be used to guide physician antibiotic selection before culture results are available. This has significant implications for the health care provider in proper antibiotic selection within the community minimizing the treatment failures and emergence of new, drug resistant bacterial strains, [9].

Methods

Antibiotic Sensitivity Test results extracted from a retrospective laboratory based study was the key data set concerned in this analysis. When an Antibiotic Sensitivity Test is performed, type of the specimen, the name of the bacterial species isolated and the resistance or the sensitivity of the bacteria towards a set of selected antimicrobial agents along with the personal information of the patient from whom the specimen was collected are recorded in all microbiological laboratories. Number of antibiotics a bacterial colony is tested for ranges from 8 to 12 depending on the laboratory where the Antibiotic Sensitivity Test was performed. The types of antimicrobial agents used for the Antibiotic Sensitivity Tests are also laboratory dependent unless a request is made by the physician to include a specific antibiotic based on the clinical condition and suspected pathogen.

Out of the above mentioned information available in microbiological laboratories, type of the specimen, date and time when the specimen was dispatched to the laboratory, the bacterial species isolated, resistance or sensitivity to each antimicrobial agents and the location of the patient were fed in to a MySQL based relational database using web based interface developed with scripting languages *PHP*: Hypertext Preprocessor, JavaScript and Python. Location of the patient for each test result was linked to a look up table in order to match location from where the microbiological sample was collected to its nearest possible latitude and longitude.

The interface developed has the capacity to filter the antibiotic sensitivity and resistance counts for each spatial location based on latitude and longitude and the type of antimicrobial agent. Several pre-formatted queries are provided through the interface to find counts based on bacterial strains, antimicrobial agent and time period.

Google Maps, [10] was used as the primary GIS layer as shown in Figure 1. Google Maps provides a Java Script based API which includes calls to add markers on the map for various data points.

However a supportive API, Gheat, [11] has to be employed to assist Google Maps layer, since the study manipulates vast number of data points and mapping those antibiotic resistance counts is beyond the capacity of Google Maps alone. An additional tile set was created with the aid of Gheat and which was layered on top of the base map tile set to visualize clustered antibiotic resistance counts of each antimicrobial agent based on the latitude and longitude as a Heatmap.

Similar to the Google Maps API, Gheat creates the final tile layer using multiple 256x256 pixel tiles knitting them together. Since the data points are time stamped, it is possible to generate these tile sets based on the time stamp of the individual Antibiotic Sensitivity Test result in a serial manner to analyze the periodical distribution of the resistance counts.

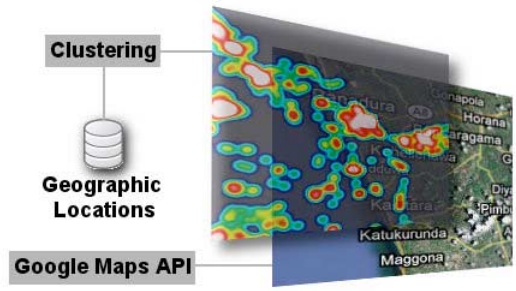

Figure 1 – Use of Google Maps API and Clustering geographic locations of test results

While frequency of occurrence are being calculated for each geographical point, those locations have to be grouped to different hierarchical layers based on the frequency of the occurrence of resistance or sensitivity reported for each cluster. In order to do this the interface accepts the individual occurrence of resistance from the database and cluster the data points, based on Agglomerative Hierarchical Clustering, [12] algorithm. The frequency clustering is possible as a cross sectional study with a single observation or as a longitudinal study with sequence of observations. In clustering antibiotic resistance results, Euclidean distance, between two data points is considered the preferred Metric as in Equation (1) to decide dissimilarity between sets of observations.

$$\|a-b\|_2 = \sqrt{\sum_i (a_i - b_i)^2} \qquad (1)$$

The selected Linkage Criteria to decide the distance between sets of observations is Single Linkage (Nearest Neighborhood) where pair wise distance between observations is used as shown in Equation (2).

$$min\{d(x,y): x \in A, y \in B\} \qquad (2)$$

The distance between two clusters is calculated as the distance between the two closest elements in each cluster. Linkage function – the distance $d(x,y)$ between cluster A and cluster B is described by, $d(A,B) = min(d(x,y))$ where,

- $d(x,y)$ is the distance between element $x \in A$ *and* $y \in B$;
- A and B are two sets of clusters within the same hierarchy

The maximum positional accuracy of storing the values for the latitude and longitude values are to the $1/1000000^{th}$ of a degree. So 0.000001 degrees of latitude or the longitude would be the closest distance for any two elements to be identified as two different clusters, as specified by the $d(x,y)$ in Equation (2) above.

Gheat color scheme consists of four channels of colors (red, green, blue, and alpha). Each channel ranges from 0 to 256. When the data is being clustered alpha channel is used to draw the base template of the Heatmap as shown in Figure 2. Then

each cluster will be colorized using appropriate combination of red, green and blue channels according to the color scheme. Once the color scheme is applied, each cluster of the Heatmap will have a unique color combination as shown in Figure 2.

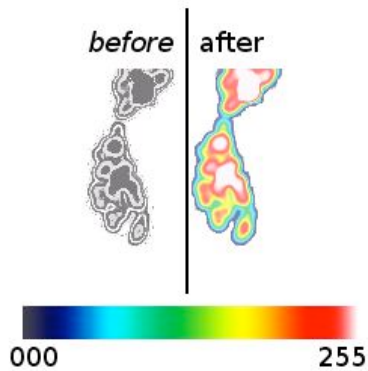

Figure 2 – Before and after colorizing clusters creating a Heatmap

This approach allows agglomerative positioning of clusters where each observation starts in its own cluster and pairs of clusters are merged as the process moves up the hierarchy. In these hierarchies of clusters, least dense clusters would occupy the bottom layers where as high density clusters would occupy the top layers. A color scale can be defined shown in Figure 2 to colorize the each layer in the Heatmap.

Results

Heatmap based on clustered antibiotic resistance counts for each bacteria. Cases were mapped with reference to the latitude and longitude of the specimens collected as shown in Figure 3.

Figure 3 – Antibiotic resistance cased mapped to the respective GIS positions

Data extracted from the Antibiotic Sensitivity Test result was fed in to the GIS system and the interface was able to generate

Similarly, cases resistant to a selected antimicrobial agent can be filtered by time stamp and Heatmap can be generated sequentially. In this approach spatial distribution of the antibiotic resistance cases can be visualized periodically as shown in Figure 4.

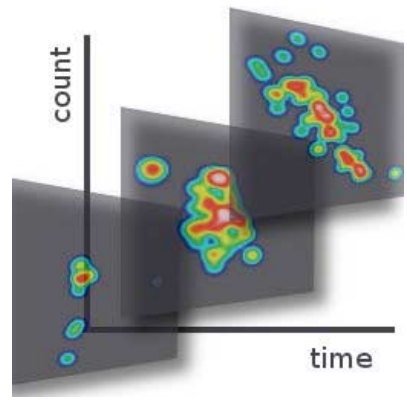

Figure 4 – Sequential Heatmap highlighting the changes of the resistance counts against time

Discussion

The serial Heatmaps generated by the interface are useful in cross sectional studies of the database, providing visual clues on the extent of the distribution of antibiotic resistant cases at any given time.

With the use of Heatmaps, large number of values can be visually presented compares to conventional map markers used with the Google Map API.

There are numbers of clinically significant statistical analysis can be performed with the help of pre-formatted database queries.

- Comparison of resistance or sensitivity of a bacteria to an antibiotic in different points in time as a longitudinal study
- Comparison of resistance or sensitivity of a antibiotic to one or more bacteria as a cross sectional study
- Comparison of resistance or sensitivity of a antibiotic to one or more bacteria as a longitudinal study
- Comparison of resistance or sensitivity of a bacteria to one or more antibiotic as a cross sectional study
- Comparison of resistance or sensitivity of a bacteria to one or more antibiotic as a longitudinal study

Conclusion

The study was able to demonstrate the ability to incorporate Geographical Information Systems with clinical and laboratory based data. Cross sectional as well as longitudinal analysis is possible with the use of cluster mapping.

Heatmaps are easy to interpret than numerical data or charts in representing pattern of distribution of antibiotic resistance cases over a geographical location.

It was also shown that, in longitudinal sampling of frequencies, a temporal analysis of the antibiotic resistance or sensitivity pattern is possible with sequential Heatmaps.

Acknowledgments

Authors would like to make this an opportunity to thank Chad W. L. Whitacre for the support rendered on Gheat API and staff of all microbiological laboratories for providing the access to Antibiotic Sensitivity Test Results.

Traffic Accidents in Crete (1996-2006): the Role of the Emergency Coordination Center

Dimitris Vourvahakis[a], Catherine E. Chronaki[b], Vasilis Kontoyiannis[b], Demosthenis Panagopoulos[b], Spyros Stergiopoulos[c]

Abstract

The general decline in traffic accidents throughout Europe is not the case for Crete, a favorite holiday destination. The extent of problem and reflections on the significant impact of the interplay of organizational, educational, & technological interventions by the Emergency Coordination Center of Crete (ECC-Crete) are presented. 10-year data from 1996-2006 have been analyzed revealing demographic, topological, and qualitative issues of traffic accidents in Grete. Primary source of data is 315000 emergency calls answered by ECC-Crete. Over this 10 year period, ECC-Crete gradually employed advanced medical technologies and electronic protocol-based handling in all phases of an emergency episode contributing to its timely and effective management. GIS/GPS technology and telemetry for biosignals in ambulances, up-to-date triage protocols combined with incidence analysis provide vital information for continuous process improvement. In 2000-2006, process improvement due to technological and organizational changes has led to increased efficiency. The mean reduction was ~75% in dispatch time, ~50% in the time at accident scene for metropolitan areas, and ~75% in time at the emergency ward, mainly due to medical interventions on site.

Keywords:

Emergency management, Road accidents, eHealth Infrastructures, Technology assessment

Introduction

Traffic accidents, one the gravest problems of our times, is projected as one of the leading causes of death in 2030 by WHO [1]. Whereas all over Europe the number of traffic accidents is declining [2], in the island of Crete the problem escalates year after year. Crete is the largest island of Greece located in the center-east part of the Mediterranean. It is a popular tourist destination with a permanent population of 750,000 people rising to 1,250,000 during the 8-month long tourist season. All health-related emergency calls (166) are handled by the National Center of Emergency Response (ECC-Crete).

In the period 1995-2006, the number of vehicles using essentially the same aging road infrastructure has more than doubled. In 2005-06, 420000 motor vehicles (30% owned by rental agencies) were on the roads of Crete [3-6]. While various traffic-accident indicators for Greece decrease, this is not the case for Crete: 1248 persons lost their lives and 18901 were seriously injured in the last decade (1996-2006).

In the period 1996 to 2001, advanced Information and Communication Technologies (ICT) were gradually introduced to the day to day operation of ECC-Crete driven by organizational changes supported by systematic educational and hands-on training activities.

In the backdrop of a comprehensive analysis of the problem of traffic accidents in Crete, this paper presents elements of the operational plan of ECC-Crete, assessing the effect of the Integrated Emergency Management Information System (iEMIS) and reflecting on the interplay of organizational, educational, and technological developments.

The next section (Materials and Methods) presents elements of the operational plan of ECC-Crete and the data sources and methodology employed in this assessment. The Results section presents quantitative and qualitative results of the traffic accidents in Crete 1996-2006 focusing on quantitative evidence for their demographics and geographic locality, and qualitative evidence on the role of ICT in the effective management of emergency episodes and traffic accidents, in particular. Discussion-Recommendation outlines further interventions to contain the problem of traffic accidents that claims the life of people in their most productive age. Finally, Conclusions summarize the contribution of this work, outlining future challenges for ICT in emergency management.

Materials and Methods

Integrated Emergency Management Information System

Since 1996, iEMIS has been gradually introduced in the day to day operation of ECC-Crete to serve its primary objective, namely to improve the health outcome of those injured in emergencies including traffic accidents, through timely and effective intervention of emergency response teams. In this context, the role of ICT is central in collecting and managing relevant information providing decision support for individual emergency episodes, but also for resource planning.

iEMIS [7,8] at ECC-Crete aims to serve as the key to effective health emergency management employing state-of-the-art ICT. The basic capabilities of the iEMIS include: (a) online archive of all emergency calls and associated information; (b) geographical tracking of ambulances and mobile ICU units using Global Position System (GPS) and a Geographical Information System (GIS); (c) decision support on optimal use of the available resources; (d) acquisition, transmission, analysis, and storage of vital signs on the ambulance allowing patient telemonitoring on the way to the hospital; (e) continuous training & education of paramedics, rescuers, health professionals, and the public.

Lifecycle of an emergency episode

Every incoming emergency call at ECC-Crete is recorded on an electronic "incidence card". The incident card employs the minimal Hector data set, which was the result of consensus among many European countries in the Hector project [9]. Operator/dispatchers at ECC-Crete are responsible for initial protocol-based triage of emergency calls, dispatching of ambulances, and their follow-up. Two screens provide access to iEMIS, i.e. on-line triage protocols, GIS, and the emergency incidence database.

Once a call for a traffic accident is received by ECC-Crete, the episode is automatically geo-located on the GIS. Thus, the operator/dispatcher may promptly identify the origin of the call and the ambulances closer to the scene of the emergency. On the incident card, the operator enters all the details as provided on the phone and assigns a color code to the episode based on its severity as assessed by triage protocols: Red, Orange, Yellow, and Green. The severity of the emergency call is dictated by this color-coding with Red being that of the highest urgency. A suitable ambulance is dispatched to provide first aid and necessary medical interventions on site and transfer the victims to an appropriate medical facility. When an episode is characterized as Red, a mobile ICU manned with an emergency doctor is urgently dispatched. In Orange episodes, an Advanced Life Support (ALS) ambulance equipped with a defibrillator is dispatched, while in Yellow episodes a Basic Life Support (BLS) ambulance is dispatched. Green episodes can be scheduled with some flexibility.

Upon arrival at the scene of the accident, the medical doctor, if present, and the paramedics use radio communication and telemonitoring of the patient's vital signs and ECGs. The incidence card remains "open" until the emergency episode is received by the Emergency Ward of the medical facility.

BLS ambulances as well as mobile ICU units (ALS-MICU) have been equipped with state of the art equipment extraction, immobilization multi-trauma patients (long spine boards, «scoop stretcher», vacuum mattress, vest KED). They are also equipped with medical devices for vital signs monitors for first aid therapeutic interventions such as defibrillator, oximeter, electronic blood pressure monitors, devices for warming of liquids, intubation set, ventilators etc.

Thus, the doctor on duty at ECC-Crete can receive real-time patient tele-monitoring of the patient's vital signs and ECGs as transmitted from the ambulance. The doctor may record in the "Clinical evaluation" section of the "Incidence Card" patient condition and immediate actions. Special effort has been focused on designing this service to require minimal intervention by paramedics. In this way, the crew of the ambulance can concentrate fully on the management of emergency and the doctor receives timely information in a transparent and efficient way.

Resource management

The resource management component of iEMIS of ECC-Crete facilitates continuous evaluation of emergency services, conveying valuable insights on the management of resources and the organization of sectors (areas where ambulances are proactively deployed). Intelligent incident data analysis provides decision support at the administrative level regarding the creation of new sectors and the positioning of ambulances to improve response times. Simulation programs apply advanced data analysis methods to the contents of the emergency archive to support administrative decisions with regards to staff performance, training and scheduling, as well as the need for special equipment.

Continuing Education and Training

The personnel of ECC-Crete undergo regular training to maintain high levels of readiness and aptitude in emergency response [10]. In 2000-2006, the educational center of ECC-Crete, offered paramedics and health personnel more than 2800 hours of training certified by the Hellenic Organization of Professional Training. BLS-AED training takes place regularly based on the protocols of European Resuscitation Council (ERC). All personnel are retrained on a yearly basis on trauma management based on the principles of Advanced Trauma Life support (ATLS) and the protocols of emergency management as customized by ECC-Crete. Since 2008, a Prehospital Health Trauma Life Support (PHTLS) Center extends training to health professionals, rescuers, and citizens alike. Moreover, ECC-Crete participates in a variety of tele-training programs to train health professionals and the public in Crete and the surrounding islands.

Data Sources and Evaluation Approach

Complementary data sources have been used to assess the effect of these interventions on the management of emergencies. In particular, the following sources of data have been used in this work:

- mortality data associated with traffic accidents referring to the whole island, which were collected with support from the Police and the Forensic Medicine Department of the University of Crete
- detailed outcome data on traffic accidents with severely injured only from eastern Crete (2/3 of the population), where assistance from ECC-Crete was requested
- emergency calls to which ECC-Crete responded in the period 1996-2006, all of which were recorded in the iEMIS i.e. 315000 emergency episodes.

Based on these data sources, the results section reports quantitative evidence on traffic accidents and their severity: (a) number of fatally and severely injured in traffic accidents; (b) age distribution and gender of the victims; (c) geographic lo-

cation of traffic accidents; (d) main causes of accidents: nationalities, alcohol, tourism.

Then, in an effort to assess the role and prospects of information technology in emergency management: (a) we evaluate protocol-based triage by comparing severity of the episodes as evaluated by ECC-Crete, with assessment by the paramedics on the scene, and doctors at the Emergency Ward of the hospital; (b) we measure average times in the management of emergency episodes over time to reflect on organizational, educational, and technological interventions.

Protocol-based triage of emergency Calls - trauma scores

As already mentioned, protocol-based triage of each episode begins at the time of the emergency call with the color-coding of its priority from the operator/dispatcher of ECC-Crete. The Revised Trauma Score (RTS) and the Hector Emergency Scale (HES) rate the severity of the episode at the scene of the accident and upon arrival to Emergency Ward.

RTS is a physiological scoring system, with high inter-rater reliability. It is scored from the first set of data obtained on the patient, and consists of Glasgow Coma Scale (GCS), Systolic Blood Pressure (SBP) and Respiratory Rate (RR). RTS is heavily weighted towards the GCS to compensate for major head injury without multisystem injury or major physiological changes. HES attempts to leverage vital signs information acquired through monitoring in the ambulance and transmit it to the ECC-Crete, to be visualized at the doctor's workstation. In HES, GCS and a set of four vital signs are used for the calculation of a score that expresses the current status of the patient under care. HES scores result from the addition of the severity scores (1-4) for each of the five vital signs that appear in Table 1. Note that a total score of 14 or lower indicates a critical condition. The primary treatment goal is to achieve HES Score of at least 15 as soon as possible. The HES & RTS scores are routinely compared to the initial color-coding to assess the effectiveness of protocol-based triage.

Table 1- HECTOR Emergency Score (HES)

Severity	GCS	NISBP	HR	RR	SpO_2
4	13-15	101-180	50-100	10-30	> 94
3	9-12	76-100	101-120	> 30	92-94
2	6-8	50-75 or 181-220	121-140	6-9	90-91
1	4-5	1-49 or >220	<50 or >140	1-5	85-89
0	3	0	0	0	< 85

Results

Quantitative evidence: traffic accidents and their severity

From 1996 to 2006, ECC-Crete was called to provide assistance in 18901 traffic accidents that involved one or more injured persons. Figure 1 shows that the number of heavily injured in road accidents in 1996 was 730. Since then, with the exception of 2001 (1453) and 2003-2004 (1619, 1713) the number of injured persons is steadily rising. In 2005, the number of injured is 2869 (7.8 injured per day) and 3315 in 2006. The total number of injured is higher than the population of major cities such as St. Nikolas, or Sitia in Crete. The rising trend on the number of deaths, particularly after 2004 (shown in Figure 1), is also alarming. After a short drop in 2003 (98 deaths), we reached 148 deaths in 2005.

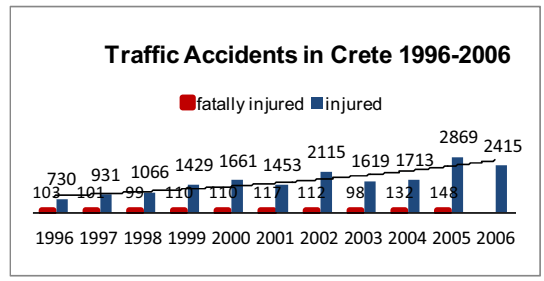

Figure 1- A rising trend in the number of fatally or heavily injured in traffic accidents. (9.4 seriously injured per day).

On the roads of Crete traffic accidents claim the lives of the young: 41% of the injured and 30% of dead are persons 17-30 years old. Moreover, 71% of the injured and 60% of the dead belong to the creative and productive ages between 20 and 50. 72% of the victims and 80% of those injured are men, compared with 28% and 20% of women, with children ranging 2-5%. Surprisingly, the number of Greeks involved in road accidents is higher than that of other nationals among fatally (85%) and heavily injured (79%). However, the tourist season pays a heavy toll in terms severely and fatally injured in traffic accidents (data not shown).

Figure 2- Location of accidents on Northern National Road.

Geographic Distribution

The largest number accidents for which ECC-Crete received an emergency call are located near the urban centers. In particular, 40% of the traffic accidents involving serious or fatal injuries were within the urban areas of Heraklion, St. Nikolas, Ierapetra, Hersonissos, and Malia. Furthermore, the number and severity of traffic accidents along the Northern National Road of Crete (NNR) and minor roads leading to the south in the Heraklion prefecture are high (20%), with the main intersections in Heraklion, claiming 10% of the total (Figure *2*).

Main causes of traffic accidents

The main causes of traffic accidents involving Greeks and other nationals differ considerably. As shown in Table 2, the most frequent cause of accidents among Greeks is violation of

traffic rules. Violation of traffic lights, high speed, and violation of priority are the top causes for severe traffic accidents involving Greeks (51%). For other nationals, the same causes of accidents account for 31%, while alcohol abuse is at the top (22%/52% for fatally injured). For Greeks, just 13% of the accidents involve alcohol abuse. Driving conditions (e.g. road conditions, light conditions) cause significant percentage of accidents to Greeks (31%) and other nationals (42%). Other nationalities are likely to drive a rented car (p=0.02) and come from countries driving on the left (p=0.02) when involved in a traffic accident. It is also worth noting the significant increase in cerebral injuries (CCS<8) among injured motorcycle drivers who did not wear a helmet (from 31 in 2000 to 195 in 2005).

Table 2- Main causes of accidents for different nationalities.

Cause of Accident	Greek	Other nationalities
Violation of traffic rules	54%	31%
Alcohol abuse	13%	22%
Alcohol abuse (among fatally injured)	35%	52%
Use of illegal substances	2%	5%
Road Conditions	31%	42%

Qualitative evidence: the role of information technology

As already noted, the aim of ECC-Crete is to improve the health outcomes of those involved traffic accidents: (a) by reducing the mean time in the different phases of handling an emergency: dispatch, access, time on site, transfer time, time in the emergency ward and (b) by employing appropriate interventions on site and en-route to the hospital to improve the RTS and HES and thus improve prospects of the emergency.

The following sections provide qualitative evidence on the effectiveness of the interplay of organizational, educational and technological interventions. iEMIS plays a central role in effectively employing technology to achieve these objectives.

Efficient handling of emergencies

Despite the increasing number of traffic accidents noted in the previous section, effective use of technology has led to a drastic reduction in the time spent at the different stages of managing an emergency episode:

- *mean dispatch time* has been reduced from 5′, 6′ in 2000 and 2001, to 1′ in 2005 and 2006 (>75%).
- *mean time to the scene* of the accident has been reduced from 10′, 12′ in 2000 and 2001 to 5′ within urban centers and in distances less than 20km (50%)
- *mean time at the emergency ward* of the hospital was reduced from 18′ in 2000 to 4′ in 2006 (>75%)

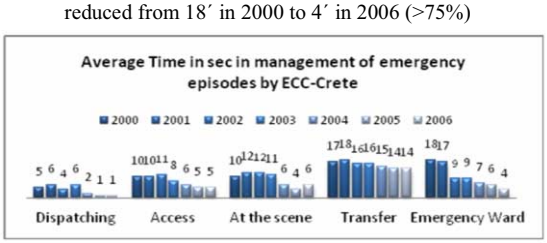

Figure 3- Response Times (sec) in emergency management

The sharp reduction in dispatch time can be attributed to iEMIS as it facilitates immediate (re)allocation of emergency resources. iEMIS provides expert assistance to operators by assessing the proximity of resources to incidents supplying scheduling data, expected times of resource availability, and accurate categorization of incident severity. The significant reduction in the mean access time can be attributed to new local sectors. ECC-Crete evaluates sector effectiveness using data mining of geolocalized incidents. New sectors were formed within the limits of urban centers and locations presenting high frequency of traffic accidents in the tourist season. Furthermore, a Special Unit of Disaster Medicine was created initially with 32 paramedics-rescuers and 4 doctors. Thus, combination of information technology, resource allocation, and training, has visible impact on the reduction of the time at the scene of the accident.

The reduction in the time spent in the Emergency Ward shown in Figure 3, can be attributed to the large number of immediate interventions at the scene of the accident. Over the last decade, the number and effectiveness of interventions on site have improved considerably both in terms of quantity and quality. Indicatively, in 2006 the iEMS database reveals that the ECC-Crete personnel have intubated after general anesthesia at the scene of the accident 95 injured persons compared to 24 in 1998. In the same time frame, 53 multi-trauma patients were extracted with the use of KED vest, collar and long spine board, compared to 8 in 1988.

Protocol based triage and color-coding of episodes

After the original color coding of the emergency episode, the health condition of the injured is regularly updated in the iEMIS database, as new values are recorded manually by ambulance crew or automatically through telemonitoring. 4680 severely injured cases were selected out of the iEMIS database, involving traffic accidents with average RTS at the critical level 9 and HES at the critical level 11. Analysis indicates that in 25% of these episodes characterised as Red or Orange in triage, response was instant and in 57% immediate. Assessment of the episodes from doctors and paramedics at the scene of the accident, showed that 31% of these episodes were characterized as RTS < 9 (mean RTS 10,04) and 26% of the episodes were characterized as HES < 11 (mean HES 14,41). Thus, there is a significant correspondence between the initial color-coding of the episodes at the time of triage and the observed severity at the scene of the accident based on the recorded vital signs. In cases where the HES score was below 15, the episode was color-coded by the dispatcher as Red or Orange, reflecting the value of iEMIS on decision support.

Discussion

Since 1869, when the first automobile fatality was recorded in a small Irish town, cars have become an integral part of our daily life. Road injuries were chosen by the World Health Organization as the focus of the World Health Day in 2004, since according to WHO resources, traffic accidents are a frequent

cause of death or a source of permanent disability. For Crete, driving conditions are grave: the 1243 fatally injured, 4680 severely injured, and 18901 injured are a quite high tall for a relatively small and closed community of 750000 people. The fact that most victims of traffic accidents are young 17-30 years old, should be a source of further concern as traffic accidents affect the most productive and vibrant part, the hope of our society. For Greek nationals, the gap in traffic education is noteworthy (31% of injured violated the traffic code), whereas for foreign nationals and tourists, alcohol is a major cause of accidents (52% of fatally injured). Nationals of countries driving on the left are involved 2.5 times more frequently in accidents that others. Driving without a helmet is critical for motorcycle drivers involved in an accident (135 in 2006).

The interventions of ECC-Crete in terms of training, education, technology, and guideline-driven procedures have positive impact. The creation of new sectors in ECC-Crete has improved overall effectiveness through improved access to the scene of the accident. Recurrent incident analysis and continuous assessment using the iEMIS database supports decision making regarding the creation of new sectors and the possible disbanding of existing ones, maintaining high operational efficiency. In terms of training and education, the recent Prehospital Trauma Life (PHTLS center) helps engage citizens, volunteers, and professional rescuers. However that is not enough, intense lessons of driver conduct to young people as part of primary education are needed, while visitors particularly those arriving from countries driving on the left should receive information or brief training before renting a vehicle.

The remarkable reduction of 50-75% in the average times of managing emergencies has lead to further thoughts regarding embracing innovation and closer collaboration with other organizations in the chain of emergency management, including not only health organizations, but also law enforcement, firefights and their disaster management units. On top of that, stronger links with primary care facilities and volunteers should be established through regular tele-education sessions based on real episodes from the iEMIS database. Innovations considered include experimenting with vehicular emergency data transmission to ECC. There are also plans for the iEMIS database that is currently episode-based to be reorganized to form a citizen-centered emergency record. That would further improve emergency management involving people of chronic conditions or special needs who are frequent or likely users of emergency services. It would assist triage by proactively supplying valuable information not only in the management of the emergency, but also to the Emergency Ward of the receiving hospital. Finally, the valuable experience reported here needs to be regularly revisited, in the frame of a long-term strategy of continuous assessment of emergency management procedures setting standards at a national and European level.

Conclusion

The island of Crete is facing a serious problem with traffic accidents, due to the ever increasing number of vehicles and poor road infrastructure. ECC-Crete has set up and continually updates its operational plan to effectively cope with increasing traffic accidents in Crete. The cooperative use of technology, training, and organization change has proved particularly effective in terms of Time, the most precious emergency resource. A major challenge for ECC-Crete is to develop and establish integrated technology-driven processes with all actors in emergency management using technological progress and innovation for better health outcomes in traffic accidents.

Acknowledgements

Development of iEMIS at ECC-Crete could not be realized without the valuable input of ECC employees and efforts of E Leisch, M Tsiknakis, Y Doulgerakis, F. Chiarugi, and others.

Abstract

The traffic road accidents (ATT) are non-intentional events with an important magnitude worldwide, mainly in the urban centers. This article aims to analyzes data related to the victims of ATT recorded by the Justice Secretariat and Public Security (SEJUSP)in hospital morbidity and mortality incidence at the city of Cuiabá-MT during 2006, using data mining technology. An observational, retrospective and exploratory study of the secondary data bases was carried out. The three database selected were related using the probabilistic method, through the free software RecLink. One hundred and thirty-nine (139) real pairs of victims of ATT were obtained. In this related database the data mining technology was applied with the software WEKA using the Apriori algorithm. The result generated 10 best rules, six of them were considered according to the parameters established that indicated a useful and comprehensible knowledge to characterize the victims of accidents in Cuiabá. Finally, the findings of the associative rules showed peculiarities of the road traffic accident victims in Cuiabá and highlight the need of prevention measures in the collision accidents for males.

Keywords

Traffic accidents, Data mining, Public health informatics

Introduction

The traffic road accidents are non-intentional events with an important magnitude worldwide, mainly in the countries with medium and low income. The numbers show high number of deaths, disabilities and psychological sequelae, being one of the negative factors of the epidemiological transition that Brazil has experienced over the last decades [1-2].

Brazil is among the countries that have registered the largest frequencies of individuals injured in traffic accidents, with rates showing that in 2002 the number of victims were 219,5 per 100 thousand inhabitants [3] and 18,7 deaths per 100 thousand inhabitants [4].

In 2006, death by traffic road accidents were in a rate of 39,4 per 100 thousand inhabitants. In the same year, the state of Mato Grosso, presented a risk of 56,8 per 100 thousand inhabitants, and the capital Cuiabá recorded a lower rate of 25,2 per 100 thousand inhabitants [4].

The relevance of the traffic accidents in Cuiabá is revealed by the mortality rate per external causes. The data of hospital morbidity in Cuiabá is also higher than the indexes presented by the national record, the Center-West region and by the State of Mato Grosso [5].

This article presents an analysis of relating data in traffic road accidents recorded by the Justice Secretariat and Pubic Security using hospital morbidity and mortality records at the city of Cuiabá in 2006, using data mining technology.

Materials and Methods

Type of study

It is an observational, cross-sectional, retrospective and exploratory study of the secondary databases of security and public health in the municipality of Cuiabá, Mato Grosso State, in 2006.

Source of data and ethnic considerations

The sources of data were those of the State Secretariat of Justice and Public Security (SEJUSP) that made available the database of the victims in traffic road accidents assisted by the Military Fire Brigade and SAMU including the Police Records.

Complementing the database of the public security area, we included data from the national health information systems which contain the register of the accidents and the hospital admissions records at SUS - the Hospital Information System of the Unified Health System (SIH/SUS). In addition, data from the system for recording deaths, the Mortality Information System (SIM) were also included.

The databases and the collecting data files or instruments of data collection, were provided by the Municipal Health Secretariat in Cuiabá-MT and by the State Secretariat of Justice and Public Security (SEJUSP), authorized by their directors and approved by the Ethic Committee at the Federal University of São Paulo under protocol number 1595/07.

Data processing

The databases received from SEJUSP (the Municipal Health Secretariat of Cuiabá-MT), SIH/SUS and SIM were structured in an Excel datasheet, Microsoft Office Excel 2003, comprising 2,547; 38,273 and 3,198 registers, respectively.

A manual checking of the databases was made to investigate the existing variables to verify key attributes for record linkage. The phase of the selection of the registers in the databases took into account all the registers that had the key attributes. In this cleaning phase 1.137 registers were excluded from the SEJUSP databases totalizing 1.410 selected registers.

In the SIH/SUS all the registers were selected (38.273). However, in the SIM database, there was an exclusion of 97 registers. Consequently, the total was 3.101 selected death records.

Data processing was divided into two phases: (a) the record linkage of the databases and (b) the data mining technology.

Record Linkage

The database linkage probabilistic method was used to join the data of the Information System of SUS with the data from the State Justice Secretariat and from Public Security (SEJUSP) to obtain information about common individuals that were victims of traffic accidents in the city of Cuiabá-MT.

Three record linkages were carried out separately, SEJUSP *versu.* SIH/SU which resulted 111 pairs; SEJUSP *versus* SIM with 25 pairs; and with the registers of the first record linkage SEJUSP/SIH *versus.* SIM which resulted three pairs, totalizing 139 real pairs. This process formed a single database with 139 registers. Subsequently, the 13 variables were selected as showed in Table 1.

Data mining

The tool used to obtain knowledge from the data bases of accidents in Cuiabá was the WEKA - *Waikato Environment for Knowledge Analysis.* The reasons for selecting it were: it is a tool developed in the JAVA language that has as the main feature the portability (it is easy to be executed in several platforms of the Operational System); has the source code open; easy access by internet and, available at http://www.cs.waikato.ac.nz/ml/weka/.

After processing the formating of the variables and the structure of the database for data input at the selected tool, the Weka software version 3.6.0 was prepared. It reads a text formatted file with .arff extension. In addition, in the pre-processing phase of tool, the preliminary analysis of the data was done. Next, it was perfomed the selection of the association (*Associate)* in the WEKA tool. The selected algorithm was APriori - which consists in identifying and describing associations among the variables of the same item or associations among different items that frequently occur simultaneously in the data base [6-7].

Table 1 – Variables, description and their categories

Variable	Description	Categories
VictimCode	Victim Code	Arabic number
	Gender	M, F
Age group	Age group (from 0	0-9; 10-19; 20-29; 30-39; 40-49; 50-59; 60 years and more
Month of occurrence	Month of occurrence	Jan, Feb, Apr, May, June, July, Aug, Sept, Oct, Nov, Dec
Type of Accident	Type of accident	collision, overrunning, overturn, shock, vehicle crash, fall, none
Victim's transport	Victims's means of transport	On foot, vehicle, motorcycle, automobile, bicycle, none
Type of victim	Type of victim	driver, passenger, pedestrian, ignored
Days of hospitalization	Days of hospitalization	Arabic number
Residential zone	Residential Zone	north, south, east, west, none
Ocurrence zone	Occurrence zone	north, south, east, west, none
Medical Assistance	Medical assistance	yes, no
Place of assistance	Place of Assistance	HCANCERMT, HGU, HUJM, HJDCBA, HMBOMJESUS, HPSMCBA, HSTAHELENA, HSTAROSA, SOTRAUMA, STACASA, None
Evolution	Evolution	Hospital discharge, death

As parameters for the execution of the association the *default values* of the software 0,1 (10%) minimum support (sup.); 0,9 (90%) confidence (conf.); 1,1 minimum Lift and number of rules 10 were maintained.

Results

With the application of the APriori algorithm and its parameters previously established, three sets of data were created. The first comprises five attributes which were combined to create a second set (*itemsets)* that contain six combinations; each one with two attributes. With the combination of the second *itemsets,* a third item/sets was created with two combinations and three variables.

In the three *itemstes* created, it is observed that the supports of each combination are higher than the minimum (10%) suggested by the *default* of the WEKA software. Of the last two combinations in the third *itemsets*, it is verified that 64,0% of the 139 male victims received medical assistance and were discharged from hospital.

In the second combination, of the 139 victims, 41,0% occurred by collision and also had medical assistance, receiving hospital discharge. After the combinations of the *Itemsets*, the 10 best associative rules created by the *APriori* algorithm were ordered by the *lift*. Of the 10 best rules created by the algorithm,

four were not considered since they presented one of the parameters smaller than what was established.

In addition, of the 10 rules created by the algorithm of association of the traffic accident victims it was verified that, in all the rules created, the attributes referring to hospital medical assistance (Yes) and evolution (discharge) were present, as antecedent or consequent. Two other frequent variables in the rules created were the type of accident by collision and the male gender. The frequency of these variables in the rules indicates possible standards found in the related data.

In relation to the rules, it can be observed that the first presented confidence of 92,0% (0,92), which is higher than the minimum established, (TP_ACCID=COLLISION - MED. ASSIST=SIM 62 ==> EVOL=H. DISCHARGE 57). Also, it can be observed that 92,0% of the victims according to the type of accident, more specifically, the collision, received medical assistance and were discharged from the hospital, which means that 62 collision accident victims received hospital medical assistance and 57 were discharged. Five victims died. Related to the support of 41,0% (also higher than the minimum established) of the 139 victims of traffic Road accidents that occurred in the city, 41,0% were due to collision, received medical assistance and were discharged from the hospital. This rule was classified as the Best rule by the *lift* parameter. The *lift* of the rule (1,16) was higher than the minimum *lift* (1,1) established in the *default* of the *software*.

The second rule, (MED-ASSIST=SIM 121 ==> EVOL=h. discharge 110) shows that 121 victims of accidents received hospital medical assistance and 110 presented evolution for hospital discharge with confidence level of 91,0%. From the total number of the Road traffic accident victims, 79,0% received medical assistance and were also discharged.

The third rule shows that 100,0% of the victims were discharged from hospital because they received medical assistance.

In the fourth rule, the variables male gender and hospital discharge appear as antecedents, indicating that 100,0% of the male victims were discharged because they received hospital assistance. It also can be observed that 64,0% of the total number of accident victims were males and also were discharged because received hospital assistance.

The fifth rule shows that 100,0% of the traffic accident victims by collision were discharged also due to medical assistance. But of the 139, only 57 (41,0%) collision accident victims received hospital discharge due to medical assistance.

The last rule considered by the parameters higher than those established, shows that 90,0% of the victims were males and received medical assistance, and because of this factor they were discharged.

Discussion

In this study the use of the data mining technology was presented through a data base related by the probabilistic method, since the Brazilian health databases do not present a common single identifier. Leles [8] highlighted the importance of the probabilistic method to integrate databases, mainly those database in the healthcare area.

Through the Apriori algorithm, the six rules selected, have parameters higher than those established. The knowledge obtained from the rules was comprehensible in consonance with the results and previous studies performed in Cuiabá-MT [9], and Cuiabá surroundings [10-11]. However, it is worth mentioning that these studies did not use the data mining technology to analyze the data.

The two variables that constantly appear in the subsets of the created rules indicated that there is an association between medical assistance and evolution to hospital discharge. It is also known that these can be called valid standards [12], since they were frequent presented in all the subsets. Two other frequent variables were the male gender and the type of accident by collision. The result (standards) is very similar to that found in other studies carried out by other methods and technologys of analysis in Cuiabá-MT [9], in the surroundings of Cuiabá [10-11], Alta Floresta-MT [13] and in the Distrito Federal [14].

It is worth emphasizing that the rules created, though trivial, show that the type of accident by collision makes victims and fatal victims; illustrating that all the types of vehicles are not invulnerable armors and that the drivers need to be prepared to drive.

In the rules presented, it is also emphasized that males were the main accident victims, even if a large number received medical assistance, and were discharged. It is known however, that the situation interferes in the family economy, since the most affected age group was that of the individuals economically active. There is also the immeasurable social loss that is caused by the trauma. It is difficult to evaluate quantitatively the social impact of the sequelae that the trauma causes for the population; on the other hand, there is a concern about the financial cost of their attendance (medical assistance), follow-up rehabilitation.

Finally, despite a few rules created and considered, there are enough elements to propose preventive measures of these accidents by collision involving male drivers. It is highlighted that these rules were based on real data that effectively show the scenery and can support programs dedicated to prevent violence in the traffic.

Conclusion

Finally, the findings in the associative rules revels the peculiarities of the road accident victims in the city of Cuiabá, Mato Grosso State, in 2006. It emphasize the need for preventive measures in the accidents by collision and also educational program dedicated to the male gender for the reduction of these events. The public policies on transportation, the guiding plan of the city, and the statute of the city must be reevaluated

Finally, the mining data technology can be considered a powerful tool in the analysis of secondary data, even with related data, and also to help the decision-making process, provinding

useful knowledge of databases from the health information systems and public security.

Investigating health information needs of community radio stations and applying the World Wide Web to disseminate audio products

Janus Snyders, Elmarie van Wyk, Hendra van Zyl

Web and Media Technologies Platform, South African Medical Research Council

Abstract

The Web and Media Technologies Platform (WMTP) of the South African Medical Research Council (MRC) conducted a pilot project amongst community radio stations in South Africa. Based on previous research done in Africa WMTP investigated the following research question: How reliable is the content of health information broadcast by community radio stations? The main objectives of the project were to determine the 1) intervals of health slots on community radio stations, 2) sources used by community radio stations for health slots, 3) type of audio products needed for health slots, and 4) to develop a user friendly Web site in response to the stations' needs for easy access to audio material on health information.

Keywords:

Radio, Education, Internet, Consumer health informatics, Needs analysis, Health information, World Wide Web.

Introduction

The South African Medical Research Council's (MRC) vision is "*Building a healthy nation through research".* One of the nine strategic objectives implemented by the MRC to address this is research translation. As defined by the MRC *"Research makes no difference to health and quality of life unless it is translated into interventions such as policy, practice and products, which can have an impact on the health and quality of life of the nation"* [1]. The Web & Media Technologies Platform (WMTP) which forms part of the eHealth Research and Innovation Platform (eHRIP) of the MRC focuses on the implementation of eHealth[1] solutions for knowledge transfer to specific target audiences within the framework of the strategic health objectives of the MRC.

[1] **eHealth**
According to the World Health Organisation (2005), eHealth refers to the use of information and communication technologies locally and at a distance – presenting a unique opportunity for the development of public health. The strengthening of health systems through eHealth may contribute to the enjoyment of fundamental human rights by improving equity, solidarity, quality of life and quality of care.

Research studies in today's technological age have shown that when looking for health and medical information, frequently, before visiting their physician, the health consumer's first point of call is the Web [2]. In the case of rural communities where the Web is not easily accessible, more traditional eHealth solutions are sought, such as listening to health information broadcast by community radio stations [3].

In 2006, an analysis by the United Methodist Communication Foundation [4] found that the only effective form of communication, e.g. to deliver messages or communicate health information to the poorest people living in shantytowns and rural areas throughout Africa, was through community radio stations. The research question of this study is: "How reliable is the content of health information broadcast by community radio stations?"

Community radio is defined as a service that caters to the interests of a certain area, broadcasting content that is popular to a local audience, but which may often be overlooked by commercial or mass-media broadcasters [5]. Radio has long been the most accessed form of media in South Africa, reaching beyond urban centres deep into the poorest and most remote rural areas. South Africa has more than 200 community radio stations that broadcast in many different languages [6].

A case study, conducted in 2005 by Lloyd and Fordred on Radio Zibonele, a community radio station in Khayelitsha, Western Cape [7], brought forward the importance of transferring health information and health education to their listeners.

Radio Zibonele has a daily audience of 200 000 and states that their mission is to enhance the quality of life of their listeners by improving their health standards. This is done through regular broadcasts of health care information and health education in order for individuals to take better care of themselves and their families. Self-help is the underlying theme of the station with many programmes that deal with practical issues. An example is a programme on how to take care of a sick child and health information for children on how to take care of their sick mother. Radio Zibonele's success could also be attributed to the station's endeavours to broadcast health information where possible in isiXhosa, the mother tongue of the majority of the listeners.

WMTP's pilot study utilizes the combined approach of a Radio to Public Transfer Model (RPKTM) and a Web to Public Knowledge Transfer Model (WPKTM), based on the theories of informatics and knowledge management.

The RPKTM aims to develop audio products to inform, educate and communicate health related information to the South African population. A secondary aim of the model is to guide community radio stations to source health related information that is 1) accurate, 2) appropriate, and 3) relevant.

The WMTP of the MRC has access to reputable scientists when audio products are developed. These audio products such as audio documentaries, key messages and panel discussions also undergo a rigorous editorial process to ensure that a high quality is maintained. Audio documentaries are accompanied by articles that are placed on a Web site. The articles serve as aid for the person compiling the health slots and supply background information on aspects that are discussed in the audio documentaries.

The Web to Public Knowledge Transfer Model is an eHealth approach used to transfer scientific information to audiences via the World Wide Web. The WMTP has gained experience over many years on structuring health and medical information on the World Wide Web; guiding health consumers to recognize trustworthy health information, or learn how the MRC structures such content for its consumption on the Web. The process is based on a knowledge transfer (KT) model to simplify knowledge uptake by health consumers, while linking content to generic principles and a recognised code of conduct based on ethical standards.

According to Drucker (2001), "Knowledge is information that changes something or somebody, either by becoming grounds for actions or by making an individual (or an institution) capable of different or more effective action," [8]. Thus, the knowledge transfer model can be used to influence the health decisions people make.

Research question

Community radio stations serve an important role in communicating health information to rural communities. The research project aims to answer the following question:

How reliable is the content of health information broadcast by community radio stations?

Goals

The pilot project attempts to answer four research questions. The questions are:

1. How often do community radio station broadcast health slots;
2. What are the sources of information used for health slots;
3. When obtaining health information from a Web site, do they make sure the information is accurate; and
4. What are the preferred formats and methods to receive audio documentaries?

Method

This research project focused only on community radio stations in South Africa. Commercial and campus radio stations will be considered in follow-up studies.

A list of all the South African community radio stations was obtained from The Media Connection [9]. Contact via telephone was established with 60 community radio stations representing all nine provinces. The questionnaire was then administered to 60 community radio stations of which 12 responses were received back.

A questionnaire consisting of 13 questions was developed and sent via email or fax to the participating radio stations. The questionnaire consisted of four parts. The first part dealt with general information about the community radio station. These questions related to where the participating radio station is situated and the languages used by the station. The second part of the questionnaire aimed to answer questions with regards to the frequency of health slots and the sources consulted for health slot content. The third part of the questionnaire focused on the type and format of audio products needed by community radio stations. The last part of the questionnaire focused on preferred methods of communication between WMTP and the participating community radio station.

The pilot study results are based on the feedback of the community radio stations that was received.

Results

All the responding community radio stations indicated that they have regular health slots ranging from once a week to five times a week. One radio station broadcast health information "…when the hospital or clinic needs to bring something to the communities' attention".

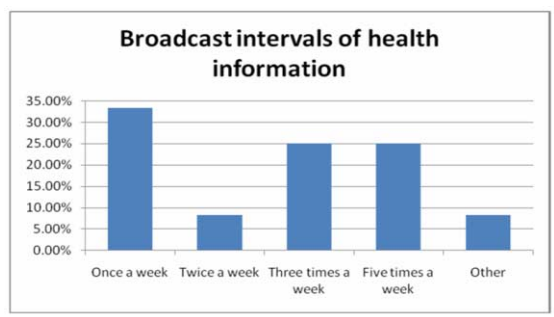

Figure 1 – Broadcast intervals of health information

Results indicated that 33.3% of the community radio stations who participated have a health slot once a week. Results have also shown that 25% of the stations have health slots three times a week and another 25% indicated that they have health slots five days a week. (Figure 1)

The respondents were asked to indicate the sources from which they obtain health information for their health bulletins. All the community radio stations indicated that they make use of multiple sources. The two most popular sources were Clinic Nurses and Community Health Workers with 75% each. (Figure 2)

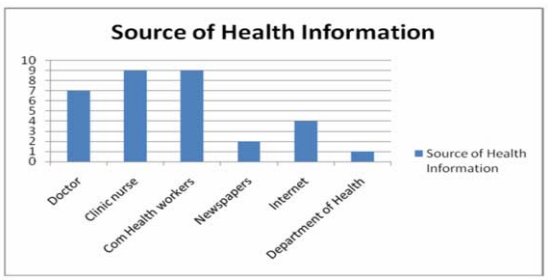

Figure 2 – Source of Health Information

Results from the questionnaire revealed that 100% of the respondents preferred audio documentaries and live interviews followed by panel discussions with 66%, and newsflashes with 58%. The radio stations were also allowed to choose more than one option.

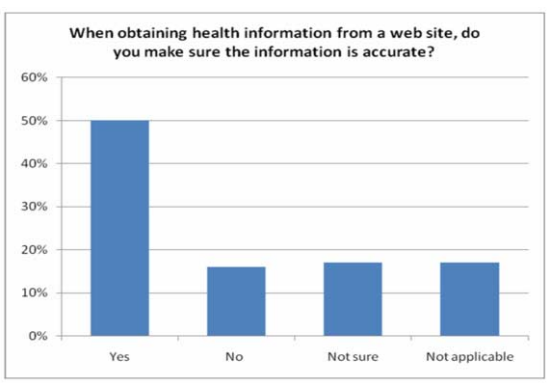

Figure 3 – Quality assurance in seeking health information?

In order to establish whether community radio stations could verify the accuracy of health information that they obtain the following question was asked; "*when obtaining health information from a Web site, do you make sure the information is accurate*". As shown in Figure 3, 50% of the respondents answered "yes", 16% answered "no", 17% were not sure and 17% said it was not applicable to them. This question was further expanded. If they answered "yes", by asking them how they verified the accuracy of the health information. The answers varied from; "they contact a specialist to verify the health information"; they "contact Department of Health and verify the health information with the relevant department"; and they "only use trustworthy sources". This is a clear indication that 50% of community radio stations in this study were not aware of the fact that not all health information on the Internet is accurate or reliable.

Table 1 – Audio documentary format and method of downloading

Indicate your preferred format for audio documentaries	
mp3	91.67%
other format (unspecified)	8.33%
Indicate the preferred method to obtain audio documentaries	
Download from Web site	58.34%
File Transfer Protocol	33.33%
Compact Disk	8.33%

As shown in the cross tabulation of two questions of preferred format of audio documentaries and preferred method to obtain these audio documentaries, Table 1 indicates that 91.67% of the respondents prefer the audio documentaries to be in mp3 format, with 8.33% indicating that they prefer the audio documentaries to be in another format. 58.34 % of the respondents would download it from the Web site, with 33.33% accessing the audio documentaries via the File Transfer Protocol (FTP) and only 8.33% would obtain the audio on a Compact Disk.

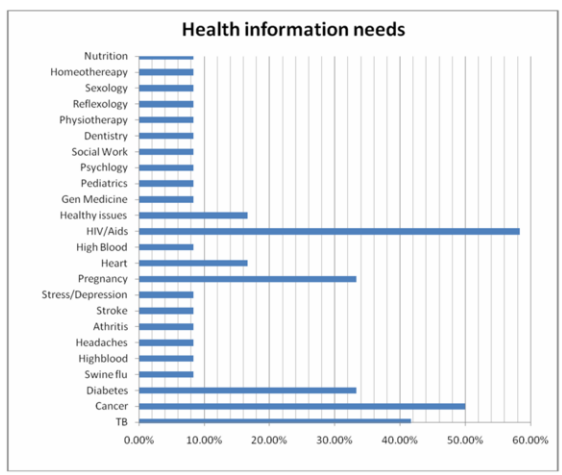

Figure 4 – Health information needs

As the MRC audio production studio develops audio health documentaries according to the health days identified by the Department of Health, which might not be the health information that community radio stations need, a question "*Indicate the preferred topics for health information*" was included in the questionnaire to establish which health topics the community radio stations were interested in. As shown in Figure 4 the health information needs of the community radio stations were as follows: 58.33% on HIV/AIDS, 50% on Cancer, 41.66% on Tuberculosis followed by 33.33% on Diabetes.

Discussion

As shown in the results of the pilot study, health slots amongst community radio stations are an important part of their broadcasting agenda ranging from once a day to five times a week.

The full study could explore whether there is any relation between the frequency of health slots, e.g. once, twice or five times a day and the amount of sources accessible to find information or audio products to fill these health slots. Thus, will community radio stations include more health slots or programmes dealing with health issues if there were more sources they could consult or audio products they could utilize to fill these programmes?

The majority of sources used by community radio stations for health slots are clinic nurses and community health workers. Although they have knowledge on certain health topics, such as diabetes and HIV/AIDS, they may not have the facts readily available to give advice on epidemic outbreaks such as H1N1 (swine flu). Therefore it is important to inform the community radio stations of the radio Web site that is available for them to expand their source of up to date, reliable and accurate health information.

As the results indicate, community radio stations prefer to receive audio documentaries of health information in mp3 format. The majority of respondents preferred to download these audio products from the Web site. These audio documentaries are already available on the radio Web site for radio stations to download as they have been developed on health topics, specified in the health calendar of the Department of Health. Based on the results of the health topics as specified by the radio stations, WMTP could further expand on the development of audio documentaries and play a role in supplying material for the health bulletins.

Results from the pilot study show that there is a definite need for accurate and reliable health information in audio format for community radio stations. In an era of increased Internet access and connectivity where more and more health consumers turn to the World Wide Web for guidance on health issues, the compliance to standards has become essential.

A full study could also determine if community radio stations would increase their health slots based on an increased amount of 'healthy' audio material.

Conclusion

The results also show that a Web site developed according to the WPKTM, incorporating the generic principles and a recognised code of conduct based on ethical standards and good practice guidelines, with the option to download audio in mp3 format, would be an effective tool for community radio stations that have access to the Internet.

The way forward would be to engage more community radio stations and to include campus radio stations and commercial radio stations in a full study.

WMTP aims to introduce the radio Web site as the preferred source of health information and a *"one stop shop"* for community and campus radio stations.

Abstract

Objectives: To assess and understand adverse drug reactions (ADRs), a systematic review of reference databases like Pubmed is a necessary and mandatory step in Pharmacovigilance. In order to assist pharmacovigilance team with a computerized tool, we performed a comparative study of 4 different approaches to query Pubmed through ADR-drug terms. The aim of this study is to assess how an ontology of adverse effects, used to normalize and extend queries, could improve this search. Material and Method: The ontological resource OntoEIM contains 58,000 classes and integrates MedDRA terminology. The entry point is a ADR-Drug term and the four methods are (i) a direct search on Pubmed (ii) a search with a normalized query enhanced with domain-specific Mesh Heading criteria, (iii) a search with the same elaborated query extended to the MeSH sub-hierarchy of the adverse effect entry and (iv) a search with a set of MedDRA terms grouped by subsomption in the OntoEIM ontology. For each of the 16 queries performed and analysed, relevant publications are selected "manually" by two pharmacovigilant experts. Results: The recall is respectively of 63%, 50%, 67% and 74%, the precision of 13%, 26%, 29% and 4%. The best recall is provided by the ontology-based method, for 4 cases out of 16 this method returns relevant publications when the others return no results. Conclusion: Results show that an ontology-based search tool improves the recall performance, but other tools and methods are needed to raise the precision.

Introduction

Pharmacovigilance is the science focusing on detection, analysis and prevention of adverse drug reactions (ADRs). Spontaneous reports of ADRs by health care professionals allows the collection of case reports by central agencies and/or pharmaceutical companies [1]. Case reports (namely *ADR*-Drug pairs) are coded with the WHO-ART[1] and/or MedDRA[2] terminologies for the ADR and the ATC terminology for the drug, and stored in databases that constitute putative knowledge on suspected adverse drug reactions.

The pharmacovigilance team has the task to code newly reported ADR-drug cases but also to document and analyze them with relevant and up-to-date information retrieved from various sources. The sources presently requested during this review task are 1) drug summary of the product's characteristics (SPC), 2) pharmacovigilance-related data sources (such as Martindale, Meyler's Side effects of Drugs, other databases like Micromedex), 3) medical literature 4) previously reported cases. We address the documentation issue in the context of the Vigitermes project[3] which aims at developing a semantic portal to improve documentation of pharmacovigilance case reports for the pharmaceutical industry and regulatory authorities [2]. In the Vigitermes platform, for a given case, one action button performs the search on the drug SPC, Pubmed and pharmacovigilance databases. The PharmARTS tool is used to group cases with a close meaning, it relies on an ontology of adverse drug reactions (OntoEIM) that is based on the formal definitions of WHO-ART and MedDRa [3, 4]. In the present work, our objective is to evaluate the benefit of using the OntoEIM ontology in the request process on PubMed database. Our aim is to automate the search of relevant publications that correspond to a given ADR case. In a previous work, we presented a Pubmed querying web service for retrieving abstracts from the MEDLINE database based on Mesh heading and Mesh qualifier pattern criteria [5]. In this study, we performed a comparison of four different search methods using our Pubmed querying web service.

First, terms clustering and information retrieval with MEDLINE are presented in the background section. We then

[1] World Health Organization - Adverse Reaction Terminology
[2] Medical Dictionary for Drug Regulatory Activities
[3] http://vigitermes.univ-rennes1.fr

present the OntoEIM ontology and PharmARTS, the browsing tool used to query the ontology. The general architecture of the Vigipubmed toolbox is described and we detail the comparison study used to assess the "plus-value" of the ontology. Results are reported on a set of 13 ADR-drug cases are presented and discussed.

Background

Information retrieval with Medline

Several studies have shown that researchers report difficulties when searching electronic resources to document adverse drug reactions [6, 7]. Among others, these difficulties are due to poor indexing, to the wide variety of articles that may potentially be useful, to variation in their qualities, as well as the lack of tools to perform systematic search. Literature, specifically MEDLINE, is the main source of documentation used to detect whether a drug may be responsible for ADRs. Nowadays, literature searches are mainly done manually. However, the exhaustive retrieval of such information may not be straightforward, for three reasons. Firstly, the query is not easy to formulate: the terms have to be translated in English (for non-English speakers), and even mapped to MeSH entry terms. Secondly, the large number of publications in MEDLINE makes the search difficult and time-consuming. Thirdly, it is not easy to determine manually the level of evidence that should be the most appropriate to characterize the relation between a drug and a possible adverse effect.

Grouping similar ADRs

ADRs are coded with MedDRA or WHO-ART in pharmacovigilance databases. The MedDRA terminology, recommended for the description of ADRs by the pharmaceutical industry and regulatory authorities, includes entirely the WHO-ART terminology, but is considerably more extensive (15,000 preferred terms versus only 3500 for WHO-ART).

The structure of relationships used to organize terms is particularly important to retrieve similar medical conditions in the database and has a direct impact on the specificity and sensitivity of pharmacovigilance signal detection [8]. We have previously shown that neither WHO-ART nor MedDRA allows similar clinical conditions to be clustered together due to the lack of polyhierarchy. For instance in MedDRA, the term "gastric ulcer hemorrhage" is linked to the "gastric ulcer and perforations" term but not to the "gastric and esophageal hemorrhage" term. This deficiency limits the detection and the evaluation of ADRs [9].

We have developed an ontology (OntoEIM) describing ADRs that enhances the structural organisation of terms [3]. A web tool, PharmARTS, was developed as an interface to this ontology [10]. This ontology is under evaluation in the context of signal detection [4]. We investigate in the present article the relevance of this ontological resource to retrieve relevant articles in Medline for a given query.

Material and Method

Material

The OntoEIM iontology was previously developed and mapped with MedDRA and WHO-ART terminologies [3] PharmARTS, an online web service tool developed to query the ontology [10], is used to extend the query by grouping .MedDRA and WHO-ART terms with close meaning using OntoEIM.

OntoEIM

OntoEIM includes ADRs concepts obtained by aligning WHO-ART and MedDRA terms with SnomedCT[4], using the synonymy link in the metathesaurus of UMLS[5]. Relations in the ontology are associative relationships extracted from SnomedCT (e.g. "bladder neoplasm" is associated with the localization "bladder structure") and the relationship "is a" is used to indicate taxonomic relationships (e.g. "renal failure" is a "renal disease"). The ontology contains 5 798 WHO-ART classes, 37,892 MedDRA classes and 14,342 SnomedCT classes and includes 1,621 defined classes. The primary concepts of the hierarchy account for 4.6% of SnomedCT (308,677 concepts in the used version).

PharmARTS

PharmARTS is a web service developed in JAVA [10]. This tool can be used for querying (related to a clinical condition) and for grouping terms together by subsumption, (e.g. the terms "BLOOD_TRIGLYCERIDES_ABNORMAL" and "CHOLESTEROL_BLOOD_EXCESSIVE" could be used to encode two cases of dyslipidemia). PharmARTS can also be used to provide a more effective visual display of groups of terms and of associated pharmacovigilance cases [10].

Method

In order to assess the contribution of the ontology in the retrieval of relevant documentation from MEDLINE, we conducted a comparative study of four methods used to query the Pubmed database. Figure 1 displays the web service workflow of the evaluation system. The entry point is a pair of ADR-drug terms of a given case.

[4] http://www.ihtsdo.org/
[5] http://www.nlm.nih.gov/research/umls/

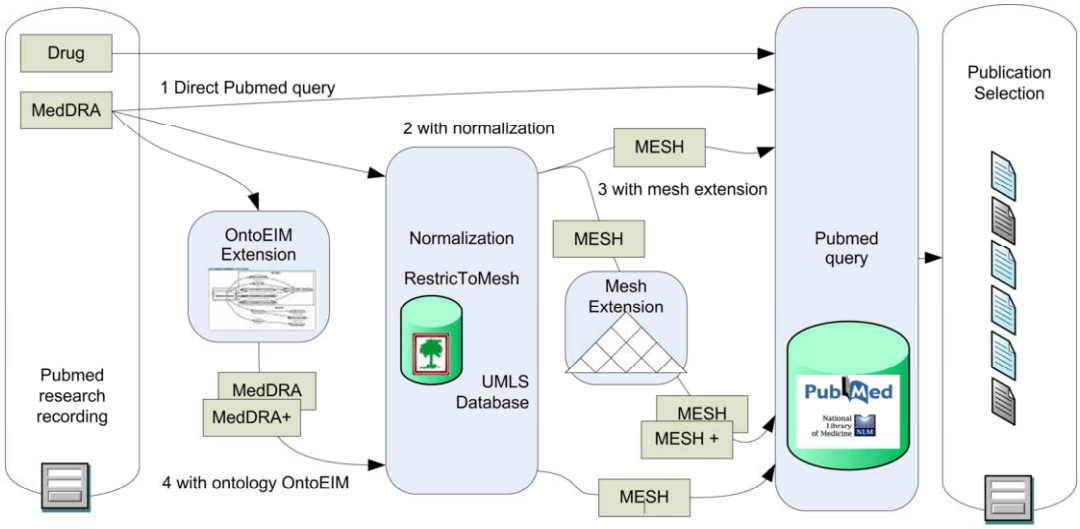

Figure 1- Web services work flow

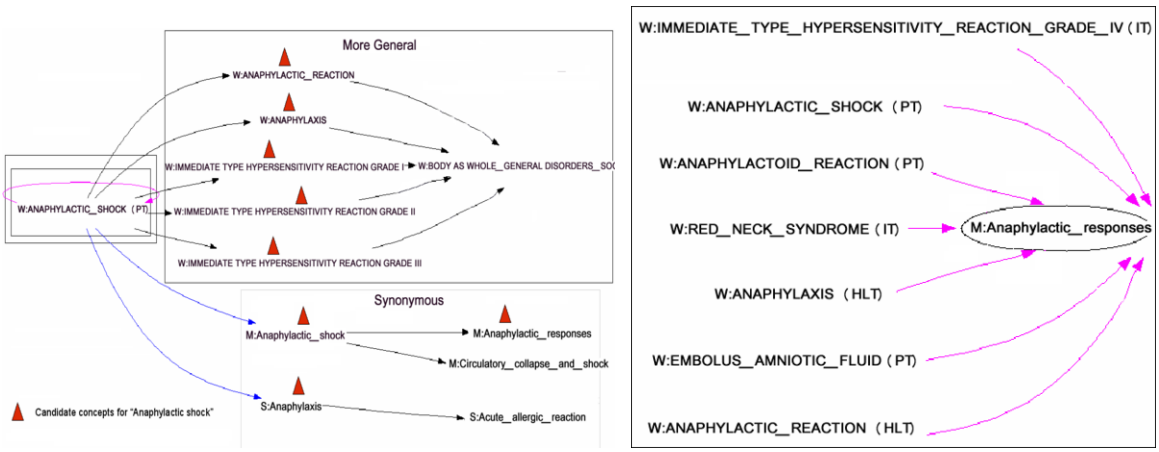
Method 1 uses the Pubmed web service without any refinement, just as the pharmacovigilant will use PubMed. Method 2 uses our own web service VigiPubmed that builds a normalized query for pharmacovigilance. The MedDRA terms are first normalized with UMLS and matched on the MeSH thesaurus [11], then the Pubmed query is built similarly to the one previously proposed [5]. Both methods 3 and 4 also use the VigiPubmed web service. For method 3, the queries are developed successively with all the terms of the MeSH subhierarchy of the adverse effect entry. For method 4, PharmARTS.is first called in order to extend the initial MedDRA entry terms with the OntoEIM ontology, then the group of MedDRA terms is processed with VigiPubmed. The evaluation system is a simple web form application developed in php that integrates the different web services written on a java/axis2 platform.

The relevance of the selected articles is evaluated independently by two pharmacovigilance experts; then the results are compared and in case of discordance, discussed until consensus. A relevant publication is a publication that contributes to the analysis of the ADR case, that helps its comprehension; it is likely to be cited in the literal case report written by a pharmacovigilant.

In method 4, the OntoEIM extension consists in searching OntoEIM for concepts similar to the label used by the pharmacovigilant. We begin by identifying one or several terms associated to the label (WHO-ART term or the SnomedCT and MedDRA Synonymous), using PharmARTS. In a second step, we select candidate concepts in OntoEIM designed by these terms as well as the ascendant when the concept itself doesn't allow any grouping (a leaf concept in the ontology). Finally, the method returns the union of concepts subsumed by all candidate concepts. For example, for the label "Anaphylactic shock" we identify three terms: 1) Anaphylactic shock from Who-ART, 2) Anaphylactic_shock from MedDRA and 3) Anaphylaxis from SnomedCT, these terms are associated with concepts in the OntoEIM ontology and we can therefore carry out three queries with PharmARTS returning three sets of concepts designed by terms from the various terminologies. Figure 2 shows a graphical representation of the organization of these concepts within the ontology.

Example : Anaphylactic shock

List of grouped terms : (ANAPHYLACTIC_REACTION, ANAPHYLACTIC_SHOCK, ANAPHYLACTOID_REACTION, ANAPHYLAXIS, EMBOLUS_AMNIOTIC_FLUID, IMMEDIATE_TYPE_HYPERSENSITIVITY_REACTION_GRADE_I, IMMEDIATE_TYPE_HYPERSENSITIVITY_REACTION_GRADE_II, IMMEDIATE_TYPE_HYPERSENSITIVITY_REACTION_GRADE_III, IMMEDIATE_TYPE_HYPERSENSITIVITY_REACTION_GRADE_IV, RED_NECK_SYNDROME)



(a) *(b)*

Figure 2-Graphical illustration of the ontological extension. (prefix W for Who-ART, M for MedDRA and S for SnomedCT) a) Candidate concepts for term "Anaphylactic shock" b) List of subsumed concepts for candidate concept "Anaphylactic_responses"

Results

The study was performed on the following entry points, based on cases or questions transmitted to the pharmacovigilance department. There are 13 cases grouped in 8 groups which correspond to 16 queries on Pubmed : 1) ADR=lupus, Drugs=statin (atorvastatin, fluvastatin pravastatin rosuvastatin and simvastatin), 2) ADR=purpura, hematoma, petechia or thrombocytopenia, Drug=levetiracetam 3) ADR=anaphylaxy , Drug=rituximab 4) ADR=neutropenia, Drug=ciprofloxacin 5) ADR=hair disorder, Drug=valproate or clonazepam, 6) ADR=Lyell Syndrome, Drug=paracetamol 7) ADR=thrombocytopenia, Drug=infliximab, 8) ADR=Aseptic meningitis, drug=sulfamethoxazole trimethoprim. For instance, in the first group, one can see that there are 5 cases corresponding to the 5 drugs. In the second group, one can see that there is only one case but corresponding to 4 different queries (4 possible terms for the ADR).

The choice of these queries was deliberate in order to check various situations : drugs largely prescribed and with extensive publications (like statins), drugs not widely prescribed (levetiracetam), ADRs that are also indications for the drug (neutropenia and ciprofloxacin), ADRs not clearly defined (purpura, hematoma, petechia or thrombocytopenia), and an expected ADR (aseptic meningitis and sulfamethoxazole trimethoprim). Table 1 displays quantitative results of the comparative study based on 13 reported ADR-drug cases. In the domain of bibliographic review the gold standard is not easily defined, in our study we use a relative reference to calculate recall and precision. For each given case, the reference is the set of relevant abstracts selected by any of the four methods.

Main publication types are "case reports" for 501, unspecified "journal article" for 421, "clinical trial" for 378, "review" for 214, "comparative study" for 96, "letter" for 75, etc.

Table 1- evaluation results of the four search methods

Method	Pubmed	VigiPubmed		
	Method 1	Method 2 Alone	Method 3 + Mesh extension	Method 4 + ONTOEIM extension
Abstracts	480	184	218	1780
Relevant Abstracts	60	48	64	74
Recall	63%	51%	67%	78%
Precision	13%	26%	29%	4%

Compared to the direct request on PubMed, VigiPubmed works as a filter as the 184 VigiPubmed abstracts are is a subset of the 480 Pubmed abstracts. Hence VigiPubmed does improve the precision however other tools are needed to get a better recall. The best recall is provided by "VigiPubmed + OntoEIM", the ontology-based method (78%). In four cases out of 13, this method returns relevant publications when the others methods return no results. For instance, in the case of anaphylactic shock with rituximab, methods 1 to 3 retrieve 8 abstracts but none of these abstracts is relevant while, for method 4, 34 articles are retrieved, and 6 of them, associated with the "RED_NECK_SYNDROME" term, normalized in "hypersensitivity", are selected by the reviewers to be relevant.

Extending the Pubmed request with the ontology causes a loss of precision (4%), this result is expected when we enlarge the context of the bibliographic search, however, for this study, our focus is on the recall in order to demonstrate the "plus value" on the ontological approach in terms of the retrieval of relevant paper. In the future, we can imagine various methods

to browse the results in an efficient manner for increasing the precision: scoring and filtering based upon Mesh heading and qualifier, graphical interface associated to the ontology, etc.

Discussion and conclusion

As of today, we don't have a good evidence for what constitutes an effective search strategy for adverse effects in the medical literature. As the combination of an ADR and a drug is infinite, any method that could normalise and help this search is useful. Moreover, interrogation should not be expert-dependant and should be reproducible whoever realizes it. In the current practice, pharmacovigilance experts start by choosing a term for the adverse effect studied. When the effect is correctly described and well-known, as the choice is easy, the results are easy to analyze, but when few or no documentations are found in the searched databases, experts extend the term to a close adverse effect. The automatic extension to these close terms may therefore be very useful.

Considering the results of this preliminary study, the best way to achieve the bibliographic review on PubMed in terms of cost (that is the number of abstracts to be read) and efficiency (that is the number of relevant articles) is a combination of the different methods. In a first step, the request can be done with the VigiPubmed web service directly or with the MESH extension, the result of the program is a list of articles reduced of about 60 % with regard to a direct request on PubMed whereas recall are 51%, 67% versus 63%. In a second step, when the first request returns no result and also to enlarge and complete the bibliographic review, the request is extended with terms provided by the ontology. The contribution of the ontology is to define a concept into a context by relationships to the others. For instance, a question about thrombocytopenia related to infliximab returns two publications but three additional publications, retrieved with the ontology-based method, reporting another close haematological effect, were useful for the analysis and the comprehension of the case studied.

Another major issue is when the potential adverse effect studied is also a condition or a disease that the drug is used to treat. The best example is neutropenia occurring after antibiotics. The addition of a term such as adverse effect, drug toxicity is not always useful as authors do not always add a specific term for pharmacovigilance data. Global recommendations about pharmacovigilance publications (Drug safety public ERICE) should be applied more systematically [13]. In this first study we adopt the point of view of ADRs. In a future second phase, a similar approach could be applied with the point of view of drugs and active ingredients.

Abstract

Problem: There is limited experience with broad-based use of handheld technologies for clinical care during home visits in sub-Saharan Africa. Objective: We describe the design, development, implementation, and evaluation of a PDA/GPS-based system currently used during home visits in Western Kenya. Results: The system, built on Pendragon Forms, was used to create electronic health records for over 40,000 individuals over a three-month period. Of these, 1900 represented cases where the individual had never received care for the identified condition in an established care facility. On a five-point scale, and compared to paper-and-pen systems, end-users felt that the handheld system was faster (4.4 ± 0.9), easier to use (4.5 ± 0.8), and produced higher quality data (4.7 ± 0.7). Projected over three years to cover two million people, use of the handheld technologies would cost about $0.15 per person – compared to $0.21 per individual encounter entered manually into a computer from a paper form. Conclusion: A PDA/GPS system has been successfully and broadly implemented to support clinical care during home-based visits in a resource-limited setting.

Keywords:

Handheld computers, Computerized medical records systems, Developing countries

Introduction

Many people in developing countries have little to no interaction with the healthcare system. The problem of accessing healthcare in these settings is usually two-fold: "*On the supply side, good quality, effective health care may not be offered. On the demand side, individuals may not utilize services from which they could benefit*." [1] As an example, in sub-Saharan nearly, 80% of HIV-infected adults are unaware of their HIV status [2] - this despite an interest by individuals in being tested [3]. Similar deficiencies are also seen in the diagnosis and management of diabetes, hypertension, chronic cardiovascular disease and tuberculosis, among others [4, 5]. Such poor access to healthcare leads to increased mortality and morbidity in these settings.

Approaches that take health services directly to individuals (as opposed to waiting for patients to come to the care facility) are being increasingly adopted to improve access to care. There is increasing adoption of home-based counseling and testing methods for HIV [6]. In addition, governments in developing countries are increasing the number of community health workers tasked with delivering care services directly into homes and communities.

By their very nature, home-based clinical encounters lead to care outside established health facilities. In the setting of sub-Saharan Africa, these visits often represent the first interaction of some individuals with the healthcare system. Such individuals typically have no established medical records, and data collected during home visits often represent the first medical records on them. As such, it becomes very important to collect this clinical information in a way that is useful not only during return visits to the home, but also for clinic-based follow up and for reporting purposes.

The USAID-Academic Model Providing Access to Healthcare (USAID-AMPATH) [7] in Western Kenya recently embarked on an effort to conduct home visits to the two million individuals in its catchment area. The goal was to collect basic health information and offer focused care services to individuals when needed. Typically, records collected for such visits would have been paper-based. We however hypothesized that it would be possible to completely leapfrog paper-based records, and create electronic health records (EHRs) for each individual for whom we conducted a home-based clinical visit.

The premise of our approach was based on the observation that resource-limited settings like ours had already made similar technological leaps [8]. The classic example was the leap from no telecommunication services to broad use of mobile telephony [9]. In addition, mobile devices had also been successfully used for limited research and clinical purposes in settings similar to ours [10, 11]. However, there was very

little evidence to demonstrate the feasibility of broad-based implementation of mobile handheld technology for direct clinical care in these settings.

In this article, we describe the design, creation, and implementation of a customizable, modular-based handheld program to support Community Health Workers (CHW)s during home-based visits in a resource-limited setting. We also reports findings of a satisfaction survey of the end-users of the program and cost implications of using this system.

Materials and Methods

Setting

This work was conducted in Western Kenya, within a catchment area served by the USAID-AMPATH partnership. This program (made up of Moi University School of Medicine in Kenya and a consortium of universities in North America led by Indiana University School of Medicine) has provided comprehensive HIV care to individuals in western Kenya since 2001 [7]. In the last two years, the program has begun a transition into primary care.

Recognizing its responsibility to improve access to care for all individuals, the USAID-AMPATH program decided to conduct population-wide, clinically focused home visits to all households in its catchment area of two million people. The primary goal of this undertaking was to identify HIV-positive patients who were unaware of their status, and to offer care services as needed. In addition, this program aimed to identify pregnant women not receiving antenatal services; orphaned and vulnerable children; children who had not received all recommended immunizations for age; and individuals at higher risk of tuberculosis infection. During the home-visits, eligible individuals were offered rapid testing for HIV, sputum testing for Tuberculosis, deworming medication, and mosquito bednets. All clinical data gathered during these visits were captured on handheld devices.

Design and Development of Handheld Program

We started by engaging an interdisciplinary team of providers (including public health providers, nurse CHWs, and physicians), overseen by an executive steering committee. This team identified the data elements to be collected during the home visits, provided information on criteria and algorithms to be used (e.g. algorithm for HIV testing), and informed the team about the workflow relevant to the home visit exercise.

Modules

Several modules were identified as necessary for the home-based visits, and were programmed into the handheld devices. (Figure 1) The modules included:

Individual registration

Each individual who was visited by a CHW received a unique identifier. Households were also assigned unique identification numbers. These identifiers were generated from one central location, and had a check-digit. For the household, we captured the Global Positioning System (GPS) location and other information about the household, including number of residents. The individual demographic information collected included: first, middle, and last name; gender; birthdate [with ability to record estimated dates]; address; and phone number (when available).

HIV Module

The HIV module collected information about each individual's HIV testing history. We documented whether the individual had previously been tested, the year of their last test and the results. If the individual was known to be HIV-positive, we captured details of the HIV-treatment program to which they were enrolled. During the home visits, eligible individuals were offered HIV testing, and details of the testing were also collected. These included information about pre- and post-test counseling during the home visit; consent or assent to testing; results of two parallel rapid tests and of a third tie-breaker test (when it was done); referrals; and information on whether the

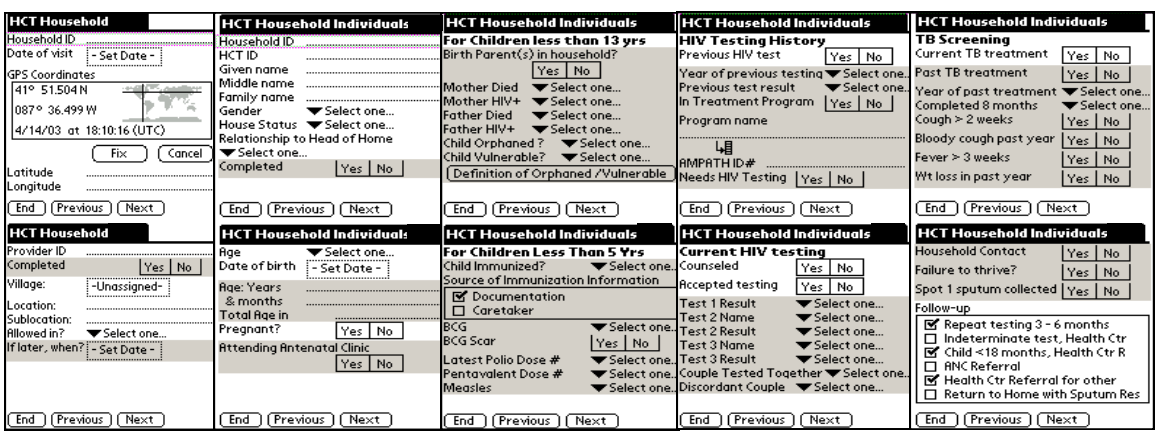

Figure 1-Screenshots outlining the various modules

HIV-statuses of a couple were discordant.

Pediatric Module

For children, we determined whether the child was orphaned or vulnerable (OVC) using a pre-defined set of conditions. A child was eligible for testing if their mother's HIV status was positive or unknown, or their mother had died or living status was unknown, and the relevant information was recorded. For children younger than five-years, we also recorded immunization history - including the source of the immunization information; details of measles, polio and pentavalent vaccination; and whether there was any visible BCG scar to signify immunization against TB.

Tuberculosis Module:

For all individuals visited, we documented history of current or previous TB treatment and responses to TB screening questions (e.g. bloody cough, fever, and weight loss). We also documented whether a sputum sample was collected for at-risk patients and the phone number to contact the individual with the results.

Antenatal Care Module:

For females of reproductive age, we documented pregnancy status. If pregnant, we documented whether they were enrolled into an antenatal clinic.

Software and Hardware

We developed the program to collect individual health data using Pendragon Forms software (Pendragon Software Corporation, Illinois, USA). Like most other Personal Digital Assistant (PDA)-based form-creation software, [10, 11] Pendragon Forms has a Windows application for designing customized data-collection forms. This program supports over 20 field types, and has scripting capability for data validation, calculations, and for form navigation control. Once developed, forms can be uploaded to Pendragon's PDA runtime application that runs on Palm-powered handhelds and on Windows Mobile Pocket PCs. Data collected on PDAs can be synchronized into a database (like Microsoft Access or SQL server) or exported to ASCII and Excel. Pendragon Forms support multiple users, and synchronization can be bidirectional.

Using the Pendragon Forms software, we programmed data-collection forms containing information for our various modules. In addition, we programmed basic data validation, branch logic, and reminders/alerts into the forms. The forms were uploaded into Palm T|X PDA devices (Palm Inc®, California, USA). We also loaded valid identifiers, a check-digit verification algorithm, detailed information about the administrative locations in the region, and provider identifiers. Global Positioning System (GPS) coordinates were captured with an external e-Trex GPS device (Garmin®, Kansas, USA) linked via a cable connection to the PDA.

Data Collection

The handheld tools were iteratively tested and improvements made. We then conducted two days of formal training for the CHWs who would be the end-users of the PDA/GPS devices and software. Each CHW was assigned a specific device, and had primary responsibility to ensure that the device was always in good working condition. The CHWs carried the handheld devices during home visits, and recorded all needed data during the encounter in the Pendragon forms after seeking consent of individuals in the household – these individuals had already been sensitized about the home visits and the use of these gadgets through a concerted community-wide mobilization effort. Data managers would, on a weekly basis, transfer the data from PDAs to a central Microsoft Access database (Microsoft Corp®, Redmond, WA, USA).

User Survey

To assess end-user attitudes toward the PDA/GPS handheld tools implemented, we gave an anonymous self-administered survey to CHWs who were present at a full-group meeting. Respondents were asked to rate the reliability of the PDA program and the GPS device. They were also asked to compare the utility of these handheld tools relative to paper-and-pen based systems. Respondents also gave information about their PDA and computer experience.

Data Quality and Cost Calculations

We used data collected during home visits in the Turbo Division in Western Kenya to evaluate completion and quality of data collected using the handheld devices. Findings are reported using descriptive statistics. Our cost calculations were based on the expected resources needed to reach the two million people in our catchment area within three years (780 workdays). From home visit data from Turbo Division, we knew the average number of individuals a CHW could see per day. Using this number, we determined number of providers (and hence handheld devices) needed to complete the visits with the three-year timeframe. Our calculations accommodate a device breakdown rate of 25% per year. We also include the cost of developing the system, training, and maintaining the PDA/GPS devices, and compare this cost with one using paper-and-pen based system.

Results

EHRs during Home Visits in Turbo

Between July and October of 2008, 93 CHWs visited 14,648 households in the Turbo Division in Western Kenya. During these visits, they interacted with and created electronic health records for 40,111 individuals. Of these individuals, 55% (22,182) were female and 26% (9,509) were below 13 years of age. On average, each CHW saw and created records for 12 ± 6 individuals per day. In the first year of use, only one device was lost, and four failed (out of 93 devices).

The visits in Turbo Division uncovered cases for which the individual had never presented for formal care in an established facility – and where no records (paper or electronic) existed. Four hundred and three of 899 (45%) pregnant women identified were not receiving antenatal care. Of the 1,131 individuals with positive HIV test results at the time of the home visits, 693 (61.3%) had never had a previous HIV test. 376 individuals had been exposed to or had symptoms sugges-

tive of tuberculosis. In all these cases, the electronic records created on the handheld devices were the first documented health records for these individuals or for their condition.

User Satisfaction

We administered our survey to a convenience sample of 70 CHW. At the time, there were 78 active CHW who had been using the PDA/GPS devices. All CHWs surveyed responded, for a response rate of 90% of all CHWs at the time. Sixty-five (94%) of the respondents had never used a computer, and 65 (94%) had never used a PDA prior to our implementation.

Compared to paper & pen-based systems and on a five-point scale, CHWs felt that using the PDA/GPS devices was faster (4.4 ± 0.9), easier (4.5 ± 0.8), and resulted in higher quality data (4.7 ± 0.7). Surprisingly, CHWs also felt that using the handheld devices made their interaction with the patient easier (4.0 ± 0.9). There was a sense that the devices made them look more professional. One CHW captured this sentiment in their written comments about the PDA: "*It boosts someone[s] moral[e] on duty, and puts [them] in a high class.*" In addition, CHWs reported being highly satisfied with the training received on the handheld tools (4.8 ± 0.5), and all wanted to continue using the devices during home visits (4.8 ± 0.5).

Data Quality

Analysis of uploaded data revealed that all individuals and households were assigned unique identifiers, with no duplicates. GPS information was captured for all households, but in 4,695 (32%) of the cases, the CHW had to enter this information manually into the PDA. Manual entry had to be done when the cable connection between the PDA and GPS device was not working properly. Despite programming the PDA to allow for easy manual-entry and verification of coordinates, there was always a chance of errors being made. Other quality checks confirmed that no males were assigned a pregnancy status, and that each record was completed. Queries of the number of daily visits recorded per provider revealed some outliers – as an example, four of the 93 CHWs had days with more than forty individual encounters entered. This seemed unrealistically high and demanded further investigation.

Cost

We plan to visit two million unique individuals in our catchment area within three years (780 workdays). To meet this goal, an average of 2,565 individuals have to be visited each workday. From our Turbo Division data, we know that a CHW visits, on average, 12 individuals each day. This would mean having about 214 CHWs with PDA/GPS systems working on any particular day. Assuming that we have a breakdown rate of 25% for the PDA or GPS devices per year, we will need about 320 total PDA/GPS units over the period of the evaluation – i.e. an additional 53 devices at the beginning of the second year, and another 53 at the beginning of the third.

At a rate of $299 per PDA, $55 per Pendragon Forms license, $189 per eTrex GPS device, and $30 for the cable to connect the GPS and PDA devices, the cost of setting up PDA/GPS units per CHW would be $573 – bringing the total to $183,360 for 320 units. The data collected on handhelds will be synchronized into computers located at one of the 18 USAID-AMPATH clinics. At $1,500 per desktop computer, the cost of 18 computers will come to $27,000. Personnel costs include one-month programming time by a dedicated mid-level programmer based in Kenya for a cost of $1,600, 50% of an IT person's time ($22,000 for three years), 50% of a data manager's time ($22,000 for three years), and two dedicated data assistants ($45,000 for the three years). Training costs will come to about $1000, assuming two day training sessions for CHWs in groups of 70 to 80.

Adding all expenses, the total implementation costs for the handheld technology comes to $301,960. For each of the 2 million individuals visited, the cost of using the PDA/GPS technology per individual will be about $0.15. This estimate does not take into account the fact that the PDA/GPS devices can still be resold, or used for other purposes in the future. For comparison, if paper-and-pen based systems were used during home visits and the data entered by data-entry clerks, it would cost about $0.21 per record to simply enter this data – a typical data entry clerk is paid $17 per day and is expected to enter 80 encounters. In fact, the pen-and-paper based system would have other costs, including the supplies, the cost of computers, data management, and data cleaning.

Discussion

Our implementation in Western Kenya represents one of the largest applications of a PDA/GPS system for clinical care during home-based visits in a resource-limited setting. Most of the previously described, PDA-based eHealth applications have been largely used for research purposes or in limited clinical settings [10]. As our home visits focus on improving access to care, we found many cases where individuals had never received care in an established clinical facility. In such cases, no medical records existed, and our system (which created electronic health records) simply leapfrogged the typical paper-based charts found in this region.

Our approach, which is well-liked by the end-users, is scalable. The software created can be easily installed to more devices, and new clinical modules can easily be added into the existing software. We demonstrate that end-users with little experience with PDAs and computers can learn to use handheld devices. The typical concerns about reliability of the handheld system and theft of devices in settings like ours proved unfounded in our case. We find that CHWs who are given primary responsibility for a PDA device take as good care of it, as they do for their own personal mobile phones.

There is mounting evidence that collecting data via handhelds has multiple advantages over pen-and-paper systems. The data collected via PDAs frequently contain less errors, are often more complete, require less cleaning, and might not be any more expensive [12]. End-users also generally prefer handheld systems over pen-and-paper methods [13] – an observation reinforced in our survey. As Dwolatzky et al. point out, data collected electronically via handheld devices are also available for re-use in queries to generate reports, for case-management, and for follow-up within established clinics. The

GPS information can also help find patients lost to follow-up and signal disease outbreaks.

The handheld system we created is being linked to the electronic medical record system currently in use at USAID-AMPATH. Since 2004, USAID-AMPATH has been using the AMRS EHRs to support care of its patients [14]. AMRS was the first implementation of the open-source OpenMRS software [15] which already interacts with several mobile applications including EpiSurveyor,[16] the Android-based Open Data Kit,[17] JavaRosa-OpenRosa,[18] and Moca Mobile [19]. We chose Pendragon Forms because of its flexibility, but were fully aware that we would eventually integrate the data collected into our functioning, clinic-based EHRs.

Despite the success of the handheld technology in our setting, several key limitations of this technology need to be highlighted. Handheld devices generally have limited storage capacity and battery life. We also noticed that the connection between the cable PDA and GPS devices was not always reliable – we will be switching to PDAs that have inbuilt GPS capability. Handheld technologies also carry the risk of security breaches - either when devices are lost, or during transmission of data. As such, it is important to authenticate all users, and to encrypt data whenever possible [20]. Collecting precise locations using GPS also increases the risk of confidentiality loss, and appropriate measures must be taken to protect individual privacy [21]. We also have to remember that the success of handheld technologies will depend heavily on the use-case and the organization within which the technology is implemented. For example, clinical encounters that required extensive free-text might not be amenable to use of handheld technology. Consideration also needs to be given to workflow issues, user-input, and training.

Conclusion

We have developed and widely implemented handheld-based systems for use during home-based clinical encounters in the resource-limited setting of Western Kenya. This undertaking has enabled us to create electronic records for numerous cases where paper records did not even exist. Users prefer these handheld systems over pen-and-paper based systems.

Acknowledgments

We thank the Turbo community for supporting our home-based initiative. Special thanks to the mobilizers and CHWs, and all HCT staff. Abbott Fund and NLM (Grant LM07117-11) supported development of the handheld tools. This research was supported in part by a grant from USAID as part of the President's Emergency Plan for AIDS Relief (PEPFAR) and by the Abbott Fund.

Cell Phone Short Messaging Service (SMS) for HIV/AIDS in South Africa: A literature review

Khatry-Chhetry Mukund Bahadur[a], Peter J. Murray[b]

[a] *Faculty of Health Sciences, Walter Sisulu University, Mthatha, South Africa*
[b] *Centre for Health Informatics Research and Development, Lincolnshire, United Kingdom*

Abstract

The HIV/AIDS pandemic is one of the most serious threats to global health. HIV/AIDS is a chronic illness, requiring patient empowerment to enhance adherence to treatment regimes if it is to be managed effectively. While healthcare costs are rising, people still have expectations of high-quality care. This literature review-based study explored the use of cell phone (mobile phone) short messaging services (SMS) in health care, in particular for HIV/AIDS in South Africa.

From an initial corpus of 212 papers, 28 were reviewed. The main findings include that SMS can improve service delivery through appointment reminders and improve communication between healthcare workers. It improves diagnosis, prevention, treatment and rehabilitation by supporting adherence to medication, and monitoring illness and medical interventions. SMS is useful in public health programmes, such as contact tracing and partner notification, therefore playing an important role in control of HIV/AIDS. As South Africa has one of the highest uptakes and demographic distributions of cellular technology in the world, SMS is feasible as a tool to deliver quality health care with low cost.

Introduction

South Africa has a population of 48.7 million, with 46% living in rural areas. Many South Africans are struggling with HIV/AIDS infection [1]. The data suggest that, in the decade to 2010, up to 7 million South Africans will die from AIDS [2], with life expectancy in South Africa falling to 43 years. With approximately 5.7 million people living with HIV in South Africa, including 280,000 children under 15 years old, young people are increasingly at the centre of the HIV/AIDS epidemic [3], [4]. Many social factors drive the HIV/AIDS epidemic in South Africa [5].

It is acknowledged that only anti-retroviral (ARV) medication can prolong the lives of people with AIDS, and the successful roll-out of the country's ARV program is therefore crucial. ARV drug treatment can maintain health and help people lead relatively normal lives, but few people in South Africa have access to this treatment [6]. By mid-2006, while some 711,000 people in South Africa were in need of anti-retroviral treatment (ART), only 225,000 were actually receiving it. [7]

Cell Phone and SMS Use in mHealth Services

ICTs (information and communications technologies) can have an important role to play in the HIV/AIDS crisis [8]. They are integral to mHealth (mobile health), defined as the 'emerging mobile communications and network technologies for healthcare systems' [9]. mHealth is a recent term that encompasses the use of mobile telecommunications devices and mobile computing, such as mobile (cell) phones, patient monitoring devices and medical sensors, PDAs, and other wireless devices, to support medical and health care, and public health practice [10, 11].

There were over 4 billion mobile devices in use around the world in 2009, with 64% of them in the hands of people living in developing and emerging economies [10, 12]. 80% of the world's population lives in areas with mobile phone coverage making mobile technology probably the most viable type of technology to reach the largest part of the world's population [13]. The National Department of Health (NDOH) has adopted a National Telemedicine Strategy for South Africa (NTSSA) which was established in 1998 [14]. However, the national telemedicine system is not working and has not solved the initially anticipated health problems [15, 16].

Cell Phone and SMS Use in South Africa

South Africa has one of the highest uptakes and demographic distributions of cellular technology in the world. There are around 30 million active cell phone users in the country, almost two-thirds of the South African population [17]. 60% of households in South Africa own a cellular telephone and 41% of adults have access to a cell phone.

People use cell phones daily for communication. They are an inexpensive and rapid way to be connected to the internet in areas where the fixed telecommunications infrastructure is poor or there is a lack of resources [8]. Low start-up costs, text messaging, and flexible payment plans, all make them

attractive to use as a healthcare intervention [18].

Since rural youth are at the front line of combating HIV/AIDS in their communities, cell phones and other ICTs might play a contributing role to linking these future leaders [19]. One of the benefits of mobile technology is that it is used as an agent for social change worldwide today [20].

Healthcare services are facing pressure to improve efficiency and meet expectations for high-quality care and customer service [21] and SMS is a well established technology and widely used around the world. SMS (short message service) is a method of communication that sends short (160 character) text messages over the mobile networks. However, it is not without limitations. There is no scope for graphics or audio, the messages are limited by size, speedy message delivery is not guaranteed and the issues of confidentiality and privacy are a matter of great concern.

Literature Review Method

This desktop literature review, mostly conducted between February and December 2008, explored the potential use of cell phone SMS in health care in South Africa. Several readily available literature sources were electronically explored, including Pub Med, Medline plus, Pub Med Central, AID Search, AIDS related database, Cochrane Library, Electronic Journals Services (EJS), and Google Scholar. Articles in a language other than in English language were excluded. In the beginning, literature was searched using these key words: enabling technologies, wireless technologies, mobile technologies, cell phone, cellular phone, mobile phone, health care, HIV/AIDS, HIV, home care, possibilities, potential, role, monitoring, working groups, volunteer organization, South Africa. Only 72 articles out of 28,703 search engine hits were included in the study.

Table 1--Summary of 28 studies.

	Study Design	**Resources Reference no.**
1	Pilot study (6)	[25-30]
2	Qualitative study (3)	[31-33]
3	Observational study (1)	[34]
4	Randomized control trial (6)	[35-39]
5	Cohort (2)	[40, 41]
6	Mix qualitative and quantitative (2)	[42, 43]
7	Case study (2)	[44, 45]
8	Interview (1)	[46]
9	Meta-analysis (1)	[47]
10	Peer review (1)	[48]
11	Systemic review (3).	[24, 49, 50]

Due to the relative lack of published articles found, the search strategy was modified, and most of the literature was retrieved from Pub Med/ Pub Med Central and Google Scholar. The key words used included: Potential use short messaging service (SMS) cell phone OR mobile phone OR cellular phone, health care, HIV/AIDS, patients, South Africa. Original articles or review articles in English were selected, and only 140 articles out of 1,656 search hits were included.

A total of 212 articles were reviewed for the study, of which, 184 (87%) were excluded from detailed review, as they did not explore the potentials of cell phone or SMS technology in detail. Finally, 28 (13%) of the original corpus of published articles were reviewed (summarized in Table 1). In addition, policy papers, such as the 1997 White Paper by the Ministry of Health for the Transformation of the Health System in South Africa [22], were reviewed.

Results

The main findings of this literature review were that:

1. SMS improves service delivery through: (a) Appointment reminders [23, 25, 34-36, 40, 51]; (b) Improving communication between healthcare workers [32, 52].

2. SMS improves diagnosis, prevention, treatment and rehabilitation of illness by: (a) Improving adherence to medication [23, 33]; (b) Monitoring illness and medical interventions [26, 30, 43]; (c) Prevention and intervention of illness [47].

3. SMS is useful in Public Health Programs via: (a) Contact Tracing and Partner Notification for communicable diseases [24]; (b) Smoking Cessation Programs [37, 51].

Discussion: SMS and Text Messaging for Health

Many of the examples of health applications of mobile phones are in the pilot stage and have yet to be implemented or evaluated on a significant scale [18]. Text messaging has been significantly used in health care, mainly as a means of reminding patients of appointments in the United Kingdom, United States, Norway, and Sweden [18]. SMS was found to have been used widely to improve quality of life in several areas, including health. All the randomized control trial studies available in this study have shown significant results ($p < 0.005$). Randomized controlled trial studies from Malaysia [35] and China [36] showed that text messaging reminders were effective in improving attendance in primary care and cost less than mobile phone call reminders. A systemic review study by Atun *et al* suggested that SMS has the potential to improve tuberculosis control, contributing to reduced non-compliance and better health outcomes with low cost [49].

Some other studies support the use of SMS reminders as an accessible, appropriate and more cost effective tool for patients needing TB medication in South Africa [54]. SMS lowers non-attendance rates, with less labor, in the UK [55] and improves attendance at outpatient clinic appointments in Melbourne, Victoria [23]. It increases patient compliance in taking medication for TB and HIV [57]. Atun and Sittampalam, in another systemic review, found that SMS improves efficiency in the delivery of healthcare. It has public health benefits [24] and is acceptable to patients. However, none of the studies included any formal economic evaluations.

Not all researchers have the same findings and opinion about

SMS technology, with some of them being more skeptical. Kaplan [50] stated that the majority of reports are pilot or feasibility studies, with limited generalization of their findings, and so possibly unreliable. More rigorous evidence is needed for drawing conclusions. Although most of the studies reported that SMS technology is feasible and that there is a good level of patient acceptance, there are methodological problems of either small sample size and lack of representativeness in many, or they were pilot studies done in a relatively short time. However, the studies manage to highlight the important issue of SMS technology and create a positive environment for further study.

Two in-depth studies claim that SMS technology is acceptable to most of the patients. One is a qualitative (in-depth interview) study done in Cape Town by Cell-Life [56], with another qualitative study (based on in-depth interviews) done in Lima, Peru [57]. However, the sample size of the studies was small, and they were conducted in limited areas and, as such, lack a holistic representation of the population such that the results cannot be generalized. There is a need for further studies despite the fact that this method gives more satisfaction to patient parties. Curioso *et al* found that most of their study participants were concerned about privacy and confidentiality as well as the wording of the messages [58]. They did not want "sensitive" words (e.g. 'HIV', anti-retroviral) related to HIV included in the system, and preferred using code words or phrases; something simple such as 'It is time for your candy/life,' but which was understood). Some participants also suggested erasing the reminder after receiving it. This study clearly indicated that the issues of confidentiality, privacy and security are serious considerations when using SMS technology.

Cell phones are widely used in health care in low and middle income countries. In addition to SMS or texting, multi-media messaging service (MMS) can be used [59]. In Brazil and Zambia, health workers consult dermatologists using newly available camera phones [18]. While only 18 percent of clinics in South Africa have Internet-connected computers, 96 percent have a least one cell phone [60]. A system created by Voxiva uses cell phones to boost HIV/AIDS care [61]. The system tracks people living with HIV/AIDS and now connects 75% of the country's 340 clinics and covers 32,000 people in Rwanda.

There are three types of benefit from SMS:

1. It has, improved efficiency in the delivery of healthcare by appointment reminders [24, 62-64],

2. SMS has provided direct benefits to patients in terms of better health outcomes and quality of service by improving the patients adherence to their medications and treatment; monitoring patients' conditions; providing psychological support to patients; communicating test results; queue management in health care facilities [64],

3. It has public health benefits as it has been used in contact tracing and partner notification for communicable diseases such as sexually transmitted infection (STI), tuberculosis (TB), HIV/AIDS and severe acute respiratory syndrome (SARS) as well as communicating health information to the public for the rapid communication of health information to the general public in public health emergencies such as an outbreak of a communicable disease [64]. SMS is also a convenient for deaf and hearing-impaired people to communicate. SMS can be used to send a message to a large number of people at a time, either from a list of contacts or to all the users within a particular area. SMS doesn't overload the network as much as phone calls, it is frequently used by TV shows to let viewers vote on a poll topic or for a contestant.

In Mali, cell phone has become a new tool to help to control the spread of HIV/AIDS [69]. However the hot application of SMS is mobile chatting. The San Francisco Department of Public Health sends safer sex recommendations to young people who request it via text messages on cell phones [66] the automated program is modeled after a similar campaign in London, aimed at youths ages 12 to 24. Mobile technology particularly SMS is used in education as a method of raising HIV and AIDS awareness [67]. In South Africa, the Dokoza system use SMS in HIV/AIDS and TB treatment for information management, transactional exchange & personal communication [68-69].

Conclusion

This study helps in understanding the present context surrounding HIV/AIDS globally and locally in South Africa. It has explored what has been done in this field both nationally and internationally. It has elaborated the encouraging finding that SMS technology could be a cost effective tool to fight against the HIV/AIDS and other chronic health conditions, such as diabetes mellitus and asthma.

HIV/AIDS is a chronic illness. It requires patient empowerment to enhance adherence to manage it effectively. SMS plays a role in adherence and therefore can play an important role in control of HIV/AIDS. It can be especially effective where other forms of communication between patients and health clinics are difficult and access to services is poor due to a weak infrastructure and geographical barriers. SMS offers further opportunities to deploy the benefits of mobile phone technology and improve access to healthcare and information [21].

This study can provide the basis for further research by the Department of Health and the Medical Research Council in South Africa, the private sector, and national and international non-government organizations to explore the potential of this technology. While the focus of this study has been on the technologies, their use for delivering effective services will also need to consider the human and socio-technical resources involved. Overall, SMS technology is feasible; it could be used as a potential tool to deliver quality health care with low cost in this beautiful rainbow nation.

Abstract

Existing telemonitoring systems provide limited support in implementing personalized treatment plans. We developed a Home Automated Telemanagement (HAT) system for patients with congestive heart failure (CHF) to provide support in following individualized treatment plans as well as to monitor symptoms, weight changes, and quality of life, while educating the patient on their disease. The system is designed to be placed in the patient's home and to communicate all patient data to a central server implementing real-time clinical decision support. The system questions the patient daily on their condition, monitors their weight, and provides the patient with instant feedback on their condition in the form of a 3-zone CHF action plan. Their medication regimen and suggested actions are determined by their care management team and integrated into the system, keeping a personalized approach to disease management while taking advantage of the technology available. The system is designed to be as simple as possible, making it usable by patients with no prior computer experience. A feasibility assessment in African American patients with CHF and without prior computer experience demonstrated high level of acceptance of the CHF HAT system.

***Keyword**:*

Telemedicine, Congestive heart failure, Self-management

Introduction

Congestive heart failure (CHF) is a major public health problem which affects over 5 million Americans and costs $33.2 billion annually [1]. CHF morbidity is reaching epidemic proportions and African Americans are disproportionately affected [1-3]. Repeated emergency room visits and rehospitalizations for symptom relief contribute to CHF being the most costly cardiovascular illness in the US [1, 4-5]. Common reasons for CHF rehospitalization include delays in symptom recognition, medication and dietary noncompliance, and lack of knowledge and skills for competent self management [6-8].

Telemedicine approaches will be useful in patients with CHF for several reasons. First, telemedicine will improve disease monitoring through more frequent assessment of symptoms. Second, use of patient self-management plans will accelerate treatment in the setting of CHF symptoms and thus decrease the utilization of health care resources [8]. Home Automated Telemanagement (HAT) is a telemedicine system designed to assist health care practitioners treat patients according to current clinical guidelines, to assist clinicians in educating patients, to assist providers in monitoring patients, and to assist patients in following individualized self-care plans [9-14]. Our aim was to design a low cost telemanagement system for CHF patients and to perform an initial assessment of patient acceptance of such a system. This paper reports the success of design and implementation of the Home Automated Telemanagement system in patients with CHF.

Materials and Methods

System Design

The HAT system is based on Wagner's model of chronic disease care [15] and supports patient self-management, comprehensive patient-provider communication, and multidisciplinary care coordination. The CHF HAT system comprises a home unit, a decision support server and a web-based clinician portal. The HAT home unit consists of a notebook computer and an electronic weight scale. CHF patients answer questions regarding symptoms, side effects, adherence, and receive disease-specific education using the home unit. The home unit automatically transmits the results to the decision support server after each self-testing session. Data transmitted from patient's home are de-identified and encrypted. The data transmission can be carried out via Internet or direct modem-to-modem communication. For subjects without an active phone line, a cell phone is provided to transmit self-testing results over a secure wireless network to the server in a similar manner. The web portal provides an interface for the collected patient data. The web-based care management portal is used to set up customized clinical alerts and individualized action plans based

on patient disease severity and other individual factors. The care management team individualizes alerts and action plans for each patient on-line whenever warranted. The updated action plans are automatically transmitted to patient home units. If certain clinical conditions are met, email alerts are sent to the nurse coordinator. The coordinator reviews the information and if necessary consults the medical provider and the patient for management changes.

The HAT server runs Internet Information Services (IIS) which collects the patient's data and integrates it into a website which can be accessed by the patient's primary care management team. IIS is one of the most widely used web servers and provides a stable and compatible system for receiving and editing patient information. The web page was developed using Microsoft's .NET framework. This is a framework for developing dynamic websites which offers extensive built-in functionality and is supported by most browsers. The system is designed so that each patient has an "Action Plan" approved by their care management team. The action plan defines what a patient's actions should be based upon their self-test data and can be viewed on the HAT home unit and the clinician website. Prior to beginning home unit use, the patient has an action plan approved by their care management team. The action plan accounts for the possible cases of good, fair, and poor health; respectively corresponding to a green, yellow, and red 'zone'. An example of yellow zone of CHF action plan is shown in Figure 4. The patient responses from the self testing portion and weight measurement are used as a gauge for determining the action plan zone in which the patient currently belongs. At any time the patient may view their current zone or review the other zones on the home unit. CHF HAT action plan information flow can be seen in Figure 1.

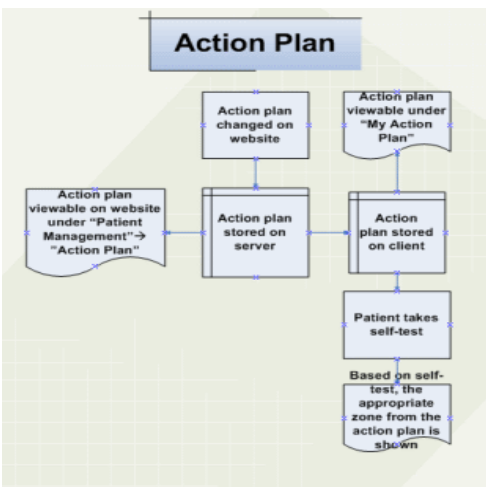

Figure 1- Action plan information flow

The HAT home unit allows a patient to complete a disease diary which asks the patient a series of questions, records their weight, and sends the information to the server, then gives the patient instant feedback on their current action plan zone, based upon their symptoms and weight measurement. This test provides the patient with immediate information on their condition and appropriate action steps for self management and provides their care management team with daily updates. Once a report has been sent to the server it can be viewed by the patient's care management team through the CHF HAT website.

On the server, the alert generator runs every night and uses the information from the self-test reports to send e-mails to the care management team when appropriate. Alert parameters are defined by a nurse case manager and can be set to generate alerts under various situations. Alerts can be generated if a patient's total score on the symptom questions falls above a specified number. They can also be generated if the patient's recorded weight falls above a specified threshold for the mean weight, percentage of last weight, or absolute change. Finally, if the patient is in a specified zone or has changed to a specified zone, an alert may also be generated.

The system also aids in medication compliance. The home unit can display a list of current medications with their dosages and frequencies. This can be updated by a nurse care manager on the website and will update on the home unit the next time it connects.

The HAT home unit also features a progress chart, which displays a graph of the patient's weight measurements or action plan zones on the most recent self-tests. The 'Frequently Asked Questions' section allows a quick access to general CHF educational information. The advanced features section on the home unit allows the patient to send a message to the server at any time. There are stock messages for the user to choose from or they can type their own messages. Upon receiving the message, an email is sent to their care manager, allowing for computerized patient-clinician communication. The message is also stored on the server and can be reviewed on the website by the care management team. The care management team may also send a message to the patient through the website. The message will be received by the patient the next time they connect to the server.

Pilot Study

A pilot study of the system has been conducted in ten CHF patients with no prior experience in using computers. Semi-structured qualitative interviews and cognitive walkthrough were used to assess patient acceptance of the CHF HAT system. In the study the patients received a twenty minute introduction and demonstration of the patient home unit and self-testing procedure. After the demonstration, the patient was asked to complete the self-test on their own and comment on the system as they performed the self-test. Once the self-test was performed by the patient, we administered a qualitative interview to get patient feedback on the system. Because

African Americans are disproportionally affected by CHF [1-3] we assessed feasibility of CHF HAT in this population.

Results

The HAT system was successfully designed and implemented on a notebook computer running Windows 2000/XP connected to a Lifesource 321P digital scale through the serial port. Information was successfully sent and received from a remote location to the IIS server using an active landline and cell phone connection. The website was successfully launched and provides full functionality. The home unit runs the HAT program when it starts up and the user can navigate through the menu using the labeled arrow keys and the enter button. The text is large and easy to read while all the instructions are kept as simple as possible. The home unit options are broken into six sections. The first section is self-testing. In this section the patient will begin with a self-testing portion where they answer a series of questions pertaining to their chronic condition. A symptom diary question screen is show in Figure 2.

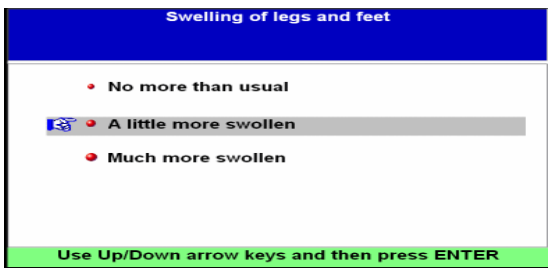

Figure 2-Symptom diary question

The responses are used to gauge the overall health of the patient, as well as to raise flags when the patient may be experiencing congestive heart failure symptoms that require immediate attention and treatment. After answering general symptom questions the patient is prompted by voice and text to correctly mount a weight scale in order for the CHF HAT software to weigh the patient. The scale instructions are shown in Figure 3.

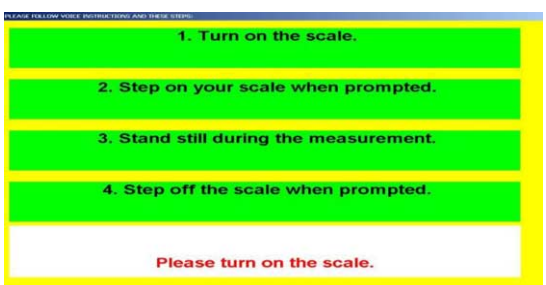

Figure 3-Weight scale instructions

The current patient's action zone is then immediately calculated and displayed. A screen displays weight and an absolute weight change from the previous day. The zone of the action plan is determined using the information provided earlier in the self-test. A sample action plan is seen in Figure 4.

Figure 4-Sample "Yellow Zone" action plan

After completion of the self-testing portion the patient is given an educational "Tip of the day." Each successive educational portion will end with a question about the previous day's tip. The question will be repeated each session until the patient is able to answer correctly. Then a new question is offered during the next self-testing session. At the end of an educational section, the patient will be asked several questions from the specific section. Upon completion of the educational portion, the symptom diary responses as well as the results of weight monitoring are stored for transmission. The system connects to the server using an active landline or wireless connection and relays all stored results/messages. This is shown in Figure 5. After transmission the main menu is displayed.

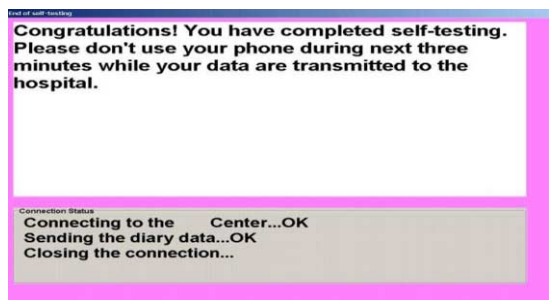

Figure 5-Data transmission screen

The HAT home unit also allows the patient to access their Action Plan. The patient can view their current action plan and their other plans for different zones. They can also view a graph of their recorded weights or action plan zones and the medications currently prescribed to them. The patient can also send either a personal or pre-written message to the care management team.

The CHF HAT website is hosted on our servers and can be accessed securely by the care management team using any computer with a web browser and an internet connection. The care management team can also view a monthly report which displays graphs and statistics of the patient's information collected over the past month. A section of a sample report is seen in Figure 6.

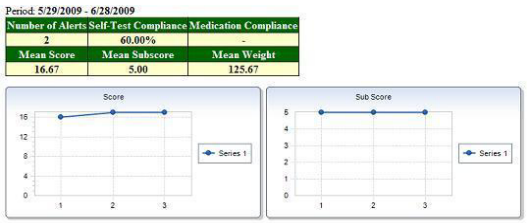

Figure 6-Sample monthly report data

The website also shows any current alerts for the patient and allows the care management team to log their response to the alert as shown in Figure 7.

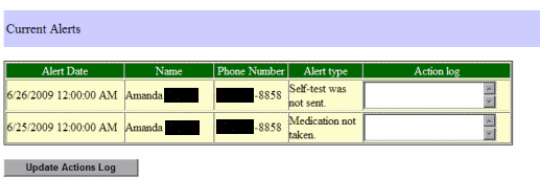

Figure 7-Current Alerts

The care manager can change their alert parameters for the patient, send a message to a patient, or view a list of the messages sent from the home unit to the server as seen in Figure 8.

Figure 8-Messages from the patient

Pilot study

After successfully using the system, patients were asked to complete demographics, attitudinal survey and qualitative interview. Average age of patients was 56 years, and they completed an average of 13 years of education. 60% of subjects were females, and 100% were African Americans. About 50% reported that they had moderate heart failure symptoms, and 50% answered that their heart failure had been about the same during the last 12 months. 60% and 70% never used the computer and internet respectively, and 30% reported that they never used ATM machine.

Table 1 – Attitudinal Survey Results

Questions	%
1. How complicated was the self-testing process?	
Moderately complicated	10.0
Not complicated at all	90.0
2. How difficult was it to use the weight scale?	
Slightly difficult	10.0
Not difficult at all	90.0
3. How difficult was working with the computer?	
Not difficult at all	100.0
4. How difficult was answering the symptom diary?	
Not difficult at all	100.0
5. Did you get all the necessary information about self-testing including the first introductory meeting?	
All information	80.0
Partial information	10.0
Very limited information	10.0
6. How much of your time did the self-testing take?	
Considerable	10.0
Very little	90.0
7. Would the self-testing interfere with your usual activities?	
No	90.0
Little	10.0
8. Would you feel safer while monitored by the system?	
Significantly safer	80.0
Moderately safer	10.0
Same as usual	10.0
9. How important for you is it to know that the results of your self-testing can be reviewed by the study staff immediately after the test?	
Extremely important	80.0
Very important	20.0
10. How often would you review the test results?	
Once a week	80.0
Occasionally	20.0
11. Would you like to use this self-testing program in the future?	
Certainly Yes	90.0
Maybe	10.0

Patient overall response to the system has been positive (see Table 1). All patients were able to complete the self-testing procedure by themselves with little or no difficulty. 100% of

subjects responded that they didn't have any difficulty working with the computer and answering the symptom diary questions. Also patients reported that length of self-testing was appropriate that it would not interfere with their usual activities. All the patients we have interviewed so far did not consider themselves computer literate and did not own a computer. Overall we have concluded that the interface is sufficient for people with no history of computer use. Patients responded favorably to the educational portion of the self-test, indicating a desire to learn more about their condition. The content and interface also received positive feedback in patient responses. Patients commented that they believed the CHF HAT system would help them better manage their congestive heart failure and reduce their amount of hospital visits.

Discussion

The CHF HAT system's ease of use and convenience can provide reluctant patients with an easy way for care management teams to receive daily feedback from the patient. While care management team visits would still be important to the patient's care, allowing the patient to monitor their health frequently and educating them on their condition will hopefully increase their condition awareness, self management, and quality of life. The CHF HAT system can successfully provide support to patients in following their CHF action plans and to aid them in being adherent to their treatment regimens. We are also looking toward expanding the HAT system to other computer platforms. Mobile computing is becoming smaller, faster, and cheaper, creating more potential environments for the HAT disease management system. Systems such as the Apple iPhone, iPod Touch, Blackberry, and mobile phones are becoming viable options for the CHF HAT platform.

Conclusion

The Home Automated Telemanagement system is a viable system to test in the management of congestive heart failure patients. This system can be efficiently implemented for congestive heart failure, as well as other conditions, and is recommended for future use and expansion.

The Emergence of Mobile-Supported National Health Information Systems in Developing Countries

Ime Asangansi, Kristin Braa

Department of Informatics, University of Oslo, Oslo, Norway & Health Information Systems Programme, Nigeria

Abstract

A major challenge for national health information systems in developing countries is their scalability and sustainability at the lowest levels where primary health care is delivered. This paper contributes to the discourse on how national health information systems can scale to the lower levels and how mobile technology is supporting the collection, handling and dissemination of data. But can mHealth go beyond the 'hype' and visions it has come to be associated with? Using an action research methodology in a long-term action research project, the usability and then scalability of mobile solutions for large scale national health information systems are studied. In this paper, initial successes and challenges with using m-Health for national public health information systems is reported and discussed.

Keywords:

Mobile, Health, Information system, Nigeria, India

Introduction

Health information systems (HIS) are having a major and ongoing impact on the lives of people in both low and high resource settings. A robust health information system is a basic foundation of public health [1]. The achievement of the health-related Millennium Development Goals (MDGs) will depend upon the effectiveness and efficiency of health systems. HIS remains the backbone for providing information to track progress for improving and strengthening the different health system components and monitoring the MDG goals. On the ground, however, HIS development in developing countries has proven to be difficult due to organizational complexity, fragmentation, lack of coordinated organizational structures (that maintain disparate information systems), unrealistic ambitions, and more generally due to the problem of sustainability. Poor availability and quality of data and a resultant poor knowledge and "culture" of use of information for planning and decision-making characterize HIS in many countries. Importantly, poor physical infrastructure has remained a serious obstacle in ensuring an efficient health information infrastructure in many developing countries.

The world over, both within the domains of research and practice, there is an increasing recognition of the role mobile technology and mobile phones can play in supporting public health systems. There is an emerging field and research domain for the application of mobile technology for health, mHealth. Mobile phones have a particular status across all developing countries. There are 2.2 billion mobile phones in the developing world, compared to 305 million computers and only 11 million hospital beds [2]. Between the end of 2007 and the end of 2008, mobile phone subscriptions increased by approximately 1 billion [3]. Mobile technology comes with the unique potential that it has already become a routine part of most peoples' everyday lives. It is becoming increasingly affordable and accessible, and has the required infrastructure (for example, the network coverage) even in villages to support its easy use and maintenance.

There are over 4 billion mobile phones, 64% of which is in the developing world [4]. The majority of the mobile subscribers are now outside the major cities and wealthiest states. For example in India there are 65 times more mobile connections than Internet connections [4]. This creates opportunities to use mobile phones to capture data at the source, thus removing significant sources of data quality problems usually associated with manual transfer of data between paper reports. In addition the aim is to use mobile phones as a channel for feedback to the community health workers. We explore to what extent this technology can be used for effective data exchange and communication in public health; how mobile phones in general can secure routine health data as well as stimulate better health provision by better communication and training. A major concern is how mobile phones can be coupled to and leverage district health information systems.

In this paper we discuss the emergence of mobile-supported national health information systems in developing countries by describing two ongoing mobile health projects in Nigeria and India. The mobile solution will also be described and discussed.

mHealth Applications

There are numerous mHealth projects in developing settings: the alliance of UN, Rockefeller & Vodafone in Feb 2009 formed after e-Health ideas exchanged in Rockefeller's Bellaio Conference (UN Foundation, m-Health Alliance) [5]; Using Mobile Phones and RapidSMS to Improve Child Nutrition Surveillance in Malawi (UNICEF, Govt. of Malawi and Mo-

bile Development Solutions) [6]; SIMPill – embedded mobile phone chip in medicine bottle to remind patients in South Africa (2007). 90% took TB medicine while earlier only 22%-60% took it; mHealth for Development paper, 2009) [7]; Text-to-Change – Sends HIV awareness messages in Uganda [8]; Cell-Preven. Health workers use mobile phones to send SMS messages with real-time data on symptoms experienced by clinical trial participants, enabling immediate response to adverse symptoms [9]; Frontline-SMS – a bulk SMS solution [10]; OpenRosa [11].

Generally, m-Health projects can be broadly discussed according to: technology, domain area of application, the hierarchical level in the data flow; and data handling processes it is used for.

By technology, m-Health applications can involve SMS (Short Message Service) or 'texting', voice services and other packet data services such as WAP, GPRS, etc. These can be simple typed SMS from any phone; coded SMS texts (following some predefined logic (which gets interpreted at a central server); or SMS-based data transfer from applications (J2ME, Android, etc) installed on the phone. WAP and GPRS have been little used in the settings we are concerned with in this paper for the reason of unreliability (at this time).

By domain, m-Health has been applied to various health areas including maternal and child health, community health volunteering support, immunization, general emergencies, monitoring of patients with illnesses such as HIV/AIDS, supporting the control of diseases such as malaria, etc.

In this study, the focus is on mobile systems feeding routine data from the lowest levels where they are produced such as communities and health facilities, through different levels up to the national trunk. In this scenario, facility/community level datasets are transmitted to upper levels through the state to the country warehouse, with health information defining a whole range of data elements spanning from utilization data, maternal and child health data, mortalities, nutrition and disease surveillance data. In developing countries, the collection of such data has historically proven to be intractable.

Most mHealth applications are in the piloting phase. A community of practice for mHealth is still being developed and mHealth standards are yet to be developed. This paper thus reports on a significant phenomenon, the emergence and early institutionalization of mobile systems for routine data collection, with data flowing from the lowest levels to the national level.

Materials and Methods

Our research approach is action-oriented and interpretative and characterized as a 'network of action' methodology. The network of action approach is based on the principle of creating learning and innovation through multiple sites of action and use, and sharing these experiences vertically and horizontally in the network [12, 13]. It is premised on collective action where connected research units are able to share experiences and learning. The cases presented here are derived from units (or nodes) within the Health Information System Programme (HISP) network of action. The authors are actively engaged in these units (HISP-Nigeria and HISP-India) which are, with their respective partners, the principal development partners for this system in their respective countries. The pilot in India started in February 2009 and is ongoing. While that in Nigeria started in July 2009 and is ongoing. However, these pilots are converting into full-blown deployments and installations as the rate of adoption has been tremendous. Data sources for this study have been primary and secondary. Primary sources have included notes from participant observations, performing training, and formal interviews with health workers at different levels as well as administrative and technical personnel. The authors have also been involved in the iterative development of the solution. Secondary sources included formal reports from the projects highlighted.

Cases

Here two cases are presented which are significant by virtue of being based in the national system of two very populous and complex countries in Africa and Asia – Nigeria and India respectively.

The Nigerian Case

With a population of over 148 million people [14], Nigeria is the largest country in Africa and accounts for about half of West Africa's population [15]. Health service delivery is largely a government function and as in all countries, the establishment of a robust national information system is a priority. Though the HMIS framework was articulated (in 1992) and implementation commenced (in 1997) in a number of states, the HMIS is only recently (2003) beginning to be institutionalized [16]. This recent strengthening efforts (mainly donor-led) can be attributed to increased demand to show progress towards attaining the MDGs. Since 2003, a free and open source data warehouse solution, the District Health Information System (DHIS) [17] has been implemented at the national and state levels. However, a recent situational analysis has revealed the very low base from which the HMIS is being developed. Computer equipment is usually either in short supply or poorly maintained where it exists. Power supply is very poor; and transportation through long distances and from hard-to-reach areas is difficult. Data use is almost non-existent at all levels of the system. Reports are submitted late and data quality is poor in the HMIS.

It is in this premise and following from the observation that the mobile networks have greatly improved that this study is set. The application of mobile technology has a huge potential for circumventing the aforementioned challenges and improving data reporting. At the time of independence in 1960, Nigeria had a population of about 45 million people with 18,724 functioning fixed telephone lines - a tele-density ratio of 0.04 telephones per 100 people [18]. At the commencement of mobile telephony in 2001, there were only a few thousand lines available from the operators and services were too expensive for the average Nigerian. By 2002, the number of mobile subscribers stood at 1.5 million and prices fell [19]. By the end of 2004, the GSM operators had recorded well over seven mil-

lion subscribers, which was a real explosion when compared with about half a million working lines from NITEL in 2001 and is now reaching 60% penetration [20]. This shows that Nigerian telecommunication industries experienced rapid growth in terms of usage and subscription. By 2007, there were 34 million telephone lines with 1,670,767 fixed lines and 32,265,827 mobile phones in Nigeria [21].

This study thus set out to explore the possibilities with using mobile phones for communication of data from health facilities as well as at the local government area (LGA) level. A simple form-like data collection tool on mobile phones was developed for transmission of data securely and timely. The pilot was tested in 2 states, Katsina and Yobe in Northern Nigeria. This region is characterized by extremely low levels of health service utilisation, the existence of polio and measles outbreaks, low staffing levels and low skill levels of existing staff, absence of significant technology other than mobile coverage. It involved health workers in 26 busy facilities and 34 local government area Monitoring & Evaluation office thus covering the whole state of the Katsina and parts of Yobe.

Findings

A major finding was that the application was well received. As one of the state resource persons said, "let us not call this a pilot because it is bringing very useful results and is now part of the system". With this rapid adoption at facility, LGA and state levels, came specific interests in the sustainability of the system. Facility workers were concerned that they did not understand the data elements properly. The data elements used in the system were from the national standard for facility but they had not been properly trained on it. The implementers therefore had to do training on the data collection and what the elements mean. The LGA officers were particularly interested in an increase in the datasets collected particularly the addition of the full complement of disease surveillance reports. The state level officers were more concerned about the ability of the tool to strengthen the LGAs. As one expressed, "I am sure you have tested it elsewhere. Let us think of how to improve it and include other relevant data elements that the LGAs also need very much". Thus, the rapid adoption and acceptance of the mobile system led to an early discussion by stakeholders at different levels to improve it. These improvements have occurred at a rapid pace when compared to the DHIS computer-based installations. This is attributed to the fact that the mobile application is seen by many users (network effect) and its ease of use has allowed the health workers to be more engaged in data capture.

The Indian Case

India has more diversity within its border than any other country and its population of 1.1 billon people lives and work in very different circumstances and geographies. The mobile penetration is 30% and is the fastest growing market in the world.

The Society for Health Information System (HISP India) [22] which has more than 10 years experience of working with health information systems in India, and are developing and implementing the District Health Information System (DHIS) software for health management that is currently being deployed in almost all states in India to support sub district data registration and analysis activities, and is integrated with the national database through the Ministry of Health web portal. The DHIS deals with aggregated (non-patient) data collection and analysis in an integrated manner across health programs, including important monitoring of MDG 4 and 5 indicators.

Implementing software solutions at the lower levels of the Indian health system is a huge undertaking due to its enormous scale in terms of the vast number of installations, system maintenance and training activities. A mobile solution to strengthen the work of community health workers need to be coordinated and supported by backbone systems e.g. to produce the mobile collection forms, to store, process and report the data collected by mobile phones, and generate work schedules and feedback reports back to the mobile clients. The strategy was to install such a backbone system at the Block PHC level as lower levels is hard to computerize, and link the transmission of data from the mobile (such as through a SMS) to this backbone.

A pilot project was initiated by National Health System Resource Centre in India in collaboration with HISP India. Health workers in facilities at the lowest level were provided with a tool to report routine data to the district and state level through the DHIS. The mobile application for sub-centre reporting was piloted in 5 states: Kerala, Rajasthan, Gujarat, Himachal Pradesh and Nagaland. 189 health workers were given mobiles for reporting.

Findings

After 6 months the results are very promising. Data is reported and 100% said they prefer this way of reporting as it saves time – they do not need to travel to report – and it is more efficient. The role of social networks has a appeared in several ways as one users supports the other. Introducing mobile phones among health workers have changed the communication patterns and seems to go beyond what used to be hierarchical borders. For instance, an HMIS manager now could contact directly the health worker and vice versa. Earlier he/she had to send a written request to the PHC to get them to contact the health worker, for instance, to invite for a meeting. The work related communication increased and 88% said they had called other health officers for help and 85 % said they had contacted doctors for medical help in case of emergency. Introducing mobiles into public health is not only about introducing a tool for data capturing but it seems have the potential of changing the way of working and communicating which can have great effect on health provisioning.

The Application

In Nigeria and India, an open source Java-based mobile platform was built on the already existing DHIS-based national health information infrastructure. The solution consisted of a native Java mobile application installed on a mobile phone and a server gateway that plugged into the DHIS data warehouse (See Figure 1 below). In Nigeria, the mobile application was developed based on the existing national HMIS facility forms and implemented at the facility and district levels. In India, it

was based on the national HIS form for (ANM) coordinated by the National Rural Health Mission.

The application was designed to support the health workers in the filling and sending of the reports through the mobile phone. It is based on free and open software development facilitated by a commons-based production network established between developers in the HISP network.

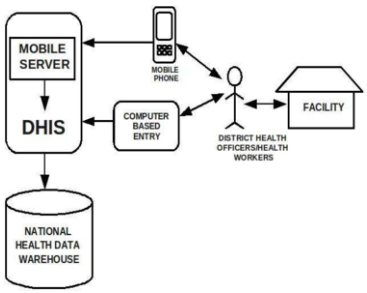

Figure 1 - An illustration of the mobile-supported health information infrastructure

The application allows for data entry based on period (e.g. by month) and by (sub-centre or health facility). Data elements collected are those for **antenatal care and pregnancy outcome, mortalities and births, family planning, immunization, nutrition and growth monitoring, community outreach services and facility utilization**. In designing the application, mobile network coverage fluctuations typical of such settings were considered. Data is stored on the phone using basic Record Management Store (RMS) functionality. This allows data to be stored on the phone and forwarded when reception of the mobile network returns. It thus allows for the retrieval of previously filled reports. Technically, it is a J2ME application utilizing only the basic Java functionality (MIDP 2.0 and CLDC 1.1) functionalities and it can be installed on very low end phones.

Discussions

The emergence of mHealth applications and projects is a significant phenomenon – not only because of a fast rate of adoption but also the ability to achieve instant results with data handling. This can be attributed to the relatively small means with which the important issue of the lack of quality data can be addressed. In short, mobile technology provides a fundamental leverage that had been lacking in these settings – a network infrastructure for electronic data transmission. This, combined with the ease of use of mobiles compared to computers, has allowed many applications of mobile technology to emerge. It is important to note that; as this is a relatively new phenomenon, it may be too early to discuss with precision the possible success rates. But it is an important question to ask if these will translate to institutionalized systems for large-scale national systems. We have found that this is the case - mobile phones have been adopted for the day-to-day work of data handling in cases of Nigeria and India.

In leveraging the mobile technology and infrastructure, there are inter-related challenges that have been encountered. We discuss these as use-oriented, technical and sociopolitical.

The introduction of mobile phones among health workers has changed their communication patterns and has led to a challenge of the hierarchical borders and bureaucratic protocols often associated with public work routines. Health workers can be contacted directly by the state bypassing levels in the data flow but allowing for rapid exchange of information.

In addition, mobile health solutions for national health data systems suffer from being coupled to an underlying installed base. This can have consequences if such underlying base is problematic and poorly functioning. It was seen that the introduction of the mobile solution made existing problems with the underlying system more transparent and addressed. This happened in the Nigerian case where the national reports were not well known due to lack of forms and the lack of competence to use them. The phone thus provided a 'window' into the operation of the system and allowed quick corrections to be made. In both countries, the mobile application was found to be an effective tool for training the health workers on the meaning of the data elements.

Planning and involving stakeholders – expectations are difficult to define as requirements were desperately varied. By growing the system gradually, we have found that stakeholders could be involved gradually and more easily. Cost of SMS has been an issue in Nigeria since the prices are much higher in Nigeria than India which has among the lowest prices in the world.

The phones are costly and the question of who shall own the phones arose. The challenge that people could lose them or sell them is there. In India we saw that the phones were very well taken care of and seen as very valuable for them individually. In a case where a phone was stolen, the health worker was able to negotiate the phone back with help from the community by paying 500 rupees (5 USD).

The fear of deleting the application as happened in India could be solved by installing the application in mobile chip memory, but we have seen that there are be frequent changes to application so flexibility is more important. As such, an over-the-air (OTA) approach is advised. We observed that only low-level phones are purchased for personal use and it is difficult to leverage robust applications on such. For example, in Nigeria in one of the states piloted, only two of the district health information officer surveyed had a Java-enabled phone. The phones found were mainly cheap Chinese-made phones. This implies that funds are needed to fully utilize the user friendliness of mobile application.

By adopting the 'the low-end phones' approach, the risk of phones being stolen is reduced, more phones could be purchased and scalability thus more easily achieved, especially when compared to deploying relatively expensive personal digital assistants (PDAs) and smart phones. In situations where only few data elements will be collected, where there are low funds or where the number of users is staggering (e.g. in the thousands), pure (typed) SMS solutions such as Frontline-SMS

may be advisable. Such systems may not be advised for forms with many data elements to ensure high levels of data quality. The cost of the phones therefore has been a concern when planning for scaling. There are ongoing negotiations with manufacturers in this regard.

Conclusion

m-Health support for public health systems is being institutionalized in developing countries. The rapid adoption and gradual institutionalization is partly due to the individual acceptance and familiarity with the mobile application as a standard tool for data collection and dissemination. However, beyond the mobile phone as a standalone device there is a systems perspective observing the other components and kinds of infrastructure – such as the paper registers at the facilities, the computers at the district levels, the networks and the servers at the state level, and also the basic infrastructure required to support the mobile phone use (charging facilities, support, network coverage etc). Mobile applications can be sensitively designed and introduced, so as to support the development of an 'integrated mobile supported health information infrastructure' in developing countries.

Future work would explore the incorporation of improved technologies (GPRS and X-forms) as well the role of social networking in supporting mobile-supported networks.

Clinical users' perspective on telemonitoring of patients with long term conditions: understood through concepts of Giddens's structuration theory & consequence of modernity

Urvashi Sharma, Julie Barnett, Malcolm Clarke

Department of Information Systems and Computing, Brunel University, Uxbridge, United Kingdom.

Abstract

This study involves conducting focus group discussions with clinical users (nurses and technicians) prior to the launch of telehealth service in Nottingham, UK, to elicit their initial perceptions about the service. It describes the findings from preliminary phase of otherwise a larger longitudinal study. Using Giddens's concepts from structuration theory and consequence of modernity, we were able to acknowledge trust and sense of security as two very salient aspects that govern adoption of new technological innovation. Unattended, these aspects contribute to arousal of conflict and contradiction within a system. In order for successful telehealth implementations in health care setting, providers of the service, need to focus on ways in which clinical users' trust can be gained and sense of security can be promoted while using the telehealth service and technology.

Keywords:

Telemonitoring, Structuration theory, User perception.

Introduction

Integrating telehealth with nursing case management has potential to improve patient health outcomes, clinical outcomes and allow clinical user to work more efficiently [1, 2]. However, despite its evident and noticeable advantages, telehealth has not been widely adopted. Although a search of literature reveals reasons for low espousal to range from technical difficulties to financial constraints and political motives [3, 4] , not much has been explored in relation to clinical users views on telehealth services especially in relation to nurses and technical staff involved. In addition, of those who have considered this aspect mostly questioned the users' motives behind the use of technology and extent of its integration in their routines, with users often being the stakeholders like GPs and managers [4, 5].

Taking the above argument on board, this qualitative study mainly aims to delve into main questions that need to be asked when implementing telehealth alongside case management such as: what does the user perceive the given technology as? and what issues surround its taking-up within a given context? We adopt Giddens structuration theory in combination with his work in consequence of modernity to guide data analysis and elucidate results presented in this paper [6, 7]. We found that telehealth by its very nature triggers conflict and contradicts the nursing practice, which depends on human contact and face-to -face interaction. This furthers the issues of trust and ontological security, previously not explored in its entirety. Understanding clinical users' perception and their concerns allows exploration of basic but dominating social aspects that govern successful implementation of technological interventions and at the same time provide an opportunity to resolve them [8].

The remainder of the paper unfolds as follow. We first present theoretical framework applied. After giving a brief overview of data collection and analysis method, we summaries the results and finally provide discussion on theoretical and practical implications of this study.

Materials and Methods

Theory

Our research uses concepts from Giddens's structuration theory (ST) and consequence of modernity to understand clinical users view on telehealth service when first introduced in their work setting. The main notion of structuration theory is that structures in terms of rules and resources are produced and reproduced by knowledgeable actors who continually monitor their actions [6, 9]. These structures are enacted through social interaction, and are therefore continually influenced by the agents' perception and in turn influence their perception. Giddens advocates use of specific constructs from ST to understand the duality of structure and expound their enabling and constricting effects [6, 9]. One study that presents an example of this is by Walsham and Han [10]. They use concepts of conflict and contradiction from structuration theory in order to depict reasons behind the resistance to introduction of new accounting system in an established accounting firm. According to Walsham and Han, contradiction is a "disjunction between different principles of system organisation" and conflict as "a struggle between actors and collectivities which tends to coincide with structural contradiction along its main 'fault

lines'" [10]. In our study, this concept helped in elaborating how inadequate training provision, support, and lack of information could lead to potential problems in up-take of service. Also, that the initial procedures of patient selection and education, and the monitoring of staff for their effectiveness levels by Primary Care Trust (PCT) contradict telehealths' original purpose of allowing clinical user to be more efficient with their time.

Although, Giddens does not consider technology in ST, in his later work- the consequence of modernity, he acknowledges the role that technology plays in modern world by "stretching" of social systems through disembedding mechanism [7]. By disembedding mechanisms he alludes to "lifting-out of social relations from local contexts of interaction and their restructuring across indefinite spans of time-space" [7]. Out of two types of disembedding mechanism, telehealth can be described as an expert system as it combines 'technical accomplishments' with 'professional expertise' that organise delivery of care for patients with long term condition in a modern healthcare system. According to Giddens, all disembedding mechanisms are based on trust due to absence of face-to-face interaction and hence lack of complete information available through facial expressions and body language [7]. In telehealth service various issues can be categorised under the main heading of trust, as it introduces dilemma of working with technology to monitor patients whom nurses use to visit at home prior to introduction of this service. It also questions the reliability of technology used, competence of new staff and managements' initiatives.

In addition, Giddens also presents definition of an abstract system in consequence of modernity, thus adding another dimension that would provide and interesting view on how change in routines in abstract system threatens ontological security [10]. According to Giddens expert system together with faith (which forms trust) constitute abstract systems and the "routines which are integrated with abstract system are central to ontological security", where ontological security refers to 'feeling of security' [7]. This notion explains how disturbance in daily routines threatens security of an actor within that system.

The combination of above theoretical prospective permitted to establish link between conflict & contradiction, trust and security as very salient social aspects that affect clinical users in modern healthcare setting and their decision on whether to use technology provided or not.

Research Approach

This study follows an interpretative approach using qualitative data. It is an approach that "goes beyond understanding the meaning of the data because it points the researcher to "read" the social world behind the words of the actors" [11].

Data collection method

As this research aimed to understand initial thoughts of clinical users about the newly introduced telehealth service, focus group discussions were chosen as a tool for data collection. Barbour argues that these discussions guide and lay foundation for later data collection and therefore should be conducted in preliminary research phase [12]. She further describes that focus group discussions are often seen as a feminist research method "for eliciting the prospective of women-patterns of interaction and exchange", and in our case 87.5% (14) participants were females [12].

The clinical users participating in this study were involved in delivering care to patients who were taking part in a randomised controlled trial, evaluating clinical effectiveness of telemonitoring of patients with chronic conditions such as heart failure and obstructive pulmonary disease in the city of Nottingham, U.K. Four main groups of clinical users namely the Community Matrons (CM-registered and highly experienced nurses), Congestive Heart Failure nurses (CHF), Chronic Obstructive Pulmonary Disease nurses (COPD) and Community Support Workers (CSW-staff recruited to provide technical assistance to nurses) were involved with the use of telehealth service. A purposive Sample of staff participating in this project was used, and their equal participation was ensured by requesting a representative from each group in each meeting. In total, 3 focus group discussions were held at Nottingham Primary care trusts' settings in the month of July 2009 and total of 16 staff took part in the discussions. During these meetings, it became quite apparent that nurses were often on call and due to nature of work at times could not attend the meetings or were bound with time restrictions. In one meeting for instance, none of the nurses could turn-up due to an emergency. This can be considered as a design issue, that other researchers would like to take on board.

Data analysis

The qualitative data colleted through discussions was transcribed and thematically analysed using Nvivo8 version3 software package. Guidelines for thematic analysis were adopted fro Braun and Clarke 2006 [13].

Results

Three main themes evolved after analysing the data collected from focus group discussions as shown in Table1.

Table1-Main themes

Theme	Contributing factor
Conflict and contradiction	Telehealth as 'monitoring tool' Management strategy Research strategy
Trust	Technology Patient Support staff Management
Security	Lack of control Work routines

These three of themes of conflict and contradiction, trust, and security often inter-mingle with each other and manifestation of one would lead to another. Following sections present detailed outline of each theme.

Conflict and Contradiction

The first concept mainly highlighted the concerns of clinical users due to the introduction of telehealth. Users discussed the impact of telehealth implementation in relation to working with technology, managements' strategy on granting support, and research ethics.

Telehealth as 'monitoring tool' only

Clinical users argued that telemonitoring of patients only allowed access to objective measurements of blood pressure, oxygen saturation level and weight gain related to main illness like CHF or COPD. However, theses parameters sometimes were inadequate to discover underlying infections such as urinary tract infection, which could be easily picked during personal visit.

Clinical users also feared that introduction of technology would lead to subtraction of human touch and face-to-face interaction and loss of 'Nursing Intuition'. In addition, clinical staff saw telemonitoring as contributing factor to social exclusion of elderly patients.

Management strategy

Telehealth was mainly seen as a service that would decrease clinical users' workload and allow them to work more efficiently. At least, this is partly how the project managers introduced the service to the users. Ironically, clinical users' workload, especially nurses increased and contributing factors included lack of appropriate support, patient assessment, equipment installation, and use of computer system to access data.

The issue with support revolved around promise to provide each nurse with a community support worker by the PCT. However, due to late CSW recruitment and training requirements, their assignment to nurses was severely delayed.

It was also noticed that CSWS had problems of their own. They were promised instant engineering support for faulty equipment but as one CSW put it-

"..once its passed the easier to fix things we need engineer support, I have never seen one yet. I have never seen the engineer. We got some people waiting two months for the repair of their equipment"

Research strategy: Randomized controlled trial

Staff expressed apprehension towards the randomisation of patient and maintained that handpicking of patients would have been a desirable feature. They did not fully appreciate the aims and objectives of randomised trial taking place. According to clinical users, handpicking of patients would have avoided anxious patients from getting telemonitoring equipment.

"It is about how you assess the patient. It is the thing. It is good doing what we are doing. Research is good thing, because its worth waiting. You choose the right patient for that. I mean I have got a lady who's really hypertensive who I would really really look to put on it, but it actually sends her stir crazy because she would not know how to cope with it……It is about assessment and putting the correct people up"

Staff felt uneasy about getting patient's consent to taking part in the trial as they believed it would be unfavourable towards patient's emotional and mental well being.

"I don't understand why everybody has been consented. Because I feel there is a physiological element there…..I think that does affect them. I cannot understand why 250 patients were not picked and then we consent them"

Trust

This concept draws association between the interaction of various clinical users and their expectation from this service. Reliability of the data transmitted, guarantee of correct equipment use by patient and dependence on other staff were emphasised as key topics.

Technology and Patient

As patients are to take their own measurements using telehealth equipment, clinical staff questioned the reliability of these observations and questioned whether machines were calibrated routinely and were functioning accurately.

"I am not sure how long is this equipment in some body's house for before it is tested? Just a regular check, you don't know if there is a hole in the blood pressure or getting the wrong reading or what?"

In addition, nurses trained patients on how to use the equipment, for example not to run to machine and take measurements. However, despite ongoing efforts by the clinical staff, examples of inappropriate use came to light.

New staff members: Community Support Workers

Recruitment of Community Support Workers (CSWs) was a welcomed initiative. However, some senior nurses expressed anxiousness over handing over part of their responsibility to the new staff and trusting them.

Management

One of the biggest concerns that nurses had was being monitored by PCT for number of patient visits. This currently adds to their workload but as telehealth consultations are not accounted under the current scheme, nurses' workload might appear lighter.

Security

The third and final concept of security widened the understanding of clinical users' personal dilemmas that they were feeling due to introduction of telehealth service.

Lack of control

Staff especially nurses, were uneasy about their patient using the equipment and perhaps start depending on it in long term. In addition, they expressed doubts about relying on newly recruited community support workers for monitoring the patient observations and informing them in case of possible deterioration.

"its that little bit of vary of actually saying well we are gonna do it all over the telephone from now on, obviously that is an

exaggeration ...doing it all on the telephone... but whether its fear of my own loss of control I don't know?"

Change in work routines

Clinical users recognised the advantages of telehealth, but due to heavy workload were hesitant about possible changes in their work routines because of this service.

"there is this change and transfer period ….so during this time having to reconfigure I suppose the way we work will be very difficult"

Discussion

This research contributes to the theoretical and practical consideration related to assessment of user perception.

Main **theoretical contribution** would be employing Giddens concepts, firstly to enable telehealth to be defined as an expert system and secondly explain features that need attention and require maturing for allowing this expert system to develop into a fully sustainable abstract system.

An abstract system involves 'faceless commitments' that are based on trustworthiness vested at access points which can be described as the ground where experts within an abstract system meet lay people (in our study the experts are clinical users and the lay people are patients) [7]. However, original nursing practice, involves trustworthiness established between different individuals based on "facework commitments' that relates to copresence. Introduction of telehealth creates access points, which lead to clinical users being overwhelmed by the feeling of loss control. In parallel to that, the level of expertise of experts with in a system is also an issue of concern. Many clinical users complained of inadequate training and support as this questioned their own expertise over certain issues such as equipment installation, computer system use and training of their patients.

It is also noticed that many clinical users questioned the reliability of telehealth equipment. This coincides with vesting trust in an expert system, and therefore, one could argue that unless full trust of experts is not gained; telehealth service could not become a self-sustaining abstract system.

From **practical view**, firstly it allows to understand the perceptions and feeling of clinical users as social beings' (view) then just abstract clinical users with defined mechanised roles and routines. Secondly, it permits to scrutinize conflict among groups and contradiction with managements' strategy associated with the launch of telehealth.

In a term 'bargain with modernity', Giddens describes the nature of trust that actors invest in an expert system to be *"governed by specific admixtures of deference and scepticism, comfort and fear"* [7]. Moreover, these are the feelings that are exhibited by participants in this study. Hence, they find it difficult to trust a technologically sophisticated patient monitoring system despite its much-appreciated success in other areas of healthcare delivery and other countries. Other cause of clinical users' trust being rattled is perturbing their daily work routines by introducing telehealth. Daily routines of an actor constitute their sense of security and when this is disturbed, trust in system is shaken. These various resultant conditions wreak direct insult on trust and security, and actors with such emotions continuously enact structures that are inherent with conflict and contradiction.

One of the lessons learned from this study is that clinical users tend to operate on very basic units of trust and security, like any other social beings. These feelings and emotions are much intense in instances where care of people is involved, as clinical users perceive themselves to be responsible for any outcome of their patients' health. Lapses in acknowledging these emotions can lead to differences in groups' interests and create misunderstanding with managements or systems' objectives. Which when stagnate lead to power practice as a direct result of conflict, for example, some nurses will refuse to use the service at all. This will also enact structure of domination due to the presence of contradiction for example where the management will use tactics such as firing staff for not using the telehealth service [6].

This study proposes to handle these issues by providing optimal training to the staff involved, giving clear information on what is required from each clinical user involved and offer technical support to nurses when and where required. It also calls for clinical users to be instructed on clinical trial methods so questions on patient randomisation and consent do not crop-up. Assurance that 1) telehealth will not replace nurse visits to their patient, 2) telehealth equipment is calibrated and safe to use and 3) telehealth would not impinge on daily routines of nurses is very crucial to win the trust and provide sense of security thus alleviating conflict and contradiction.

Conclusion

Trust and security are very crucial and play an important part in clinical users' decision of using a new telehealth service. If not acknowledged, these feelings dwell in form of conflict among individuals within a group or different groups and contradicts overall system objective. For telehealth service to be free of conflict and contradiction, equipment providers and management of healthcare facilities should recognise clinical users as social beings with heightened sense of responsibility. Taking users' view on board and allowing them to participate in decision-making (implementation etc) would be the first step to ensure that their need to establish trust and security are met.

Acknowledgement

We thank MATCH (Multidisciplinary Assessment of Technologies Centre for Healthcare) for funding this research. We also thank Nottingham City PCT for allowing us to interview their staff (especially, Sally Parker for arranging the meetings).

Usage of international standards for integrating extramural monitoring and personal health device data into medical information infrastructure

A. Mense, S.Sauermann, G. Gerbovic, M. Frohner, B. Pohn, R. Bruckner, Ph. Urbauer, F. Eckkrammer H.Wahl

University of Applied Sciences Technikum Wien, Vienna, Austria

Abstract

Integrating extramural measured devices data into medical information systems is becoming more and more attractive for integrated medical care. A lot of devices already have the ability to transfer measured data to mobile devices or computers and a few systems offer submitting data to a centralized information database or information system. Unfortunately, all of these devices use proprietary protocols and processes which makes integration into other systems a major problem. To address this problem the Healthy Interoperability project has been created with the objective of creating a framework for transferring health data based on international standards. The paper outlines how the framework architecture takes full advantage from the definitions of the international standards ISO 11073, HL7, IHE and CEN 13606. Even the definition of the user profiles and the security framework is based on standards from ETSI, ISO and CEN. By using these standards the framework can also perfectly be used for intramural communication.

Keywords:

e-Health, Medical device, Device communication, Personal health, PHD, ISO 11073, HL7, IHE, CEN

Introduction

Integrating extramural measured devices data into medical information systems is becoming more and more attractive for integrated medical care. Existing and new upcoming devices offer a big variety of possible use cases ranging from monitoring and alerting up to observing the own health status by using personal health devices. Using such device data is as useful for observing chronic disease parameters as for prevention. A lot of these devices have the ability to transfer measured data to mobile devices, mobile phones or personal computers and it would be very valuable to submit the data to health provider information systems or to integrate it into an electronic health record or a personal health record. At the moment there are only a few companies and systems that offer transmission of data to a centralized information database or information system. Unfortunately, device connectivity to enterprise services is however currently very proprietary and all of these systems use proprietary protocols and processes which makes integration into other systems a major problem. To address this problem the Healthy Interoperability project has been started in January 2009 with the objective to overcome the problem of non interoperable interfaces by designing and developing a communication framework that is solely based on international standards and thus enables technical and semantic interoperability. This framework shall also facilitate access to the many different types of available data and provides this data to intelligent personal services.

Materials and Methods

System Architecture

In addition to the main goals of the project some further requirements were defined to be considered in the first phase of the project.

- Sensors and devices should be capable of being integrated into the framework on a plug & play basis which means, that no specific setup has to be done be the user to start communication.
- The framework shall be very flexible and allow easy extension of functionality by integrating new software modules with a plugin concept.

Figure 1 outlines the systems components and architecture.

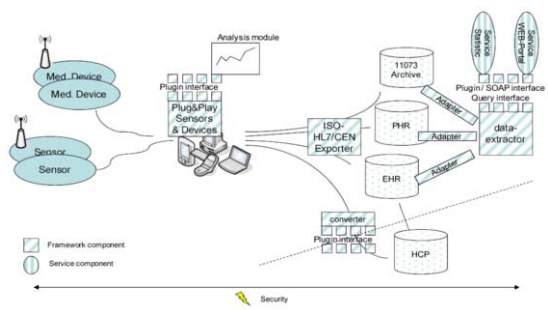

Figure 1- System overview

The framework has a modular architecture that enables a lot of different configurations and therefore the functionality of the system depend on the modules used in a specific configuration.

International standards and standard based framework

During the first six month of the project a lot of international standards have been evaluated to be used in the framework. The following standards have been chosen to be implemented in the framework modules:

- ISO/IEEE 11073 [4]: defines device communication and information exchange on a plug & play basis. Core part of the concept is an agent – manager communication where the device is the agent.
- HL7: the HL7 definitions of both message based standards are used in the project. The Version 2 messaging as part of the IHE profile definitions and the CDA specification (part of V3) for generating medical documents on a XML basis. The HL7 "Personal Healthcare Monitoring Report (PHMR)" implementation guide is used to convert device data to a CDA document.
- IHE: To integrate patient care devices into medical data flows IHE defined the "Patient Care Device Technical Framework" [6] with the DEC profile. In principle this definition fits well to the requirements of the "Healthy Interoperability" project but it had been developed for intramural processes. Nevertheless the profiles are implemented and the upcoming problems will be dealt with. But using the DEC profile means a lot of other profiles get involved – Figure 2 gives an overview of needed IHE profiles.

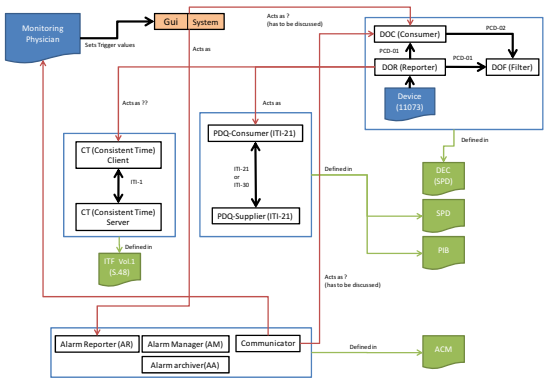

Figure 2- IHE profiles needed (without XDS)

Furthermore, the XDS profile definition of the IT Technical Framework is used to implement a document consumer module for the framework to integrate data into an IHE based EHR.

- CEN 13606 [3]: has been evaluated for defining domain models and flexible data structures. This standard really has high potential but as it is not part of the definitions of any other international framework (e.g. IHE) the usage in the project has to be further evaluated.
- Continua Alliance: the open industry coalition focuses their work to personal health (fitness, wellness), chronic diseases and solutions for aging population. They published the "Continua Design Guideline" which defines the basic conditions for device data communication (the guideline is based on ISO/IEEE 11073 and PHMR). They also offer a certification process for devices and systems.

Results

Device communication

Based on the ISO/IEEE 11073 basic and profile definitions device communications for three different devices has been set up and tested so far: a pulse oximeter (Nonin, USB based), a data logger (Bluetooth based) and a clinical thermometer (see next paragraph). Overall five device profiles for different device classes and the central 11073 manager module were implemented. The manager is already being able to integrate devices and start communication on a plug&play basis. At the moment the manager runs on mobile devices with Windows Mobile operating systems but because of the Java implementation it can be easily ported to any other system.

Clinical thermometer device

For testing purposes and to demonstrate the usage of the framework for intramural setups a hardware prototype for a clinical thermometer was developed (Figure 3) and the software for ISO 11073 conformant communications was implemented on the used microprocessor. The device has a RFID module to identify a patient via a RFID wrist band and it communicated with the manager via Bluetooth. At a further project stage the RFID identifier will be used to query demographic data from the HIS or any other system and the device displays the name of the patient the device display.

Figure 3- prototype of a clinical thermometer

Module architecture

After conception phase the module structure for the framework was defined and the basic modules to be implemented first were selected - Figure 4 shows the architecture and the modules. The core of the system is called "controller" a module which manages all the other modules and applications that are plugged into the framework.

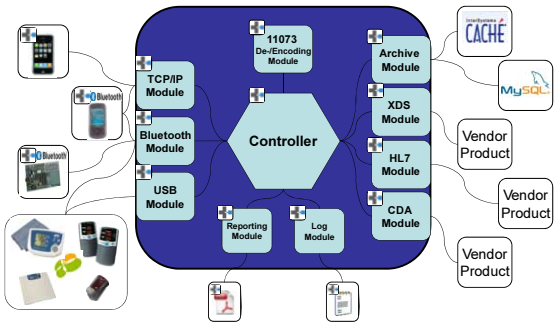

Figure 4-Module architecture

A module can be added easily by simply providing a java library file at a specific location. The controller mentions the new application and integrates it into the framework. At a second step each module has to register itself at the controller and as a part of the negotiation process the new module defines the type of data it can provide (write) or it wants to have (read). The controller administrates all the modules and manages a common data container. This container can be filled by different modules and can be accessed by others. The controller takes care of the data request done by all modules and notifies a module as soon as all requested data is available by releasing an event. This means that for instance a module needs data that can only be served by two other modules (e.g. a CDA Module needs data from the device and from a demographic query). Using this plug and play interface also third party modules can easily be integrated without any change of the framework.

All of the 11073 based modules (on the left side of Figure 4) have already been implemented. Also development of the log and archive modules was finished. The archive model writes the data into the object oriented Cache database. The HL7 and IHE modules are currently under development.

Standard based controller data container

The controller holds one or more data container, which are used for data exchange of the modules. The design of this container is also based on the selected standards. The container can hold ISO 11073 structured data (also raw data is provided for compatibility issues), HL7 data, a CEN 13606 EHR-Extract or any other data structure. The demographic data is currently designed to be stored in the HL7 RIM model. Figure 5 shows an UML overview of the container. Access to data is controlled by the controller.

Use case analysis

In parallel to the technical development the analysis of possible use cases and the related processes, which started at the beginning of the project, is continued. Among others this includes scenarios for patient to doctor communication, chronic diseases but also intramural use cases (see clinical thermometer). The results of this analysis project and the documentation will be published by ISO as part of an official ISO.

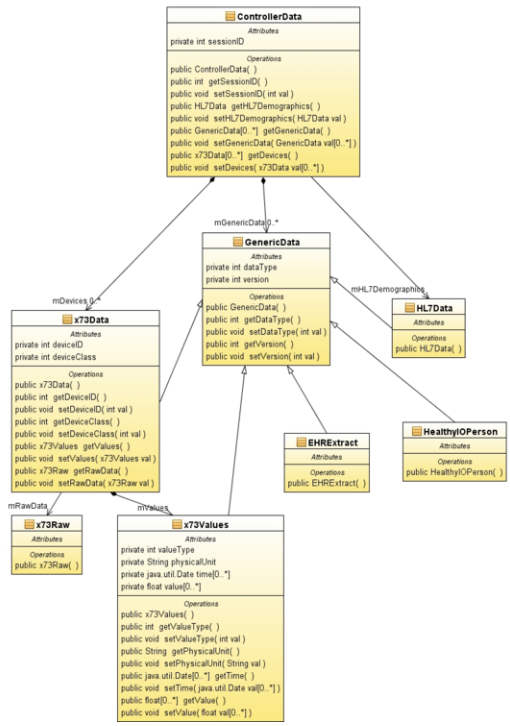

Figure 5-UML Model of the data container

Discussion

Continua Alliance

The Continua Alliance, their definitions and their certification process gets more and more attention as the interest in devices, which support data transmission to mobiles or PCs, grows.
Especially the market for consumer devices and devices supporting ambient assistant living (AAL) is growing. Especially for AAL the communication based on an international standard is a very important issue because it enabled interoperable systems and that massively reduces costs. But therefore the availability of Continue certified devices gets more and more into the focus. At the moment there are only a few certified device classes on the market, but according to Continua in January 2010 a lot of compatible devices should come to the market.

ISO 11073 reverse channel

At the moment the ISO 11073 agent – manager communication is mainly unidirectional, which means the device is sending data. The only exemption is that some devices can get configuration parameters from the manager. In some cases (e.g. the clinical thermometer) this seems to be too limiting, because sometimes the reverse channel should be usable for data transfer (e.g. clinical thermometer: questioning the patients name to be displayed on the device).

Remote configuration

It seems to make sense that a doctor who is monitoring a patient's data should be able to change the configuration of the monitoring device. But this raises a lot of problems especially in regard to security because it has to be ensured that a specific configuration really was entered by a doctor and that it is not a fake. This also has a lot of legal aspects. Therefore at the moment the communication is only unidirectional.

Security

As the Healthy Interoperability frameworks handles medical data special security and data protection definition has to be applied and sufficiently addressed. End to end encryption would be nice to have but fails because of current technical limitations, such as key distribution or using electronic certificates on medical devices. Hence also the security requirement of non repudiation is still vacant.

For securing the communication route from the mobile to the health provider information system currently the ISO/TR 11636:2008 about "On-Demand VPN" is evaluated.

Also the process for assigning a device to a patient is still not satisfactorily solved. The assignment still requires manual interaction. To optimize the assignment process or find a automated reliable solution will be part of future work in the next month.

Profiles

The behavior of such a system depends on the situation when and where it is used. So the system has to provide different profiles. Profiles can have different categories, for example "communication profiles" which control the data transmission channel or "situation profiles" like "at home" or "at restaurant" which for example controls the audio response of the systems. Profiles can be active or not and usually more than one profile is active.

Pilots

For the next year two pilot installations are planned to demonstrate the operation of the system. First pilot will be patient monitoring in the home care area. The pilot addresses older people at the age of 70+ who are currently served by a care organization. The pilot aims to monitor health parameter online and on a second step implement a kind of alarm management for abnormal data.

The second pilot will address self management of oral coagulation. Concerned people get a device for home and self measured device data is transferred to a server where a medical attendant periodically validates the values.

Acknowledgments

This project is supported by the Austrian Research Promotion Agency (FFG) within the "FHPlus in Coin" program and by the City of Vienna Municipal department 27 "EU-Strategy and economic development" following the "Fachhochschulförderrichtlinie" 20.

Abstract

Objective : demonstrate the feasibility of deploying portable ultrasonography with remote assistance to improve the diagnostic capabilities of isolated physicians in Africa. Methods : the approach is based on the training of general practitioners for the use of ultrasonography, and the remote support by radiologists using dedicated tools for image transfer over low-bandwidth internet connections. Results : our early results in a pilot project in Mali show that this approach is feasible, and that isolated physicians can productively use ultrasonography to improve diagnosis and management decisions such as the need for a medical evacuation towards a reference hospital. Conclusion : these encouraging early results must be confirmed by larger-scale studies, in order to better understand the organizational requirements and demonstrate outcomes and return on investments for such telemedicine services. This scale-up project will start in 2010 in collaboration with the International Development Research Center of Canada.

Keywords:

Telemedicine, Teleexpertise, Teleradiology, Ultrasonography, Africa

Introduction

The usefulness of ultrasonography for improving diagnosis and patient management in rural Africa has been demonstrated by several studies [1-4], in particular for obstetrical and abdominal pathologies.

The possibility to train non-radiologists to the use of ultrasonography for emergency situations [5] and for obstetrical evaluation [6] has also been established. Such training requires significant efforts for initial and continuing education, as well as monitoring by radiologists.

However, such specialists are rarely found outside of capital cities in Africa. For example, there is only one radiologist outside of Bamako in Mali, a country of 2'421'000 square kilometers with a population of 14 millions. Projects have therefore been developed in order to provide a remote support by radiologists, to improve the quality of the service and to support isolated care professionals facing challenging cases.

In addition, projects enabling the remote control of ultrasound imaging have been developed, such as the TERESA project [7] of the University of Tours in collaboration with the European Spatial Agency.

As portable ultrasonographs are becoming cheaper and connectivity of isolated hospitals is improving, it becomes realistic to deploy such tools in remote areas, but there are still many questions related to the training of the professionals, the organization of the remote support, the usability of telemedicine software, and the effective use of usually poor internet infrastructures.

In this study, we investigate the feasibility of deploying portable ultrasound imaging devices in remote hospitals, with distance assistance, through low-bandwidth connections with national reference hospitals. The pilot site is a rural hospital in Mali, the reference hospital being based in Bamako, the capital, 875 kilometers away.

We use the infrastructure and organization deployed by the RAFT (Réseau en Afrique Francophone pour la Télémédecine), which provides connectivity to dozens of hospitals in French-speaking Sub-Saharan Africa [8,9] in order to support continuing medical education and tele-expertise for isolated physicians and care professionals. We also make use of the CERTES, center for expertise in telemedicine in Bamako, which provides services to telemedicine users in Mali, and more generally in the West African region [10].

Materials and Methods

Materials

The ultrasound imaging device is the Voyager® Compact Imaging Device [11] (Ardent Sound Inc., Meza AZ, USA) equipped with two probes (4 and 10 MHz) and powered by an

external battery. It is connected to a standard laptop computer via a USB cable. The imaging software, Ardent Examiner®, runs on the laptop and produces DICOM images which can be exported.

An additional software, Medbook©, has been developed within the scope of this project in order to receive these DICOM images, compress them and securely transmit them on a distant server where they can be retrieved for review by experts. The goal of this software is to be able to rapidly transmit these images over a low-bandwidth internet connection of 30-40 kilobits/second, the bandwidth that can currently be obtained on the cheap DSL or mini-VSAT connections deployed in the RAFT network. It contains a DICOM listener based on the open-source dcm4che platform [12], and uses the Theora [13] open-source video compression. It can produce various images at different compression levels (Figure 1.) thus enabling very high-level of lossy compression, as well as lower-, lossless compressions for specific images. This is particularly useful in order to define imaging and image transmission protocols that take into account the actual possibilities of the existing connections. Medbook© also helps collecting structured information to be sent to the expert, as well as an identity management tool to label cases.

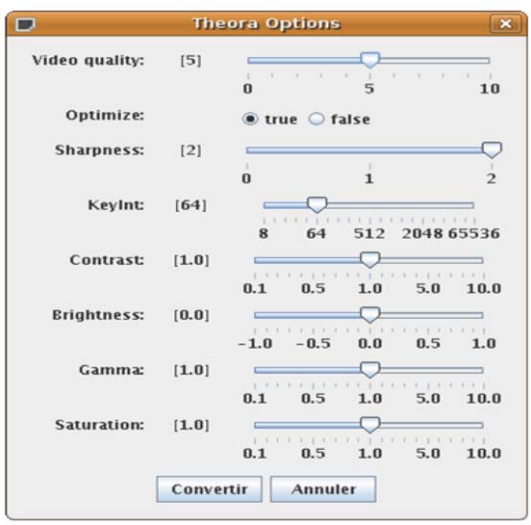

Figure 1 - Medbook interface screenshot: Theora options for defining and testing various compression levels

Methods

The RAFT network

Continuing education of healthcare professionals and access to specialized advice are keys for the quality and efficiency of a health system. In developing countries, these activities are usually limited to capitals, and delocalized professionals do not have access to such opportunities, or even to didactic material adapted to their needs. This limits the interest of such professionals to remain active in the periphery, where they are most needed to implement effective strategies for prevention and first-line healthcare.

In order to address these needs, the Geneva University Hospitals have developed a telemedicine network in Africa (the RAFT, Réseau en Afrique Francophone pour la Télémédecine), first in Mali, then in Mauritania, Morocco, Cameroon, and, since 2004, in Burkina-Faso, Senegal, Tunisia, Ivory Coast, Madagascar, Niger, Burundi, Congo-Brazzaville, Algeria, Chad, and Benin.

The core activity of the RAFT is the webcasting of interactive courses targeted to physicians and other care professionals, the topics being proposed by the partners of the network. Courses are webcast every week, freely available, and followed by hundreds of professionals who can interact directly with the teacher. 70% of these courses are now produced and webcast by experts in Africa. A bandwidth of 30 kbits/second, the speed of an analog modem, is sufficient, and enables the participation from remote hospitals or even cybercafés.

Other activities of the RAFT network include teleconsultations, and collaborative development of educational on-line material.

The network is currently organized and run by more than 30 national coordinators and a small coordination team based in Geneva. In each of the partner countries, the RAFT activities are supervised by the focal point, a medical authority (usually a university professor) that links the project to the national governmental bodies (ministry of health, ministry of education). A local medical coordinator (a junior physician) and a technical coordinator take care of the day-to-day operations, including communication with the care professionals, identification of training needs, technical training and support of the various sites within the country

Pilot site

The pilot site is the rural hospital of Dimmbal, in the Dogon country in the north of Mali, 875 kilometers away from Bamako, where the radiological expertise resides. Before being connected to the RAFT network, Dimmbal was quite isolated, the first telephone 15 kilometers away, and the first internet connection 120 kilometers away. The hospital, serving a population of about 30'000, and staffed with a physician, a nurse and a midwife, was equipped with a mini-VSAT satellite connection in 2004 (Figure 2.), and has served as a laboratory for the RAFT network to investigate the feasibility of deploying distance-education, telemedicine and de-isolation activities for care professionals in rural Sub-Saharan Africa [14].

Figure 2 - Dimmbal rural hospital, in the Dogon country (Mali), equipped with a mini-VSAT internet connection

Reference hospital

The reference hospital is the Hôpital Mère-Enfant "Le Luxembourg", one of the three main reference hospitals in Bamako, capital of Mali. This hospital hosts the CERTES, center for expertise, education and research in telemedicine. Amongst others, CERTES provides basic computer and internet skills courses, as well as specific courses for the use of distance education and telemedicine tools.

Computer and internet skills development

This is an essential phase as many care professionals still have limited computer and internet usage skills. Although the current physician of the Dimmbal hospital has acquired these skills through previous training courses, any deployment of such tools must be accompanied by such basic training, as the internet connectivity will be the umbilical link between the remote hospital and the centers for expertise, whether medical or technical. These skills are usually acquired through a one-week course, either in the CERTES in Bamako, or at decentralized workshops in regional cities where 10-15 care professionals are regrouped.

Additional skills for the specific usage of the ultrasound device and the image transfer systems are also needed.

Ultrasound imaging training

Basic training for the proper usage of the ultrasound imaging device requires approximately one month of practice with a trained radiologist. The duration of the training depends in part on the availability of appropriate cases. The goal is to develop the basic skills and make sure that the trainee will be able to reproduce the main, key images that are used for the evaluation of patients.

Organization of the tele-expertise service

Once trained with the basic skills for acquiring and interpreting ultrasonographic images the trainee is also taught how to decide when to seek expert advice for the analysis of an image or a video sequence.

At CERTES, a center of expertise is setup and physicians receive tele-expertise requests and route these to the appropriate specialists.

Ultrasound images, first acquired in a DICOM format, must be exported and compressed using Medbook©, then uploaded on a secure server where the specialists can access them for review. The requesting physician is then informed directly by the expert through the teleconsultation platform.

Results and lessons learned

A case-report from the Dimmbal pilot site

A 22-year old woman, at the seventh month of pregnancy, consults the Dimmbal hospital for musculoskeletal and abdominal pain. Anamnesis reveals that she has been battered by her husband. Physical examination shows multiple contusions. The ultrasound examination (Figures 3 and 4), reviewed in near real-time by the radiologist in Bamako, confirms that the fetus is not showing signs of suffering. The patient is therefore kept for observation at the Dimmbal hospital, and not evacuated to the regional hospital.

Image compression and image quality for diagnosis

One of the key limiting factors for this application is the bandwidth. It is unlikely that a remote hospital will be able to afford more than a basic internet connection, given the high cost of these outside the main cities. Currently, a reasonable bandwidth is about 200 kilobits per second for downloads, and 30-40 kilobits per second for upload.

For this tele-ultrasonography scenario, the uplink is critical, as images are sent from the periphery to the center of expertise. A video sequence of 150 frames (10 seconds), uncompressed, in DICOM format, weighs 170 megabytes. A frame-by-frame compression in JPEG 2000 will reduce it to 5.4 megabytes, whereas a Theora video compression will reduce it to 1.4 megabytes, with an output quality judged sufficient for diagnosis by several radiologists who participated in these experiments. With such compression rates, it is possible to send such video sequences in 4 to 5 minutes over a 40-kilobits per second uplink. This obviously requires a careful selection of the video sequences by the requesting physician.

Figure 3 - Portable ultrasonography setup. The same computer is used for acquiring the images, and then transmitting them, compressed, to the reference center

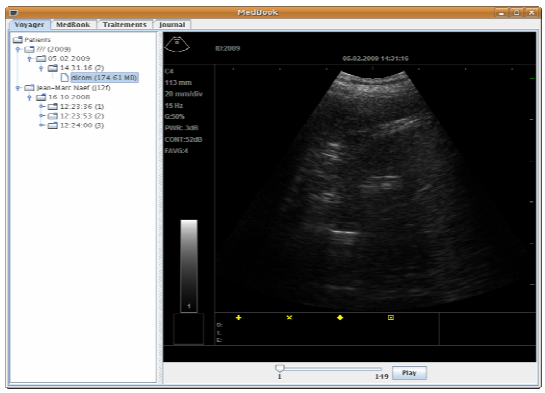

Figure 4 - Medbook screenshot: selection, compression and transmission of an ultrasonography video sequence

Localization of these activities within the health system

Although we piloted the tool in a rural hospital, it appears that the level of activity is not sufficient to justify such investments, and we are now moving to the first level of reference, i.e., district hospitals, where the number of cases is higher, and where the overall infrastructure of the hospital is sufficient to take care of many of the patients evaluated with this telemedicine service, thus improving the value of the ultrasound imaging for deciding whether or not to evacuate the patient to the next level, i.e., the regional hospital.

The same remark pertains to the sustainability of financing the internet connection, which is very difficult to achieve at the rural level.

Delegation of the ultrasound imaging to other care professionals

There are good arguments, and needs, to train non-physicians for the use of ultrasound imaging, in particular for midwives performing obstetrical evaluations. It is however important that these professionals don't replace specialists and that they respect the ethical and deontological rules for reference of patients. An easily accessible link to specialists has the potential to maintain a balanced distribution of roles and facilitate quality monitoring and continuing education of these care professionals.

Availability of timely expert advice

A critical success factor is the ability to access expert advice in near to real-time. If the delay is too long, or the expertise insufficient, then the requesting care professional will not bother trying to access it.

The experience of the CERTES, in Bamako, shows that this can be achieved through a properly-staffed operational center. Obviously, such a center can only be maintained if there is a high-enough level of activity, which can be challenging initially.

Conclusion

This pilot study demonstrates the feasibility of deploying portable ultrasound imaging in remote hospitals and providing timely access to expert advice for difficult cases. The success relies on the proper training of the users, the rigorous organization of the call center and the use of an adapted software for the secure transmission of the images over low-bandwidth connections.

This service complements other services already deployed to help de-isolating care professionals who work in remote areas [8,9], thus creating a critical mass of added value that can justify the investments and maintenance of telemedicine tools in district hospitals.

Although technical evaluations and anecdotal evidences are confirming the potential of these tools to strengthen health systems, it is now important to demonstrate patient outcome improvements and measure financial returns on investments, as these stronger evidences are necessary to drive the further development and deployment of such systems.

Acknowledgments

This work is supported by a grant from the Geneva University Hospitals and by the Fonds de Solidarité Internationale of the Geneva State.

Web-Based Asynchronous Teleconsulting for Consumers in Colombia: A 2-year Follow Up

José Ignacio Valenzuela, Catalina López, Yuli Guzmán, Roosevelt Fajardo

Centro de Educación Virtual y Simulación e-Health, División de Educación, Fundación Santa Fe de Bogotá, Bogotá, Colombia

Abstract

Background: Remote consultation was implemented in 2006 in our institution, through an open-access Web-based Teleconsulting service: Doctor Chat. This tool was created with the aim of improving access to health care services in Colombia, especially in underserved areas. Objective: The aim of this paper is to report our experience with the free Web-based application for teleconsultation. Methods: After validating the tool, we analyzed the queries submitted between May 2007 and June 2009. Requests were classified into three axes: purpose of the query, specialty, and geographic area of origin. Descriptive statistics were gathered for each category (name, email, city, country, age, gender). Results: We received 1624 consultations, with an average of 59 requests per month. 52.7% of the users were aged 18 to 29 years. Users asked mainly about sexual and reproductive health issues. 79.2% of consultations came from Colombia and 32.91% of the users were students. Conclusions: Doctor Chat is an innovative tool to deliver health care information, but advertising, preventive and technical strategies must be implemented to improve its impact on Colombia's health system.

Keywords:

Colombia, Remote consultation, e-Health, Teleconsultation, Telemedicine.

Introduction

Among technological applications available today, teleconsulting services stand out as significant means to improve access to healthcare information [1]. Many concerns about health issues can be answered by a medical guidance through the Internet [2]. Due to high worldwide impact of these services, the Center for Virtual Education and Simulation (Centro de Educación Virtual y Simulación e-Salud, Fundación Santa Fe de Bogota [3]), offers a noncommercial, free web-based teleconsulting service in Spanish, called Doctor Chat [4]. This application was developed in 2006 with the aim of providing a tool that could serve as a basis to improve access to health care services in Colombia, especially for populations in-need located in underserved areas of the country. In 2007, we presented the first results of our experience with Doctor Chat [5]: During the first six months of operations, 270 teleconsultations were received. At the time, Internet penetration was already showing a steep rise, ascending from 2.1% in 2000 to 12.9% in 2006 and 44% in 2009 [6, 7]. This evolution is shown in Figure 1. Additionally, the number of internet subscribers raised 54% between June 2008 and June 2009 [7]. This information allowed us to expect fewer barriers in terms of Internet connectivity, more access in underserved areas, and therefore a progressive increase in the number of teleconsultations, which could translate into a continuously growing impact tool towards community health information empowerment. These facts served as strong motivators to continue with the program on a subsidized basis with a social sense. Three years after Doctor Chat´s launch, we analyze the follow up experience with the use of web-based asynchronous teleconsulting for consumers in Colombia and Latin America.

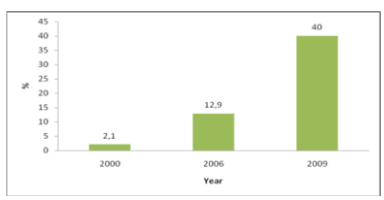

Figure 1- Evolution of Internet Penetration in Colombia

Materials and Methods

Doctor Chat´s Nature and Upgrades

Since its conception, Doctor Chat has followed a user-centered approach to allow anonymous virtual health consultations openly available to any Spanish-speaking person in the world via Internet. Compared to its first version described [5], in March 2009 structural changes were introduced:

(1) The formats for asynchronous teleconsultation and response were redesigned, allowing us to retrieve and analyze digitally more information about the requests, i.e. the purpose of the queries, the Specialty they corresponded to, and the Profession/Occupation of the consulter. To that date, this information was retrieved and stored manually, and for this reason, the data in those last categories analyzed in this paper were only retrieved since that date (see Results); the first data field ("Name") was replaced by ("Name or alias") to further protect user´s confidentiality. Also, the interface was modified to increase its dynamicity. (2) the supporting platform migrated

from a Web-based application structured as a series of HTML pages with e-mail feedback to one that is managed through a tailor "home-made" XHTML scalable application for Contents Management Systems (i.e. Joomla 1.5.X), which allows web-control for information capture and results generation, with transactional reporting via web, anti spamming security (Captcha) and Security Sockets (SSL), created by a Web server (Red Hat Enterprise Linux 4, Apache/2.0.63 Unix) to store and retrieve data in a relational database (MySql 5 – MySqli 5, PHP 5).

The new platform has allowed response automation: whereas previously each user query was directed to a centralized Doctor Chat email account to which only the medical team had access and responses were given by simply replying to the message, now the queries are stored in a web accessible data base, and the responses are given directly through the web-based application. This has significantly facilitated data analysis by allowing computerized data mining, while assuring all the data fields that are important for the analysis are collected.

All queries are received and filtered by a coordinating physician, who responds to primary-level health questions and redirects those specialized to the corresponding Department of our fourth level University Hospital.

(3) The user's satisfaction survey was extended and automated. Before March 2009, a single-question informal survey of user's satisfaction was sent along with the response ("Are you satisfied with Doctor Chat's service? Please send us your comments to improve the service"). Now, the new satisfaction survey includes 5 mandatory question fields (QF) with drop-down menus for each answer (A): (1) QF: "Did the answer provided by Doctor Chat meet your expectations?" / A: "Yes – No"; (2) QF: "Was Doctor Chat´s answer to your question clear?" / A: "Yes-No"; (3) QF: "What´s your general opinion on Doctor Chat´s response according to the following criteria" / A: "Insufficient – Indifferent- Acceptable – Good – Excellent"; (4) QF: "Given that the standard response time of Doctor Chat is 48 hours, what is your overall satisfaction with the response time?" / A: "Completely satisfied – Satisfied – Unsatisfied – Completely unsatisfied"; (5) QF: "Comments and suggestions" /A: Blank field.

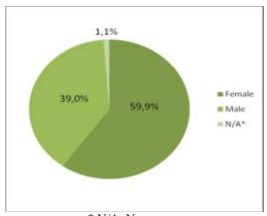
Data Analysis

Content analysis was performed according to three classifications: (1) the purpose of the query, (2) the specialty, and (3) the geographic area of the query. Kravitz et al [8] "taxonomy of patient requests" was used to categorize the purpose of the query, and each request was classified according to the topic into one of the 31 specialties available at our institution.
Descriptive statistics were gathered for each of the data categories (name, email, city, country, age, gender and the newly included profession/occupation) and the location from which each query was submitted was determined by the response to the "country" and "city" cells.

Results

Gender and Age Ranges

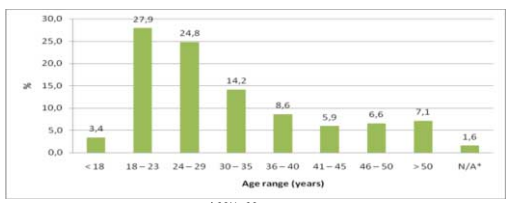
Between September 15th 2006 and July 8th 2009, we received a total of 1624 remote consultations, 973 were submitted by women and 633 by men, which represent the percentages shown in Figure 2.



* N/A: No answer

Figure 2- Distribution of consultations by gender

The monthly average of remote consultations was 59, whereas a mean of 2.3 were received per day. This average practically doubles that of 1.4 consultations per day, found from September 2006 to march 2007 [5]. Regarding the age groups, most of the users were aged 18 to 29 years (52.7%), as shown in Figure 3. This result is very similar to the one we reported in 2007, in which 54% of the users belonged to this same age range [5].



* N/A: No answer

Figure 3- Distribution of consultations by age range

Purpose of the requests

By taxonomical category (as described by Kravitz et al [8]), the majority of teleconsultations were requests for information (n=1482; 91.3%), and particularly about symptoms, problems or diseases (n=991; 66.8%). Inquiries for medications/treatments accounted for 22.2% (n=330) of the Request for Information category.

Requests for Action accounted for 7.2% (n=117) of all consultations, and among these, 70.9% (n=81) belonged to the Medication/treatments, 15.3% (n=17) and 12.6 % (n=14) to the "Referral to other physician" and "Laboratory test, x-rays, or other study" subcategories, respectively. These results are shown in Table 1.

Table 1 – Distribution of consultation per taxonomical category

Taxonomical category	n	% of the category	% of total
Request for Information	**1482**	**100**	**91,3**
Symptoms, problems, or diseases	991	66,8	61,0
Medications/treatments	330	22,2	20,3
Other administrative issues	44	3,0	2,7
Test or diagnostic investigations	48	3,2	3,0
Other request for information	44	2,9	2,7
Prevention	17	1,2	1,1
Other physicians	7	0,5	0,4
3rd party payer or managed care issues	0	0,0	0,0
Index physician-patient relationship	0	0,0	0,0
The physical examination	0	0,0	0,0
Psychosocial problems	2	0,1	0,1
Request for Action	**117**	**100**	**7,2**
Medication/treatments	81	70,9	5,0
Laboratory test, x-rays, or other study	14	12,6	0,9
Referral to other physician	17	15,3	1,1
Other administrative action	2	1,8	0,1
Referral to nonphysician	1	0,9	0,1
Administrative action: 3rd party payer	1	0,9	0,1
Physical examination	0	0,0	0,0
Other request for action	81	70,9	0,0
N/A* (Information or Action)	**25**	**100**	**1.5**
Consolidated Total	**1624**	**100**	**100**

*N/A: No Answer

Requests by Specialty

As shown in Figure 4, most of the teleconsultations fell into the Gynecology and Obstetrics (GO) (n=414; 25.5%) and Urology (n=178; 11.0%) areas. These requests corresponded to sexual and reproductive health issues, i.e. Sexually Transmitted Infections (STIs) including HIV/AIDS (65.2%), and contraceptive methods (30%). Among the remaining questions related to GO, 20% concerned pregnancy, 6% infertility and 6% vaginal infections. Requests for information on Dermatology accounted for 9.8% (n=133) of all teleconsultations. In this area, most of the questions asked for information regarding removal of moles, scars, striae or tattoos (40%) and allergic reactions (30%). Other questions on Dermatology included topics such as treatment of acne and skin cancer.

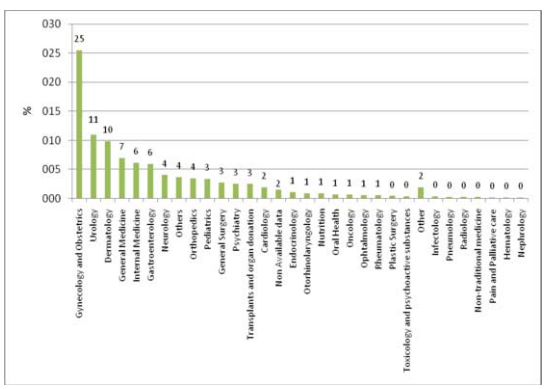


Figure 4- Requests by specialty

Origin of the Requests

79.2% (n=1286) of the consultations were originated in Colombia. However, as shown in Figure 5, we received inquiries from all around the world, especially Hispanic countries like Mexico (n=87; 5.3%) and Spain (n=63; 3.8%).

In Figure 6 we can see that most consultations from Colombia were originated in Bogota (n=690; 55.4%), Medellin (n=89; 7.1%) and Cali (n=66; 5.3%), the three main cities of the country. 22.7% (n=283) came from intermediate cities (State capitals except those described above), and 9.4% (n=118) from remote or underserved areas.

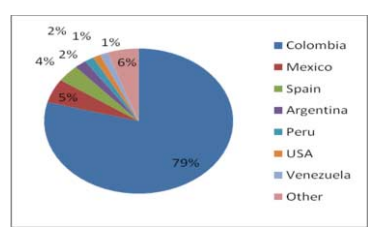

Figure 5- Requests by country of origin

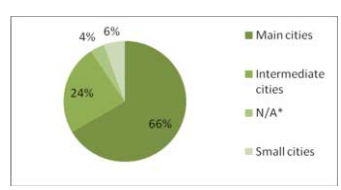

Figure 6- Requests by city of origin (Colombia)

In Table 2 we can see that in comparison to the 2007 results [5], the percentage of consultations originated in intermediate and small cities presented an important increase, whereas the percentage of requests from the main cities varied only slightly.

Table 2 – Comparison of distribution by city of origin between 2007 and 2009

Group	n (%) 2007	n (%) 2009
Main cities	137 (67.2)	693 (66.5)
Intermediate cities	40 (19.7)	251 (24.1)
Small cities	2 (0.7)	58 (5.6)

Requests by Profession/Occupation

From March 16th (date in which the "Profession/Occupation" field was added) to July 8th 2009, we received 237 teleconsultations. Among these users, the majority were students, followed by "other" types of Professions/Occupations, housewives and Merchants. The results are shown in Table 3.

Table 3 – Distribution by Profession/ Occupation

Profession/Occupation	n	%
Student	78	32.91
Other	56	23.64
Housewife	27	11.39
Merchant	14	5.91
Assistant, manager	10	4.22
Employee	10	4.22
Teacher	8	3.38
Lawyer	7	2.95
Administrative	7	2.95
Engineer	7	2.95
Miscellaneous	7	2.95
Independent	6	2.53
Total	**237**	**100**

Discussion

Since its implementation in 2006 and as seen in Figure 7, Doctor Chat has shown a fluctuating behavior. The peak in May 2008 shows its sensibility to "publicity". Although no marketing has been put in place to promote the tool among potential users, when the service was presented in an interview for Semana [9], a nation-wide spread magazine, a dramatically rapid increase in the number of teleconsultations shown in Figure 7 was accounted, with a total of 240 requests received only during that month. Nevertheless, without ongoing publicity, the use of the service declined as rapidly as the peaking rise, to stabilize at the previous baseline, thereby probably behaving accordingly to Eysenbach´s Law of Attrition [10], which states that e-Health applications "allude to a common problem" consisting of a decrease number of users through time, due to a loss of users over time. It would be interesting to put in place a continuous marketing strategy and evaluate its impact in terms of usage among the community, but because we predict a massive response, we would need financing to support the infrastructure and human capacity to anticipate to that demand. In this scenario, we consider that the tool may behave differently from Eysenbach´s Law trend, but a further follow up in the presence of continuous publicity would be needed to confirm this hypothesis. Another fact that must be considered in this matter is that the number of users of our application varies a great deal over time, with new users entering each day, some of the old users dropping out or consulting one time only, and some others using the application regularly.

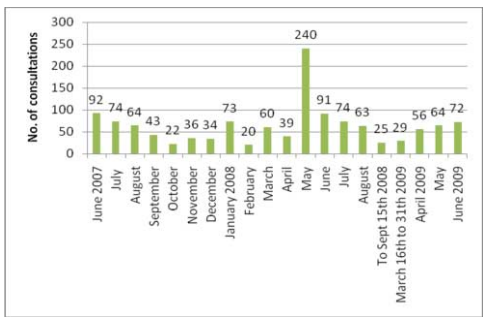

Figure 7- Number of requests per month

Regarding the geographical origin of the requests, few changes have occurred since 2007 [5]. Despite the increase of internet penetration in Colombia, 58.2% of all Internet connections are concentrated in the four main cities of the country [11], probably explaining the fact that most of the requests are still coming from non-distant places. However, it is fortunate that we have also accounted an important increase in the number of consultations coming from smaller cities and underserved areas.

Colombia´s National Plan for IT has established the year 2019 as the cutting point for universal internet coverage among the country [12], and is currently undertaking important efforts to achieving this goal. As internet penetration continues to expand as well as an "IT culture" to incorporate in the daily lives of distantly-located populations, we anticipate an exponential growth of the usage of teleconsulting services such as Doctor Chat as means to obtaining reliable health related information. Another interesting information retrieved from this study is the fact that most of the users of Doctor Chat are young students and housewives and that the majority of consultations were related to sexual and reproductive health issues. This is particularly important in developing countries like Colombia, where unplanned pregnancy is a main cause of school desertion and a major cause of unsafe abortion [13]. The importance and the impact of tools such as Doctor Chat to support sexual and reproductive health prevention and promotion activities and strategies is still to be assessed.

Penetration of mobile phones in Colombia is one of the highest of Latin America, reaching 85.45% [14] (compared to the national 44% internet penetration [6]) with a total of 40.28 million subscribers in the second trimester of 2009 [11]. Additionally, there has been an increase of 56.8% in the number of Internet connections through mobile networks in the last year, with a total of 495.730 users by the end of June 2009 [6]. With these data in mind, in collaboration with Universidad de Los Andes we are currently developing a new application for mobile phone consultations called mobile Doctor Chat ("*Doctor Chat móvil*"), which will be available for all-types of mobile technology users all over the country by the end of the first semester of 2010. With this application, we aim to reach communities with limited or no internet access, especially in underserved areas, as well as that majority of the Colombian population which have incorporated mobile phoning –but not internet- into their daily routines.

Conclusion

Doctor Chat has proven to be an innovative tool to deliver health care information to Spanish-speaking communities. However, strategies like publicity, specific prevention and promotion activities and expansion of the services through mobile telephony should be strongly reinforced in order to effectively reaching underserved areas and achieving population-wide impacts in developing countries like Colombia .

Acknowledgments

We thank the working team at the Division de Educación of Fundacion Santa Fe de Bogota, the institution´s Center for Telehealth, the University Hospital and its specialists, without whom the case experience hereby presented would have been impossible or irrelevant. We also thank the group of Systems Engineering at Universidad de Los Andes for its continuous support in the materialization of mobile Doctor Chat which has constituted a long-lasting goal of our R&D team.

Medical Education & Health Informatics: Time to join the 21st Century?

Nicola Shaw

Department of Family Medicine, Faculty of Medicine & Dentistry, University of Alberta. Edmonton. Canada

Abstract

This paper reports a component of a larger study, Informatics: enhancing the Clinical Experience? (ICE), which explored the impact on the therapeutic relationship of the implementation and use of Electronic Medical Records (EMR) in British Columbia, Canada. As anticipated, EMRs were found to negatively affect the relationship in many clinics. However, surprisingly paper-based clinics were as likely as EMR-based clinics to report problems with maintaining eye contact with their patients. This led to an interesting finding; that as a result of this difficulty few family care providers actually chart when their patients are with them, preferring to build rapport and chart at a later time. Consequently three recommendations are made: 1) Improve medical education in the area of charting (paper & EMR-based) with the patient present; 2) Explore the affect different technologies and skills have on the ability of providers to chart with the patient present and 3) Develop an understanding that unless the technology and training improve Canadian family medicine will never gain the asserted benefits of EMRs, and that other incentives are needed if Canada is to meet its target of delivering Electronic Health Records (EHR) to 100% of all Canadians by 2015..

Keywords:

Medical education, Charting, Therapeutic relationship, EMR/HER

Introduction

Traditionally general practitioners have been taught that the way to develop and maintain a good relationship with their patients is through developing a personal interaction style that relies a great deal on direct eye contact with the patient. Likewise, it is the nuances of body language and facial expression that often cues a doctor in to what is really troubling a patient as opposed to the words they are speaking. Consequently, the introduction of an Electronic Medical Record (EMR) into family medicine brings with it a number of challenges. Not least of which is the interference the use of an EMR could potentially cause with this requirement for direct eye contact.

Methods

This paper reports part of a much larger study (ICE) undertaken in British Columbia, Canada during 2005-2008. It involved 30 family medicine/general practitioner clinics representing all demographic populations as well as rural/inner city and large and small (single-handed) clinics. Extensive interviews were undertaken with all members of staff within each clinic, on three occasions, during the three-year period. Additionally, interviews were also undertaken with random patients from each clinic over that same three-year period, a program of information management facilitation was conducted with 2/3 of the clinics, and a mail-out survey and a workshop were held with all participating clinics. Data from these activities are not reported here.

Clinics were categorized into one of two groups: Paper-based (a computer was used for billing and administrative activities only), or EMR-based (a full EMR was used, with charting conducted on the EMR and not in paper charts). The focus of the ICE study was the impact of charting method (paper vs. computer) on both the therapeutic relationship and patient outcomes.

We purchased a mailing list from the British Columbia College of Surgeons and Physicians, and then sent a recruitment letter to all 4,319 registered family physicians in B.C. inviting them to take part in the study. Several hundred physicians responded, representing a total of 78 clinics.

Clinics which had been using an EMR for more than twelve months were then excluded from the sample as we wished to investigate clinics in the dynamic early stages of implementation, rather than those whose work practices had already adapted to the EMR. There were no exclusions based on culture, religion, race, disability, sexual orientation, ethnicity, gender or age. Clinics were geographically dispersed, and represented each of the five Regional Health Authorities in British Columbia.

Clinics were then categorized into three groups. Group 1 clinics had had an EMR in place for less than 12 months as of January 2005. Group 2 and Group 3 clinics did not use an EMR at the time of enrolment, and did not plan to do so for several years.

Knowing that our EMR-based clinics had encountered varied training experiences from their EMR vendors, we provided all our EMR-based clinics with training in information management. Thus, in addition to participating in data collection, all clinics from Group 1 participated in a facilitation program led by myself. Additionally, Clinics from Group 2 and Group 3 were also randomly selected for participation in this facilitation program. These sessions, held over the lunch hour at the

clinic involved all staff. Sessions consisted of a program of change management, information management, and skills training and development designed to improve practice function regardless of the type of information management system in place.

Clinics in the three groups were clustered geographically. That is, Clinics 1a, 2a and 3a were all located in the same town, or region within British Columbia.

In the interest of retaining the desired goal of 30 participating clinics, the research team over-recruited and initially included 33 clinics in the study (11 in each group). As anticipated, three clinics did not complete the entire study. Two clinics withdrew from the study and the research team de-enrolled one clinic. Thirty primary care clinics completed the entire study during 2005-2008. The clinics selected for data collection were randomly assigned to the two project interviewers.

Data Collection

The ICE study employed a mixed methods approach to data collection. Qualitative interview guides were developed to interview health professionals. Patients were both interviewed and completed surveys; using semi-structured interview guides and questionnaires (see details of data collection below). General observations about each clinic environment were documented within the field notes and in sketches of the clinic layout. Facilitation data included a combination of field notes and survey instruments. In addition, the final stage of data collection involved administering a mail-out survey, designed to tap into organizational culture issues as well as patient information management and patient care. This paper reports on the face-to-face interviews with healthcare providers only.

To obtain rich data about a clinic's patient information management practices, and insights into the therapeutic relationship between the patient and health care providers in clinics, semi-structured face-to-face interviews were conducted. In addition to obtaining general demographic information about the respondent (age, sex, educational/training background of health care providers and the primary contact physician, employment status of patients/providers, and a profile of the clinic), we asked physicians and other clinic staff a series of questions about patient record management practices, both in paper-based and EMR-based clinics, including questions about:

- charting practices, record transfer practices, administrative tasks involved in the management of patient records;
- accessibility to all patient information during and after consultation, stewardship of the record, confidentiality and privacy issues;
- training opportunities;
- perceived competence in technology use, the perceived effects of EMR versus paper-based system on patient relationship/care, including patient self-care training/education, decision support capacity and use; perceived effects on interface/communication with external providers;
- overall perceptions of problems with current information management practices (and desire for improvements/changes).

Interviewers were careful to avoid asking specifically about the clinic's EMR system. They remained neutral in their questioning, asking only about the nature of patient information management practices, to collect both positive and negative evaluations.

Interview guides were semi-structured and flexible. Over the three interview periods the guides evolved to respond to the unique management and performance practices of each clinic, and accommodate changes occurring in the clinics.

Sample Characteristics

During the three interview phases, the research team conducted 263 semi-structured, face-to-face interviews with 124 physicians, nurses and office staff [such as medical office assistants (MOAs)]. Of the 30 clinics that completed the study, 38 physicians were interviewed, with a total of 99 interviews taking place over the three interview periods. Seventeen of the 38 physicians worked in EMR-based clinics, while 21 of the 38 physicians were from our paper-based clinics.

The majority of clinics served patients in an urban/suburban setting (13 paper-based clinics, 6 EMR-based). Four paper-based and 2 EMR-based clinics served patients in a small town. A small minority of clinics served patients in a rural region (2 paper-based, 1 EMR-based), while 2 EMR-based clinics were located in a geographically isolated/remote region of B.C.

Data Collection Period and Procedures

Data collection was spread over three interview phases, each about five months apart. The first set of interviews provided us with baseline information about patient information management practices. To examine any changes over time, we conducted our first set of follow-up interviews approximately five months after the baseline interviews. A second follow-up interview occurred approximately five months later. We chose to interview in 5-month intervals in order to ensure that we interviewed participating clinics at different times of the year.

The first interview phase began in July of 2005 and extended to October of 2005. Phase-three site visits were completed by September 2006. All interviews took place inside clinics, during regularly scheduled office hours. The interview date and time was negotiated with clinic participants, giving priority to their availability.

When the ICE study commenced, the research team planned to conduct five interview phases. In 2006, however, those plans changed. The British Columbia Physician Information Technology Office (PITO) was established as part of an agreement between the British Columbia Medical Association and the provincial government to develop and implement a standardized system of EMRs in B.C. As a result we found during our third round of interviews that our EMR-based clinics were on hold waiting to hear if their specific system would be approved for funding and our paper-based clinics were concerned about being forced into using EMRs. As a consequence, we suspended plans for interview rounds 4 and 5, anticipating that we would recommence them once the PITO had established guidelines for progress in the province. When it became apparent that this wasn't going to occur within our timelines we

adapted our protocol and replaced interviews 4 and 5 with the mail-out survey and a workshop, including all participating clinics.

Ethics and Analysis

Ethical approval was received and maintained from the University of British Columbia and the University of Alberta's human research ethics boards. Informed consent was obtained from all participants prior to each interview. All interviews were audio-recorded and transcribed verbatim. Following transcription, interview transcripts were anonymized, with references to names, places, clinic names and websites removed and replaced with codes. All transcripts were then independently analyzed by two researchers using the constant comparison technique and the framework approach.

Results

The results reported here pertain to the impact on the therapeutic relationship during the use of paper-based or EMR-based charting, and based on the interviews with healthcare providers only. Future papers will report on other findings from this and from other data collected during the ICE study.

Interference with therapeutic relationship

As anticipated providers reported that both they and their patients found that using the EMR for charting interfered with their relationship:

"But they don't like a person spending time with the computer and not with them."

(Clinic C4 PH2 Int. 1)

"They'd rather you take the time to talk to them."

(Clinic C5 PCP Int. 1)

Eye contact

The main issue for providers was the inability to maintain eye contact during charting. However, much to our surprise, paper-based providers reported this to be an issue just as commonly as EMR-based providers.

"I think it looks very impolite to do it [chart on the EMR] during the consultation and I've tried it but I feel like I'm losing eye contact with my patients…"

(Clinic C3 PCP Int. 1)

"Because I'm always a person who talks to the patient I very rarely ever - the only time I ever look down [at my paper chart] is if we're looking through the chart for old lab work or something..."

(Clinic A5 PCP Int. 1)

Charting after the patient leaves

Interestingly, although they reported that the inability to maintain eye contact and chart at the same time was an issue, providers didn't report that this impact was as significant as we thought that it would be. Consequently, we spent a considerable amount of time exploring how providers were managing their charting.

We found that it was very rare for providers, whether paper or EMR-based, to chart while the patient was with them. Even clinics which had invested heavily in their EMR, and were proficient with the technologies, opted to chart after the patient left.

"Well I think it's easier on the patient they feel that you're not sort of looking down all the time and writing. I find it much more easier for them."

(Clinic A5 PCP Int. 1)

"Because it detracts from the interview. It detracts from the building up of rapport. And it detracts greatly the ability to, the clinical skills, to take a history and do an examination. You just become much less observant because you're looking at the computer all the time."

(Clinic C4 PH2 Int. 1)

Communication style

Despite a prevailing tendency to chart after the patient left we did find cases where charting was undertaken with the patient present, and where the providers and patients didn't complain about charting being a negative impact on their relationship, but rather spoke glowingly of their ability to communicate. Invariably these cases were ones where the communication style of the provider was exceptionally interactive and personable. Whether using paper or EMR-based charts the providers drew the patients into a mutual review of their charts and discussion of their ailments and treatment plans.

"They feel more involved. It's not like I'm looking into a little book and secretly writing things."

(Clinic C7 PCPC Int. 3)

Mitigating technology

For some it was the choice of specific technologies that allowed them to chart with the patient present and to engage them in their own care:

"..that's probably the best way so that you can talk to them and introduce the information at the same time. If you have a tablet you can face them, … is a little bit better, because you don't have to sit it any way, you can just hold it with you in your hand. It looks like a famous paperclip [clipboard] thingy."

(Clinic C1 PH1 Int. 2)

"They [patients] really like the graphs, I mean if you show them the graph, you know, how their weight is going, how their blood pressures are going, they like that 'cause it lets them see, you know, am I getting better?, am I getting worse?. I really think they like going through the results at the same time as you are going through them. I think they think, yeah, "They actually did get a result and it really is there," you know. Pointing out, you know, well see here - this is good, you know, this is excellent."

(Clinic C3 PCP Interview 3)

Discussion

To my knowledge this is the first time that such a study has investigated the impact on the therapeutic relationship of charting including both paper-based and EMR-based charting. When planning this study I expected that we would find that EMRs interfered with the interpersonal relationship, that the forced lack of eye contact necessitated by computer-use would negatively impact the patient. However, instead we found that:

1. Providers often find that the use of a paper chart also directly affects their ability to maintain eye contact and to develop rapport with their patient. Consequently, many professionals do not chart, on either paper or computer, when the patient is with them;
2. When the EMR is used with the patient, providers report that patients find the encounter satisfactory. However, we noted that this was true only when the provider's personal interaction style led to the patient being actively included in the documentation and review process;
3. Some technologies can mitigate some of the negative impact of charting while with the patient.

Given that many of the anticipated benefits of an EMR rely on the provider charting while actively engaging with the patient, it is discomforting to realize how rarely this actually takes place. Let's just look at one example: the use of computerized alerts and prompts within an EMR which have been reported to have a positive impact on clinical outcomes[1].

Consider the instance of a female patient taking oral contraceptive medication being prescribed an antibiotic. Common belief suggests that when the provider is prescribing the antibiotic the EMRs integrated decision-support system would first check for allergies and other contraindications, and then remind the provider to inform the patient to be sure to use other precautions against pregnancy while she completes the course of treatment. Therefore if the provider doesn't chart until after the patient has left the clinic this alert and decision-support will not be provided. This timely informational discussion and relationship building opportunity would then be left to the dispensing pharmacist alone.

Perhaps this is acceptable in this scenario. However, what about when the provider misses the alert to remind them that their patient, who rarely comes in to see them, is overdue for their PAP smear, again? Since the patient has left it's now up to the provider to follow-up with that patient at a later time. Or will it slip their mind with the result that the patient may miss an opportunity for preventative care potentially leading to a delay in treatment for an, as yet, undiagnosed cervical cancer.

Initially I wondered whether this choice to chart after the patient had left was a behavior specific to British Columbia however our recent (2008) series of 20 Canadian case studies of EMR use that included representation from all Canadian provinces and one of the territories also observed the same behavior [2-3] suggesting that this is a general behavior in Canadian family practice.

Therefore, it is clear from the fact that so many providers opt to chart after the patient has left that much remains to be understood about how charting impacts the therapeutic relationship; specifically when using an EMR. Consequently I turned to medical education* to ascertain what new providers are being taught in this area.

Medical Education

Sadly, it quickly became apparent that while informatics is recognized [4] as a necessary component of training for our new providers it tends to concentrate on either 1) the use of information technology as a teaching tool for educating (E.g. [5]); or 2) information retrieval and appraisal (E.g. [6]). Additionally, it seems that not only is EMR training currently inconsistent but that actual use of an EMR is rarely considered a training need. As one faculty respondent stated in this 2007 scan *"The teaching on the use of health informatics and EHRs is very limited but that doesn't seem to be an impediment for new grads. They learn on the job."* [4 p.5].

Personal experience suggests that this attitude is pervasive within medical faculties internationally. Additionally, while the vast majority of medical schools do evaluate clinical skills in terms of history taking and the ability to synthesize information to arrive at a diagnosis or management plan [7] such evaluations do not take into account the impact that an EMR has on these skills.

Given that we are also continuing to graduate new providers with doctor-centered and paternalistic attitudes despite a greater emphasis on patient-centered attitudes in medical schools [8] it is of great concern to me that we are not addressing these technologies within our medical curriculum.

If you give a child a stethoscope they can fairly quickly work out which ends to put in their ears and that you can hear things through it - learning on the job. Yet, we still spend hours in the medical curriculum teaching our students how to listen with a stethoscope and how to interpret what they hear. How then can we justify *not* teaching our providers how to use a new tool that can have such a strong impact, both positively and negatively, on their relationship with patients?

It is clear from the fact that so many providers opt to chart sent.

Conclusion

Canada has a mandate, charged to Canada Health Infoway, to provide Electronic Health Records to 100% of all Canadians by 2015 [9]. Whilst progress towards this target is ever-increasing with 5 jurisdictions on target for the former goal of providing EHRs to 50% of Canadians by 2010, the prior lack of support for EMRs in primary care within Infoway's remit was a significant omission. The revised mandate [9], which recognizes this gap, specifically addresses support for chronic disease management across the continuum of care. For this to be achieved in primary care EMRs (a necessary foundation for EHRs) must contain clinical decision support [10] which means that providers must chart while the patient is present to gain the benefits of these technologies.

* Medical Education being that training provided to educate new health professionals whether that is doctors, nurses, pharmacists etc

It is clear from the fact that so many providers opt to chart after the patient has left that much remains to be understood about how charting impacts the therapeutic relationship. Therefore my first recommendation is that this be explored further both in research, and also within medical education. Subsequent to developing an understanding as to how charting affects the relationship we need to improve medical education in the area of charting with the patient present. Using a chart, paper or EMR-based, with the patient present is a skill that needs to be developed and taught within our medical curricula.

This leads to my second recommendation, which is that we need to explore how different technologies such as tablets, or the development of skills, such as touch typing, affect the ability of providers to chart with patients present.

Providers are voting with their actions and only using EMRs *with* their patients when they can use them in an interactive manner, drawing the patient into the documentation and review process. Therefore, EMR designers must seriously reconsider the way that their product supports workflow. Rather than simply presuming that providers will use the EMR with a patient present they must design their applications so that they make it easier for the provider to build a rapport with their patient, as they chart. This may mean that EMRs should be keyboard driven (rather than mouse driven) during charting as it is possible to maintain eye contact and touch type whereas it is not possible to maintain eye contact and use a mouse.

Finally, proponents of electronic records must understand that many of the benefits they attribute to EMRs will never be fully realized until these issues are addressed. Chronic disease management relies heavily on primary care where the therapeutic relationship is of the utmost import. Anything that negatively affects this must be mitigated. Critics have decried Canadian providers for being behind other countries in their take-up of EMRs. However, this research suggests that there are good reasons for these delays which must be addressed. I believe that the willingness to engage exists but that our knowledge, understanding and most importantly our provision of medical education in the area of charting with patients present is distinctly lacking. As one provider succinctly summarized:

"Some [patients] are quite impressed that we're-have entered the 20th century. Shame it's the 21st Century now!"

(Clinic C7 PH1 Int. 3)

If we want to provide 21st Century care isn't it time we left the 19th Century?

Acknowledgments

Dr. Shaw is the senior author and principal investigator for the ICE study. Drs' McNab, Carleton, Ansermino, Zitner, Lee, Leonard, Houbé, Pusic and Mitton were co-investigators and assisted with study design. Laurie Kilburn and Cheryl Ulmer undertook the initiation, development, interview and primary analysis phases of the study. Shelby Mitchell Corley and Dr. Navjot Lamba performed later-stage analysis, the mail-out survey and the final workshop. Riva Benditt and Bernadette Harvey provided general research assistance. Audrey Seehagen provided editorial review. The study was funded by the Canadian Institutes of Health Research (CIHR MOP 68946).

Abstract

The objective of this paper is to assess the future adaptability of e-Learning platforms within postgraduate modules. An ongoing empirical assessment was conducted amongst postgraduate students, based on the Technology Acceptance Model (TAM). The current paper presents the outcomes from the second phase of a survey, involving fifty six participants. Data analysis was performed using a structural equation model, based on partial least squares. Results highlighted the very strong effect of perceived usefulness and perceived ease of use to attitude towards using e-Learning platforms. Consequently, attitude towards use proved to be a very strong predictor of behavioral intention. Perceived usefulness, on the contrary, did not prove to have an effect to behavioral intention. Implications on the potential of using e-Learning platforms are discussed along with limitations and future directions of the study.

Keywords:

Educational technology, Technology assessment, e-learning.

Introduction

Over the past few years, the use of Information and Communication Technology (ICT) in education is gaining momentum, with e-Learning initiatives becoming more popular within university curricula, both at undergraduate and postgraduate level. Such frameworks provide flexibility on teaching and learning methods, as they are primarily characterized as location and physical presence independent.

In that context, the aim of this paper is to empirically assess the adaptability of e-Learning frameworks to a postgraduate course. By investigating the perceptions, the beliefs and the attitude of students towards e-Learning platforms and Web-based courses, useful deductions can be drawn for future implementations.

The rest of the paper is organized as follows: The first section provides a description of the methods, emphasizing on the theoretical framework used and the formulated hypotheses. The second section presents the results obtained along with their interpretation. The last section highlights key findings, providing a discussion on limitations and future work in the current field.

Materials and Methods

Theoretical framework and hypotheses

In order to assess the potential adaptability of e-Learning platforms within the postgraduate curricula, an adaptation of the Technology Acceptance Model (TAM) [1] was performed. TAM defines a set of dimensions under investigation along with a set of causal relationships amongst them. In particular, perceived usefulness interacts and affects attitude towards using a technology and behavioral intention, perceived ease of use affects attitude towards use and perceived usefulness whereas attitude towards use affects behavioral intention [1]. A variety of research works in the literature adopt TAM, in its original form or with proposed extensions in conjunction with other theoretical models or by introducing new dimensions under investigation, in order to conduct empirical studies. Such research works span into a plethora of disciplines [2-11], including healthcare [12-15].

In the context of the original TAM, a specific set of hypotheses, based on the theoretical relationships, were formulated. In particular, perceived ease of use (coded as PEOU) positively affects perceived usefulness (coded as PU) (H1+), perceived ease of use positively affects attitude towards Use (coded as ATT) (H2+), perceived usefulness positively affects attitude towards Use (H3+), perceived usefulness positively affects behavioral Intention (coded as BI) (H4+) and attitude towards use positively affects behavioral intention (H5+) [1, 6,10]. The notion of behavioral intention, in the context of the current study, attempts to measure the attitudes and intentions of the participants with regards to the potential use of e-Learning initiatives as part of the learning process at their studies.

Procedure and measures

The Faculty of Nursing at the University of Athens, either independently or through joint University initiatives, offers a broad range of MSc courses, varying from traditional nursing specializations to Health Informatics/Management and Crisis Management. The current study was initiated and focused only to the MSc specialization in Health Informatics-Health Management [16] and then extended in order to gather perceptions and beliefs from past and present MSc students from the whole range of MSc courses offered. Preliminary

results of the current initiative can be found at [16]. The adoption of TAM involved the creation of a questionnaire. Measures from previous research works were chosen, in order to utilize as much standardized metrics as possible (Table 1).

Table 1 - Constructs, measures and relative sources

Dimension	Questions	Source
PEOU	I find that online courses are very easy to use	[14]
	I find that interacting with online courses' doesn't demand much care or attention	
PU	Using e-learning would enhance my effectiveness in learning	[10]
	Using e-learning would improve my course performance	
	Using e-learning would increase my productivity in my course work	
ATT	The idea of using ILM is: (very bad _ very good)	[8]
	The idea of using ILM is: (very foolish _ very wise)	
	Using ILM would be: (very unpleasant _ very pleasant)	
	Using ILM is an idea: (dislike very much _ like very much)	
BI	If I get to use online courses, I intend to use the online courses	[14]
	If I get to use online courses, I expect that I will use online courses	

The questionnaire followed a seven-Likert scale of answering, varying from "strongly disagree" to "strongly agree". All questions were translated from English to Greek accordingly and migrated into a Web based environment, through Limesurvey [17]. Participants were asked to access the web survey through a Uniform Resource Locator (URL). Participation was anonymous and no data that could be correlated with any of the participants was used.

Data analysis was based on structural equation model, specifically partial least squares. Such an approach is well-established at the literature and can be found in a variety of empirical studies adopting TAM or other theoretical frameworks [18-20]. Regarding the software package, SmartPLS M3 v2 was used [21].

Results

Based on the current students enrolled to a variety of MSc specializations, a sample of fifty six (56) postgraduate participants responded at the current study, aiming to submit their intention to use Web based courses. Demographics data is outlined at Table 2.

Table 2 - Generated demographics data

Frequency		Percent (%)	Frequency		Percent (%)
Gender			**Postgraduate Program**		
Male	25	44.6	Health Informatics	23	41.1
Female	31	55.4	Health Management	20	35.7
			Clinical specializations	13	23.3
Age					
20-25	33	58,9	**Previous Experience**		
26-30	15	26,8	Yes	22	39.3
31-35	3	5,4	No	34	60.7
36-40	5	8,9			

Partial Least Squares analysis involved the assessment of the measurement and the structural model [18-20,22,23]. In terms of the measurement model, individual item loadings, internal consistency, convergent validity and discriminant validity were investigated [18-20,22]. All values for individual items loadings were considered reliable (exceeded 0.7) [18-20]. With regards to internal consistency, Cronbach's alpha and Composite Reliability produced values greater than 0.7 and 0.8 respectively [18-20] whereas convergent validity values exceeded the threshold value of 0.5 [24] for reliable results (Table 3). At last, discriminant validity was assessed based on the square root rule of the Average Variance Extracted (AVE) [24]. All constructs produced reliable results (Table 4).

Table 3 - Internal consistency and convergent validity results

	Cronbach's Alpha	Composite Reliability	AVE
ATT	0.8455	0.8969	0.6869
BI	0.7676	0.8937	0.8081
PEOU	0.7171	0.8691	0.7695
PU	0.8684	0.9189	0.7917

Table 4 –Discriminant validity results

	ATT	BI	PEOU	PU
ATT	**0.8287**	0	0	0
BI	0.6907	**0.8989**	0	0
PEOU	0.579	0.5109	**0.8772**	0
PU	0.6799	0.5984	0.3846	**0.8897**

Subsequently, the structural model was observed (Fig. 1). A bootstrapping technique was applied (500 resamples) [18-20, 22] with three statistically significant levels ($p<0.05$*, $p<0.01$** and $p<0.001$***), based on a two-tail test [18]. At Fig. 1, insignificant hypotheses are represented with dotted lines.

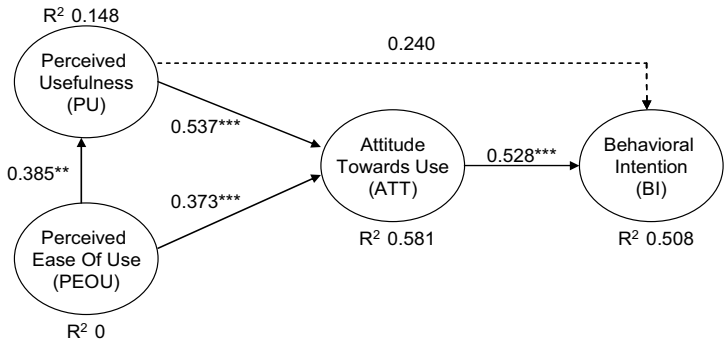

Figure 1 - Structural Model

Discussion

The findings of the structural model highlight the very strong effect of perceived usefulness (β=0.537, $p<0.001$) and perceived ease of use (β=0.373, $p<0.001$) to attitude toward using e-Learning platforms. Furthermore, attitude towards use is a very strong predictor of behavioral intention (β=0.528, $p<0.001$). Moreover, perceived ease of use proved to have a strong effect on perceived usefulness (β=0.385, $p<0.01$). The only hypothesis that was not confirmed is related with the effect of perceived usefulness to behavioral intention; this could be explained by the fact that the majority of the sample had no previous experience on e-Learning and clearly they could not assess pragmatically the usefulness, and consequently the behavioral intention to use such initiatives.

A comparison with the early stage of this research highlights several similarities and differentiations. Initially, most of the relationships were confirmed, with the exception of perceived ease of use in relation to perceived usefulness and perceived usefulness in relation with behavioral intention [16]. The outcomes of the current study strengthen the relationship of perceived ease of use with usefulness, leaving intact, however, the effect of usefulness to behavioral intention. At this point it should be noted that preliminary research was conducted with a limited sample of twenty (20) people. The enrichment of the sample from a diversity of MSc degree cycles reinforced the reliability of the overall model and its respective dimensions. Such an observation assists in producing more reliable results.

Conclusion

The current work attempted to focus on the empirical acceptance of e-learning initiatives from postgraduate healthcare students. In the basis of the Technology Acceptance Model (TAM) [1] adaptation, several dimensions and causal relationships were assessed and presented. Despite the known limitations, a positive proclivity towards the encapsulation of e-Learning initiatives within the learning lifecycle of postgraduate studies curricula was observed.

The current study possesses a series of limitations, mostly related with the hypothetical nature of the investigation. The assessment is not directly related with an actual e-Learning implementation or a specific class module. It attempts to examine the potential applicability of e-Learning platforms, towards the modernization of lecturing and class practices. Having this as a fact, participants may over or under estimated specific measures throughout the survey process. However, despite the known limitations, the current work aims to shed light and further exploit the adaptability of e-Learning initiatives within healthcare education.

The aforementioned limitations underline the framework for future research in the current field. In particular, a further enrichment of the sample and the assessment of specialized stakeholder groups may be applied as part of future research. In addition, an investigation of moderating factors such as gender or age, as proposed by Venkatesh et al. [25] that could potentially affect the intention to use e-Learning initiatives may also be conducted. Overall, the produced findings of the current work assist in identifying the attitude of students towards learning through technology. Consequently, the results obtained from 'pre-adoption' studies of this kind, may act as a valuable input towards the design and implementation of future plans for incorporating e-Learning initiatives within University educational curricula.

Acknowledgements

The authors would like to sincerely thank the past and present postgraduate students for their participation at the current study.

Abstract

Many papers report and convey positive opinion about the use of e-learning in the healthcare sector. The issue is how to exploit at best such a powerful instrument. Starting from data regarding the usage of a CME e-learning course, attendance dynamics and users' behaviour have been inspected with the aim of getting some hints about how to improve the development and the delivery of e-learning courses for CME, and to promote knowledge acquisition at best. The different paths followed by 7811 users have been modeled, from enrolment to conclusion/drop-out, then the behaviour in terms of effort, elapsed time, achieved result have been analyzed. The obtained results point out: good acceptance (retention rate 83%) of a not basic educational model and effectiveness (success rate 79%). At the same time the inspection of behaviour has shown that there is a good margin of possible improvement in terms of knowledge acquisition. Conclusions provide a list of issues to keep in mind during system development, in order to provide CME e-learning meeting both credit and knowledge acquisition goals.

Keywords:

E-learning, CME, Attendance, Users behaviour.

Introduction

Many papers report and convey positive opinion about the use of e-learning in the healthcare sector. Quoting one for all [1], "E-learning represents a quantum leap forward in the education of healthcare staff. It has the potential to...provide a flexible, adaptable and highly accessible route to learning, which delivers a myriad of benefits for staff, hospital management and ultimately the patient". The issue is how to exploit such a powerful instrument at best, to let potential benefits become everyday reality.

As regards Italy, under-graduate distance education has gained ground, but e-learning for CME has been moving only short steps for years, despite of the common positive opinion of the potential users. This fact is due to two main reasons. First, problems related to the accreditation of e-learning courses within the not problem-proof co-existence of national and regional CME credit systems; for this reason the offer is limited. Second, the lack of consensus about the term "e-learning", often confused with simple delivery of documents and questions through the internet. This basic modality limits the evaluation of the learning experience and probably also the effectiveness of the intervention.

Within an experimental project funded by the Italian Ministry of Health, an e-learning system for CME has been developed for free of charge usage on the internet (http://fad.cbim.it). As described in the following section, the educational model proposed to users is not the basic one already experimented by Italian healthcare professionals.

International literature is quite rich of studies inspecting the attitude of users, and nurses in particular, to e-learning [2], but, as far as in our knowledge, lacks papers dealing with the behaviour of students attending e-learning CME courses and the relative dynamics. This information could be useful when starting developing a new system, in order to take advantage from previous experiences, and to limit, if not avoid, already faced problems and mistakes.

Thanks to the availability of a quite large amount of data regarding the usage of e-learning courses for Italian health professionals, an heuristic study of what works, what goes wrong, what can be improved has been carried out. Among all the available courses, a course about patients' handling (PHC) in hospital environment has been considered for the study presented here. The choice was motivated by a quite large number of enrolments and the fact that it addresses a large population of users (nurses and physiotherapists) for which the course is accredited by the CME system.

Aim of the present paper is hence to understand the dynamics underlying the usage of the system, and in particular:

- Users' flow from enrollment to conclusion/drop-out
- Students' behaviour and preferences in attending the course and achieving the final goal

in order to get some hints to improve the development and delivery of e-learning courses for CME, to verify the applicability of the educational model chosen, and find the best way to promote knowledge acquisition.

Materials and Methods

The patient handling course

PHC deals with: basic knowledge relative to musculoskeletal disorders, specifically linked to biomechanical load during lifting actions and flexed postures; Risk factors and the characteristics of spaces, patients, devices, furniture, and work organization which affect the way the operator works, and the ergonomics of movements; Proper use of different types of devices (ceiling and active lifter, low friction and assistive devices, bariatric solutions, ...) which concur to risk reduction and patient safety enhancement.

The educational model is based on:

- An initial test (IT) (one attempt allowed), mandatory to access the learning modules;
- Self-learning structured modules for free navigation (including PDF printable versions);
- Case-study exercises/test (CST) (4 attempts allowed, minimum score to pass the test: 75%), particularly effective [3] in order to reinforce the learning process;
- A final test (FT) (4 attempts allowed, minimum score to pass the test: 75%) for the evaluation of the results of the learning process in comparison with the IT;
- A satisfaction questionnaire that evaluates the subjective perception of the users.

PHC is expected to be concluded in five hours, tests included. To stand the course both CST and FT must be positively concluded.

Evaluation methods

All the enrollments to PHC in the span of time of 20 months have been retrieved and exported from Moodle database, and have been catalogued in terms of:

- Characteristics of the student: age, sex, profession
- Characteristics of the event: date of enrollment, IT result, CST result and number of attempts, FT result and number of attempts, date of course conclusion, final outcome (passed /not passed).

To identify and describe users' flow from enrollment to conclusion/drop-out, a Markov-like model has been used, taking into consideration time variance, due to the existence of the drop-out event.

Drop-out was defined according to the rule "course not concluded .AND. (end of the inspecting period – date of enrollment) > 30 days". This choice was necessary to avoid declaring as drop-out those students that have enrolled in the month just preceding the final date of inspection, and that maybe could have concluded the course subsequently.

To analyze users' behaviour and preferences regarding the way of achieving the goal, number of attempts to pass the tests and time used to conclude the course have been calculated. At this last purpose, the difference between date of conclusion and date of enrollment has been used; it refers to elapsed time, not to continuous learning activity.

Results

Users' flow model

Figure 1 provides a schema of the paths followed by users to conclude the course or abandon it. Basic actions have been used to describe the steps of the process such as: enrollment, IT execution, first and second test execution with results. In the graph circles represent actions and squares represent reached conditions (success, failure, drop-out). Branches represent the flow extent, expressed as number of users.

During the observed period, 7811 users have enrolled in PHC, but 5.2% of them dropped-out (*immediate drop out*) even before having performed the initial test (IT).

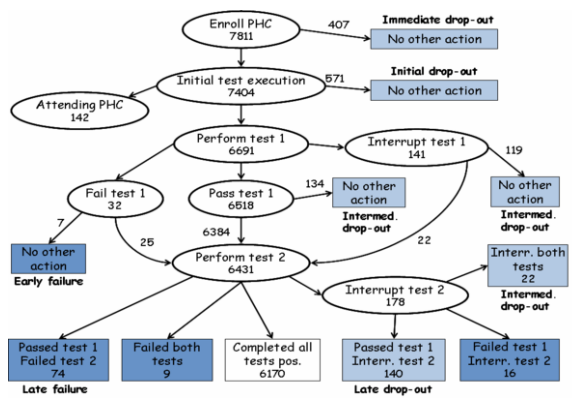

Figure 1 - Schema of the paths followed by the users

7404 users have regularly executed the IT, and hence they have got the possibility to view the contents and potentially attend PHC in an active way. This sample (mean age 40.6, range 21 – 58) is composed mainly by female (5513/ 7404, 74.5%). As regards professions, nurses (N) represent 80.0% (5922/7404), therapists (T) 13.6% (1008/7404), and the remaining 6.4% (474/7404) belong to other healthcare professions for which the course is not accredited.

At the time of the present analysis, 142 users were still attending PHC, so they were excluded. A second quite large drop-out event (*initial drop-out*, 571/7404, 7.71%) occurred before performing at least CST or FT. The sample of people actively involved into PHC attendance is hence composed by 6691 users, representing 85.66% (6691/7811) of the enrollments.

In the graph, "test 1" indicates one of the two tests without distinction between CST and FT. In case a student had performed two tests, priority has been given to the one success-

fully finished, or, in case of a combination failure/interruption, to the failed test.

The very great majority of students has stood one test (6518/6691, 97.41%). Only 1.8% has interrupted the test and has not undertaken any other action, reaching the condition of *intermediate drop-out*. The same condition is reached by those students (134/6691, 2%) who stopped attending, even in presence of a positive result, and by the users who have interrupted both the tests (22).

Considering the few cases of first test failed, 7 out of those 32 students abandoned the course definitively, reaching the condition of *early failure,* while some others (25) decided to perform the second test, even if they knew that they would have never been considered as eligible to get any credits.

The second test was performed by 6431 students representing 86.9% (6431/7404) of the population that actively attended the course and 82.33% of total enrollments. The group is composed both by many of those users who have stood the first test, and by some students who have already failed or interrupted the first test. Combining the results of both tests, the graph shows the ending points of the different paths. Success condition is reached by 6170 users representing 92.2% (6170/6691) of the active users. The second largest group is the drop-out group: overall the drop-out rate is 17.8% of all the enrollments, and *intermediate + late drop-out* represents 6.2% of the active users. 106 students didn't pass the tests of the course, but 70% of them belong to the status *late failure* since they have positively concluded one test. Table 1 represents the summary of the final conditions.

Drop-out

Looking at the users that have dropped-out, few issues can be analyzed but hypothesis are possible or reasonable. For *Immediate drop-out*, belonging to a not accredited professional category is not relevant. Only 51 out of 407 users could have dropped out for this reason. A further hypothesis is that the educational model with a mandatory IT, double typology of tests, and a limited number of attempts is not well accepted by users. In this case the educational model is not appreciated by a small number of people (4.7% of all the enrollments).

Initial drop-out: Out of the 571 users, only 42 belong to professions different from nurse or physiotherapist, similarly to what happens for immediate drop-out. Maybe the message sent to the user as evaluation of IT result has discouraged the student to go on. For IT results lower than 70, the message is "you do need to attend PHC …". This was the message received by 434 out of the 571 users that have abandoned just after the IT. But, as it will be pointed out in the next session, the same message was sent to at least other 1443 students, who have anyway concluded the course achieving positive results. Personal characteristics play anyway an important role in people behaviour.

Students' behaviour

The very great majority of the courses have been concluded (6276/7404, 84.8 %).

For positively concluded and failed courses, Table 2 shows a summary of students' characteristics and learning process indicators. Outcome in terms of knowledge acquisition can be evaluated through the mean values of test results. In particular Table 2 reports data grouped according to the different professions. Group "other" represents the users who have no right to get credits. The number of days used to conclude the course is calculated as difference between date of conclusion and day of enrollment, and if they occur in the same date, 0.5 day has been considered.

Table 1 – Summary of the final conditions

	% out of 7811 enrolments
Immediate drop-out	5.2
Initial drop-out	7.3
Intermediate drop-out	3.5
Late drop-out	1.8
Success	79.0
Failure	1.4
Total	98.2
Attendance still going on	1.8

The mean value of FT results for successful students points out that there has been a pretty good gain in terms of acquired knowledge. Similar comment can be done for students who didn't pass the course. CST and FT success rate are 23% and 51%, hence case-based tests seem to be more difficult. Anyway, the number of people (82) who failed CST is very small, in comparison with the number of successful students.

Table 2 - Summary of students characteristics and learning process indicators

		#	Mean elapsed time	Median elapsed time	Mean IT result	CST mean result (%)	CST mean # attempts	FT mean result (%)	FT mean # attempts
Course passed	N	4901	7.3	1	62.74	94.16	1.42	92.7	1.24
	T	897	10.3	2	71.39	93.8	1.48	93.7	1.21
	Other	372	9.19	0.5	65.71	93.10	1.53	93.5	1.29

Behaviour in terms of elapsed time and attempts

The relationship among result of the course (passed, failed), effort (as number of attempts) and elapsed time has been analyzed. In order to understand the influence of pre-course knowledge on users' behaviour, the sample of successful students has been split according to the result of the IT (<50, >=50).

Table 3 shows the distribution of cases along the dimensions *number of attempts* and *elapsed time* for the three groups: success with low (SL) IT (1443), success with high (SH) IT (4727), failure (F) (106). A large number (2194) of successful students have completed the study of the learning objects and have performed both the tests in just one attempt each, on the same day of enrolment.

SL group, expected to need more time and effort to positively conclude the course, has the greatest level of task orientation: 42% performed 2 attempts with 0 day of elapsed time. From this point of view SH and SL show a statistically significantly different behaviour.

As regards F group, 41 out of 106 students have believed their learning activity sufficient, and have then used all the chances they had to stand tests in an elapsed time of 0 day. Among these students, 12 belong to the late failure category, having stood 1 test and missed the opportunity to pass the course.

Time flexibility offered by e-learning and the multiplicity of available attempts should have induced F users to study again in order to achieve the goal of standing the course. These opportunities have not been used by those people who could have needed them more.

Independently from the number of attempts and from the final result, most of users finalizes their activity not later than the day after enrolment: 57.9%, 64.4% and 55.7% respectively for SH, SL, F.

About 30% of the students in all groups have an elapsed time greater than 3 days. Most of them have probably started attending, then interrupted to restart and perform the tests only after a certain span of time. The range of the elapsed times is very wide (0-267 days), as the differences between median and mean duration in Table 2 show. The minimum mean value is 7. Elapsed time of 7 days has been hence chosen to distinguish between students who have been attending PHC for a quite long time, from those who have initially enrolled but have attended the course only "lately". Using this distinction, in Table 3 the total percentage (36.7%) of students that failed with an elapsed time greater than 3 can be split into long lasting attendance (9.3%) and late attendance (27.4%). For successful students, the percentage of long lasting attendance is higher. Considering for example in 2 attempts completion for SH and SL globally considered, 247 students out of 942 (26.2 %) behaved according to the definition of long lasting attendance.

It can be hence concluded that, in any case, there is a common attitude to finalize the course in a short span of time.

Behaviour in terms of achieved results

For the successful users, the previously reported results raise a question: have the users, who passed the course with few attempts, achieved the best possible results?

Taking into account the final score of the course, that is the sum of the best results of CST and FT (range 150 – 200), Figure 2 shows the mean final score values versus the number of attempts still available. Since the number of allowed attempts is 8, "6 remaining attempts", for example, means that the user has stopped performing both tests after the first attempt, having reached a sufficient result to pass the course. For each value of remaining attempts, the mean final score values are quite far from the maximum value (200). This fact points out that, once reached the condition for getting credits, the majority of users didn't exploit the possibility offered by the system to understand where they have done mistakes and hence to go back to the modules and further improve their knowledge.

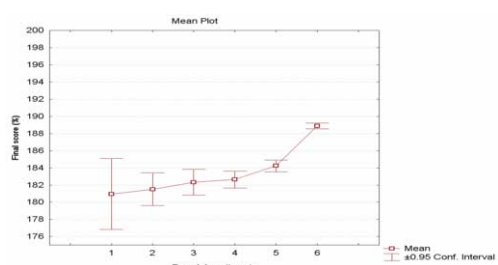

Figure 2 - mean final scores values versus the number of attempts still available

Discussion and conclusions

Attendance dynamic and students' behaviour, when applied to e-learning courses, should approach various processes related to the learning activity. In the present study only the basic actions have been inspected such as tests' completion, without taking into account, for example, how students have exploited the resources in terms of contents, and if they have preferred navigation to the usage of the printable version of the course. This issue will be addressed in a next study.

As regards the dynamics followed by the users, the reported results show that PHC has been attended, step by step, by a large number of users, until they have reached their goal.

For distance learning, literature [4] reports high drop-out rate. Moreover attrition plus limited informatics literacy and attitude are often mentioned as the most frequent causes for drop-out. In the present study retention rate is pretty high (83%), and probably it could have been even higher in case PHC had not been free of charge. The initial choice of developing giving priority to technological simplicity and usability [5] of the e-learning system has probably paid out. Some other causes for drop out have been analyzed [6].

The large number of attendees and the high success rate support the applicability and acceptability of the educational model with the constraints that have been used. Inducing a responsible learning approach, it should be more effective than the one with no limit to the number of attempts, commonly used in Italy.

Not only nurses and physiotherapists have attended the course, but also 474 health professionals for whom PHC doesn't provide credits. 80.6% of these users have completed the course. This fact points out that CME e-learning courses are appreciated and requested, but also that maybe people don't read carefully the instructions when on the internet. This last same hint comes also from the messages sent to the tutor. For the behaviour parameters that have been analyzed, there are no comparable results in the literature, as far as in our knowledge. The attitude to finalize the course in a short span of time is, in some way, in contrast with the valuable manage-your-time approach typical of e-learning. In particular, since PHC was expected to take up around five hours overall, the student, who have finalized it with elapsed time of 0 days, must have done it fairly quickly. The result of passing the course is often achieved, but not with the best possible outcome in term of knowledge acquisition. A way to promote and incentive better quality of results thanks to the flexibility of e-learning should be put in practice.

For this last purpose, but not only, the presence of a figure with role of mentor could be very useful. When dealing with e-learning systems available on the internet, the number of enrolments can be very large and mentoring very resource consuming. A sort of automatic mail delivery system with scheduled controls and planned remainder and encouragement messages could represent a good feasible solution.

We are aware that conclusions are based on heuristics and direct experience only. Anyway, we dare to give a list of advices to keep in mind, in order to help developing e-learning systems that could be useful tools to provide knowledge improvement and not only machines to collect CME credits.

- Robustness of the educational model doesn't imply reduced attendance
- Give priority to technological simplicity and usability
- Feedback messages should be designed considering different possible reactions
- State clearly and in a very visible way the rules and basic information. Redundancy is boring, but disappointment is even worse
- Develop courses that take up a limited numbers of hours (five hours are probably too much)
- Look for incentives to achieve the best results in term of knowledge acquisition, to prevent to go just for the credits
- Plan an affordable system to provide mentoring.

Multidisciplinary Education in Medical Informatics – A course for medical and informatics students

Bernhard Breil[a], Fleur Fritz[a], Volker Thiemann[a], Martin Dugas[a]

[a] *Department of Medical Informatics and Biomathematics, University of Münster, Münster, Germany*

Abstract

Design and implementation of healthcare information systems affect both computer scientists and health care professionals. In this paper we present our approach to integrate the management of information systems in the education of healthcare professionals and computer scientists alike. We designed a multidisciplinary course for medical and informatics students to provide them with practical experience concerning the design and implementation of medical information systems. This course was implemented in the curriculum of the University of Münster in 2009. The key element is a case study that is performed by small teams of medical and informatics students. A practical course on management of information systems can be useful for medical students who want to enhance their knowledge in information systems as well as for informatics students with particular interests in medicine.

Keywords:
Medical informatics, Health informatics, Education, Management information systems.

Introduction

Information technology has a strong impact on public health and medical information systems play a fundamental role in the everyday life of many health professionals. Physicians spend about 25 % of their daily clinical work on documentation tasks which become more and more supported by information systems [1]. The use of the Electronic Patient Record (EPR) is increasing and has the potential to improve the quality of care [2].

Therefore health care professionals and computer specialists need knowledge about the management of health care information systems [3]. Already in the year 2000 the International Medical Informatics Association (IMIA) published recommendations on education in Health and Medical Informatics emphasizing on the management of information systems [4].

In the current curriculum for medical students in Münster there is only one compulsory subject in the domain of medical informatics including the main topics of hospital information systems, electronic patient records, information acquisition as well as classification and coding systems. At least in Germany, education concerning the management of information systems is not mandatory for medical students. On the other hand, due to the lifecycle of medical IT systems healthcare professionals are confronted with specification and implementation of information systems.

Haux et al. described programs for medical informatics students as well as for health information management students with a focus on system analysis and project management [3]. This training might be useful for healthcare professionals too. For example to conduct realistic case studies regarding the design and implementation of information systems the expertise both from medicine and computer science is beneficial.

Healthcare professionals, in particular physicians, need skills and knowledge regarding information systems, not only as end-users, but also regarding requirement specification and evaluation. On the other hand, computer scientists need to understand processes in hospitals, medical documentation and physicians' workflows in order to design and implement adequate systems.

Former course evaluations by medical students showed that the teaching in subjects like medical informatics can be improved through practical oriented inputs [5, 6]. It also became evident that the need for health informatics training is increasing [7]. Therefore, our main objective was to design a multidisciplinary course with practical training for medical and informatics students. This course should be integrated in the current curriculum of both medicine and informatics.

Materials and Methods

The design of the new course concept is mainly influenced by three factors:
At first it is based on the standard evaluation of an existing course in informatics for medical students. We reviewed the evaluation of this course from winter term 2007/2008 to summer term 2009.

Secondly we used experiences from a pilot course on management of medical information systems which was introduced in the last year.

Thirdly we analyzed literature concerning medical informatics education with a focus on multidisciplinary courses.

Results

Evaluation of the current course in medical informatics

In the respective terms more than 400 medical students attended the course and evaluated education in medical informatics on a scale from 0 (very good) to 100 (very bad). Table 1 shows the results. The average score is between 38.9 and 56.3 while the median ranges from 32.0 to 53.5.

Table 1 – Evaluation of the course in medical informatics

Term	n	Avg	Mdn	Std Dev	Min	Max
2007/2008	129	39.5	34.0	25.4	2	99
2008	108	56.3	53.5	25.2	4	100
2008/2009	107	41.8	38.0	26.5	3	98
2009	113	38.9	32.0	26.1	1	100

Evaluation of the course in medical informatics from winter term 2007/2008 to summer term 2009 on a scale from 0 (very good) to 100 (very bad). n = Number of students, Avg = Average score, Med = Median score, StdDev = Standard deviation, Min = Minimum, Max = Maximum.

We also assessed the free text comments to explain the big range in the students' evaluations. On the one hand, students evaluated the course as "*one of the most important courses for the working life*" and "*good to gain insight into hospital information systems*", but on the other hand they missed the "*practical relevance*" and evaluated it as being "*abstract without practical examples*".

Therefore we decided to focus on practical tasks in the new course.

Experiences from a pilot course

In the summer term 2009 we conducted a pilot course for the management of information systems for medical students. We combined lectures with a practical part based on a case study.
In the case study the students have to analyze an existing tumor documentation process that should be described and modeled in order to specify requirements for a new system.
In the free text evaluation at the end of the course the students stated that the "*course was good, because it followed a central theme*" and that it was "*informative to work in small groups*".

Due to this positive feedback we decided that a case study should be a central part of our new course concept.

Literature analysis

In the literature regarding medical informatics education we identified a trend towards multidisciplinarity. The Committee on Interdisciplinary Research (IDR) of the National Academy of Science, the National Academy of Engineering and the Institute of Medicine analyzed "problems whose solutions are beyond the scope of a single discipline" [8]. The IDR provided also recommendations for students and postulated that "students should seek out interdisciplinary experiences […] that address societal problems and research experiences that span more than one traditional discipline" [8].
In 2008 van Bemmel added that this interdisciplinarity begins in the classroom [9]. Current research in medical informatics shows that interdisciplinarity should be a considerable part in medical education [10]. Also in the domain of clinical research informatics there is a strong need for cross-discipline education [11].

Regarding the practical relevance of such a course it is shown by Stang et al. that the use of examples which are close to reality helps students to understand the clinical relevance [12].

Besides the multidisciplinarity the concept of cooperative learning itself is an important aspect in teaching sciences and should therefore be utilized [13].

New concept for the multidisciplinary course

The main idea was to have mixed teams of informatics and medical students who work on realistic case studies and benefit from each other. Domain knowledge and IT skills should complement each other but also communication and collaboration should be fostered.

In addition to an existing curricular course for medical students the multidisciplinary course "Health Care Information Systems" was introduced for both medical and informatics students.

The course comprises lecture parts to introduce the theoretical background and practical parts in which students work on a case study with respect to an information systems project.

The main contents which will be described in the following are:

- Project management
- System analysis
- System selection
- System implementation
- Project conclusion

The course starts with a case study based on the following objective: "Hospital department X needs new software for their electronic cancer documentation".

The course design is shown in Figure 1. In the middle part the main contents of the course are listed. In each phase the tasks vary for informatics students (on the left) and medical students (on the right). Only the first and last tasks are the same. In the project management phase both groups have to create a project plan. In the system analysis phase medical students have to search for information about documentation needs and workflow which is then transferred into process models by informatics students. Medical students have to specify their requirements as prospective healthcare professionals during the system selection phase while the informatics students provide the functional specification. During system implementation informatics students should program and implement a system that can be evaluated by the potential users. Finally both groups complete the project report in the conclusion phase.

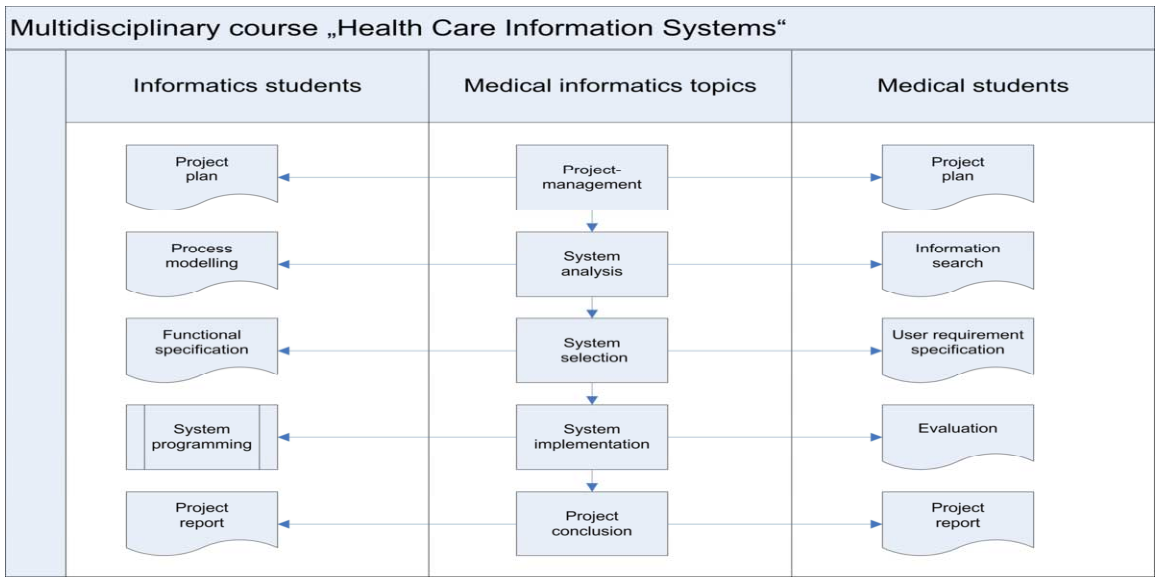

Figure 1-Multidisciplinary course contents.
The middle column shows the course contents. The external columns show the tasks of the informatics and medical students according to the single topics.

To avoid that poor contributions from one of the student groups affects the work of the other group we provided an individual feedback via Email, presented sample solutions according to the respective home-work and discussed the student solutions during classroom teaching.

Besides expert knowledge the students will also need to develop soft skills like communication abilities. Therefore the students work in small groups to enhance efficient conversation and teamwork. The course is integrated as an optional module in the curriculum of the medical students and as a compulsory elective module in the curriculum of the informatics students.

The course consists of 16 hours classroom teaching plus comprehensive project documentation and implementation tasks for the informatics students. In total there is a workload of 2 ETCS-Credits. The course is designed for 16 students per term (eight medical and eight informatics students).

Last term we started with 12 students (four medical and eight informatics students). A post course evaluation showed that the content and the integration of theory and practical tasks were in general good but there is still room for improvement. The overall rating was excellent.

Table 2 – Evaluation of the multidisciplinary course

	excellent	**good**	**fair**	**bad**
Course content	33 %	67 %	0 %	0 %
Integration of theory & praxis	33 %	59 %	8 %	0 %
Overall rating	87 %	17 %	0 %	0 %

Evaluation (in percent) of the multidisciplinary course from winter term 2009/2010 on a scale from 1 (excellent) to 4 (bad).

Discussion

With the course “Health Care Information Systems” informatics students gain insight into processes and documentation requirements of hospitals and can act as IT system providers while medical students learn about process description and modeling so that they can act as clients. Besides the domain knowledge students from both disciplines get experience in teamwork, presentations and communication which are important especially in cross-discipline projects. A critical aspect for establishing good communication is to create common theoretical foundations and a common terminology. The joined work on the case studies is designed to enhance communication between the two different domain groups.

Apart from the advantages for the students attending the course, also research in the domain of medical informatics will be fostered through the discussions between both domain

groups. As van Bemmel stated "interdisciplinary research can not be effective without interdisciplinary education" [9].
There are some discussions at what point in time in the curriculum a course in medical informatics should be placed and how such a course can be integrated in the education. Lungenau stated that after an introduction in the preclinical stage the problem-based-learning should be placed in the clinical part [13]. We agree with this and integrated the course as a compulsory elective module in the clinical stage to provide medical students with a possibility to extend their knowledge in medical informatics.

As a next step we plan to further extend the practical part by using videos - based on existing storyboards of clinical cases – in order to provide even more realistic clinical settings. Furthermore, we plan to complement the course by a seminar in which students can focus on specific topics from the course.

In addition further courses will be thoroughly evaluated by both student groups. Last year the University of Münster introduced the *Münster Audience Response System* (MARS) which is a system through that the students can use an electronic device to actively participate in lectures. We intend to use this technology to improve our multidisciplinary course.

Conclusion

Multidisciplinary education in healthcare information systems for medical and informatics students based on case studies is feasible and both disciplines can benefit from it.

Competing Interests

The authors declare that they have no competing interests.

Abstract

In many developing countries, electronic medical record (EMR) systems are being implemented in resource-poor settings. Essential to such implementations are software developers with a high technical capacity, a good understanding of medical informatics and an awareness of local clinical needs. This paper describes a training program which has been run in Rwanda to enable local computer science graduates to play a significant role in that country's forthcoming implementation of a national EMR system. Such a training program is unique in that region of Africa and we discuss the challenges inherent in such an undertaking. We describe the development of the curriculum and the evolution of the teaching methodologies over the course of the year and discuss its potential integration with academic institutions in Rwanda. Finally we propose that training programs of this nature which produce local software developers who are familiar with medical informatics are a requirement for successful and sustainable eHealth implementations in the developing world.

Keywords:

Rwanda, Education, Software, Electronic medical record

Introduction

In the last decade, electronic medical records have become increasingly central to healthcare in developed countries, and such systems are also now being used in many developing countries. This trend has increased markedly in recent years as large projects have been established to treat HIV, Multi-Drug Resistant Tuberculosis (MDR-TB) and Malaria. Funding for these projects, which comes from the Global Fund to Fight Aids, Tuberculosis and Malaria, the US PEPFAR program and others, has supported the development of a range of information systems in Africa, Latin America and the Caribbean. These systems range from spreadsheets and simple databases, to commercial software packages (which may be modified for the new purpose), to sophisticated, custom built software solutions. They are used for a wide variety of purposes from clinical care and telemedicine to reporting, supply chain, accounting and research.

There are many challenges to implementing such systems in resource-poor areas ranging from lack of stable electricity and communication systems to basic problems of heat, humidity and physical security. Additional to the hardware and software costs there are important human costs in terms of training of staff that will be using the system. However, training of local staff is normally limited to end-user training and does not include maintaining or extending the software itself. With the use of closed source propriety medical records software, this is usually not an option anyway. However, with the use of community developed open source software, it is not just an option but an important way of connecting developers with users, thus realizing the benefits of open source by enabling implementers to customize the software to their needs. Such training means that implementations are not dependent on ex-patriot software developers for all improvements and fixes, which improves sustainability and supports broader development goals.

Background

The OpenMRS project, which is co-lead by Partners in Health (PIH), the Regenstrief Institute in Indiana, USA and the South African Medical Research Council, is an open source initiative built by many collaborating groups around the world [1,2]. A key strength of this initiative is that the software is free and developed through the experience of a growing number of different parties, including many in resource-poor areas. To date, OpenMRS is implemented in at least 23 developing countries and is supporting the care of over 1 million patients, more than 150,000 of which are HIV/AIDS patients on antiretroviral treatment. An important aspect of OpenMRS, especially for a developing country, is its modular architecture. This allows developers to independently add their own functionality to the EMR without having to make changes to the main application. Developers in different countries can share and collaborate on such modules. For this reason, OpenMRS is more accurately an extensible platform rather than an application.

In 2006, the Rwandan Ministry of Health (MOH) decided to begin plans for a national roll-out of OpenMRS for the purpose of tracking patient medical information in all health centers and hospitals around Rwanda. The MOH requested that

PIH, who had already implemented the system in six health centers and one hospital in the country [3], provide expertise and support for the project. It also called on the Treatment and Research AIDS Center (TRAC), an institution within the Ministry of Health responsible for treatment and research related to infectious diseases including HIV, tuberculosis, and malaria, to lead the roll-out of such a system throughout the country. Since 2006, PIH has expanded its use of OpenMRS to 12 sites, and the Government of Rwanda has invested heavily in their telecommunications sector, to provide power and internet to hospitals and health centers around the country.

It was determined in 2007 that in order to support the large and ambitious endeavor of a national OpenMRS roll-out and to prepare Rwanda to sustain the system internally, many Rwandan software developers and IT staff would need a considerable amount of further training. Additionally there was the immediate need to fulfill additional functionality requirements that the government had identified for OpenMRS. The principle of Rwandans building and supporting such a national system is consistent with the government's plan to move to a predominantly knowledge-based economy by the year 2020, commonly referred to as "Vision 2020". Therefore, it was vital for Rwanda to build the necessary technical capacity to take ownership of its development agenda, and it was for these reasons that PIH developed the plan for a mentor-driven, software development training course.

Such a course may be unique in the developing world. There are several examples of less developed countries such as South Africa [5] and Brazil [6] where health informatics courses have been established for medical students and professionals. Currently the Government of Rwanda is working to establish a health informatics center of excellence which would provide access to such training in this region of Africa. It is a difficult task given the lack of academics with a suitable background and it will likely require the sharing of resources and curricula with other neighboring countries as proposed in [7]. This training course is however, quite different from those initiatives in that it aims to produce graduates capable of developing the system rather than using it. Despite extensive literature search in the biomedical (Pubmed) and computer science fields, no reports of similar courses were found.

A 3 month pilot training program was started in November 2007 in partnership with RDB-IT (Rwanda Development Board – Information Technology). This pilot consisted of one mentor and six students who were a mixture of recent computer science graduates and existing employees of RDB-IT. The course content consisted of web design, Java programming and some of the technologies used by OpenMRS, and culminated in the development of at least one module that was deployed and used at TRAC. The limited time of the course unfortunately meant that by the end of the course, most of the students were not able develop software for OpenMRS without significant supervision. However, the students did leave with a good understanding of the technologies involved from an implementation point-of-view. One of the students became the EMR manager at TRAC, and has now been tasked by the MOH with overseeing the OpenMRS rollout.

It was clear from this pilot that the level of experience with software development that most of the students had received at their universities was not sufficient to enable them to grasp the advanced programming skills required for developing a large enterprise level software platform such as OpenMRS with only a few months of additional training. This was finding was consistent with experience of other similar programs which considered the use of local software developers such as [4]. Thus plans were made for a more substantial training course which would have the resources and time to produce local software developers capable of independently contributing to the OpenMRS project. Based on the experiences of the pilot program it was decided that the course should:

- Be one year long to give sufficient time to cover all the necessary technologies.
- Have a thorough screening of applicants to ensure that only high quality students were recruited.
- Involve enough mentors to ensure all students received a practical "hands on" experience, with no more than 6 students per mentor.

In addition to these requirements for the actual training of students, it was important to develop a course which was relevant in the context of the government's plans for a national EMR, and adhered to a model that was sustainable and scalable. The following goals were decided:

- Create a cyclical course where some of the students become mentors in subsequent years.
- Develop a comprehensive curriculum which can be shared, peer-reviewed and refined by other institutions and organizations.
- Indentify health management needs within Rwanda, and develop and deploy customized OpenMRS software modules to meet those needs.
- Include teaching of core medical informatics principles and expose students to non-technical issues through site visits and other activities.
- Undertake an evaluation of the technical training program and the software tools developed to assess the effectiveness of the program.
- Document the experiences and lessons of the OpenMRS adaptation process and capacity building effort to provide policy guidance for the scaling up of the initiative beyond the pilot phase in Rwanda and for a wider application in Africa.

Methodology

Different training and academic course models were considered and it was decided that this training course should use the model of a sponsorship program where students receive salaries. This was important because in this initial year of the course, it would not be able to offer a qualification accredited by an academic institution, and so to attract strong candidates

there had to be a financial incentive. This model is also familiar to public institutions in Rwanda where employees are often sent on training courses whilst still receiving a salary. The employee is then contractually obliged to continue working for that public institution for a period of time proportional to the amount of training they received. Such a contract would be essential to meeting the goals of this course, as it would ensure that the training invested in the students benefit Rwanda's health sector. To facilitate such a model the students would be employed by RDB-IT and obliged to work for the MOH for 2 years after completing the course.

For practical reasons the course length was set at 11 months. The first 7 months were split into two teaching sections. The first would be 3 months long and used as a probation period, and thus an opportunity to drop any students who were not performing well enough. The final two months were set aside as a production stage to ensure that there would be sufficient time for students to develop software modules for OpenMRS.

Screening of candidates

One of short-comings of the pilot program was the lack of entrance qualifications of the students before they were accepted onto the course and so a screening exam was developed which would test the candidates':

- Understanding of basic IT concepts.
- Knowledge of the software development lifecycle.
- Ability to construct simple algorithms.
- Awareness of more advanced software development concepts such as object-oriented programming.

In October 2008, RDB-IT selected 40 computer science graduates from applications they had received, and facilitated them undertaking the screening exam. In addition to enabling the selection of the best students, the results also enabled the course mentors to begin creating a curriculum appropriate for the students' understanding of the relevant technologies. The results of the screening exam also showed that although students were generally familiar with theoretical IT concepts, most struggled to construct even basic algorithms. It was evident that students generally had little practical experience of software development, especially with modern object-oriented languages such as Java. From the 40 candidates who sat the screening exam, the top 19 were called for an oral interview. These interviews allowed mentors to examine non-technical criteria such as:

- Students interest in healthcare
- Communication skills
- Ability to mentor others

The final selection of 10 students was based on the combination of their screening exam scores (weighted at 70%) and oral interview scores (30%).

Development of the curriculum

The screening exam results showed that some topics which the students studied at university would have to be covered again in the new training course. So a curriculum was developed that would start with very little assumption about what the students already understand, and then throughout the teaching stages, introduce all of the core technologies required for OpenMRS development. Even where students were familiar with the topics, there would be a new emphasis on best practices. The curriculum was broken down into 8 units to ensure that all of the important topics would be covered (see Table 1), and each of these topics is described briefly in the following sections.

Table 1 – Course curriculum

Unit	Title	Weeks
1	Foundations	2
2	Basic Web Design	4
3	Basic Java Programming	5
4	Advanced Java Programming	7
5	OpenMRS Implementation	4
6	Enterprise Java Programming	6
7	OpenMRS Development	7
8	Medical Informatics	-

Foundations

This was a high level overview of many topics from IT and Medical Informatics. The intention of this short un-assessed unit was not so much to give the students an understanding of the topics, but rather

- To start building a common technical vocabulary for students and mentors. This proved to be very important given that *for most of the students, English was their third language*.
- To ensure that all of the students are familiar with the basic tasks of maintaining their computer, and using its software to make documents and presentations.
- To introduce the students to the broader ideas of eHealth and their role as software developers.

Basic web design

This was to build on the students' prior experience of HTML, introducing XHTML, CSS and JavaScript. It emphasized the importance of separating content from design and developing standards compliant web pages.

Basic Java programming

This was to give students a firm foundation in the Java language. It would cover all the syntax of the language, and introduced the students to object oriented concepts, with which many were not familiar.

Advanced Java programming

This covered more advanced topics in Java programming such as design patterns, multithreaded applications and unit testing.

OpenMRS implementation

A break from development in general, this unit covered OpenMRS from an implementer perspective. This included:

- Basic setup and maintenance of a Linux based server as well as how to manage the necessary server software such as Tomcat and MySQL.
- Infrastructure issues such as power and internet connectivity.
- Staffing and training issues.

Enterprise Java programming

This covered most of the Java Enterprise Edition (J2EE) technologies at the core of OpenMRS such as JSP, JSTL, MySQL and Hibernate.

OpenMRS development

This covered some J2EE technologies not covered in the previous unit (e.g. Spring), and teaches development of OpenMRS modules using the OpenMRS API.

Medical informatics

Unlike the other units of the course, this unit was taught throughout the year. The content was largely provided by guest lecturers, either in person, or through remote lectures using Skype. Topics covered included medical data and coding, EMR systems, decision support systems, pharmacy systems, evaluation of medical information systems. These were taught with a focus on developing country environments.

Course implementation

It was clear from the start that the course needed to emphasize practical experience over theoretical understanding. Each of the students was given a laptop for the duration of the course to ensure that they had an adequate machine for completing course exercises and projects (of the ten students, only a few had their own laptop). Typically each day, a mentor would give a lecture to introduce a new topic, and then set small exercises to reinforce the content of the lecture. At the end of each week, a project would be set which would involve many of the topics taught that week. Students were given a few hours each afternoon to work on these, and also expected to work on them at home.

Assessment

At the end of each unit (except the first), students were given a week long project which would incorporate many of the technologies from that unit. Most of these projects were related to eHealth, and included:

- An online health check website (Basic Web Design)
- A simple console based EMR (Basic Java Programming)
- A virtual OpenMRS server and deployment plan (OpenMRS Implementation)

Students were also given a written exam at the end of each module. Because students were encouraged to help each other with projects, the written exams were generally a more accurate indicator of an individual student's performance.

Module production

The last two months of the course were set aside for development of modules for OpenMRS sites in Rwanda. The EMR managers at TRAC (MOH) and Rwinkwavu hospital (PIH) were asked to compile a list of additional functionality they would like to have implemented at their sites. Course mentors then discussed these requests with some of the OpenMRS programmers, in order to determine which were the most suitable for implementation as modules by the students. A list of 5 potential modules was agreed upon, and then allocated to pairs of students, depending on the complexity and the students' ability (see Table 2). As much as possible these student projects were managed as real software projects. All are now in clinical use.

Table 2 – Modules developed by students

Name	Description
PMTCT	Registers mothers and their children on the Prevention of Mother To Child Transmission program
Patient Alerts	Alerts that notify clinicians of patient data indicating the need for immediate action
Drug Order Export	Allows drug order data and patient regimen histories to be exported
TRAC Data Quality	Produces lists of potential errors or omissions in data entered into the EMR
Data Entry Delay	Provides statistics about the time it takes for encounters between clinicians and patients to be entered into the EMR

Discussion

The curriculum described here and the teaching materials are all available online for other people to download[1]. It is hoped that this will lead to collaboration with other similar training programs around the world, and allow the materials to be peer reviewed and further developed by others. Much of the materials are not specific to OpenMRS and thus a suitable resource for any similar Java-based training course.

Teaching methodologies

One of the advantages of creating a new training course has been the freedom to explore different teaching methodologies, some of which would be difficult to incorporate into a traditional academic course. One method that was found to be particular effective and increasingly used as the course progressed, was asking stronger students to explain complex con-

[1] http://openmrs.org/wiki/EHSDI_Training_Course

cepts to the rest of the class in the language of their choice. This usually led to discussion amongst students - often involving those students who would be less inclined to ask a mentor for clarification. On other occasions all of the students would be assigned a different topic and required to give a presentation to the rest of the class. This had the added benefit of improving their presentation and communication skills.

Institutionalization

The creation of an independent training course was considered necessary in this first year, to satisfy the immediate need for local software developers capable of producing OpenMRS modules. Likewise the sponsorship model used was considered necessary to attract high quality students and to provide a mechanism for placing students in jobs with the MOH. However, moving forward it is important to explore ways of making the course more sustainable and scalable. We have already begun discussions with one of the universities in Rwanda about how this course could be integrated into their postgraduate programs. This presents a challenge because our emphasis on "hands on" mentoring is at odds with the requirements of most post-graduate academic courses. We would also need to reduce the overlap in topics covered by this course and the undergraduate computer science courses, perhaps by finding ways of assisting them in strengthening their courses. Even in an academic institution, it may be possible to maintain the sponsorship provision for some or all of the students. We must continue to partner with the MOH and other groups who are implementing OpenMRS in Rwanda, giving them the opportunity to invest in the training of their staff, and to ensure that the course continues to be relevant to their needs.

Collaborations

We believe that there is much that other organizations implementing eHealth solutions in the developing world can learn from this training course. First and foremost we hope that other organizations are encouraged to initiate similar programs, and can see that it is both possible and beneficial to train local software developers, rather than relying on ex-patriot staff. We are also keen to explore ways of collaborating with similar training programs that OpenMRS is involved in such as Google Summer of Code, which provides grants for students to spend several months working on an open source project and being mentored by a developer. It is hoped that this course will eventually integrate with the health informatics center of excellence that the Government of Rwanda is trying to develop with funding from IDRC and Rockefeller Foundation. It will link this developer training program with training in medical informatics for physicians, nurses and other clinical staff, data manager training, and also include research and evaluation. Another important collaboration linked to this course is the American Medical Informatics Association GPP program to create collaborative training programs in medical informatics in Africa (funded by the Gates Foundation).

Conclusion

This training course was created to provide high-quality Rwandan software developers with the necessary programming skills and grasp of medical informatics to contribute to the further development of OpenMRS in that country. The students developed OpenMRS modules which are being used at the TRAC and Rwinkwavu Hospital sites. They worked closely with the EMR managers from those sites, who were satisfied that the modules were of sufficiently high quality to be deployed on EMR servers. They graduated in October 2009, and in February 2010 the course was restarted with 12 new students. Clearly, it is difficult to objectively measure the success of the course without external assessment of the students, so it is intended that the students will sit exams for Sun certifications for J2EE development. We will also carry out a more detailed review of the modules in the near future.

Acknowledgments

We thank IDRC for the funding and RDB-IT for support.

Strengthening Health Systems through training of Health Care Providers in the conduct of Routine Waiting Time and System Efficiency Surveys

Gavin Reagon and Ehimario Igumbor

School of Public Health, University of the Western Cape, Bellville, South Africa.

Abstract

The effective functioning of Health Systems is reliant on good quality information being available for decision-making. Routine surveys exemplify an under-utilised source of such information that could enable Health Departments to gain insights into the performance of health service provision, from both the stand-point of the providers and users. Amongst these, Waiting Time and System Efficiency Surveys (WTSES) directly responds to the commonest complaint of users of healthcare services. There is, however, little information on approaches to routinely implement robust and sustainable facility-based WTSES especially in resource-constrained settings. This paper describes the conceptual and methodological basis for implementing WTSES in health care facilities, using a method that places the conduct of the survey within the purview of the normal service activities of health care providers, and thus makes the routine assessment of Waiting Times possible at low cost and with high benefit. The authors aver that the universal implementation of the WTSES presents the potential for enriching patient and health facility information systems, particularly in resource-constrained settings, where efficient use of limited resources is critical.

Keywords:

Patient waiting times, Routine surveys, Health facility surveys

Introduction

The collection, processing, reporting and use of routine health information is ineluctable for the effective and efficient functioning of health delivery systems [1]. Routine health information systems (RHIS) are important to guide and improve decision making including *inter alia*, strategic planning and policy development, daily operational activities, and controlling resources such as finances and personnel [2]. It is for this reason that they are aptly described as *health management information systems*. Effective RHIS will also directly increase the staff and community's understanding of the functioning and outputs of the health delivery system; will help to identify problem areas and areas where health services need to be improved; will improve the motivation of staff by highlighting improvements where appropriate and advocate for changes to facilitate further improvements in the health service [2]. A number of health facility-based information systems such as public health surveillance, health system monitoring and mortality information systems exist, and to varying degrees have been successful in meeting some of the aforementioned potentials.

Routine large-scale surveys however, exemplify an under-utilized source of information that could enable Health Departments to gain insights into the performance of health service provision from both the stand-point of providers and users. Amongst these, the Waiting Time and System Efficiency Survey (WTSES) directly responds to the commonest complaint of users of health care services [3]. The WTSES primarily measures how long people wait for a service and the amount of service time they receive at health facilities. Importantly, in addition to identifying long waiting times, the survey identifies the reasons why these arose and suggests ways to reduce them. The survey also measures the workload of the staff, the efficiency of service provision and the percentage of time staff spend attending to patients. There is, however, little information on approaches to routinely implement robust and sustainable facility-based WTSESs especially in resource-constrained settings. This paper describes the conceptual and methodological basis for implementing WTSESs in health care facilities using a method which places the conduct of the survey within the purview of the normal service activities of health care providers and thus making routine assessment of Waiting Times possible at low cost and with high benefit.

Methods

The focus of the survey is to measure the time patients' spend at the health care facility for any service. This includes the amount of time that patients spend waiting for a service, and the time taken to provide the service. This requires that patients are tracked from their time of arrival at the health facility till the time they depart the health facility. The sample size required for a valid survey is typically quite large, so all patients seen at the facility in a time period (e.g. a session, a day, a week, or a month) are included in the sample. The more heterogeneous the services provided at the facility the longer the time period required and conversely the more homogenous the service the shorter the time period required. The starting point for the survey is therefore a decision on this time period. For

primary level care facilities where services rendered do not significantly change from day to day, an average day within an average week of the year should suffice. For secondary and tertiary level care facilities a longer time period is usually required in order to assess all services.

Data collection is done via a timesheet. As patients enter the health facility, they are handed a timesheet on which their arrival time is recorded. The patients are then asked some basic questions, such as their age, whether they have an appointment and how they travelled to the health facility. The timesheet has a list of every point or station in the facility at which the patient may receive a service (hereafter referred to as a "service point"). Each of the health workers (such as receptionist, doctor, pharmacist, nurse, etc) who attend to the patient on that day, then fill in the time they start seeing the patient and the time they finish seeing the patient, against their service point on the timesheets. When the patients leave the health facility, the departure time is recorded and they are asked questions about how long they are willing to wait at the health facility for the services which they had just received. See Figure 1.

The health workers also complete a personal timesheet. On their personal timesheet, they record the time that they commenced duty at the service points at which they worked and the time that they completed their duty at that service point. They may work in more than one service point through the day and are expected to document all of these on their timesheets. The health workers also fill in a short questionnaire on the amount of time that they think it is appropriate for patients to wait and on whether they have sufficient equipment and space to properly attend to the patients.

Both patient and staff timesheets are then captured using a customised database. Using a combination of data from the patients' timesheets, the patients' questionnaire, the health workers' timesheets and the health workers' questionnaire, the waiting times, service times and patient workload for every service point is then calculated.

Data Analysis

A database application has been developed to facilitate the capturing, cleaning, analysis and storing of data as well as the production of standardized reports. The simple individual patient calculation of waiting and service times is shown in Figure 1 and 2. These are then aggregated for all patients surveyed to develop composite tables and graphs on key indicators for the health facility.

The first primary table is a detailed service point table which reports descriptive statistics on the numbers of patients who attend the facility, the number of staff who work in the facility, the number of patients who visit individual service points, the daily full-time equivalent staff present at the facility, workload of staff per service point (calculated as the number of patients seen per full time equivalent staff per day), workload efficiency index (calculated as the percentage of available staff time spent providing services to the patients), percentiles (5^{th}, 25^{th}, 50^{th} and 95^{th}) of service and waiting times per service point and then overall for all service points.

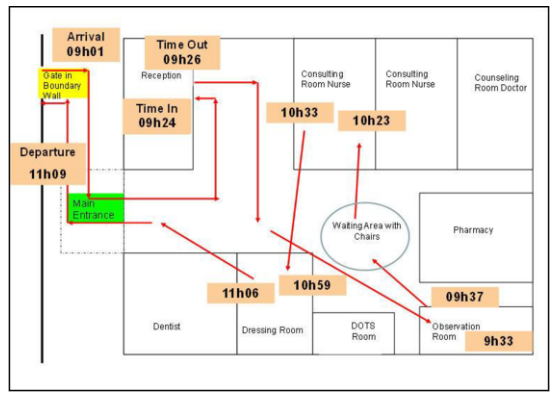

Figure 1 - Measuring Waiting and Service Time at a health centre by following a patient with a timesheet. The patient arrives at 9:00, waits 23 minutes before being attended to by the staff at reception at 9:24. Receives a service for 2 minutes until 9:26 and is then sent to the observation room. Similarly the patient waits at and is attended to at the other points.

Calculating Waiting and Service Times

Arrival Time 9:01

Service Point	Time In	Time Out	Service Time	Waiting Time
Reception	9:24	9:26	2 min	23 min
Observation Room	9:33	9:37	4 min	7 min
Consulting Room Nurse	10:23	10:33	10 min	46 min
Dressing Room	10:59	11:06	7 min	26 min
Complete ST			23 min	
Complete WT				102 min

Departure Time 11:09

Figure 2- Calculating the Waiting and Service Time of a patient

In addition, "arrival time graphs" are used to display the arrival times of patients and the median waiting and service times according to hour of arrival. This is done for every service point and then for the entire facility (i.e. all service points combined). Another set of graphs, the "snapshot graph" shows the waiting and service patterns for every service point in the facility in relation to the staff available to provide the service.

Results

To date, surveys have been implemented in over 200 primary level care facilities, 11 secondary level (regional hospitals) and 3 tertiary hospitals within 2 provinces of South Africa and three districts in the United Republic of Tanzania. Waiting and Service time calculations have been done for over 110 000 patient visits to health facilities.

For all of these health facilities, customised patient and staff timesheets have been developed together with customized database applications. From these, standardized reports for health facilities have been generated showing *inter alia*, the "detailed service point table", "arrival time graphs" and "snapshot graphs" (See Figures 3, 4 and 5).

Importantly, in all the surveys health workers themselves collected and interpreted the information as described earlier and this has translated into very enlightening information about their service points. Findings indicate that facilities and service points show a wide variation of waiting and service times. Overall, staff time usage efficiency ranged from low to modest, while waiting times ranged from minimal to excessive. Eight immediate causes of long waiting times have been identified. These are:

1. *High Workload*: if staff are overworked, then patients have to wait longer as staff have too many patients to attend to.
2. *Batching and inappropriate arrival patterns*: if many patients arrive at the same time then most of these patients would have to wait a long time to be seen, as the staff member would be busy seeing the patients who were first in the batch and the rest would be waiting.
3. *A lack of efficiency in attending to patients*: patients are waiting and yet staff members are present at the service point but they are busy doing something else instead of attending to the patients who are waiting.
4. *A mismatch*: a mismatch occurs when patients arrive to be seen but staff are not yet at that service point.
5. *A logistical problem*: patients are waiting to be seen and staff are available to see the patients but due to a lack of equipment, rooms or other logistical needs, staff are unable to attend to the patients.
6. *Flow problems:* Staff are available to see patients and patients are at the facility but they are being delayed at some other service point.
7. *Queuing problems:* This occurs when patients are attended to by staff in an illogical order, i.e. the patients are not attended to in the order that they arrive at the service point.
8. *High Service time:* An inappropriately high service time for a particular service point would result in higher waiting times for the other patients waiting in the queue.

Prior to the surveys, it was anecdotally believed that high waiting times were mainly due to high workloads. However, in all settings surveyed so far, high waiting times were rarely linked to high workloads but were consistently linked to lack of appointments and the resultant flood of patients arriving at facilities in large batches, especially in the early hours of the day [4].

Service Point	% Staff Time Spent Attending to patient	Median Service Time	Median Waiting Time	Logistics Problem
Surgical Intern	90%	20	50	N
Medical Doctor	52%	30	42	Y
Emergency Room Doctor	14%	28	9	N
Doctor Resuscitation Unit	63%	105	1	N

Figure 3- Detailed Service Point Table
The surgical intern is overworked with a resultant high waiting time. The high waiting time for the medical doctor is due to the logistical problem of awaiting laboratory results. The resuscitation doctor has an appropriately low waiting time.

Health Care Systems uptake of the Survey

Having successfully developed and piloted the WTSES in primary level clinics and health centres in Cape Town (South Africa), we were able to develop simple and efficient methods to analyze waiting times and identify the major causes of long waiting times using a robust methodology supported by a customised database. Based on the experiences of this first survey, we extended the methodology to allow for the identification of all the causes of excessive waiting times, and we standardized the methodology to enable the widespread roll-out of the survey. The methodological procedures were then tested by doing surveys of all clinics and health centres in Cape Town in 2007. It proved to be highly successful in measuring waiting times and identifying the causes of those that were excessively long. Solutions for these problems were then developed. Our success spurred replication of the survey in KwaZulu Natal Province, South Africa and further on to East Africa where we surveyed health facilities in 2 regions of the United Republic of Tanzania

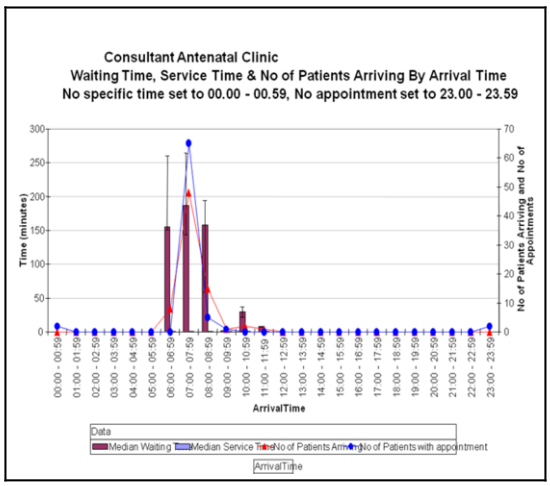

Figure 4- Arrival time graph of a service point in a health facility showing batching between (0700hrs-0800hrs) caused by inappropriate appointment times. Ninety-nine percent of the patients have arrived by 08.00 even though the clinic operates from 08.00 to 13.00.

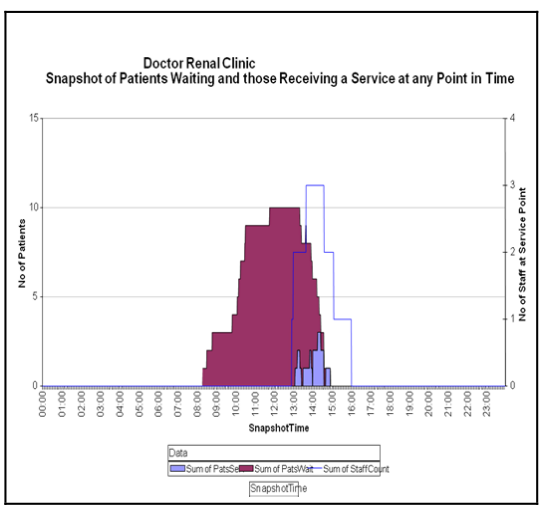

Figure 5- Snapshot graph of a service point in a health facility showing mismatch. Patients start arriving at 0800hrs for a service which starts at 1300hrs

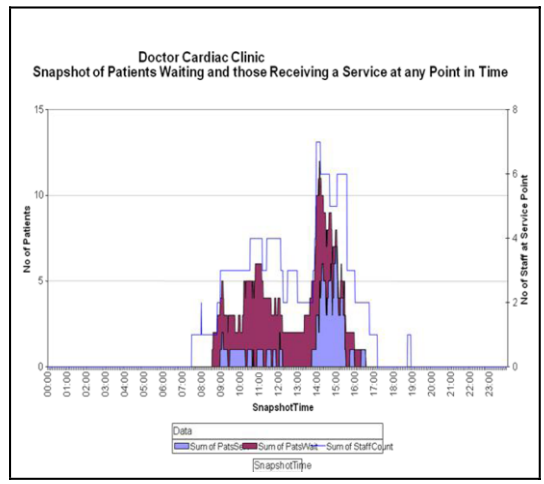

Figure 6- Snapshot graph of a service point showing relative inefficiency between 0900hrs-1200hr (3 Staff in the facility but only one patient is attended to at any point in time); absolute inefficiency between 1200hrs-1350hrs (staff present but no patients are attended to) and good efficiency between 1400hrs-1630hrs. Flow problem between 07.30 and 08.30 as staff are present but no patients have arrived yet.

By the second half of 2007, we had all the valid and necessary ingredients to allow the rollout of the WTSES: a robust methodology and a database had been developed, a training manual had been produced and we had demonstrated that it could be done in a very cost-effective, standardized manner. We had also successfully conducted repeat surveys in a total of 125 primary level care facilities in the Western Cape and supported several others in KwaZulu Natal. The only thing lacking was trained health workers and a desire by health managers to implement the survey routinely. It was also unclear whether the methods successfully used at primary level care facilities would be appropriate for larger and more complex secondary and tertiary level care facilities.

In 2008, we were asked to undertake surveys of regional and academic/tertiary level facilities in the Western Cape. This required that the survey took into account the complexities associated with the delivery of these higher level healthcare services and the vagaries in the process of service delivery in such sections as Trauma and Emergency units. Working with Quality Assurance Managers of the Department of Health we conducted surveys in 7 secondary and tertiary-level hospitals in the Western Cape Province.

Discussion

We have developed a robust method of measuring how long patients wait for services. Importantly in addition to determining the extent of long waiting times and the service points affected, our survey method identifies the reasons why the long waiting time arose and consequently suggests ways to reduce

them. The survey also measures the workload of the staff, the efficiency of service provision and the percentage of time staff spent attending to patients.

Beyond merely being a time measurement activity, our experience has espoused a wide scope of benefits of the WTSES in primary care, *inter alia*; it serves as a process evaluation tool of service time efficiency; a quality measurement tool; an epidemiological profiling tool; and has been successful in its primary aim of identifying and suggesting solutions to long waits for health care services.

The WTSES is quintessential of a routine large scale survey with universal applicability across the tiers of the health care delivery system (primary, secondary and tertiary). Our experience provides evidence that:

1. Regular monitoring and evaluation of health services via large scale routine surveys such as the WTSES is possible in health systems of developing countries
2. Such high benefit surveys can be undertaken using valid and robust methodologies and yet be conducted at a low cost.
3. Existing human resources within health systems can be used to implement the survey in its entirety – including planning, data collection, data cleaning, analysis, interpretation, presentation of results and then development of appropriate interventions based on the findings

Routine surveys must have sufficient depth to assess all the major contributing causes of the problem being investigated.
With the addition of routine large scale surveys such as the WTSES to their routine health information system, health departments would be in the envious position of having an unprecedented amount of high quality information to guide strategic and operational planning, as well as to assist with day to day decision making.

Conclusion

Given the current tools, it is possible for health facilities in developing countries to routinely conduct WTSESs. The benefits of increasing systems efficiency and reduction in waiting times allows increasing improvements in quality of services over a period of time. Because health workers undertake the survey themselves, not only is the survey conducted at a low cost, but also it imminently impacts high staff morale as service provision improves and staff assume the role of researchers in their own right. However, health delivery systems will need further support in modifying particular work environments and mode of service provisions and further training of staff to do this adequately.
Further research is needed to evaluate the success of interventions undertaken to reduce waiting times at facilities and to explore the integration of the survey database application with other large databases utilized by Health Departments.

Acknowledgments

Funding for this project was provided by research grants from the National Research Foundation (South Africa), Research Council of Norway, Atlantic Philanthropies and Rockefeller Foundation. Dr. Abie Zogoe, Mr. Fred Koopman and Ms. Natasha Titus are thanked for their contribution to the development of this project.

Abstract

The article discuss challenges and solutions when an existing course programme, in which contributions from the group form an integral part, is to be converted into an online programme. The focus is on division of labour between technology and supervisors. The case is the Norwegian online version of Chronic Disease Self-Management Program from Stanford University. The interplay between humans and technology is discussed from a theoretical framework developed from the works of Latour and Nonaka. In special difference between human modelling and a technological systematic and rule-based approach is emphasised. By delegating parts of the role in classroom courses to the e-learning solution, it has been possible to create a solution where participants are learning from each other. This demands knowledge on the part of the supervisors so that they help to increase the effect of the technology and not work against it.

Keywords:

Patient education, Distance education, Educational technology, Man-machine systems, Lay knowledge.

Introduction

The volume of health related e-learning programmes is supposed to increase. Provided by public, voluntary and private sector. Many of those natural to offer online exist already as ordinary courses, which means that they must be transformed from classroom to online. This article discusses this transition, with an emphasis on how interaction between technology and human resources can facilitate good learning processes.

The case investigated is the Norwegian online version of Chronic Disease Self-Management Program from Stanford University [1]. This was transferred from classroom to online as a design-based research project [2, 3]. The transformation is discussed on the basis of learning theories and theories about the interaction between humans and technology.

As part of their final reflections, participants are asked to say what they felt to be most useful. It is quite obvious from these that participants have felt that they have been part of a group. Against this background we discuss challenges and solutions when an existing course programme, in which contributions from the group form an integral part, is to be converted into an online programme. The focus is on division of labour between technology and supervisors.

Background

In its traditional form Chronic Disease Self-Management Program is a 15-hour course spread over 6 weeks. The course intends to help participants manage their illness, carry out normal activities and tackle emotional challenges. The programme aims both to impart knowledge from a set syllabus and to enable the participants to share their experiences. The course has been translated to a number of languages, among others Spanish, Chinese, Australian English and Swedish. The course also forms the basis of The Expert Patient Programme that is offered by the Department of Health in Britain. The programme was translated into Norwegian in 2001.

Chronic Disease Self-Management Program is not linked to any specific diagnoses and is a supplement to normal treatment and education in managing specific illnesses, both for people with chronic illnesses or disabilities and their families. The course content and programme are set out in a detailed instructor handbook. The pedagogical foundation of the course is to be found in the work of Albert Bandura [4]. The programme has been developed and modified over a period of time through close cooperation between health professionals and users.

Among others the course has been tested on persons with heart and lung diseases, strokes and rheumatoid arthritis (e.g. [5, 6]. The results showed a significant increase in among other things training, mastering symptoms, improved communication with health professionals, own experienced health situation and exhaustion. It was registered that the participants also had fewer social inhibitions and a reduced use of health services. In the American health system the programme gives a cost/effect score of 1:10.

Method

The course was transformed from classroom to online within the framework of design-based research. Brown [2] and Collins [3] are regarded as portal figures for this type of research, but several directions exist, such as e.g. formative research [7], design research [8] and theory-based design [9, 10]. It is theory-based design that will be adopted in this project.

In design-based research the key feature is that the research aims and the developmental aims are closely interwoven [11]. In this project the aim is of developing a good learning environment coincides with the aim of developing an understanding of the connection between technological and human organisation for learning. Moreover, in design-based research it is essential that the development take place in iterative development processes. Here this has been solved through so-called extreme programming [12].

What is special about theory-based design [9, 10] is that it is based on the assumption that all learning environments consist of five elements that stand in a dialectic relationship to each other. These are: 1) psychology that forms how one understands learning and thinking, 2) pedagogy that dictates how to organise learning environments, 3) culture that reflect values appriciated, 4) technology which support, govern or make for a richer learning environment, and 5) pragmatism with regard to the availability of resources.

Thus the precondition for enacting a successful transformation from classroom to online is knowledge about the course and combined with knowledge about e-learning. With the aid of this knowledge the course is built up pragmatically within the framework provided by the culture and the technology in accordance with the fundamental psychological and pedagogical principles.

Norwegian Net School has developed PedIT, an online e-learning platform well suited to the course. In May and June 2004 the course was run as a pilot using this e-learning solution. The pilot had 18 participants and four supervisors, all of whom were experienced instructors from classroom courses. The pilot led to minor alterations in the online solution, which in accordance with extreme programming were implemented during the test period. Even so, the most important outcome was the experiences gained by the supervisors in how to organise this type of activity.

In the autumn of 2004 a trial programme was run, consisting of 2 courses with a total of 78 participants in 8 separate groups. The material presented here originates from this trial. The material contains 3200 utterances. 75% of these are related to action plans.

A similar model was tested in 2008 with 48 participants. From 2009 the project is part of the regular portfolio of the Norwegian Study Organization for Disabled.

Theory

In our discussion of e-learning as technology we shall make use of theories that in the main have been developed by the French sociologist Bruno Latour. An important point in his work is that both humans and technology are actors with agency [13]. Latour's colleague Madeleine Akrich [14] compares this agency with that of a film manuscript that defines the framework of the actors' actions.

In the remainder of the text we will discuss the interaction between the e-learning tool and the supervisors. In this discussion we shall make use of the terms delegation, programme and anti-programme. Delegation involves leaving control of action to others, programme is what one is steering towards, and anti-programme refers to others' actions with the aim of neutralising control. Since it is Latour's work that is a basis for our discussion, these 'others' may be both human and non-human actors.

In one article Latour [15] discusses strategies used by hotels in order to keep possession of their keys. Three of these are: 1) the staff remind the guests to hand in their keys before they leave the building, 2) display notices that politely request the guests to hand over their keys, and 3) attach heavy key-rings to the keys. All of these are delegation, but whereas the first two involve describing a desired action, the third action is inscribed in the key.

Reminding the guests to hand in their keys convinces one group of guests, putting up a sign a larger group, and attaching heavy weights to the keys an even larger group. It is easy to imagine that hotel guests are very keen to take their keys with them, which mean that they remove the key from the key-ring. In that case this is an anti-programme to the hotel's programme. If the hotel chooses to weld or nail the key-ring to the key to avoid this happening, this would be a case of an anti-anti-programme.

Where the balance between programme, anti-programme and anti-anti-programme goes is a matter of opinion, especially when one delegates things to technology, since technology does make judgements. In what follows, we shall discuss how technology can and must take over part of the supervisor's tasks on an online course, and what responsibilities are best left to the supervisor. But first we ought to look at learning.

Learning

The aim of an educational programme is learning, but this is a difficult concept to define, which explains why so many pedagogical theories and approaches exist. Here we shall make use of an approach developed by Nonaka et al (e.g. [16, 17]). This approach focuses on how the surroundings must facilitate four types of transformation of knowledge if learning is to be effective:

Socialization: this involves experiencing things together. Here individual tacit knowledge is shared, and becomes common tacit knowledge. In this process, shared experience and empathy are important.

Externalization: This is the process by which tacit knowledge becomes explicit knowledge. In this process a key feature is to articulate the joint tacit knowledge from the socialising process.

Combination: In this process, 'old' and 'new' knowledge is combined to form more complex knowledge structures. In this process reflection is essential in order to achieve this combination of new and 'old' knowledge.

Internalization: This is the process during which what one thinks in the combination phase becomes practice, and thus where explicit knowledge forms the basis for tacit knowledge by its becoming part of our behaviour.

Nonaka combines these transformations into what he calls an SECI model. In what follows we shall discuss in more detail how technology can be designed to support these processes.

In the model below (Figure 1) we see in the dark part of the diagram what can be included in the course, and in the lighter part what must be done by the participants as part of their daily lives / routine. In other words, the content of the lighter part must be delegated to the participants in the form of 'homework', while the content of the dark part can be delegated to the course.

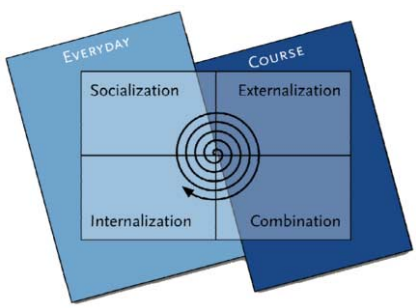

Figure 1- Didactic model based upon Nonaka [16]

Furthermore, we shall look more closely at the interplay between humans and technology in four areas of the online Chronic Disease Self-Management Program.

Group pages

When one meets in a room, one shares time and place. This is not the case when one meets online. At the same time all the participants comment on the fact that they have felt that they belong to a group. Essential to this experience are the group pages, which are the first thing the participants meet when they log in.

In addition to presenting the group, the group pages also serve as an entrance to action plans, course sections, forum and the large group. The fact that the group pages act as an entry page is an important signal that the group is a key component.

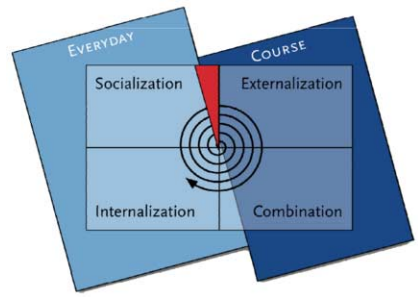

Figure 2- Socialization

In the programme, training in presenting yourself as a person with a problem is a key element, since it is represents an important opportunity to involve the course members more actively. Facilitating socialization (Figure 2) is therefore important. Parts of this function are delegated to the technology, and are thus independent of whether or not participants has logged in. In this context, weeding out those have signed up for the course but not joined has an important contribution to make. This has been delegated to the technology. The supervisors present themselves and thereby provide a model for the participants as to how they should do the same.

Course items

On traditional courses there are short lectures delivered by the instructors from a detailed manuscript. In the online version these are known as course items and take the form of texts that are to be read. On the traditional courses the short lectures are followed up by questions and group exercises. These have two different forms: brainstorming and problem-solving.

In brainstorming the question is defined by the course, and the participants offer their thoughts in relation to this. In the problem-solving the participants contribute by mentioning what they personally experience as difficult, and the other course members are challenged to help them find workable solutions. Both the brainstorming and problem-solving activities serve to incorporate the experiences of and suggestions from the participants in the course items. In this process, the supervisors are also important contributors, but most of all as equals as well as role models who demonstrate how one is expected to 'behave'.

In the SECI model [16], brainstorming and problem-solving activities are placed in the transition between dialogue and systemizing, while the course items are to be found under systemizing, where syllabus meets existing knowledge (Figure 3). The result of this meeting must be put into practice in one's daily life for it to become active.

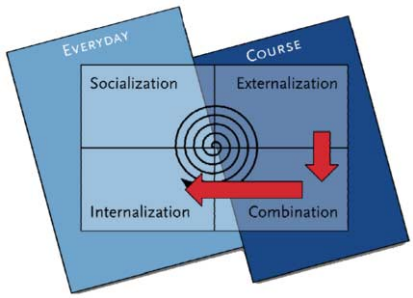

Figure 3- Brainstorming and problem solving

Action plans

An action plan can be described as a New Year's resolution meant for a week. An action plan starts with a set of targets such as, e.g. that you plan to walk a kilometre three times a week. You tell the group that you intend to do this, and when you come back a week later, you tell them about your experiences.

Moreover, the comments show that the action plans represent an important link between course and everyday life. The background for the high level of activity and positive comments with regard to the action plan is that it facilitates activity on all the four contexts indicated by Nonaka [16] (Figure 4). This is incorporated in the technology in a way which puts a focus on the group.

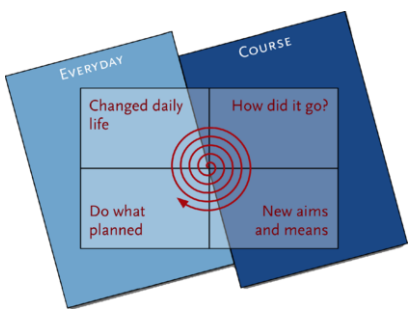

Figure 4- Action plans

Sharing the action plans in written form both emphasizes the obligatory nature of the task and offers the chance of a shared group experience. Here the technology makes a contribution in a number of ways. If the participant has written his or her action plan or their own evaluation without having received any feedback, the text 'I need comments' appears automatically on the group page. When you click on this sentence, you will be directed to the person's action plan. Moreover, 'I am proud of myself' appears if the participant checks this choice when he or she writes their own evaluation.

'I am proud of myself' and 'I need comments' are programmed into the software to focus attention on the participants' processes. This compensates for the reduced human presence in the case of e-learning, and replaces something of what is lost by the absence of body language and oral communication. Delegating this function to automatic programming and technology also has a normalizing effect.

Forum

The idea behind the forum is to provide a place where everyday experiences can be freely exchanged. In the forum it is possible to communicate in the same way as one would normally do during the breaks between classes on ordinary classroom courses. In other words, the discussion forum is an unstructured part of the dialogue and systemizing in the SECI model [16] (Figure 5), and creates a place for everything that does not fit in naturally elsewhere.

The discussion forum has little or no structure or control, with the exception of a desire to offer support to good discussions and put a stop to or give a twist to those that might seem unfortunate.

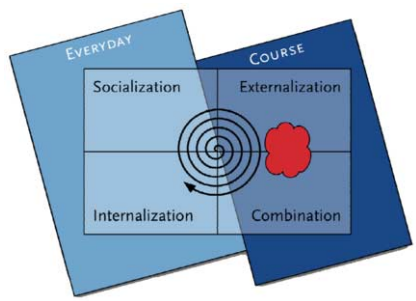

Figure 5- Forum

Supervisors can post messages from the forum onto the group page. Even though the course leaders themselves decide what is to be posted on the front page, the incorporating of the messages into the group pages has been delegated to the technology.

Discussion

In developing the online version the choice was made to emphasize those areas in which the Internet can provide added quality, while feeling free to tone down those parts where classroom sessions offer their special qualities. One example is supervisor-guided dialogues whose strength lies in immediate responses, body language and the opportunity for explanatory follow-up questions. Tools and methods more appropriate to online communication have replaced some of these dialogues.

Using the four main features group, action plan, course items and forum, it has been possible to create a number of arenas for interaction between individual understanding and social

practice, and to locate these in various parts of Nonaka's SECI model [16] (Figure 6). This contributes to what has been experienced to be a successful project. In the diagram below the four features have been put together to form one single model.

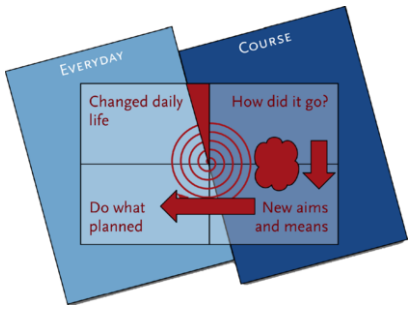

Figure 6-Single model combining the four features

Being able to claim that the development of the programme has been successful is due to a large extent to the high degree of correspondence between the course in the classroom version and the technology that has been applied. Chronic Disease Self-Management Program is by nature rigid and based on a cognitive understanding of knowledge and learning.

By delegating parts of the role of the supervisor in various ways to the e-learning solution, it has been possible to make sure that the participants feel that they are both seen and respected by other participants, at the same time as they are learning from each other. Moreover, this demands knowledge on the part of the supervisors so that they help to increase the effect of the technology and not work against it. Only then will the technology become an integrated part of a well-functioning course team.

Acknowledgments

First of all, a debt of gratitude goes to all the participants and the colleagues in the project. Thanks are also owed to those who have read the text and passed on their comments to the text. Finally, I would like to thank the Central Norway Regional Health Authority, The Norwegian Directorate for Health and Social affairs and EXTRA funds from the Norwegian Foundation for Health and Rehabilitation that has financed the project.

Abstract

Technology enhanced education has been recently established as a new approach for all stages of education. However, among these new IT media it is computer games playing the central role in delivering education in particular to children and teenagers, however, real world sound evaluation is often given little attention. The EU funded e-Bug project developed web games aimed at children to teach basic principles of prudent antibiotics use, hand and respiratory hygiene and aims to reinforces an awareness of microbes, hand and respiratory hygiene among junior and senior school children in 10 countries in Europe. An educational pack implemented in schools across Europe is complemented by Internet web games for two age groups teaching a set of learning objectives (LOs) using a fast and interactive platform game design for junior children and investigate detective games based on PBL principles for senior children. In this paper, we present the design of e-Bug junior and senior games and evaluation results.

Keywords:

Infectious disease, Educational games, Platform game, Detective game, Antibiotic resistance, Microbes, Hand and respiratory hygiene

Introduction

E-learning has been widely established as the use of Internet technologies to enhance knowledge and educational performance [1]. The value of e-learning tools and packages in supporting medical education is now well-documented [1,2], however little attention has been given to the use of web games that are particularly suitable teaching media for the e-native generation of children.

There are a few health education programmes targeting children (e.g, Do Bugs Need Drugs [3], Bugs Investigators [4]), however, this target group is often omitted in public campaigns. Raising the awareness of antibiotic resistance and improving hand and respiratory hygiene among children has proven to have strong impact on children health and school absences [5, 6].

In this paper, we describe e-Bug games developed in a DG SANCO-funded Europe wide project aiming to fill this gap by developing web games to teach children basic principles of microbes, hygiene and antibiotic resistance and translate into 10 EU languages and implement across Europe.

e-Bug Project

The reason EC branch DG SANCO funded this large EU educational project was that antimicrobial resistance remains one of the key problems within community and hospital settings within Europe. Increasing antibiotic resistance is related to increasing antibiotic use and lack of awareness of this phenomena among parents and children is contributing to the problem [5].

Many EU countries have public educational campaigns to encourage prudent antibiotic use, however, children are not the typical target group. Research has shown that respiratory and gastrointestinal infections have been identified as a major cause of childhood illness in schools and that the implementation of proper hand hygiene practices has reduced absenteeism within the school environment.

e-Bug (www.e-bug.eu) is a DG SANCO funded antibiotic and hygiene teaching resource aiming to reinforces an awareness of basic knowledge of microbes, hand and respiratory hygiene and the benefits of prudent antibiotics use among junior and senior school children across Europe. There are 17 countries involved in e-Bug covering 62% of European population.

There are two complementary products for both age groups – en educational pack taught at school science lessons and online games, currently launched in 10 EU countries. Education packs, covering the appropriate part of the learning curriculum, are complemented by web-based interactive games teaching the same e-Bug learning outcomes (LOs). Therefore, e-Bug combines traditional methods of classroom delivery with online, web-based games to teach a set of agreed Learning Outcomes. Education games teaching through the mechanics of the game have been successfully evaluated as effective educational intervention [7].

e-Bug Project Aims

The set of LOs were derived, implemented through the games, from the e-Bug project aims:

- To compliment national antibiotic and hygiene educational campaigns
- Develop an antibiotic and hygiene teaching pack & website with online games for both junior and senior schools
- Translate and implement the pack across associated countries in close collaboration with local Ministries of Health and Education
- Evaluation of use and impact of pack and website
- Disseminate and market the e-Bug resource to collaborating partner countries

The project is aimed at two age groups, for each a different style of games was developed to better suite the playing needs and cognitive abilities of children. Therefore, the first game style, aimed at junior children, is a fast engaging platform game while the senior children game design is rather a cognitive detective game. In each of the game the learning outcomes were taught through games mechanics and seamlessly tested.

The e-Bug Junior Game

The junior platform games (designed for the age group of 9-12 year olds) consists of a number of "levels" each teaching a set of learning outcomes. Player, shrunken inside human body, interacts with useful and harmful cartoon microbes and antibiotics and viruses. Teaching the LOs is implemented through the way the player interacts with microbes. Children knowledge is tested seamlessly before and after each level in a Game Show style similar to the popular TV game "Do you want to be a Millionaire?"

The game was designed to incorporates elements of platform games (similar to the Mario series), fast-reaction games (similar to Whackamole) and quiz games. These types were identified through focus groups and market research as being popular with this age group.

In the platform game elements, the player is shrunken to the size of a bacterium and uses a hoverboard to navigate environments that microbes inhabit. Learning outcomes are implemented through the way the player interacts with microbes. For example, the player throws soap at bad microbes to wash them off skin.

The quiz elements are used to assess player knowledge gain in a seamless fashion. For evaluation purposes, we use a pre and post questionnaires which will be changed to post-questionnaires for the real version. Immediately prior to each section of the game, the player is asked a series of questions in the quiz that assess their knowledge of the content of the coming section. The same questions are asked immediately following the section. By comparing the player's response before and after each section, we are able to determine the effectiveness of the game mechanics used to teach each learning outcomes.

The game is split into 5 sections, each of which is designed to teach one set of learning outcomes. Figure 1 illustrates the process of the junior game.

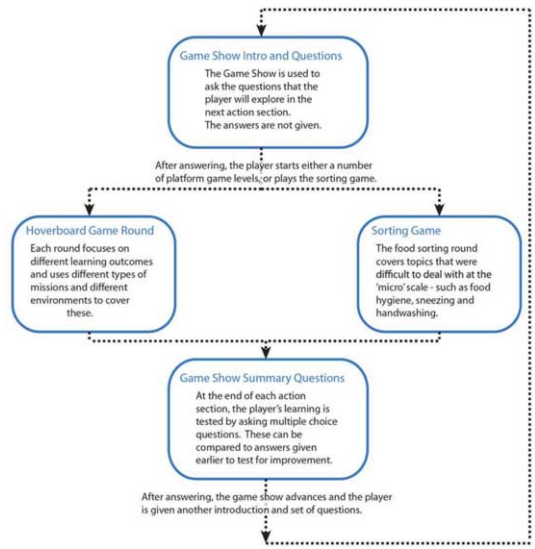

Figure 1 - Junior games process

Implementation of Levels

The first section of the game covers basic information about microbes. To teach the difference between the tree main types of microbes (bacteria, viruses and fungi), the player is tasked with using a camera phone to take photographs of one type at a time. In the game, the three types of microbe are visually designed to show the differences in size and shape, as illustrated in Figure 2.

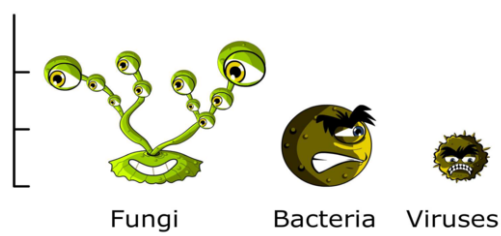

Figure 2 - LO: Bugs are different sizes

The second section of the game introduces the idea that some microbes can be harmful. The player is damaged through contact with bad microbes. Additionally, the player uses soap to wash harmful microbes off skin and uses white blood cells to destroy microbes that have infected a body (see Figure 3).

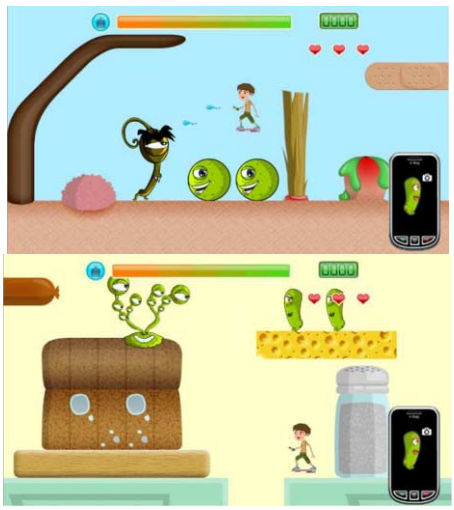

Figure 3 - Bugs are shown in different locations – on the skin and in the kitchen

The third section of the game seeks to demonstrate the usefulness of some microbes. The player has to push lactobacillus microbes into glasses of milk in order to turn the milk into yoghurt; as illustrated in Figure 4.

.

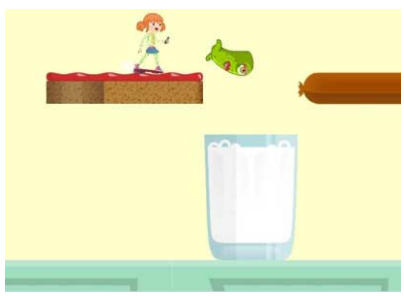

Figure 4 - Player transports lactobacillus to make yogurt

The fourth section of the game covers appropriate food storage guidelines. The player aims to put shopping away in a fridge and cupboards, making sure to wash hands after handling meat and to put each item in an appropriate place to prevent contamination and use a tissue when sneezing to test appropriate respiratory hygiene skills. This is illustrated in Figure 5.

Figure 5 - The food sorting game is used to show hand and respiratory hygiene.

The final section tackles appropriate antibiotic use. Seeking to show that antibiotics kill good and bad bacteria but no viruses, we implemented a 'smart bomb' effect for antibiotics. To show the importance of finishing a full course of antibiotics, the player is shown an infection grow back after initially appearing dead following a partial antibiotic course. By using the remainder of the course, the infection is fully eliminated. This level is illustrated in Figure 6.

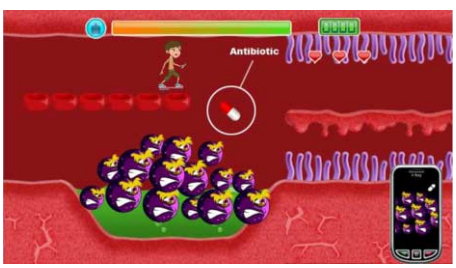

Figure 6 - Player delivers full course of antibiotics to infection

The player pre and post knowledge responses gathered during the quiz show elements are used to assess the effectiveness of each of the above game mechanics.

Evaluation and Results

In addition to the pre and post knowledge gain evaluation, from February until March 2009, a beta-version of the game [8] was evaluated for playability and user-friendliness using a questionnaire to assess user satisfaction and focus groups with a number of primary schools in the UK.

29 pupils took part in the focus groups (and fully completed the pre and post questionnaire) from three schools. Whilst this is a small number of participants, the results were promising. Before playing the game, only 4 pupils "agreed" that fungi were microbes. After playing, 18 agreed. Smaller improvements were seen in other questions including: "We use microbes to make things like bread and yogurt" (11 correct before, 23 correct after playing), "Soap can be used to wash away bad bugs" (20 before vs 24 after) and "Bacteria and Vi-

bugs" (20 before vs 24 after) and "Bacteria and Viruses are the same" (19 correct before vs 23 after playing).

The main evaluation of the games took place in the period of May – August 2009. Each of the completed level (many users dropped out during the game) was evaluated for statistical significance of knowledge change of the LOs. As many questions were correct before and after the game, the statistically significant improved responses were measured (using McNemar's test), for the following questions: "if you cannot see a microbe it is not there", "most coughs and colds get better without medicine" and in particular "we use good microbes to make things like bread and yogurt". There was a trend towards improved knowledge however in other questions did not reach statistic significance. The full report of this study can be found in [9]. Therefore those particular game mechanics seem to teach the LOs very well. Further study would need to be conducted to evaluate an impact on behaviour change.

The e-Bug Senior Game

Senior games, aimed at age group 12-14 year olds, use a detective style investigating a series of infectious related cases or outbreaks in Europe where the player has to discover the source of infection or contamination to successfully solve a puzzle. The game design is similar to that of Phoenix Wright [10], a popular detective game available on the Nintendo DS.
In order to avoid what Habgood calls "Chocolate Covered Broccoli" [11] where the game offers no educational benefit beyond extrinsic motivation, it is necessary to integrate learning through game mechanics. Problem Based Learning (PBL), "any learning environment in which the problem drives the Learning", is a natural approach to games based learning [12]. That is, before students learn some knowledge they are given a problem." [13]. The stages of PBL vary between implementations. For e-Bug, the Queens University definition of 5 stages of learning was used [14]. The full description of the 5 stages implementation on eBug could be found in [15]. The player explores a crime scene narrative, interviewing characters and finding evidence that illuminates their understanding of microbes, hygiene and antibiotics and learning the given set of LOs. The player is presented with a scene, talks to characters, collects evidence, investigates evidence in a laboratory and presents an answer to "puzzle" – the cause of infection or reason for an illness to the boss of e-Bug ("Big C" character).

Figure 7 - Big C character

There are three puzzles to solve, each testing several LOs. First puzzle is based around hand hygiene LOs, 2nd and 3rd teach appropriate use of antibiotics and the issue of antibiotic resistance. For better illustration of the PBL concept we present an example from the first puzzle. A famous actor gets sick by infection transmitted as a result of poor hygiene at a bathroom but poisoning food and insufficient hygiene in the kitchen must be eliminated by collecting and testing evidence samples. Figure 8 illustrates so called "micro-vision" feature allowing users to see microbes on the scene, collect samples and test them.

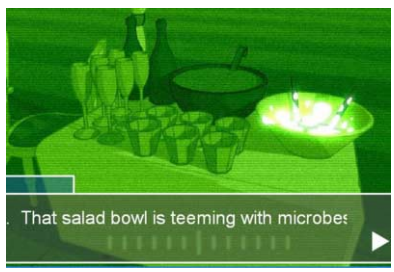

Figure 8 - Microvision of the barbecue scene – microbes visible in the salad bowl

The evidence is being collected into a PDA-like device, tested and hypothesis about the cause of the infection either proved or disproved. These are testing the learning objectives in a seamless way throughout the game while at the end of the game user reports to the Big C summarizing the findings.

Evaluation and Results

The game is complete and an evaluation has taken place with 346 pupils. Evidence for knowledge and attitude change has been collected through an online pre and post game questionnaire. Qualitative feedback has also been collected through focus groups and an open ended questionnaire. The results demonstrated a statistically significant knowledge improvement in puzzle 2 and 3 (puzzle 1 was found too complicated by children). Over 55% children would play the game again. The full results set will be presented at the conference.

Implementation and International Dimension

E-Bug is implemented in Flash 6 and supports all common browsers (IE6, IE7 and Firefox). The multi-lingual e-Bug web site is hosted at IBM Lotus Domino 6 web server and provides full access to the complementary pack sections for both junior and senior schools. E-Bug involves 17 European countries; 10 of those are currently translating the pack and the games and will be implementing the resources in their school systems. These include, UK, Denmark, Czech Republic, France, Poland, Italy, Portugal, Spain, Belgium and Greece.

Monthly web server logs evaluation demonstrates that the user base is steadily growing[1]. In particular, the importance of the resource was highlighted around the peak of the wine flu epi-

[1] http://www.e-bug.eu/ebug_secret.nsf/England-Project-General/eng_eng_p_wp_gn_stats

demics in April-May 2009 when the number of visitors quadrupled, as illustrated in Figure 9.

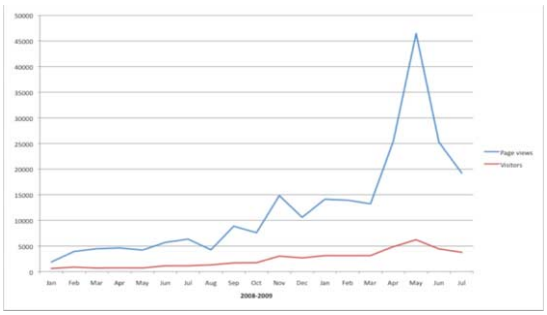

Figure 9 – Traffic on e-Bug web site

International interest in e-Bug is growing. The ease and cost-effectiveness of translation of the games to other languages and localisation to serve as education tools for children in other countries could help to bridge the financial divide and assist in effective and playful healthcare education in less-wealthy countries like Uganda where we received interest in a partnership with local NGOs. Technology transfer of e-Bug games engines can allow successful hosting of any similar kind of platform and puzzle games from any medical or other domains.

Conclusions

e-Bug project a unique example of hygiene and AMR intervention aimed at children implemented and evaluated across Europe. In this paper we described the development and evaluation of e-Bug web games complementing an educational pack aiming to teach junior and senior children basic principles of hand and respiratory hygiene and antibiotic resistance e-Bug games were translated to 9 European languages, after being developed in the UK. Games evaluation investigating players' knowledge gain demonstrated effectiveness of teaching given LOs through the game mechanics for both age groups. International user base is steadily growing and the support to non-UK users, in particular from other EU countries, ECDC, WHO as well as from developing countries.

Acknowledgments

We acknowledge DG SANCO for providing funding for this EU project and all partners who contributed to the development or the pack and games (http://www.e-bug.eu/ebug.nsf/Home?OpenPage). We also acknowledge all schools taking part in evaluation and children playing first versions of the games. We also acknowledge an invaluable input from the e-Bug artists: Nancy Lai and Sandy Beveridge.

Ambulatory Orthopaedic Surgery Patients Knowledge with Internet-Based Education

Katja Heikkinen[a], Sanna Salanterä[b], Helena Leino-Kilpi[b]

[a] *University of Turku, Department of Nursing, Turku, Finland*
[b] *University of Turku, Department of Nursing and South-Western Hospital District of Finland, Turku, Finland*

Abstract

There is a growing need for patient education and evaluation of the outcomes of it. The aim of this study was to compare the ambulatory orthopaedic surgery patients' knowledge with Internet-based education and face to face education with a nurse. The following hypothesis was set: Internet-based patient education (experiment) is as effective as face to face education with a nurse (control) in increasing patients' level of knowledge and sufficiency of knowledge. In addition the correlations of demographic variables were tested. The patients were randomised to either the experiment (n=72) or to a control group (n=75). Empirical data were collected with two instruments. Patients in both groups showed improvement in their knowledge during their care. Patients in experiment group improved their knowledge level significantly more in total than those patients in control group. There were no differences in patients' sufficiency of knowledge between the groups. Knowledge was correlated especially with patients' age, gender and earlier ambulatory surgery. As a conclusion, with the Internet-based education could achieve positive results on patients' knowledge. Internet is usable method in ambulatory care.

Keywords:

Patient education, Internet, Outcome assessment

Introduction

There is growing interest on the effectiveness of patient education with Internet. Internet interventions is a concept that encompasses various types of web programs, including behaviorally-based and empirically validated web-based treatment programs as well as patient education sites [1]. There is evidence of the effectiveness of the Internet –based education on patients' health-related behavior [2, 3]. In addition there are reviews about Internet –based education effects on patients' knowledge [3-11]. However, there is scarcity of studies made with surgery patients and especially with ambulatory surgery patients.

In this study wanted to focus on Internet-based intervention studies with ambulatory orthopaedic surgery. This limitation was made because patient education with ambulatory orthopaedic surgery patients is a different than for example long term care patients. The content of education and the knowledge differs with different patients. Ambulatory orthopaedic surgery patients are usually young and health patients. They need a lot of knowledge about their care and they have to handle quite independently in their care. There are some studies about the use of Internet in patients education with ambulatory orthopaedic surgery patients [12,13]. Hering et al. [13] studied the impact of a website on patient knowledge with a randomized controlled trial (n = 164) with a control intervention of nurse based-education (standardized verbal instructions). They found that, the use of a website was more effective in improving patients' knowledge of anaesthesia. However there is no research about the effect of demographic variables on patients' knowledge.

The aim of this study was to compare the ambulatory orthopaedic surgery patients' knowledge with Internet-based education (experiment) and face to face education with a nurse (control). The following hypothesis was set: Internet-based patient education (experiment) is as effective as face to face education with a nurse (control) in increasing patients' level of knowledge and sufficiency of knowledge. In addition the correlations of demographic variables were tested.

Materials and Methods

Study design

Study design was a randomised controlled study. This clinical trial has not been registered, since at the time when we started we did not have a trial register in Finland for this kind of studies. All ambulatory orthopaedic surgery patients (n=173) in one of the five university hospitals in Finland, between July 2005 and September 2006, were eligible for inclusion in this study. The final response rate was 86% (149/173). Patients fulfilling the inclusion criteria got an invitation to participate in our study via a letter of invitation they received for the ambulatory surgery operation. At the same time, they got the first instrument (baseline). The inclusion criteria were that a patient needed to be over 18 years of age, Finnish-speaking, have access to the Internet at home and the capability to use it, have no cognitive disabilities, and have the capability of completing the instruments and informed consent. The exclusion criteria were an ASA-classification over II (ASA). (Figure 1.)

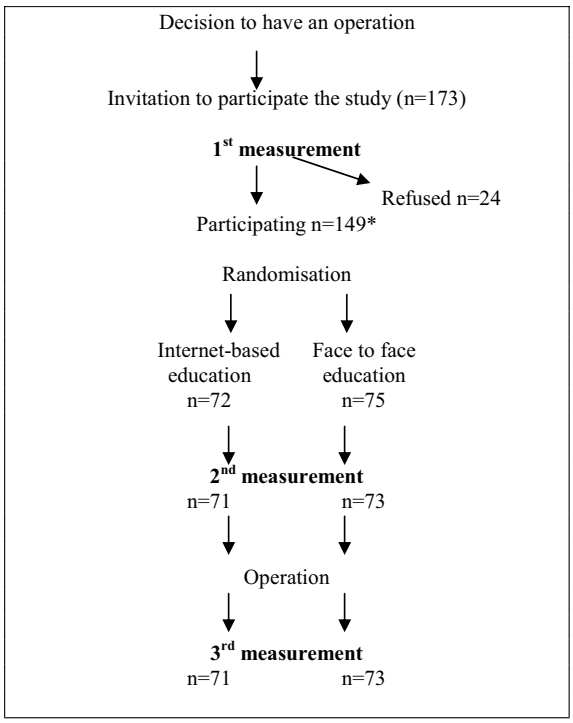

*Figure 1- Study design and flow of patients; *two patients of these were randomised to control group, but they were excluded from the study because they did not come to patient education*

Randomisation and stratification

The patients were randomly assigned (based on: gender, age, and the location of the operation) to either the experiment group (n=72) that received patient education through Internet-based education or to a control group receiving oral education by nurses (n=77). Two patients in the control group were excluded from the study because they did not come to the patient education sessions. Neither the patients nor the study coordinator were aware of the educational assignment until after everyone had been randomly assigned to their groups.

Patients in the experiment group participated in the Internet-based patient education designed for this study. The educational programme was structured based on six areas of knowledge: bio-physiological, functional, experiential, ethical, social and financial [14, 15], which are defined as being important in the cognitive empowerment process [16]. The website consisted of knowledge about nine topics on surgery (i.e. instructions for preparing for the operation, the schedule of events on the operation day, follow-up care, financial aspects, and frequently asked questions by patients). Patients visited the website 1–121 days (mean=14, SD 19.1) before the operation. Patients were asked about their usage and the application time on the website. Patients used the website four to six times (mean 2.3). The application time for the website ranged from 10-300 minutes (mean=81, SD 66.7).

Patients in the control group participated individually in face-to-face patient education with a nurse (in total eight nurses) in a separate room in the ambulatory surgery unit. The theoretical base for the patient education with a nurse is the same as the Internet-based education. Patients were given a leaflet about the content of the session. Nurses were trained for this study and they knew the content of the website (Internet–based education) and they had the printed version of the website available. The face-to-face education session took place on average 9 days before the operation (range 1–55 days, s.d. 7.1) and lasted on average 22 min (range 10–40 min, s.d. 7.0).

Instruments and data collection

The data were collected using two structured instruments: the Knowledge Test (KT) and the Sufficiency of Knowledge (SoK). These two instruments were used before the preoperative education session (baseline), after preoperative education (2nd measurement) and two weeks after the operation (3rd measurement).

KT has 27 items and six subscales: the bio-physiological (8 items; e.g. knowledge about symptoms, treatment, complications), functional (4; e.g. mobility, rest, nutrition, body hygiene), experiential (3; e.g. emotions, hospital experiences), ethical (5; e.g. rights, duties, participation in decision-making, confidentiality), social (3; e.g. families, other patients, patient unions) and financial (4; e.g. costs, financial benefits) dimensions of knowledge. The KT-instrument has a three point scale: correct, incorrect and do not know. The patients were asked, for example, if it is correct or incorrect that they can eat before the operation that they can drive home after operation or that they can see all their care documents. The proportion of the patients' correct answers in each dimension and in total was calculated. The respondent received a score in each dimension and in total calculated by adding the correct answers (max 27) and calculating the mean. For example, the bio-physiological dimension consisted of eight items, so the correct answers were proportioned to eight items. Thus the maximum score was 1 (correct answer) and the minimum was zero (incorrect or do not know answer) in all dimensions and in total.

The SoK has 32-items (plus 13 sub items =45 in total). It includes the same six subscales as "KT": bio-physiological (7items + 13 sub items), functional (7 items), experiential (3 items), ethical (9 items), social (2 items) and financial (4 items). The patients were asked, for example, if the patients had enough knowledge about pain, symptoms and costs of care. The SoK has a four-point scale (1 = strongly disagree to 4 = strongly agree), with a higher score indicating higher levels of sufficiency of knowledge. The SoK was constructed on six dimensions of knowledge by calculating the means for the sum variables. The sum variable was accepted if the patient had answered at least 50% of the items. The total indexes of sufficiency of knowledge were calculated by using the means of the six sum variables.

The following demographic characteristics were asked from the patients at baseline: gender, age, basic and vocational education, and the amount of ambulatory surgery operations.

Statistical analysis

The data were analyzed statistically using SPSS for Windows (version 16.0). Results are shown in frequencies, percentages, means and standard deviations. The Pearson Chi-Square test was used for the comparison of the sample demographic characteristics between the groups.

The effect of sociodemographic variables (age, gender, basic education, professional education and earlier ambulatory surgery) from the pre- to postoperative phases on knowledge level and sufficiency of knowledge was tested using one way analysis of variance.

Ethical considerations

Ethical approval for the study was obtained from the ethical research committee of the hospital district. Patients were informed and they agreed to participate in the study on a voluntary basis and gave written informed consent.

Results

Demographic variables

A total of 147 (=n) ambulatory orthopaedic surgery patients were enrolled: 72 in the experiment group and 75 in the control group. There was no statistically significant differences between the groups in the demographic variables (p = 0.189-0.976). The average age of participants in the Internet –based education group was 44.2 years (range 18-69, SD = 12.73) and 43.5 years (range 18-67, SD = 12.74) in the face to face education group. (Table 1)

Table 1- Patients' demographic variables

Variables	Experiment group (n=72)	Control group (n=75)
Gender		
*male	46	44
*female	54	56

Results

Knowledge level and sufficiency of knowledge

Patients in both groups showed improvement in their knowledge during their care (Table 2). Patients who received Internet-based education improved their knowledge level significantly more (p = 0.033) than those patients who underwent face to face education with a nurse. There were no differences in patients' sufficiency of knowledge (p>0.05) between the experiment and control group.

Table 2-Patients knowledge level and sufficiency of knowledge in three different phases of care (A=experiment group; B=control group)

Knowledge	Before education mean A/B	After education mean A/B	Two weeks after operation mean A/B
Knowledge level	0.48 / 0.48	0.63 / 0.57	0.65 / 0.62
Sufficiency of knowledge	2.73 / 2.73	3.29 / 3.05	3.40 / 3.22

Relationship between knowledge level and sufficiency of knowledge and demographic variables

Knowledge level was related to the patients' professional education in the experiment group. After education patients who had no professional education evaluated their knowledge level lower (0.53) than those who had secondary (0.59) or upper secondary (0.66) or polytechnic or university (0.70) education. The age, gender, basic education and earlier ambulatory surgery were not related to the patient's knowledge level

In the control group age and earlier ambulatory surgery experience were related to patients' knowledge level. Two weeks after operation youngest (18-34 years old) experienced their knowledge level lower than the older ones (0.53-0.63). Knowledge level was related to the patients' experience of earlier ambulatory surgery in the control group. Patients' who had had earlier ambulatory surgery, experienced higher knowledge level than those who had not (0.55-0.39) before education, (0.62-051) after education before operation and two weeks after operation (0.66-0.56). The gender, or basic and professional education were not related to knowledge **level** in the control group. (Table 3)

Table 3- The relationship between patients knowledge level and demographic variables (A=experiment group; B=control group)

Object	Before education A/B	After education A/B	Two weeks after operation A/B
Age	0.080/0.172	0.570/0.157	0.927/**0.028**
Gender	0.643/0.374	0.654/0.079	0.079/0.500
Basic education	0.902/0.668	0.155/0.786	0.574/0.764
Professional education	0.472/0.612	**0.007**/0.865	0.130/0.641
Earlier ambulatory surgery	0.116/**0.001**	0.953/**0.002**	0.919/**0.006**

Sufficiency of knowledge was related to the patients' age, gender and earlier ambulatory surgery experience in the experiment group. Before education youngest (18-34 years old) experienced their sufficiency of knowledge lower than the older one (2.43-2.90). Women's sufficiency of knowledge was higher than men's after education (3.39-3.03) and two weeks postoperatively (3.53-3.28). In addition before education the patients who had had earlier ambulatory surgery experienced their sufficiency of knowledge higher than those who had not had (2.90-2.50).

In the control group patients' sufficiency of knowledge was related to the patients' earlier ambulatory surgery experience. Two weeks after operation patients who have had earlier ambulatory surgery experienced their sufficiency of knowledge higher than those who have not had (3.34-3.07). The other demographic variables did not differ significantly. (Table 4)

Table 4-The relationship between patients sufficiency of knowledge and demographic variables (A=experiment group; B=control group)

Object	Before education A/B	After education A/B	Two weeks after operation A/B
Age	**0.045**/0.399	0.293/0.369	0.118/0.711
Gender	0.566/0.296	**0.001**/0.806	**0.010**/0.694
Basic education	0.914/0.829	0.728/0.331	0.368/0.432
Professional education	0.974/0.815	0.371/0.943	0.272/0.868
Earlier ambulatory surgery	**0.006**/0.117	0.961/0.074	0.938/**0.030**

Discussion

We hypothesized that Internet-based patient education (experiment) is as effective as face to face education with a nurse (control) in increasing patients' level of knowledge and sufficiency of knowledge. In addition the correlations of demographic variables, level of knowledge and sufficiency of knowledge were tested. The hypothesis was confirmed Patients having Internet –based education had higher knowledge levels than patients receiving face-to face education with a nurse. However there were no differences between educations in patients' experience of sufficiency of knowledge. In addition some correlations between patients' knowledge and demographic variables were found.

There are only a few earlier studies about the cognitive outcomes of Internet –based education [3-11]. This is surprising because it is known that the use of Internet is growing and more and more people are also searching the knowledge from the Internet for their health problems. According to this thus [see also 13] the Internet is usable method in patients' education.

Patients' demographic variables were slightly related with patients' knowledge. However the related variables were different in experiment and control group. It seems that in the experiment group patients who had no professional education experienced their knowledge level lower than those who had. This difference was not significant in the control group. It might be that the more educated patients are also more used to use the internet. In the control group the youngest patients experienced their knowledge level lower than the older ones (two weeks after operation). The earlier ambulatory surgery experience was related to the patients' knowledge level in the control group in all phases of care. There were not similar differences in the knowledge level of the experiment group. It seems that face to face education can not improve patients' knowledge level equally if the patient has had earlier ambulatory surgery. Could it be that nurse assumes too much about the patients' knowledge level and the content of the education is not sufficient. This problem is avoided in the internet education since the content of education is the same for all.

Patients' sufficiency of knowledge was related to the patients' age, gender and earlier ambulatory surgery experience in the experiment group. Internet-based education improved especially the sufficiency of knowledge of the youngest patients' and patients with no earlier ambulatory surgery experience. These patients might also benefit most from Internet –based education. In addition sufficiency of knowledge was highest among women after the education in the experiment group. In the control group, only earlier ambulatory surgery experience was related to the patients' higher sufficiency of knowledge two weeks after surgery.

Conclusion

Internet–based education could be used with the ambulatory orthopaedic surgery patients. Internet is a successful method in

patients' education and it improved patients' knowledge even more than face to face education.

The relation of patients' demographic variables on patients' knowledge varied. It seems that Internet is a successful method especially with young people, women and patients with no earlier ambulatory surgery experience. Face to face education could not improve patients' knowledge level equally, well if the patient had had a previous ambulatory surgery. This issue calls further research.

Acknowledgments

This study was supported by the South-Western Hospital District of Finland.

An open repositories network development for medical teaching resources

Gérard Soula[a], Stefan Darmoni[b], Pierre Le Beux[c], Jean Marie Renard[d], Badisse Dahamna[b], Marius Fieschi[a]

Abstract

The lack of interoperability between repositories of heterogeneous and geographically widespread data is an obstacle to the diffusion, sharing and reutilization of those data. We present the development of an open repositories network taking into account both the syntactic and semantic interoperability of the different repositories and based on international standards in this field. The network is used by the medical community in France for the diffusion and sharing of digital teaching resources. The syntactic interoperability of the repositories is managed using the OAI-PMH protocol for the exchange of metadata describing the resources. Semantic interoperability is based, on one hand, on the LOM standard for the description of resources and on MESH for the indexing of the latter and, on the other hand, on semantic interoperability management designed to optimize compliance with standards and the quality of the metadata.

Keywords:

Open Access, Open Archives Initiative, Open repositories, Interoperability, Metadata, Teaching resource.

Introduction

In view of the quality and cost of production of digital resources, reuse of digital resources is a major issue for producers wishing to enhance their digital heritage and for the bodies of players wishing to share them. Reuse of digital resources runs up against two major difficulties: the geographical dispersion of the data and their heterogeneity.

The open repositories approach offers some elements of response. The approach is based on two complementary initiatives:

- The Open Access (OA) initiative,
- The Open Archives Initiative (OAI).

The Open Access initiative [1] is at once a commitment to a principle, to a strategy and to a financial involvement which has laid down the rules of free access to the resources.

The Open Archive Initiative [2] has specified an interoperability technique for heterogeneous and widespread repositories. This technique defines the modes of exchange of the metadata files describing the resources. It thus deals exclusively with aspects of syntactic interoperability. On the other hand, it does not manage the semantic interoperability of the metadata and the added value services related to these metadata.

The techniques formulated by the OAI have been widely used in numerous projects [3]. However, the setting up of open repositories involves more than technology alone [4] and the research performed into the role, design and management of digital libraries falls within in the scope of this problem.

Research has evolved from a narrower view emphasizing enabling technology to one that encompasses the social, behavioral and economic context in which digital libraries are used. As suggested by Borgman [5], digital libraries should be much more than search engine portals. Search and access over a set of resources, while important to any digital library, are not sufficient. Digital libraries should provide advanced services that facilitate use of resources by their target community.

Lagoze [6] proposed that this added value consists of establishing context around those resources, enriching them with new information and relationships that express the usage patterns and knowledge of the library community. The digital library becomes a context for information collaboration and accumulation and much more than just a place to find information and access it.

Digital libraries are not static and require management and long-term evaluations to determine their quality and to identify new directions for growth. Zuccala's approach [7] is to carry out evaluation using a set of qualitative and quantitative research techniques, including webometric analyses and an online survey of repository users.

This paper describes the process we used to develop an open repositories network for the diffusion and sharing of digital teaching resources created by teachers at French-language Schools of Medicine.

The architecture and management of the open repositories network are described with emphasis on syntactic and semantic interoperability. The main results are presented and the benefits and limits of the system are discussed.

Objectives

The widespread adoption of digital technology in universities and, in France, an incentives policy adopted by the Ministry of Higher Education and Research has triggered a considerable increase in the number of teaching resources. These resources are easy to consult via digital workspaces located in universities. However, availability at national and international level raises frequent problems in the absence of interoperability between the different systems

In the medical field, the CISMeF team [8] set up a centralized system for the inventory and indexing of, and access to teaching resources in French.

This efficacious system is nevertheless faced with two constraints:

- It is based upon centralized indexing which takes no account of the ever greater autonomy of the different institutions regarding indexing,
- It uses proprietary standards and technologies which greatly hinder interoperability.

With the support of the UMVF, the French Virtual Medical University [9], we have been led to rethink the overall referencing, indexing and accessing model.

Our project is focussed on the creation of an open repositories network designed to enhance the visibility, accessibility and sharing of the teaching resources produced by medical faculty.

This new model takes account of the pooling of documents produced by different institutions while avoiding centralization of the indexing system.

The orientation of the project towards an Open Access approach has led us to define a number of priority objectives:

- Establishment of a network of interoperable repositories,
- Compliance with international standards in order to ensure syntactic and semantic interoperability between the different repositories,
- Strong management, at national level, in order to optimize compliance with semantic interoperability.

The open repositories network

The metadata providers and service providers-based architecture

The architecture of the environment (Figure 1) is based on a set of shared protocols and interoperability standards aimed, firstly, at using shared metadata to describe the resources and, secondly, to allow exchange of these metadata.

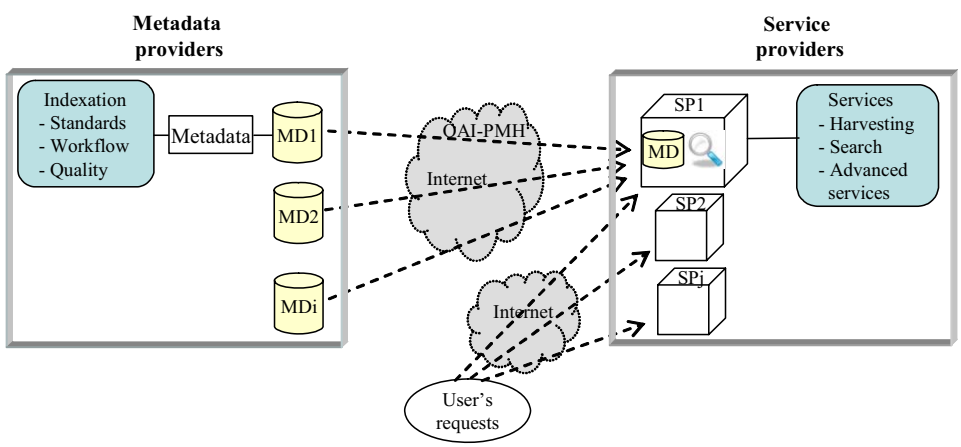

Figure 1 - Open repositories network architecture

The urbanization of this system calls on two types of players:

- The metadata providers who expose metadata passively in standardized repositories and which can be queried by service providers,
- The service providers who first harvest metadata actively by querying the metadata providers before providing services using these metadata.

Any structure can serve as a metadata provider or a service provider, or both simultaneously.

Successful implementation of this environment centered on metadata exchanges is dependent on the syntactic and semantic interoperability of the metadata.

Syntactic metadata interoperability

Syntactic interoperability is provided by the OAI-PMH protocol (Protocol for Metadata Harvesting). OAI-PMH [10] is a simple and powerful framework for metadata harvesting. With OAI-PMH, metadata providers are never directly accessed by end-users. Service-providers harvest metadata-providers and the result is used to create services covering the content of several metadata repositories. OAI-PMH specifies the syntax of 6 query verbs (Identify, ListSets, ListMetadataFormats, ListIdentifiers, ListRecords, GetRecord) used for metadata harvesting. Queries via HTTP allow recovery of metadata XML files.

Semantic metadata interoperability

The quality of the environment is conditioned upstream by the semantic interoperability of the metadata. We chose to describe the teaching resources using the LOM (Learning Object Metadata) standard proposed by the IEEE Learning Technology Standards Committee [11]. The purpose of the LOM standard is to facilitate search, evaluation, acquisition and use of learning objects, for instance, by learners or instructors or automated software processes. This multi-part standard also facilitates the sharing and exchange of learning objects, by enabling the development of catalogs and inventories while taking into account the diversity of cultural and lingual contexts in which the learning objects and their metadata are reused.

LOM defines a hierarchy of data elements for learning object metadata. At the top level of the hierarchy are nine categories: General, Lifecycle, Meta-metadata, Technical, Educational, Rights, Relation, Annotation and Classification. Each category contains sub-elements which, in turn, contain elements or sub-elements. The LOM standard includes more than 80 data elements and it was established as an extension of the Dublin Core metadata element set (15 elements) [12].

Implementations of the LOM are normally based on application profiles to meet community context-specific needs, without losing interoperability. Despite its many elements, the LOM conceptual data schema may be extended by adding new vocabularies and by adding new elements. We used this possibility and, to meet the specific needs of medical teaching resources, we defined an LOM application profile integrating the MeSH thesaurus. Each medical teaching resource is indexed in MeSH using the Describer/Qualifier/Major-Minor triplet. We used the classification category for the MeSH extension. Figure 2 is an example of an LOM XML MeSH integration.

    </lom:string>
   </lom:entry>
  </lom:taxon>
</lom:taxonPath>
```

Figure 2 – Example of LOM MeSH integration

Adoption of a standard such as LOM is an essential, but insufficient, precondition. To achieve optimum metadata quality, it is vital that all players share the same understanding of the semantics of the items in the LOM and use the same vocabularies. In France, the SupLOMFR group, set up by the Ministry, is the reference providing guidance in the use of the LOM. The number of items defined in the LOM standard is very large and SupLOMFR specifies whether LOM data elements are optional, recommended or obligatory. SupLOMFR also:

- Provides information on how elements are interpreted in the French teaching context,
- Specifies the use of vocabularies and of taxonomies,
- Specifies the classification schemes.

SupLOMFR is making a major contribution to the management of semantic interoperability.

Services

The function of the service providers is to trigger relevant harvesting of metadata, i.e. to target metadata providers according to the profile of potential users. Each service provider offers users a search engine to exploit the harvested metadata.

Results

Technical implementation

Under the aegis of the Ministry, the French ORI-OAI [13] consortium is assisting in the technical deployment of the open repositories network by integrating open source tools (Orbeon form builder, OSWorkflow, LIUS, Nuxeo). Seven packaged modules are available: document storage, OAI repository, OAI harvester, workflow manager, vocabulary manager, indexing engine and search engine. These modules dialogue with one another using web services. Each module is highly configurable to meet specific contexts.

Metadata production workflow

Good quality metadata are a key component in the successful implementation of an open repositories network. The need for good quality metadata must be fully understood by the community.

A solely teacher-generated metadata model has many limitations. Teachers may lack knowledge of indexing principles and are more likely to generate insufficient and poor quality metadata. Both teachers and metadata specialists play important roles in the metadata production process. This collaborative approach needs to specify the metadata production workflow.

Metadata creation should be identified as an incremental process and as a shared responsibility. This responsibility should be distributed in a practical and reasonable way within the institution. The creation and refinement of a workflow is dependent on operational and strategic factors. Several more or less complex workflows can be established. The main difference between workflow models is in the number and the roles of the players involved in the process.

A four-level workflow model including the teacher, information and communication technology specialist, librarian and legal department seems to fit the French university context. Each player produces metadata in his/her area of competence. This workflow can be represented using a state transition diagram as in Figure 3.

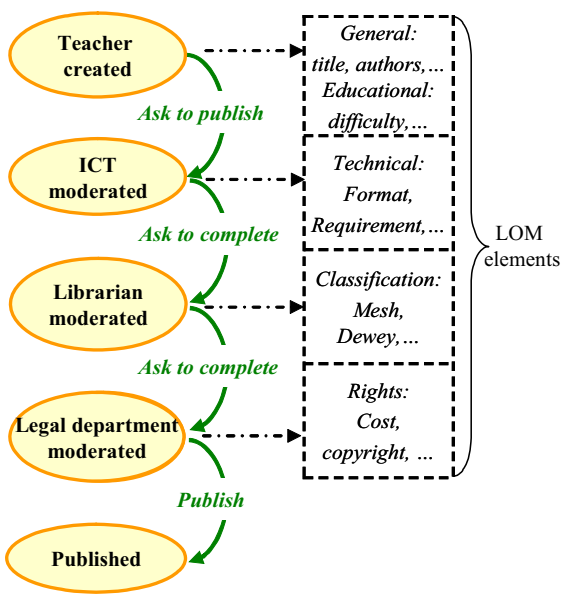

Figure 3 - A four level workflow model

Metadata creation comprises five successive states from the teacher-created state to the published state. The Metadata creation workflow starts with a teacher initiative in which general elements are produced. ICT and librarian complete the metadata. The Metadata creation workflow ends with a legal department decision after validation of the rights aspects.

Operational providers

Today, the network is based on several operational metadata providers and service providers.

During the last quarter of 2008, 4200 resources indexed by CISMef and 2000 resources indexed by Canal U, the French Higher Education and Research Web TV channel, were integrated into the first repositories.

To allow integration of the CISMeF 4200 teaching resources in the ORI-OAI repository, the CISMeF team developed a mapping function to restructure the original XML files according to the LOM metadata schema. CISMeF information about indexations (MeSH keywords, MeSH qualifiers and CISMeF resources types) and CISMeF metaterms for categorization are mapped to LOM metadata elements. The transformation from one metadata schema to another is ensured by XSLT processing. Figure 4 shows an example of mapping.

In 2009, other universities (Aix-Marseille, Paris, Rennes,…) joined the project. The CISMeF ORI-OAI repository will now receive an additional 4000 teaching resources.

An overall picture, at national level, of the network deployment covering all the themes, is provided by the French thematic digital universities portal [14]. The 12300 resources listed in July 2009 reflect the deployment status of the two themes involving medicine (4200) and science and techniques (8100). All the other themes (law, economy,…) will gradually be added to the network.

Discussion

The choice of the open repositories approach for the diffusion and sharing of medical teaching resources has provided us with elements of response towards a solution of the heterogeneity issue.

The OAI-PMH protocol has enabled us to achieve complete control of syntactic interoperability. On the other hand, semantic interoperability is more difficult to ensure. Despite the adoption of a standard such as the LOM, the players in the community are not all equally demanding regarding observance of standards and control of the quality of the metadata. The increase in the number of players and indexing facilities raises the issue of indexing quality. Improvements in quality should be attainable by defining a supervised workflow designed to harmonize indexing practices. The management of semantic interoperability is a key factor in the creation of a high quality open repositories network.

For users, one of the added values is the search engines integrated in the service providers. These search engines are often general in scope and do not take sufficient account of user profiles. This partly explains the utilization rate which fails to match the efforts devoted to the system [15]. One avenue of research is to establish connexions between the resources in order to take account of the context [16]. The OAI-ORE (Object Reuse and Exchange) [17] aims to describe and exchange compound and semantically linked objects and is working in that direction.

Conclusion

This paper described an open repositories network development for the diffusion and sharing of medical teaching resources.

Driven by the Ministry and thanks to the efforts of the ORI-OAI consortium, the open resources approach is being rolled out in France, and in all sectors, and not only in medicine.

The next steps will seek to extend the network of players, develop services which take into account user profiles and evaluate usage.

The open repositories approach can be applied to documents other than teaching resources such as theses, training curriculum, or scientific publications. The aim is thus to enhance a whole digital heritage backed by high-quality semantic interoperability management.

Acknowledgments

This work was partially funded by the French Virtual Medical University.

Using the Virtual Reality World of Second Life to Teach Nursing Faculty Simulation Management

Elizabeth Weiner, Ryan McNew, Patricia Trangenstein, Jeffry Gordon

Frist Nursing Informatics Center, Vanderbilt University School of Nursing, Nashville, TN, USA

Abstract

Healthcare faculty members have come to depend on the advantages of teaching with clinical simulation, but not all faculty are competent in their ability to manage students during the simulation experience. This federally funded proposal provided the opportunity for nursing faculty to participate in a synchronous learning event using the virtual reality world of Second Life (SL). Based on competencies, faculty participants were guided through the simulation process by a "Master Teacher." Participants then became the teacher and chose the settings, objectives, and clinical data to manage their own simulation using avatar role assignments. Feedback populated the participant informatics dashboard, so that progress towards their competencies was recorded. Another unique informatics application was the use of the Synthetic Derivative project to use de-identified patient data to promote better clinical realism. Additional evaluation activities regarding content, appropriate use of the technology, and design features were assessed. The development of the SL environment for this educational study provides the setting in which to pilot test the provision of actual clinical care that does not require "hands-on" interventions.

Keywords:

Computer simulation, User-computer interface, Nursing education, Nursing faculty.

Introduction

Despite the fact that the US is beginning a documented nursing shortage, nursing schools across the nation turned away an unprecedented 49,948 qualified applicants to baccalaureate and graduate programs primarily due to insufficient numbers of faculty [1]. For the faculty members who remain, they must be able to rely on efficient teaching strategies that promote more independent student learning and critical thinking. For those nurses who are preparing for faculty roles, they must be able to select appropriate teaching strategies for the goals they wish to accomplish. Both groups must become competent and confident in their abilities to use technology in order to impart these skills into the learning of today's students.

Clinical simulations have the potential to provide such solutions, but only if nursing faculty are competent in simulation management. As part of a Robert Wood Johnson Partners Investing in Nursing's Future Grant, the Tennessee researchers surveyed nursing programs across the state. Results revealed that although 100% have some sort of simulation equipment, 74% state they are not using simulation at 100% of capacity. The reason cited for not using simulation technology by 72% of the respondents was a lack of trained faculty.

The virtual reality world of Second Life (SL) provides an environment that allows users from around the world to "log on" to this web-based platform. Second Life is a 3D virtual world, created by its residents. The world is driven by the interactions of real-world individuals and their "inworld" residents or "avatars" [2]. Thus, for every avatar one encounters in SL, there is a live person somewhere in the world who is dictating that avatar's actions, emotions, words, dress, etc. SL provides the place for interactions with people, businesses, and organizations in a 3D environment but requires only an Internet connection and working computer rather than extensive travel arrangements. Hansen notes that the major strengths of virtual worlds are one's ability to design and construct unique environments and then share them with others in a collaborative fashion [3]. A pilot postgraduate medical education program was delivered in SL. All participants (12 of 12) agreed that this experience was an effective method of medical education, that the virtual world was superior to other methods of online continuing medical education, and that they would enroll again as well as recommend this format to others [4].

The purpose of this project was to provide a computer application for nursing faculty that would allow them the opportunity to manage clinical simulations while advancing in their own competency and proficiency levels of simulation management. The virtual world of SL was chosen for the delivery of the geriatric cases because it could be used as an educational meeting place that requires no travel arrangements. Although the educational session took place in a synchronous fashion similar to a face-to-face meeting, it required much more effort to build the virtual environment according to user needs. In addition, planning was also necessary to design the learner experience. A unique complication of our development efforts was the fact that the learners were also faculty members. Their purpose in attending the event was to learn to provide the appropriate faculty guidance in simulation rather than to learn the details of the simulation itself. Prior to attending the learn-

ing session, participants were required to complete an orientation session to SL that has been specifically designed for our use. Competencies provided the structure for both the orientation and educational simulation sessions and were presented graphically using a color-coded dashboard.

Materials and Methods

Competency Development

Most faculty required orientation activities to the SL platform. One of the negative implications of using the SL platform is that most users start their experience on "Orientation Island." Many times there are other avatars on the Orientation Island who are predators and are there only to harass new users either verbally or through the use of nudity or sexual innuendos. It was possible to bypass this island by providing participants with the specific island location for the intended education session via a SLURL (Second Life Universal Resource Locator). In doing so, however, participants do not learn how to manipulate their avatars. As a result, orientation activities specific to this project were required.

Video sessions and one-on-one orientation sessions ensured that all participants reached pre-determined competency levels in this environment. Competencies included the following:

1. *Getting Started Tasks* (setting up an account in SL, selecting a name and password; installing the SL client; creating an avatar, alter appearance, alter clothing; learning how to walk, run, fly, land, sit, turn around, teleport, alter your viewpoint, use gestures; learning how to use the various maps; bringing up chat bar, chat window; acquiring and managing inventory);

2. *Intermediate Tasks* (using search tool; adding a "friend"; instant message a friend; going to a SL URL; selecting and configuring of headset; bringing up and using audio chat; acquiring and spending Linden dollars; uploading and playing a PowerPoint presentation); and

3. *Social Tasks* (awareness of how to teach and learn within this environment; how to identify and report abuse; how to document care in this environment; how to get technical help).

Competencies for faculty in simulation management do not currently exist and thus had to be developed by the project faculty. Rather than an extensive Delphi technique with content experts that takes valuable time, project faculty drafted proposed competencies and received feedback from two consultants recognized for their international expertise in nursing simulation development. [1] Informal focus groups were then conducted using members of the International Nursing Association for Clinical Simulation and Learning (INACSL). Although it is not within the scope of this paper to list every developed competency, general categories for the nurse educator were as follows: plans simulations, participates in simulations, provides debriefing and reflection, and evaluates simulation. In addition, competencies for the simulation coordinator/specialist were developed (although not used for our SL experience).

[1] Consultants were Dr. Pamela Jeffries and Dr. Sharon Decker

Informatics can be applied to the competency process with the development of visual dashboards that illustrate at a glance the progress users have made in meeting the identified competencies. The use of dashboards in the clinical setting has been validated as an effective measure of quality improvement in Vanderbilt's fight against ventilator acquired pneumonia [5]. With the use of dashboards designed by evidence-based care parameters, the number of ventilator acquired pneumonia cases dropped from over 300 a year to 140 a year. The impact of this project was prevention of 16 deaths per year, more than $4 million in savings per year, more than 100 hospital days per year avoided and more than 400 ICU days per year avoided. The project illustrated the behavioral implications of visually seeing progress in the clinical domain, and the SL project team sought to replicate this positive behavior in their project environment.

Second Life Development

The first priority for beginning the development in SL was the leasing of the island itself. In order to do this, the project team had to determine a name for the island. Because this project is a collaboration between the Vanderbilt University School of Nursing and the University of Kentucky College of Nursing, it was determined that the name of the island should not reflect either institution. Instead, the name "NURSIM4U" was chosen and a welcome sign was designed that contained the logos from both institutions (see Figure 1 below).

Figure 1 – Welcome to Conference Center

Because the team wanted to provide nursing participants with a variety of choices, it was determined that there would be an outpatient facility, a nursing home facility, an acute care facility, and a variety of homes on the island. A conference center was planned for the center of the island, and would be the place in which all participants would start after entering the NURSIM4U SLURL. All of these locations were mapped onto a graph of the island to determine both size and location of the buildings. It was also determined that two new facilities (outpatient diabetes clinic and acute care critical bed tower) would be replicated in the SL environment, allowing for the use of existing plans to dictate the room dimensions and layouts.

Simulation Development and Populating the Electronic Medical Record

Content experts were faced with the challenge of ensuring that the clinical data they used for simulated patients resembled reality. After determining the types of patients to be included in the case scenarios, clinical data were accessed using the unique database at Vanderbilt University called the Synthetic Derivative (SD). The Synthetic Derivative is a database containing clinical information derived from Vanderbilt's electronic medical record, labeled with a unique research ID, and stripped of personal identifiers [6]. Thus, the SD is a set of records that is no longer linked to the identified medical record from which it is derived and has been altered to the point that it no longer closely resembles the original record. The SD interface allows the user to search data extracted from most of the major health information databases at Vanderbilt. The database contains records for over 1.7 million unique individuals. The search interface allows the user to input basic clinical and demographic information, such as ICD9 codes, medication, lab values, age and gender and returns de-identified data to the user for review and selection.

Use of the SD requires approval from the Institutional Review Board as well as completion of a data request form by the SD administrators. Both approvals were received by the project investigators so that the clinical simulation cases could be population with realistic data values that had actually been demonstrated by an individual at some point in time.

Several simulation design issues surfaced during scripting. How much of the simulation should be scripted versus depending on knowledgeable participants who were assigned roles with descriptive parameters for behaviors? How much choice should faculty participants have in the selection of singular objectives versus groups of objectives? How do you teach faculty while they are also playing roles in the simulation? How do you make certain that the experience allows the "Master Teacher" to role model behavior but at the same time critique the teaching behaviors of the faculty participants? These issues were frequently discussed by the project team before final decisions were made as to how to guide the simulation experience.

Evaluation Tools

There is a need for more empirical research in order to unearth the pedagogical outcomes and advantages associated with this type of e-learning technology. The relevance of this innovation on a large scale is yet to be demonstrated and requires empirical research [7].

Many of the original evaluation tools selected for use in this study were developed by the National League for Nursing in conjunction with Laerdal who funded a national, multi-method project with the following purposes: 1) To develop and test models that nursing faculty can implement when using simulation to promote student learning, 2) To develop a cadre of nursing faculty who can use simulation in innovative ways to enhance student learning, 3) To contribute to the refinement of the body of knowledge related to the use of simulation in nursing education, and 4) To demonstrate the value of collaboration between the corporate and not-for-profit worlds [8]. The research goals were to explore how to design simulations, implement simulations as a teaching strategy, and evaluate selected learning outcomes using simulations. The study was designed with eight project coordinators and one Project Director (Jeffries).

Selected tools for this SL project included the Simulation Design Scale and the Student Satisfaction and Self-Confidence in Learning. The Simulation Design Scale, a 20-item instrument using a five-point scale, was designed to evaluate the five design features of the instructor-developed simulations used in the NLN/Laerdal study [9]. The five design features include: 1) objectives/information; 2) support; 3) problem solving; 4) feedback; and 5) fidelity. The instrument has two parts: one asks about the presence of specific features in the simulation, the other asks about the importance of those features to the learner. Content validity was established by ten content experts in simulation development and testing. The instrument's reliability was tested using Cronbach's alpha, which was found to be 0.92 for presence of features, and 0.96 for the importance of features. The second tool was the Student Satisfaction and Self-Confidence in Learning, a 13-item instrument designed to measure students' satisfaction (five items) with the simulation activity and self-confidence in learning (eight items) using a five-point scale. Reliability was tested using Cronbach's alpha satisfaction = 0.94, self-confidence = 0.87.

Additional evaluation tools designed specific to this SL project included a content evaluation tool (effectiveness of teaching/learning methods, whether program met the stated objectives, whether the content was relative to their work, whether the online environment was conducive to learning, whether the participant was able to achieve own personal objectives, whether attending the event was an appropriate use of time, and whether the participant would recommend this workshop to others). Scales ranged from A (Strongly Agree) to E (Strongly Disagree) or A (Very Effective) to E (Very Ineffective). Furthermore, an Instructor Feedback tool was designed by the project team in order for the faculty participants to receive feedback from both the "Master Teacher" and the other faculty participants.

Pilot Testing

Pilot testing is just beginning as of the writing of this paper. By the time of paper presentation, results will be available for not only the pilot testing for the first six months of the continuing education offerings for nurse educators. Nursing faculty members from both schools constituted the 20 pilot testers in five different groups.

Results

Content experts had no familiarity with the SL environment and were unsure of the potential capabilities of providing a simulation experience in this world. They continued to want to rely on video production rather than graphic representation of situations. A standardized scripting format including the "props" for the simulation was helpful in moving the project forward. Scripts were developed for each setting (outpatient,

in-patient, nursing home, and home) that included three different sets of objectives with three matching scripts. This provided the faculty participants with choices and allowed the "Master Teacher" to role model teaching behavior in one of the scripts while allowing two student teachers to guide the remaining two scripts. Practicing these scripts and providing the appropriate feedback was a crucial development activity for the project team.

Much was learned in the development of the SL environment. Using the plans of real buildings resulted in a claustrophobic effect when using an avatar to navigate. This was because of the camera angle being above the head of the avatar. Hallways and rooms were widened to accommodate this problem. Figure 2 illustrates the expanded hallways.

Figure 2 – Expansion of Hallways

In addition, once a group of avatars were clustered within one room for a simulated experience, the room became crowded and difficult for the designated caregiver to navigate. Early attempts at having the "observer" avatars either suspend themselves in the air or sit on an observation wall were dropped when it was determined that the inexperienced faculty participants had too much difficulty with these maneuvers. Assigning the observers places to stand in the rooms provided a more viable alternative, as well as enlarging the actual square footage of each room (see Figure 3).

Figure 3 – Nursing Home Room

At the current writing of this paper, the project has completed nine months of a 36 month project period. After pilot testing has been completed, it is planned to offer the simulation modules as continuing education sessions for nursing educators in the states of Kentucky and Tennessee. The final year of the project will offer the sessions as continuing education for nurses in the Southern region of the United States.

Discussion

The environment of SL is one creative solution to synchronous learning that is only beginning to be used in nursing education. A more popular application of SL has been to meet within the SL world in order to present information to one another, usually using a typical Power Point presentation. Another popular use of SL is to have information resources available for a variety of support groups. Several universities have replicated their physical campus within the SL world, and the Duke University School of Nursing has created a popular You-Tube video that demonstrates their SL use [10].

It was never the original intent for this project to build a simulated environment that could be used for both education and clinical care. Because the SL clinical environment has already been created for this educational application, it now becomes feasible to also use the facilities for the provision of actual care that does not require a "hands-on" approach. Faculty at the Vanderbilt University Schools of Nursing and Medicine are partnering to pilot test the delivery of maintenance care to diabetic patients in the outpatient environment (which is a replica of the current Eskind Diabetes Center). It is postulated that these virtual visits will require less time and expense while providing a resource rich environment for those patients willing to enter the SL world for their care

Early in the development efforts the issue of privacy was of monumental concern for the provision of patient care. Anyone on the island that was within 65 meters could hear conversations that were intended to be private between a patient and healthcare provider. In order to ensure that the audio portion of care delivery could not be overheard by others, selected patient care rooms were elevated to levels that could not be accessed by other avatars who were "flying" on the island. In other words, avatars in SL can only fly at 200 meters, but buildings can be built as high as 300 meters. Private patient interactions thus required teleporting by the healthcare providers and patients from within designated privacy protected rooms. A privacy button placed within the room required the avatars to touch the button in order to be teleported to the elevated private room which was suspended above avatar flying levels. Once the visit was completed, the privacy "off" button teleported participants back down to the original building in order to complete any post visit activities and exit the facility. A recent feature added to the SL world now allows for point-to-point discussion between two avatars so that this elevation feature is no longer necessary.

Conclusion

It is feasible to use SL as an environment for nursing faculty to learn how to manage clinical simulations. Although currently

in pilot testing, early results indicate that a "Master Teacher" can provide enough structure and coaching to provide "student teaching" experiences when a cadre of seasoned nursing faculty is not available to all. Using SL does require orientation to that environment for those learners who are not familiar with its features, but it remains a viable choice for those willing to take on the challenge. At the same time, production of various clinical facilities allows for them to be used with groups of students (nursing and interdisciplinary). Perhaps the most important contribution to this project will be the use of constructed facilities to provide an alternative choice for the provision of patient care in an era when computer usage is ever increasing.

Acknowledgments

Authors would like to acknowledge $1.6million in funding from the US Department of Health and Human Services Health Resources and Services Administration. The grant is part of their Innovative Nurse Education Technologies program. Additional thanks are provided to the grant consultants Dr. Pamela Jeffries (Johns Hopkins University) and Dr. Shelia Decker (Texas Tech University Health Sciences Center). Other members of the grant team include: Carla Beals, Stephania McNeal-Goddard, Sally Miller, Kathryn Moore, Maria Overstreet, Suzanne Prevost, and James Self.

Teaching During a Pandemic Event: Are Universities Prepared?

Jeffry Gordon, Elizabeth Weiner, Ryan McNew, Patricia Trangenstein

Frist Nursing Informatics Center, Vanderbilt University School of Nursing, Nashville, TN, USA

Abstract

As the threat of pandemic events streaks across the planet, the question then becomes can universities, particularly health science centers charged with producing the next generation of health care providers, continue their teaching and educational mission by offering classes in a distance environment, completely uncentralized, away from the traditional centralized campus? A sampling of campus websites were reviewed to gather a sense of how well prepared we are, followed up with a survey administered to faculty and staff in the School of Nursing at Vanderbilt University. The concern being that if a technology rich environment such as Vanderbilt is not fully prepared to continue teaching in a pandemic event, what concerns should we have for other institutions providing health care provider education that may not have access to the resources a Vanderbilt has? Finally, a set of recommendations to schools is presented, based on the findings.

Keywords:

Educational technology, Audiovisual aids, Multimedia, Education distance, Videoconferencing, Education nursing.

Introduction

This is an interesting time to be teaching. The threats of a pandemic event on the mission critical functions of a teaching university can be overwhelming. With the threats of pathogens and natural and man-made disasters impacting schools and businesses around the world, it is important that universities, (particularly with health care programs producing the disaster responders) be prepared to carry on their academic mission through the event. Lim et al [1] clearly describe the problems associated with closing professional schools with a healthcare orientation. While it may very well be accepted practice to close schools and give credit to students for work covered (as what happened in many institutions in the United States during the Kent State University event in 1970 [2]) it is inappropriate to extend that practice in today's world, particularly to those training to enter the field of healthcare. This means it is important that schools of nursing, medicine, dentistry, and pharmacy be prepared to continue the instructional process even while a school closure and suspension of teaching activities is happening all around them.

The question then becomes how well prepared are institutions and the faculty and staff in those institutions to continue educating during a pandemic or disaster event? If a pandemic event, perhaps caused by H1N1 swept across an institution, would that institution be able to quickly implement new teaching environments to replace the traditional face to face lecture presentations currently in place now?

Materials and Methods

A quick perusal of institutional websites around the world show that colleges and universities are giving this issue real thought. A number of institutions have posted websites outlining various features faculty should consider using in the event of an official or unofficial closing. [3-8]. For purposes here we will define an "official closing" as one in which the school administration has told students and faculty to stay home. They may dismiss students from the dormitories. Of course the problem about what to do with students who are too sick to travel home, or have no place to get to quickly is a confounding factor. But precedent for official closings does exist. Probably the most well known were the closing across the United States that took place after the Kent State University incident where national guardsman open fired upon student protest demonstrators resulting in four deaths. [2] However, that was a different situation as students, and faculty were angry, but not sick. While over 4 million university students "struck" by refusing to go to classes nationwide after the event, they could, if they so desired, continue to read, organize and meet face to face. Also at that time there were few options for continuing collective education when the students were suddenly dispersed across the country. While the current situation with regard to H1N1 may result in some official school closings, it is far more probable that we will begin to see large numbers of "unofficial school closings". For the purposes here an "unofficial school closing" is one in which the faculty member and/or large numbers of students are too sick to come to class. The university does not officially close the institution, rather people are just too sick to show up for work, either as a faculty member, staff person supporting the academic environment, or the students themselves.

As one examines this problem of continuing the educational process in the face of a pandemic event, it is clear that there are three stakeholders in this problem. Obviously there are the students themselves. While many students would briefly relish the time off, most students in professional schools recognize that this creates a direct hit on the quality of their education. There are knowledge, skills, and content they know they need to know, and simply giving students "time off" will not ac-

complish their goals. Many spend a lot of money on their tuition and they have a reasonable expectation to be taught.

The second stakeholder is the faculty member. They have defined content they know they need to get through so that the student may advance in the program. They have spent considerable time and effort refining their course syllabus and providing the right types of lectures and presentations, typically in a face to face traditional classroom environment. They have assignments that make and papers that need to be submitted for grading and evaluation. Finally, of course there is the typical sit down examination at various points in the course. Even if students are able to meet for a test, these exams would have to be completely rewritten to account for the fact that significant content may have been missing because of lost lectures. Included in this group are deans and associate deans who not only teach courses in their academic programs, they make sure the correct policy decisions are implemented and enforced. If closing decisions are made at the college level, these administrators need to have a significant presence during the entire decision making process, even if they too are home sick.

Lastly there is the academic support staff that many faculty members rely on to accomplish the more mundane tasks of collecting papers, duplicating handouts, typing exams, and providing library materials on reserve. Without these people the academic mission can grind to a halt. In addition, support staff members provide the administrative support needed to continue the infrastructure of the school such as making sure that people are paid correctly and on time, tracking work time, and paying the bills the school incurs. Finally there is the technology support staff to be concerned about. If the people maintaining the servers, software, and network become ill what happens when their efforts are needed to provide support to the faculty, staff, and students of the institution?

Reviewing the academic plans institutions are providing their people is an interesting exercise. While none reviewed made reference to any type of data collection process to see what is needed, they did, instead, focus on what their institution can provide currently for their stakeholders. Some websites were very specific, dealing with the applications and services they can provide. Others were more general and dealt with why one should use various approaches rather than the specifics of how to use a specific application.

Four assumptions seem to dominate the discussion online. First, there is the assumption that institutions "know" what is best for their stakeholders and have no need for data collection. Secondly, there is the assumption that the institutions already have in place the correct technology in terms of mission and quantity to address the problem. Third, there is the assumption that the stakeholders have the right type of technology at home to deal with any type of work from home situation (whether they are faculty, staff, administrators, or students). Finally there is the assumption that the stakeholders will be able to train themselves quickly and just in time on any technologies needed to work from home. These assumptions are very short sighted. Let us deal with each of these assumptions in sequence.

Assumption 1: Institutions know what is best for their stakeholders. The problem with this approach is that the decision makers typically are not "in the trenches" and have very little knowledge about what is really needed. These decision makers often have no teaching responsibilities and typically do not interact with faculty, support staff, and students regarding the act of teaching. While they may know in general terms, the devil really is in the details and they never have a real opportunity to learn the details from an instructional point of view.

Assumption 2: Institutions already have in place everything they need. Academic budgets are eclectic. When money is available a product or two may be acquired, but typically this happens with little planning and lots of penny pinching. Hardware and software licenses are frequently underestimated (or overestimated) with little effort to build the environment to capacity correctly. For example, at Vanderbilt University, which would be regarded as a rather typical institution using a course management system, such as Blackboard, less than half of the classes have a significant Blackboard presence. If suddenly the other 50% decided to use the course management system extensively, could it handle the sudden increase in load? Often it is one or two vocal stakeholders who decide what should be purchased and implemented, often times at cross purposes with the rest of the institution. If the products are acquired with grant monies, they may not meet the direct needs of the institution because of grant limitations. Furthermore the grant investigator gets to decide what he will spend his resources on. Finally, grants are typically not cross disciplinary. This means they acquire software specific for their situation and often mount it on servers they are directly involved with and not shared with the rest of the institution. Universities are often "silos" fostering this behavior.

Assumption 3: Stakeholders have the right technology at home. Do they and what are the consequences if they do not? Later we will report survey data at our own institution that clearly belies the opinion that even in 2009 our faculty and staff are appropriately configured at home. Failure to have the right setup at home means they cannot function as they do at work. Furthermore, as the data that follows shows, there is a strong reliance in the Vanderbilt University School of Nursing, for example, on the use of administrative assistants (secretaries) who, for a variety of reasons are less configured at home than the faculty. Finally, none of the technology does any good if the students are inadequately prepared at home.

Assumption 4: Stakeholders will train themselves in what they need to do just in time to do it. Will they? Some of this technology is complex with a significant learning curve. Most institutional websites we reviewed offered little in the way of real training, opting instead to let the users train themselves as best they can once they have identified what technology they wanted to use for their classes.

The question then becomes how well prepared is the health sciences academic area, to provide real education to our students in the event of a pandemic closure? The answer appears to be "not very." The Vanderbilt School of Nursing (VUSN) has one of the premiere informatics support areas of any school of nursing in the world. With 18 faculty and staff members in informatics, out of a total of 242 employees, with

expertise in educational informatics, software development and design, use of interactive communication tools such as web and video conferencing, and with extensive course management system experience (two of the faculty actually developed an early prototype of a CMS in the mid 1990s), VUSN is well positioned to help faculty and staff use technology extensively in their teaching. In addition, 7 of the 9 masters specialties have a significant distance education component as part of a blended program that has the students show up on campus only one or two long weekends per semester. In short, the faculty are very well versed in the tools of distance education (the exact set of tools they will use if their students cannot come in at all) and do just about everything on Blackboard including administering exams, even if the program is not a distance specialty. Therefore, it was natural to assume that the faculty and staff would be exceptionally well prepared to continue the educational mission of the school, even in the event of a pandemic closing.

A careful review of institutional websites about teaching in a pandemic situation is rather enlightening, more in what it does not say than what it does say. First of all very few institutions have program specific websites related to this issue, opting instead to have a general university approach to the problem. This "one size fits all" approach may play well in the press, but in practice, with a myriad of programs and needs it is doomed to fail many times. Most likely individual schools within a university do not have the support personal, hardware, and software to go it alone and must rely on an institutional response to succeed. Clearly some things must be institutionally based. (It makes little sense for individual colleges in a university to have their own course management systems for example) but the tools that are promoted in a specific program (even down to the specific tools and features in a course management system) must be college and program identified and supported. For example, the instructional technology needs teaching statistics in a Doctor of Nursing Practice (DNP) program are far different than the technology needs of an English Professor in an undergraduate Arts and Sciences program. A statistics professor needs presentation programs that demonstrate statistical techniques to his students, whereas the English professor needs tools to allow students to engage in more real time discussions. What universities typically do is provide a collection of tools hoping the individual faculty members will find an appropriate tool in this smorgasbord and learn how to use it, and then learn how to use it effectively, all within a very short period of time.

In order to determine where the Vanderbilt School of Nursing is, in terms of faculty and staff technology capabilities at work and at home, a brief survey asking them about their capabilities was prepared and electronically distributed through Survey Monkey. A small number reported themselves as administrator, but administrators were asked to report themselves as faculty if they do a reasonable amount of teaching during the year. The thinking here is that the focus of the effort for the relatively brief closure time needs to be the direct support of the instructional mission. Most likely software required for teaching would be a superset of software access required for administration. The survey was divided into two components. The first component was filled out by everyone and dealt with infrastructure capabilities at home. The second component dealt entirely with teaching needs. This second section was filtered by role so that only those reporting as doing a significant amount of instruction, either didactic or clinical, were asked these questions. The faculty and staff were given 10 days to complete the survey. The students were not surveyed because the students need to have the correct hardware and software, as a prerequisite for admission into the program, to function in a distance environment (even if their academic program is not a distance program). All of Vanderbilt's nursing students have contemporary PCs (including some Macintoshes) and broadband connectivity. The only area where students appear to be deficient is in the number of systems with webcams for video conferencing, but in the event of a closure, because of class size, video conferencing would probably not be used outside of the PhD program anyway, and those students already have webcams. Furthermore, the costs of webcams and their ease of use means they could quickly acquire one should the need arise. Interestingly, students rarely complain about the technology requirement. While that could be the type of student Vanderbilt attracts, more likely it is that today's students in the health professions just know that personal ownership of contemporary technology is an important component of their educational responsibilities.

Results

Based on the survey results and follow up interviews with faculty and staff the following competencies were identified but everybody does not need to know everything:
Competencies (infrastructure):

1. Installing/using Virtual Private Network
2. Creating drive mappings/transferring files
3. Using Remote desktop
4. Checking bandwidth
5. Configuring headset and/or webcam

Competencies (applications):

1. Posting documents and hyperlinks
2. Creating/administering a test
3. Using discussion board/wikis/blogs/social networking
4. Using web/video/text conferencing tools
5. Creating/posting narrations (Powerpoint/screen recordings)
6. Using assignment submission

The following tables show the response rate to the survey as well as the areas that are deficient.

Table 1 – Overall Response Level

	Faculty	**Support Staff**
Total. Number	109	78
Reporting (%)	87 (80%)	63 (81%)

Table 2 – Strengths and Deficiencies at Home

Capability at home:	Faculty	Support Staff
Computer	85 (98%)	60 (95%)
Broadband	85 (98%)	53 (84%)
VPN	25 (29%)	20 (32%)
Narrated Powerpoint	33 (38%)	N/A
Headset	33 (38%)	N/A
Other software needs	30 (34%)	N/A
Assignments in Blackboard (Bb)	66 (76%)	N/A
Post Material in Bb	59 (68%)	N/A
Test in Bb	18 (21%)	N/A

Faculty members teach extensively with Powerpoint, yet have learned to use Powerpoint to provide "talking points". Simply providing the students their slides without any audio narration to accompany the slides renders the presentation essentially useless. Currently only 38% of our faculty know how to narrate a Powerpoint presentation for posting in the course management system. Audio quality is a significant issue. Built in microphones in laptops provide a hollow sound making the narration difficult to understand. The solution is to narrate Powerpoint slides using a microphone headset, yet less than 40% of the faculty have such a device. 34% of the faculty want to show things other than Powerpoint slides, yet only two have the ability to create screen recordings and convert them into a format that can be posted in Blackboard. While 76% of the faculty know how to receive assignments from students in Blackboard, only 21% have the personal ability to create and administer an exam in Blackboard. However, since almost all the faculty use the Blackboard examination feature, how can this be explained? It turns out, upon further questioning that faculty rely heavily on administrative assistants to do this type of work for them. They provide the assistant with test, in Word format, and the assistant then puts that effort in the Blackboard utility. The implications for this are significant if the school becomes involved in a pandemic event. The question then becomes if a faculty member creates an exam or wants to post content to Blackboard, and they typically have their administrative assistant complete the effort, is the administrative assistant going to be able to work with this from home? The answer, even in a technology rich environment such as Vanderbilt University, is equivocal. While 84% of the administrative staff can reach the internet from home, that includes all 15 information technology (IT). support people as well. It appears that only 46 of the 63 true administrative assistants reporting have that capability. That means 1/3 of the support staff either do not have that ability or haven't indicated that they have that ability. Preparing for a worst case scenario requires the assumption that no response likely means they cannot do it. In short, faculty are relying on personnel who will not have the ability to do this ,from home. The problem is compounded by the fact that only 32% of the administrative assistants have true Virtual Private network (VPN) knowledge and connectivity to be able to carry out the complete academic mission from home. VPN software allows the user to access IP restricted resources on the campus. The situation regarding administrative assistants is very serious when it comes to broadband connectivilty. Only 84% of the administrative assistants have some form of broadband connectivity from home. This means some do not have the infrastructure to their homes to provide real service to the faculty, even if they have the correct software and are trained in its use.

The faculty situation is appreciably better. 98% have a functional home computer (either desktop or laptop) to work from and 98% have broadband capabilities to their home. One concern is that only 29% of the faculty have the VPN client installed on their home computers. Lack of VPN capabilities mean they will not be able to get to their office desktop machines, through remote desktop nor will they be able to get to files stored on departmental servers.

Implications

The implications for what this means in terms of carrying out the educational mission of the school of nursing are profound. On the staff side, the administrative assistants need to acquire broadband services at home. Part of the problem is that some of these individuals live in locations where broadband connectivity is either unavailable or prohibitively expensive. Their personal resources may be low and they may have to be financially incentivized to do this. At the very least those without capability at home need to be identified with what responsibilities they are in charge of, and develop methods for shifting those responsibilities either back to the faculty member or to other administrative assistants who have capability from home. As the data show, currently faculty are very reliant on administrative support personnel to do a lot of the work related to technology, for them. Relying on individuals who, in much larger measure, do not have the capabilities at home to carry out the task makes little sense.

Specifically what do institutions need to do to be able to continue the educational mission of these professional schools during the pandemic event? First, the faculty need to become aware of what technology teaching solutions are available, both inside their institution and what can be acquired from outside the university. They need to conceptualize how they would teach their courses from a distance and what software they need to do this. Trangenstein [10] has created a toolkit set that explains the various options available to the faculty in schools of Nursing. There are perhaps some course content that cannot be taught through distance education techniques. This content will have to be put on hold until face to face classes reconvene after the pandemic event is over.

Secondly, software needs to be acquired in sufficient license quantities so that faculty can continue the teaching mission of the institution. At Vanderbilt School of Nursing we have Blackboard as the course management system, Camtasia to record narrated Powerpoint presentations, Centra for synchro-

nous web conferencing, and Scopia for small group video conferencing with webcams. Vanderbilt also provides servers to store video files to be viewed in classes asynchronously.

Third, support materials need to be created to teach faculty and staff the tools they need quickly and in a timely manner. Production of PDF brief training manuals, quick reference guides, and brief (3-7 minutes in length) narrated screen recordings can all be posted online. Break longer videos into shorter segments each centering around a specific technique or concept. Faculty and staff will not listen to long winded presentations when they are attempting to get a class up and running quickly. Examples from Kent State University [6] and Vanderbilt School of Nursing[10] are demonstrations of ways of doing this effectively. Avoid generalized approaches that do not get specific quickly. In an emergency, faculty do not have the time or patience to wade through pages of general explanations. They want to learn how to do what they want to do quickly and immediately. Avoid wasting time by discussing features they have little chance of acquiring or using.

Fourth, give the faculty the opportunity to try these techniques before they need them and strongly encourage them to do so. At Vanderbilt a new server was installed to use with narrated Powerpoint presentations. The use of this server is now required even though it really would not be technically necessary until a closing. Attempting to learn how to use new software applications or hardware in a crisis is often just not successful.

Fifth, make certain that the IT support people are philosophically on board and realize it is their responsibility to keep the technology running during the pandemic event. Give them the tools they need to manage servers, networks, and software licenses from home. They may not be allowed on campus either.

Sixth, determine what prerequisite hardware and software are required to manage each application. Faculty may need headsets, webcams, robust network connections, and expensive software, all in their home environments.

On the school side, training materials (consisting of online printable manuals and screen recordings of the actual application) will have to be created, aggregated onto a website, and made available to staff and faculty well in advance of the need. Convincing faculty and staff to learn this material well in advance of the need is an interesting training challenge but one we are overcoming. In the past 72 hours since this article was outlined, traffic to our website has dramatically increased, two faculty have requested additional one on one help, and three administrative assistants have asked for additional work in this area. Faculty are transitioning to taking charge of their own technology and the administrative assistants are recasting their role from what has traditionally been highly secretarial to one of technology support. This shows people are ready to make the move if given the correct tools, training, and resources.

An approach to simulate and visualize intraoperative scattered radiation exposure to improve radiation protection training

Abstract

Intraoperative radiography based on mobile image intensifier systems (C-arms) is widely used during the treatment of trauma and emergency patients. These devices produce scattered radiation, potential hazardous for surgeon and operation room personal (ORP). The propagation and intensity of scattered radiation is not intuitive, is not perceivable by human senses and depends on many variables. At courses on radiation protection the knowledge of the behavior of scattered radiation and the modus operandi to minimize the radiation exposure should be taught to ORP and surgeons. Currently this can only be done theoretically using fixed pictures and precalculated videos. This paper presents an approach to interactively simulate and visualize scattered radiation with a computer based training system for mobile image intensifier systems. The simulation depicts radiation propagation and intensity for arbitrary C-arm adjustments and different irradiated materials. This teaching component focuses on improving the current radiation protection training with interactive visual and practical aspects.

Introduction

During surgical treatment of human and veterinary trauma and emergency patients or in catheterization laboratories mobile image intensifier systems (so called C-arms) are widely deployed to produce intraoperative radiographs. These radiographs are used for controlling, monitoring or documentation purposes during the intervention. Using C-arms the surgical outcome can be enhanced and by this the number of follow-up operations can be reduced. Due to the mobility of a C-arm, achieved by mounting the radiation source and the image intensifier on a freely movable C-construction (see Figure 1), one can create radiographs from every point and viewing angle around the narcotized patient. But this freedom in movement leads to the problem that radiation shielding arrangements, well known from stationary X-ray devices, are very hard or even impossible to install. Beyond that the surgeon, respectively the operation room personal (ORP) cannot leave the operation theatre (OR) during the radiograph generation process, as it is mandatory for stationary X-ray devices. Hence the staff in the OR is frequently exposed to radiation. The biggest amount of this exposure for surgeon and ORP is caused by scattered or so called stray radiation [1, 2]. The scattered radiation is emitted by the irradiated area of the patient every time a radiograph is generated and spreads in all spatial directions. The propagation and intensity of this radiation depends on many variables, for example the intensity and direction of the primary beam, the density values of the irradiated materials and the positioning and type of different objects in the OR [3]. Therefore the prediction and understanding of scattered radiation behavior is not intuitive. In spite of mandatory radiation protection clothes there is still a permanent stochastic risk for the staff regarding radiation injuries through the frequent radiation exposure. Thus to minimize the radiation exposure for all persons in the OR it is necessary that the surgeon and the ORP are able to position and adjust the mobile image intensifier correctly to get a meaningful radiograph with a minimum of scattered radiation. This implies that they understand the behavior of scattered radiation and that they know where regions of high radiation doses for certain adjustment situations are located, so they can take the safest position during the radiograph generation process. This knowledge about scattered radiation is usually presented to ORP and surgeons in courses on radiation protection. In Germany and other countries ORP have to visit these courses by law. Due to the fact that training with real radiation is potentially dangerous, which makes it prohibitive, and that radiation itself could not be perceived by any human sense presentation and education of the knowledge on how to diminish scattered radiation exposure during these courses is only done in a very theoretical way with images, textbooks or precomputed videos. Here the question arises if it is possible to enhance the radiation protection courses with interactive simulation and visualization of scattered radiation embedded in a computer based training system to be able to

demonstrate the complex correlations in a practical and visual way.

This paper demonstrates an approach to simulate and visualize scattered radiation for the mentioned training purposes during radiation protection courses.

Materials and Methods

The computer based training system virtX

In order to improve the teaching and training of the correct adjustment of mobile image intensifier systems the computer based training (CBT) system virtX was developed at the Peter L. Reichertz Institute for Medical Informatics in cooperation with the Georg-August-University Goettingen and the University of Applied Sciences and Arts, Hannover. This CBT system (see figure 1) offers exercise based training of the correct positioning of the C-arm for routine adjustments. A trainee can move three-dimensional virtual representatives of the C-arm, the patient and the operation table in a virtual operation theatre by using mouse and keyboard or by moving a tracked real C-arm and patient manikin which control their virtual pendants. During an exercise the trainee can generate a digitally reconstructed radiograph (DRR) at any time based on real CT-datasets and gets feedback via a traffic light, if the correct positioning is achieved. For detailed description of the system see [4-7]. Different prototypical versions of scattered radiation simulation and visualization have already been integrated in the virtX system and described and evaluated in [7] and [8]. The new simulation and visualization approach described in this paper uses the results of [8] as a foundation.

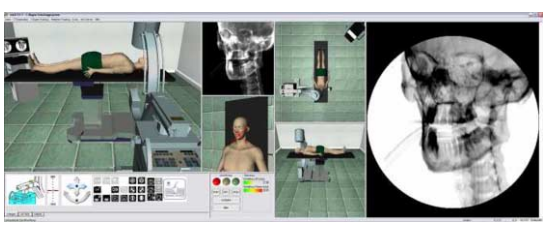

Figure 1 – Graphical user interface of the computer based training system virtX

Simulating scattered radiation using GEANT4

To calculate the physically correct behavior of radiation Monte Carlo simulation methods are a widely used and accepted procedure [9]. For the new approach of scattered radiation simulation which was integrated in the virtX training system we used the GEANT4 (*Geometry And Tracking*) toolkit in the version 4.9.3 Beta 1 [10] which uses such Monte Carlo methods to simulate the passage of particles through matter. This toolkit which uses the *Class Library for High Energy Physics* (CLHEP) is written in C++ and was developed at the European Organization for Nuclear Research (CERN). With GEANT4 a virtual environment can be constructed in which the physical interactions between a specific number of particles or photons with different objects are simulated. The user can create these objects using different geometries in the GEANT4 simulation world and specify their material properties and electromagnetic fields. For these geometries sensitive detector areas can be defined, which protocol every hit of a photon or particle. Furthermore it is possible to create primary generators in the simulation world, which emit a specific number of primary particles or photons with a discrete energy and moving direction. During one run GEANT4 simulates for every primary its way through the simulation setup until it is absorbed or it has left the simulation world.

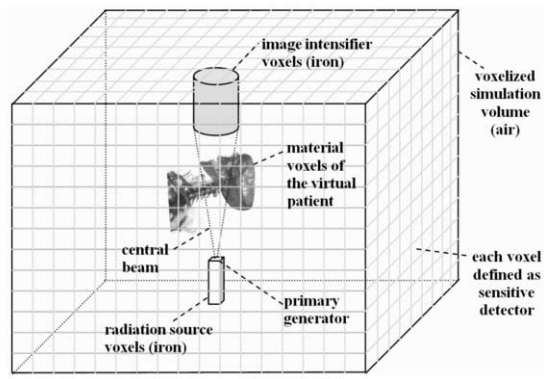

Figure 2 – Schematic description of the simulation setup in GEANT4

Similar to [8] the GEANT4 Toolkit was ported into the Visual Studio 2009 IDE so it could be integrated in the virtX project. In contrast to the simulation setup described in [8] the new approach uses a complete voxelization of the simulation environment. The simulation world, which was set to the size of 3m x 3m x 3m, was divided into 27 million voxels (300 x 300 x 300) of equal size. Each voxel was defined as a sensitive detector which protocols, depending on the simulation settings, either the energy deposit (respectively dose) in this voxel or the photons with their energies that are entering the voxel. During the initialization phase of the simulation first of all each voxel is set to the material *air* to briefly represent the operation theatre. Subsequently voxels for the C-arm are set to material *iron* depending on the geometrical properties of the simulated image intensifier (e.g. tube-image intensifier distance, image intensifier diameter).

For every simulation step the materials of the virtual patient are integrated in the corresponding voxels in the simulation setup depending on how the C-arm and the primary beam are adjusted over the patient. This is done by using the CT-datasets from the virtX system which are utilized to generate the DRR (comp. [4] and [7]). These datasets contain scaled Hounsfield values and are matched to the 3D patient model. To get the different materials for the patient-voxels in the simulation these scaled Hounsfield values are mapped to different types of tissue and their material compositions. Afterwards the indices of the voxels (where the material values have to be

set) are calculated using the rotation and location differences between the primary beam and the movable CT-datasets of the virtual patient. Similar to the simulation setup described in [8] a primary photon generator was defined next to the voxels, which represents the radiation source of the C-arm. This primary generator produces a user defined number of gamma photons with an energy which could be adjusted by the tube voltage parameter in the virtX training system. The moving direction of these photons is set randomly in the area of the central beam of the C-arm, which is defined by the tube-image intensifier distance and the image intensifier diameter. The schematic simulation setup is depicted in Figure 2.

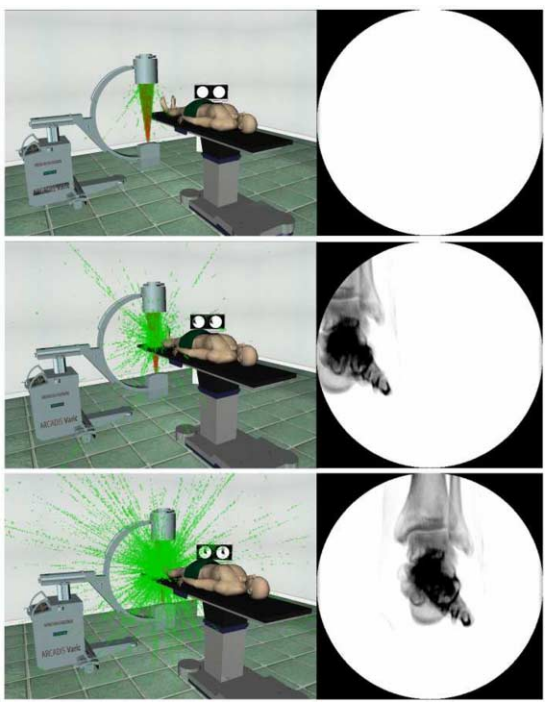

Figure 3 – Visualization of the scattered radiation simulation results in virtX

To visualize the simulation results of the GEANT4 toolkit a volume with the same voxel count and dimension as the simulation volume was integrated in the existing virtual operation theatre of the virtX CBT-system. This volume was coupled with the movement of the virtual C-arm and each voxel was set in correspondence with the sensitive detector voxel of the simulation volume. A transfer function was implemented which maps the resulting values (for example energy deposit or photon flux of the voxel) to semitransparent color values. In this way the color of every voxel in the visualization volume depicts the simulation values. In the current visualization version the colors green, orange and red are used to illustrate low, medium and high resulting energy deposit respectively photon flux for a voxel. The threshold values for the mapping of the calculated values to the colors can be adjusted over a graphical user interface in virtX. Figure 3 depicts the scattered radiation visualization results for three different C-arm adjustments over an ankle joint with the DRR and the corresponding photon flux for a tube voltage of 80kV. In these examples 5000 photons were simulated and the values represent the sum of the energy of passing photons (threshold values: green 0.1 MeV, orange 1 MeV, red 10 MeV).

Table 1 – Calculation times for the scattered radiation simulation for different numbers of simulated photons and irradiated materials

number of photons	Calculation time in seconds		
	only air	half ankle joint irradiated	full ankle joint irradiated
1000	6.1	9.9	11.4
2500	10.7	17.7	22.6
5000	17.8	30.8	41.6
10000	32.8	57.3	80.7
15000	47.2	85.8	116.7
20000	60.4	113.7	157.3

Results

Comparing the simulation results with isodose curves, which were measured during the operation of a real mobile image intensifier system, the presented simulation and visualization method represents the same information in a more interactive and spatial way for the teaching purposes during courses on radiation protection. A problem calculating physically correct behavior of scattered radiation for varying setups using Monte Carlo simulation methods is calculation time. The approach described in [8] already showed that it is possible to simulate and visualize the propagation of scattered radiation in an acceptable time for the mentioned training purposes with a certain abstraction layer. The new approach presented in this paper decreases this abstraction by integrating density values of a real CT-dataset into the simulation, cutting the simulation volume into voxels and visualizing the simulated results on every point in the virtual operation theatre. This offers a more realistic simulation and a more intuitive visualization than the previous approach. But this improvement increases the calculation time for every simulation step. In table 1 the calculation time for different numbers of photons and irradiated areas is listed (calculated on a standard PC: Intel Core2 Quad Q9000 CPU at 2.00GHz, 3GB RAM, Nvidia GeForce 9800M GS). Caused by the simulation algorithm of GEANT4 the calculation time gets bigger the more different materials are irradiated respectively gets smaller the more similar materials are irradiated. So the resulting calculation time only seems to be appro-

priate for a use during teaching courses for a small number of photons.

Discussion

Summarizing the aspects of this new simulation and visualization concept integrated in the virtX CBT-system one can say that it is possible to demonstrate the behavior of scattered radiation for different C-arm adjustments and irradiated materials in a virtual environment. However a faster calculation time and a more intuitive visualization (like isodose or risk curves) would be preferable. Currently the calculation for the simulation is done sequential. A speedup of the simulation by using multithreading or General-Purpose Computation on Graphics Hardware (GPGPU) methods for example with the CUDA architecture and programming API [11] has to be analyzed in future work. Furthermore not all objects in the operation theatre are currently taken into account for simulation. It would be preferable to simulate the effects on the scattered radiation behavior when using different types of operation tables, different positioning of surgical or anesthetic equipment or the different position of the surgeon and the ORP.

It would also be helpful for teaching and training during the radiation protection courses, if the virtual operation theatre in the virtX system contains movable avatars of the surgeon and ORP, which measure and visualize their individual body part radiation exposure. Through this trainees could test different C-arm adjustments and personal locations and instantly get a feedback over the specific radiation exposures and areas with high radiation risks. Also a correct modeling of the radiation source for better simulating radiation leakage or the X-ray spectrum of the central beam and an integration of the aperture functionalities of the mobile image intensifier in the simulation setup would additionally increase the level of realism of the whole scattered radiation simulation. Further research has to be done to evaluate the learning effect of this new teaching tool and to improve the level of realism and physically correctness at an acceptable amount of calculation time.

Acknowledgments

We would like to thank everyone who supported the virtX project with professional and technical knowledge and sometimes with muscular strength.

A Compositional Personalization Approach for Designing Personalized Patient Educational Interventions for Cardiovascular Risk Management

Selena Davis, Syed Sibte Raza Abidi, Sam Stewart

NICHE Research Lab, Faculty of Computer Science, Dalhousie University, Halifax, Canada

Abstract

Providing patients with personalized educational messages can improve self-management of Cardiovascular Disease (CVD) risk factors. We present our compositional personalization approach that generates personalized educational material by dynamically selecting fine-grained information snippets, as per the patient profile, and then synthesizing them in a educational template to yield personalized patient education interventions. We apply our personalization approach in the PULSE system—Personalization Using Linkages of SCORE and behavior change readiness to web-based Education—that generates personalized patient education for CVD risk management. The PULSE framework involves the calculation of CVD risk assessment using the Systematic COronary Risk Evaluation (SCORE) algorithm, the estimation of readiness to change using the Transtheoretical Model (TTM) of intentional behavior change. The educational interventions were derived from evidence-based staged lifestyle modification materials and Canadian guidelines for CVD risk management.

Keywords:

Patient education, Self-management, Risk assessment, Cardiovascular, Information personalization

Introduction

Patient education, especially for chronic health conditions, is an integral component of disease management, especially in a self-management context. Patient empowerment through education is geared towards encouraging patients to take increasingly responsibility for the management of their own health and wellness, whilst the role of the healthcare providers is the medical management of the disease [1]. Lately, there have been a number of programs that aim to empower individuals through educational programs to help them make informed choices about therapeutic options, risk assessments and lifestyle modification to ensure healthy lives. Such patient education programs offer evidence guided interventions, disease-specific care plans/maps and access to healthcare resources to improve patients' health status by influencing changes in patients' health behaviors and/or attitudes.

In general, patient education is practiced through the provision of 'generic' health educational material in the form of print materials (pamphlets or booklets) and/or Internet based health portals. Despite the benefits of patient education the rate of uptake of the educational material by patients is always a major factor in determining the impact of the educational program towards meeting the desired self-management targets. Typical educational material is designed to cover general issues pertinent to the needs a patient population, and from a patient's perspective they provide useful information but the information is not customized to the patient's specific needs. Lately, in an attempt to engage patients to self-manage their health and risk factors, patient education researchers have developed various approaches to personalize the rather generic patient education material towards the specific needs of individual patients [2, 3]. Personalized recommendations are more likely to be acted upon by patients since they can relate it to their own health targets. Lately, computer-based personalized patient education programs have made significant changes in the health and behavior of their targeted audience [4, 5].

Personalized patient educational programs can be made more impacting if we take into account the patient's underlying (a) perceptions and attitudes towards his/her health risks; and (b) behavioral disposition towards the uptake of any risk modification information [6]. If the patient is not fully prepared to accept the educational interventions to make lifestyle modifications, then even a personalized education program may be rendered ineffective in achieving the desired health outcomes. Therefore, we argue that the personalization of patient education material should be guided by patient's behavioral readiness to uptake educational interventions (in addition to the patient's health profile). Our strategy to personalize patient education is: (a) *determine* the patient's attitude towards his/her health condition and the associated risks and then establish their readiness level to make lifestyle changes; (b) *educate* the patient so that he/she contemplates lifestyle changes; and (c) *modify* the patient's lifestyle through personalized educational material that targets both the patient's behavior and health conditions.

In this paper we present a computer-based system to personalize patient education programs for the CVD risk management. The PULSE system—Personalization Using Linkages of SCORE and behaviour change readiness to web-based Education—personalizes educational material based on the patient's (a) ten-year CVD risk assessment calculated using the Systematic COronary Risk Evaluation (SCORE) algorithm [7]; and

(b) readiness to change risky behavior, which is determined using the Transtheoretical Model (TTM) of intentional behavior change [8]. We present a compositional information personalization method that involves the dynamic composition of a personalized educational package by (i) systematically selecting multiple, topic-specific, individual *snippets* of information based on the patient's behavioral and health profile; and (ii) synthesizing the selected snippets based on a patient-specific presentation template. The personalization logic was derived from Canadian clinical guidelines and behavior change literature, and was represented using Medical Logic Modules (MLM). The educational material covers both medical and psychosocial aspects of CVD risk management, derived from a combination of staged lifestyle modification and non-staged messages based on Canadian clinical guidelines. A web-based interface was developed for PULSE to interact with and to present a personalized educational package to the patient. We also report a small pilot user-study involving patients with CVD risks—the results highlight the efficacy of PULSE.

Materials and Methods

The key aspect of the technical design of PULSE is our compositional information personalization method [9]. The entire educational material is decomposed into multiple individual educational messages, called *snippets*, where each snippet addresses a particular health issue, targets a specific set of patient parameters and is relevant to a specific stage of change. Our strategy is to dynamically construct a document by systematically (a) selecting a set of snippets that are directly related to the patient's health conditions and behavioral stage of change; (b) synthesizing the selected patient-specific snippets to yield a seamless personalized educational package. Our compositional information personalization strategy accounts for fine-grained distinction between patients along multiple dimensions, and hence generates highly personalized educational packages [10]. In the forthcoming discussion we discuss the main components of PULSE—i.e. (a) a behavioral change model; (b) a patient data capture template; (c) a patient profile; (c) a message library storing the educational material as snippets; (d) the personalization logic that maps the patient profile to relevant snippets; (e) a presentation template to synthesize the snippets; and (f) a delivery medium to present the personalized educational package to the patient.

Behavior Change Model

For CVD risk management, we leverage behavioral models to explain and predict the patient's adoption of health-promoting behaviours or elimination of health-damaging behaviours. We use the Transtheoretical Model (TTM) of intentional behavior change as it guides the patient through the process of modifying problem behavior(s) and acquiring positive behaviors [9]. TTM consists of three key constructs: (i) Stage of Change - a characterization of a person's readiness to take and sustain action; (ii) The behavioral processes of change, representing how change occurs from one stage to another; and (iii) The decisional balance measures that indicate the patient's progress through the stages. In PULSE, we designed educational interventions that correspond to patient's needs at different stages of change. Table 1 shows our abstraction of the integrated TTM variables as used in personalizing interventions for CVD risk management.

Table 1 – Transtheoretical Model for CVD risk management

Stage of Change	Behaviourial Change Process	Decisional Measures	Pros Vs. Cons
Stage 1: Pre-Contemplation	Consciousness Raising, Dramatic relief	Confidence low Temptation high	Pros < Cons
Stage 2: Contemplation	Self Reevaluation, Self Liberation	Confidence low Temptation moderate	Pros <= Cons
Stage 3: Preparation	Social Liberation	Confidence moderate Temptation moderate	Pros >= Cons
Stage 4: Action	Stimulus control, Counter conditioning	Confidence moderate, Temptation low	Pros > Cons
Stage 5: Maintenance	Contingency management, Helping relationship	Confidence high, Temptation low	Pros > Cons
Habit	No message needed	Confidence very high, Temptation very low	Pros >> Cons

Patient Data Capture Template

The patient Data Capture Template (DCT) systematically records patient information—i.e. demographics, behaviour and clinical risk factors—needed to generate personalized educational material. We used the commercially available Wellsource Coronary Risk Profile that assesses CVD risk based on the FHS risk calculator. We made some modifications to it to meet (a) SCORE requirements; and (b) Canadian healthcare standards—in particular target levels for risk factors suggested by the Canadian Association of Cardiac Rehabilitation report.

We divided the DCT into four distinct sections: *(1) Demographic Data; (2) Health History Data; (3) Clinical Data; and (4) Risk Behaviour Data*. The first two DCT sections collect data describing the patient's characteristics and his/her non-modifiable risk conditions, whereas the last two DCT sections collect clinical and behavioural data relating to CVD risk factors (such as smoking, dietary choices, alcohol consumption, stress, depression), which can potentially be modified through lifestyle changes. In total the DCT collects 28 parameters that cover a range of risk conditions and risk factors, such as age, smoking status, amount of regular exercise, eating practices, alcohol consumption, stress, depression, blood pressure, glycemic control values, and behaviour change readiness. The patient data for all the parameters is used to design a patient profile.

A feature of the DCT is that it automatically prompts lifestyle change readiness questions whenever the patient's response is not in accordance with the accepted targets as suggested by Canadian guidelines. Figure 1 shows the readiness question posed to the patient after he/she confirms a smoking habit.

Behavioural Data: Smoking	Indicate your present smoking practices. ___ never smoked ___ quit smoking more than a year ago ___ quit smoking more than 6 months ago ___ quit smoking within the last 6 months √ currently smoke cigarettes
Behavioural Data: Readiness to Change	Are you ready to make lifestyle changes to improve your health by stopping to smoke ? ___ no interest in making any lifestyle change *(Stage 1)* ___ thinking about making a lifestyle change *(Stage 2)* ___ making plans to achieve a change *(Stage 3)*

Figure 1 - DCT for checking on smoking and then based on the patient's response we ask the readiness to change.

Patient Profile

The patient profile characterizes the patient along multiple dimensions in order to guide the selection of patient-specific snippets. It includes: (a) patient information collected via the DCT, (b) new patient information calculated using the DCT data, e.g. patient's body mass index, (c) the patient's computed SCORE value, and (d) the patient's stage of change for each risk behaviour, as illustrated in Table 1. The patient profile comprises three components as follows:

CVD Risk Profile describes the patient's absolute risk of CVD death and co-morbid conditions using the SCORE algorithm [8], which estimates the 10-year total cardiovascular risk of death. SCORE uses patient data on age, gender, smoking, systolic blood pressure (SBP), and total cholesterol (TC) and HDL cholesterol ratio to calculate the patient's risk category as percentages that lead to tertiles of risk as follows: ≤1% (low risk); 1 - 5% (moderate risk); and >5% (high risk). For example, a 60 year-old, non-smoking female patient with a SBP of 140 mmHg and TC:HDL ratio of 6.2 mmol/L would have a 10-yr CVD death risk of 2%, which means moderate risk.

The *Staged Risk Factor Profile* contains the patient's behavioural information and stage of change for specific modifiable CVD risk factor behaviours, such as smoking. We use the TTM to determine the patient's stage of change, for all potential risk behaviours, based on his/her response to questions relating to her/his readiness to modify the risk behaviour. We ask a readiness question—e.g. are you ready to make lifestyle changes to improve your health? The patient's response is used to determine the readiness to change along the five stages shown in Table 1—i.e. No present interest in making any lifestyle change infers *Stage 1*; Thinking about making a lifestyle change infers *Stage 2*; Making plans to achieve this change infers *Stage 3*; Recently started implementing this change infers *Stage 4*; and Have been doing this for six months or more infers *Stage 5*.

Non-staged Risk Factor Profile comprises additional information pertaining to other risk factors and conditions that are not integrated with TTM, for instance risk factors concerning eating practices, blood cholesterol levels, blood pressure, etc. This information is used to select educational messages for all non-staged risk factors and risk conditions.

Message Library

The message library contains a large volume of topic-specific educational interventions represented as fine-grained *snippets* of information. Each snippet addresses a specific aspect of a risk factor pertaining to specific patient feature. Snippets form the building blocks for a detailed and personalized educational package. Snippets vary in information coverage, ranging from a single sentence to a number of paragraphs and they collectively cover the range of potential variations of patient characteristics. Their sources were (a) staged lifestyle modification materials, based on the TTM, for the risk factors—i.e. smoking, overweight, stress, depression, and physical inactivity; and (b) non-staged educational resources for other risk factors—i.e. BP, lipids, eating practices, glycemic control, and alcohol. This material originated from the these Canadian sources: (a) "The Healthy Heart Kit" from the Public Health Agency; (2) Cardiovascular & Pulmonary Health in Motion Cardiac Rehabilitation Program at the QE II Health Sciences Centre in Halifax; (3) The Heart Disease: Prevention section of the Heart & Stroke Foundation website; and (4) Health Canada's "Food Guide to Healthy Eating" and "Physical Activity Guide to Healthy Active Living."

In the message library, at the first-level the educational material was categorized in terms of staged and non-staged. At the next-level, the staged material was categorized into five snippets categories, corresponding to the five Stages of Change. And, the non-staged material was categorized into six snippet categories—i.e. introductory (opening statements), informational (suitable action), definitional (meaning), motivational (incentive), factual (evidence), and gender-specific (suitable for one gender). In each case, the key educational information was selected from the original material to form a risk factor's snippet. For example, information from the cholesterol brochure was used to create snippets as follows. An initial sentence containing "Cholesterol is …" was converted to a *definitional snippet*. Information following the heading "Get the Facts …" was converted to a *factual snippet*. The sentence "What you eat plays an important role..." led to an *introductory snippet*. Discussion of cause and effect such as "Decreasing your blood cholesterol level by 1% …", led to a *motivational snippet*. Statements such as "If you want to lower your risk of heart disease try…" formed *informational snippets*. Gender-specific information, such as "Women tend to …", resulted in a *gender-specific snippet*. Local experts in CVD prevention and rehabilitation were engaged to verify the information content and coverage contained within each snippet.

Personalization Decision Logic

The personalization decision logic determines the selection of the relevant snippets based on a given patient profile. To establish the decision logic, we first developed a mapping matrix that contained the 14 risk conditions identified in the DCT and potential messages targeting these risk conditions. Next, the matrix was translated into symbolic decision rules—i.e. if-then statements—that map the profile elements in the IF part of the rule to specific messages listed in the THEN part of the rule. Figure 2 shows exemplar personalization decision logic. We developed around 300 rules that are executed by a rule-based engine employing forward reasoning.

```
If Gender = female and Exercise = no regular exercise
   Then <GenderF link> and <GenderF premenopause&exercise link>
If Gender = female and Exercise=five or more days per week
   Then <GenderF link>
If Gender = postmenopausal female and Depression=yes
   Then <GenderF link> and <GenderF post menopause> and
          <GenderF post menopause&depression>
If Gender = postmenopausal female and Depression=no
   Then <GenderF link> and <GenderF post menopause>
```

Figure 2 - Sample personalization decision logic

Information Presentation Template

The function of the information presentation template is to organize the selected snippets in a meaningful manner. The presentation template was divided into four sections: (1) The *Introductory* section provides a brief description about the document title, patient's name, date, clinic name (site) and the contents of the personalized document; (2) The *CVD Risk Profile* section provides both textual information and a graphical display of the patient's absolute risk of CVD death as computed by the SCORE algorithm. We present (a) a bar-chart displaying the 10-year risk of CVD death with comparison to a patient with an ideal risk profile; and (b) a pie chart displaying the contribution of a patient's modifiable risk factors to her/his total risk (see Figure 3ab); (3) The *Progress* section provides a graphical display of changes in a patient's modifiable risk factor values over time; and (4) The *Risk Factor Management* section provides information on each risk factor relevant to the patient. Each risk factor has its own sub-section complete with an introductory brief, the patient's current results, evidence-based target values, and lifestyle modification and risk management education. We recognize that managing risk factors may require lengthy educational messages leading to information overload. Therefore, the template contains 'expandable' segments that can be accessed by clicking a hyperlink that leads to detailed information.

Delivery Method

In PULSE, the educational material can be viewed online (in a web browser) or printed as a PDF document. Interaction with the PULSE system is initiated by a healthcare professional in a primary care setting. The practitioner enters the patient data into the DCT and then PULSE generates the personalized educational package.

Working Example

To demonstrate the working of PULSE we generate educational material for two patients. Through a comparison between the education packages generated for each patient we will be able to demonstrate the efficacy of PULSE. The two hypothetical patients are: Ms. Adams, aged 48 years, with a SCORE value of 1% (moderate CVD risk) and Mr. Brown, aged 60, has a SCORE value of 8% (high CVD risk). Figure 3ab displays the CVD risk profile presented to Mr. Brown.

Table 2 shows for each patient their data used to calculate risk assessment, the stage of change for their risk factors and the messages selected by the personalization logic. The personalization effect is illustrated by viewing the diversity of the number and type of messages received by each patient. Ms. Adams receives 25 snippets in comparison to Mr. Brown receiving 42 snippets. Overlap is their profiles results in the selection of some similar snippets. Yet, differences between their profiles results in selection of different snippets—Mr. Brown receives 3 BP messages as his BP levels are not normal, whereas Ms. Adams does not get any messages as her BP level was normal; Mr. Brown receives 2 additional lipids messages as his LDL and TG levels are higher than accepted targets, whereas Ms. Adams' values for these variables were normal; Ms. Adams receives an additional gender-specific exercise message at Stage 2 (Contemplation), whereas Mr. Brown receives at Stage 1 (Pre-contemplation). In summary, the diversity of snippets selected for each patient illustrates fine-grained personalization of their educational packages.

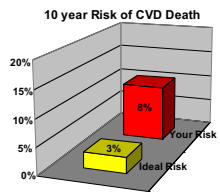

Figure 3a-Risk profile

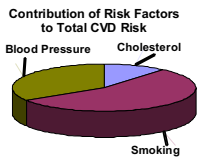

Figure 3b-Risk factors

Evaluation Study

We conducted a survey-based pilot study to evaluate (A) patients' willingness to follow the suggestions offered by PULSE, and (B) the quality of the information being presented with respect to the patient's profile. The survey presented 22 questions using 5-point Likert scales. The survey evaluated patient's intention to follow treatment suggestions in part A, and their impression of the quality of the information in part B. Six (6) patients with CVD risk factors were recruited at a medical clinic where they were under treatment for those cardiovascular risks. 83% of the responses to part A were positive, and 91% responding positively to part B (Table 3). For part A the survey comprised 10 questions, such as "Do you intend to try any of the suggestions to manage your cholesterol levels within the next 30 days"; "Do you intend to try the suggestions to healthy eating within the next 30 days", and so on. For part B the survey comprised 12 questions, such as "How useful would the information be in helping you manage your cardiovascular risk"; "The information on each of the topics was individualized"; "The information on each of the topics was new"; "The information on each of the topics was personally relevant", etc.

Table 3- Survey results for part A and B

	Positive	Neutral	Negative
Part A	34	7	1
Part B	61	6	0

A patient's readiness to change behavior, based on PULSE educational messages, was as follows: Stage1-No present interest in making a change (1); Stage2-Thinking about make a lifestyle change (3); Stage3-Making plans to make a change (5); Stage4-Recently started making a change (8); Stage5-Have been doing this for 6 months or more (1). The responses show that PULSE is having a positive influence on the behavior of the patients, as Stage 3 and 4 (for their different

Table 2 – Comparison of personalization results for two patients. The underlined snippets are common between both patients

Risk Factor	Patient 1	SoC	# of Msgs	Message ID	Patient 2	SoC	# of Msgs	Message ID

conditions) are the most prevalent. The results conclude that the educational interventions by PULSE is not only accepted by patients but is also deemed by patients as personalized.

Conclusion

Human behaviour is a key determinant of health improvement, yet its importance has not been fully appreciated in designing patient-specific educational interventions. Notwithstanding the effective organization, usability and relevance of healthcare information prescribed to patients, it can still not be guaranteed that the information will have the desired impact if it does not take into account the patient's behavioral attitudes towards self-management and self-improvement. The PULSE approach presented here is grounded in the belief that the efficacy of any patient educational intervention is contingent on the patient's readiness to change their behaviour. We presented a personalized patient education system that purports a unique synergy between evidence-guided CVD risk assessment—i.e. the SCORE algorithm—and the TTM for assessing the stage of change for risk behaviours, such that their combination leads to a rich patient profile. We have developed a novel compositional personalization method that maps the fine details of the patient profile to specialized educational messages—i.e. snippets. We dynamically compose an educational package that comprises interventions that correspond to the patient's physiological data, risk category and behavioral predisposition to lifestyle modifications. We addressed the challenge of transforming a wide range of evidence based guidelines and recommendations to a set of discrete messages, where each message needs to satisfy three inclusion criteria—i.e. medical, risk and behavioral. The feature of our work is that it purports a pragmatic methodology for designing personalized educational material for other medical problems. In conclusion, this project is a step towards empowering patients with accessible, up-to-date and pertinent information about CVD risk factors, lifestyle modifications and behavior change strategies.

Abstract

Medical e-learning can benefit from the new technologies, and pervasive learning resources and tools worth to be introduced in the medical context. Micro-learning seems to be an interesting way for pervasive learning. But it is still difficult to propose pedagogical resources that are built by learners, from meaningful experiments. We conducted an analysis of the exchanges performed by Health care professionals in the hospital in order to understand where and when educational exchanges appear. We analyzed the type of documents exchanged. The residents' paper notebooks caught our attention first because it answers some clinician-needs and second because the computerization of such a notebook could add a collaborative dimension to the pedagogical resources. We propose a model of an augmented resident's notebook and we briefly describe an implementation using Content Management System and WIKI, before setting the discussion and the conclusion sections.

Keywords:

Medical Informatics, Pervasive learning, Health, Education.

Introduction

Aim of the work

Because of the diversity of situations of care, and since numerous learning resources exist in the field of medicine, we are interested in digital educational materials that health professionals are able to use in their care activities and that could offer contextualized knowledge. We wanted to know more about the pedagogical exchanges during care activity. We have analyzed where and when health care professionals use documents in learning situation. We identified the learning activities; and then how people do communicate to teach or to learn. When analyzing the documents used by the residents, we found the ones which have educational purpose, A paper notebook retains out attention because it is often used to gather useful pieces of knowledge and expertise during care activity.

Currently, everyone can easily use embedded technology through smart devices such as PDA, microPC, SmartPhone, an so on. We can thus consider electronic assistants for mobile learning. The second step of our work was then to propose a computerization of the notebook.

These researches take place in a national research program ANR-TELECOM-p LearNet[1]. It focuses on the design and the prototyping of new infrastructure for pervasive learning which is studying how the new technology (TEL: Technology Enhanced Learning) can support learning. "P-LearNet is particularly focused on the integration of technology, on providing easy use interfaces, on the possibility of contextualisation and adaptation to users, on the individual and collective training for formal and informal teaching, in relationship with the work and with the systemic and the training organizations". (our translation) [1].

Rational

Mobile tools are still rarely used in everyday health care practice. Their introduction still raises a number of basic problems e.g. size, battery life, not enough user-friendly interfaces. But thanks to the introduction of such devices, the health care professionals can avoid to switch from the place where he/she provides care to the place where he/she may consult informative resources. Moreover, ubiquitous environment could provide relevant information according to the context of use. In order to improve the dissemination of such devices, these tools must be therefore integrated into the activity. The quality and the accessibility of digital information, its nature, its structure, its granularity and its objectives are essential especially in the health care environment which is often stressful and urgent.

Scientific studies on the integration of mobile tools in the medical community are encouraging. Recent researches focus on the introduction of mobile tools such as PDA (Personal Digital Assistant) in the medical world. There is thus a quite abundant literature in this area with, for example, more than 200 articles from the raw research "Healthcare PDA" on Pubmed[2]. In a recent review [2] 48 articles describing the use of PDAs in the medical world were selected and analyzed. The results of this medical study are quite encouraging: access to databases seems to satisfy the users of such tools; access to drug information seems to be very popular as well. Another review covering articles from 1993 to 2004 proposed by Kho et al [3]

[1] http://p-learnet.univ-lille1.fr
[2] http://www.ncbi.nlm.nih.gov/pubmed/

stress the interest of practitioners for learning tools: " At the bedside, they[the PDA] can be used for clinical education by facilitating calculation of clinical prediction rules, checking for drug interactions, and consulting references to expand differential diagnoses. Handheld computers are also becoming an important part of patient care and documentation through electronic order entry and patient tracking applications".

The health educational materials are often traditional teachings resources such as slides or PDF documents, re-organized to be easily accessible on the Internet. Major projects are aiming at integrating and/or facilitating access to such electronic courses. For example, the UMVF[3] (Francophone Virtual Medical University), or the IVIMEDS[4] (International Virtual Medical School) are internet portals that gather respectively French and English educational resources. Moreover, new teaching materials are developed [4]. The design of new e-learning tools uses teaching engineering methods, organizes educational contents and takes into account interactions between learners and tutors. Most courses are however designed to be read and consulted over a period which is dedicated for learning, rather than during care activity. The learning resources consulted by the health professionals during their activity must be accurate and concise, so that information is fast and efficiently reached. Pervasive learning as defined by Thomas [5]:« Pervasive learning is a social process that connects learners to communities of devices, people, and situations so that learners can construct relevant and meaningful learning experiences that they author themselves in locations and at times they find meaningful and relevant » or micro-learning as reported in the conclusion of a 2008 conference pp121[5] "A new digital micromedia ecology, and with it new learning strategies, are emerging. The shift to fragmented digital communication and information flows affects all aspects of daily work and daily lifelong learning. This calls for innovative experiences, processes and technologies: ubiquitous, personal and dynamic, casual and volatile, but still complex and effective" worth to be carefully studied.

Materials and Methods

In general

Basic computers such as desktop PCs and mobile devices such as laptop or smart phone allow a dematerialization of information as well as a high availability of information. Different users can share some information and even collaborate to build collectively some information.

Identifying the needs for technological innovations is a difficult task. Indeed, it is very tough to project user's current activity in a technical future that in addition to being unknown could partly change their way of thinking and their way of acting. It is particularly true for pervasive devices which are taking into account the application settings. Therefore it is necessary to analyze the technical possibilities allowed by new technologies and to take into account the specificities of the user's activities. The comparison of these two aspects leads to the development of scenarios of future activity. We first decided to analyze where, when and what kind of pedagogical exchanges happen during the care. Then we focused on the identification of some learning materials whose computerization could help the caregivers.

Identification of the pedagogical exchanges

The objective was to identify the information exchanged between the caregivers in the department. We chose to observe the activity of the residents. This observation was conducted in the department of Gastroenterology at the University Hospital of Lille, where three half-days of observations were made. The following items were measured: - where were located the caregivers during pedagogical exchanges; what was the nature of the information provided; from whom or where did they obtain the learning information. An observation grid was elaborated, then implemented and completed in the software Studiocode ®.

Observers have characterized real-time information exchanged between the residents and the other people in the service. Residents spent over 51% of time in the corridor or in the patient bedroom. Residents communicate most information orally. An important part of it concerns encyclopedic knowledge and procedural knowledge. Most of the information that they received comes from the seniors and few from the other residents. They provide some information to the patients, but also to the nurses and other interns.

We inquired about the residents' needs concerning the improvement of their researches of information. They told us they have no special needs. When they haven't got the knowledge to provide the care, if the latter is beyond the scope of their specialty, they make a request to a specialist. If the knowledge is linked to their specialty, they would ask a senior, or quietly make a research on a desk computer when they have time. However, this lack of needs is also due to the difficulty they have to build a vision of the future management information (very different from the current mode). We noticed that almost all of them have a paper notebook on which they noted all information that they judge useful for their activity.

Identification of educational materials and analysis of the residents' notebooks

We made a second analysis to identify the learning materials used. In particular, we wanted to know more about the information contained in the notebook, as if it was identified as very important by the residents. The activity analysis was performed with the residents of the pediatric surgery department of Lille University Hospital. Four analysis methods were used:

Interviews which help to clarify about the nature of the residents's activity

Observations: ethnographic observations were conducted in the department of pediatric surgery.

Questionnaire: Following the initial interviews and observations, a questionnaire was done, asking about their habits and dealing with the communication tools they

[3] www.umvf.prd.fr
[4] www.ivimeds.org

used and the research information they performed. It was sent to the residents of all the departments of the hospital, in order to generalize the study. One hundred questionnaires were distributed; thirty-two were completed and returned.

Trace analysis: in addition to observation and interviews, the paper documents used by interns were analyzed. Thus, three books from three residents in anesthesia were photocopied and analyzed. By studying these traces we can identify the type of information that the caregivers are using while carrying out their tasks and we can identify the operative vocabulary they are using.

The main results of this analyze are then the following:

In order to search information, the residents have access to a computer in the medicine room or in the office. In these places the desktop computers are connected both to the information system of the hospital and to the Internet. A printer is usually also available. In these rooms, they work on the patient records and they perform their Internet researches. These researches are mainly focused on medical protocols or guidelines, on the pharmaceutical properties of drugs, on the prescription and the analysis of biological data and the detailed descriptions of diseases.

The anesthesiologists have access to a computer in the operating room. Some of them have pocket pc or smart phones.

Most of the residents also have a paper notebook. This document, pretty small, is placed in the pocket of the coat. In this notebook, they note important information for their medical practice. This document has the advantage of being accessible at any time and easily usable. In our observations, they rarely used it. However, all of them wanted to keep it with them, in case to retrieve the information it contains, if necessary.

The analysis of the residents' paper notebook.

The notebook is used to memorize some specific know-how. During actual situations of work, when a resident notices useful information, he/she uses the notebook to keep it accessible. For example, a group of new residents is in a given service where a patient suffers from a specific disease. A senior doctor explains them what to do in this situation and each resident notes his/her remarks in his/her own notebook.

Most of time, the notes are not written during the care, but they are carefully reported in the notebook after the event. Information can be duplicated in the notebook, as a same subject can be treated with different approaches or can be encountered in different contexts. Colors are used to highlight some information, but the choice of the colors that are used just depends on the color available when writing notes, it has not a specific meaning. According to the owner, the book may or not be organized in alphabetical order.

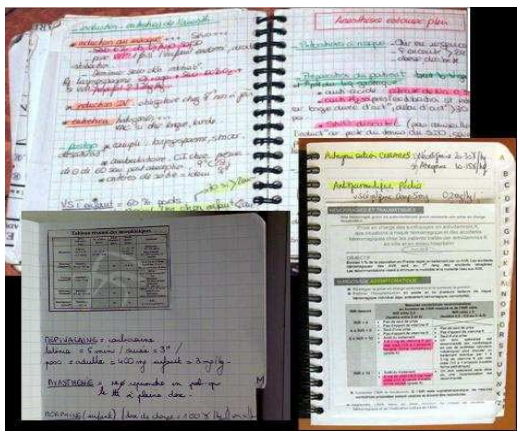

Figure 1- Examples of residents' notebooks.

Various kinds of information are included in the document: written notes but also excerpts from courses, manuals, dictionaries as well as pieces of printed paper. This notebook do not intend to be encyclopedic, it is rather a collection of "recipes" depending on services and situations. These notes will progressively create an accurate knowledge composed of useful information in a precise context of activity. Such a document is personal, dynamic and mobile; it should help to find information quickly.

Towards an augmented note book

Interest of the augmented notebook for pervasive learning

According to the specificities listed below, we have made the hypothesis that a pervasive notebook should be integrated in the activity of the residents:

At the beginning of his/her internship, the caregiver starts with an empty notebook. It is filled progressively, by the reports of important know-how learned during the activity. Obviously, this reporting takes place in the learning process since it helps to memorize the information. However, residents also copy some information manually or photocopy documents and paste them in the notebook. This process is long and bothersome. Moreover, copying is a source of significant errors. The notebook is interesting because it is made of small pieces of learning information, highly contextualized, partially indexed, annotated (color system, keywords, and titles), used during activity and used in a mobile way. The written notebook is rarely consulted but it is very important for users. When used, the consultation is brief and must immediately provide or reinforce knowledge essential for the activity. These specificities are different from usual characteristics of more traditional courses. These kinds of micro items of knowledge, very contextualized, are consulted and integrated during the care activity. It seems that to propose micro-teaching and pervasive learning activities during care, we could benefit from this experience.

Thus, we decided to experiment an augmented notebook.

The qualities of the written notebook should be preserved when computerized. *Mobility*: access to electronic notebook must be immediate and at the bedside, we will therefore emphasize mobile tools (PDA, Smartphone, NetPC, ...). *Conviviality*: the interface must be easy to understand and must lead quickly to relevant information. *Contextualization of information*: the purpose of the notebook is not to build a copy of well-known and exhaustive sources of information (as, for instance, the Vidal[5] which is one of the well known references for drug information in France) but to focus on knowledge that is relevant in a given context (as, for instance, the description of the drugs used for a child over 2 years, for disease D in the pediatric service of Professor P.). Information in the notebook makes sense only if contextualized.

An augmented notebook will enable new features.

Backup and exchange: data could be saved, transferred, with the ability to transfer its information to another media. *Efficient search*: as for example full text research or research by keyword or by category. *Relationships between concepts*: Internal links in the notebook can be proposed to connect different items of knowledge (as for instance all the items relative to acute pain). External links are also very interesting to complete the information provided in the notebook by encyclopedic knowledge, (as for instance, Vidal entries for drug information or UMVF portal for medical courses). *Multi modality*: the electronic document can easily integrate pictures, hyperlinks, sounds, videos, to the notes. It can also be consulted through different devices such as smart phone or computer terminals in the hospital. *Index and Annotation*: meta description of information can be used through tags, annotations or indexes. *Contextualization*: each note can be marked with some context : who, which country, which hospital, which services could be some of the interesting contexts to take into account. *Sharing of knowledge:* the notebook can be shared with other people once written in electronic form. *Cooperative process*: the book can be built by the capitalization of knowledge. Once collected, the information can be used by the other residents, and the information could be enriched by collaborative co-construction of the knowledge. When a new resident arrives in a service of the hospital, he could benefit of a specific know-how, which fits the habits of the service. Augmented notebook should help to share and synchronize the knowledge.

A model for the augmented notebook

We model the book as follows: a memo is the basic unit of information. This memo has a title, as encountered in the written notes. Each memo can have meta-descriptions. Each memo can be linked with other memos. A general Content Management Framework is proposed to connect the memos to external knowledge.

To perform the meta-description of the memos, in a first approach, we have retained the following axes to categorize the knowledge: (i) Geographical location, as most of the specificities comes from the hospital or the service in which the care is performed, (ii) Medicines, (iii) Syndromes, (iv) Diseases, these 3 axes covering the main entries to describe the content of the memo, and (v) Guidelines and protocols. These descriptions help to provide contextualized information. Of course, these axes could change if necessary.

The main features of the augmented notebook come from the analyses and deal with: remote access; import and export of data, collaborative authoring tool, relation to external resources; indexing of the information entered through semantic annotations or through contextual elements from the practice (as the author of the memo or the name of the service in which this resource is meaningful).

Architecture

The architecture developed for testing is based on three components: a server that hosts the memos, an experimental network infrastructure, and mobile learning devices. The server is accessible both from the internal network of the hospital as the Internet, so that residents can learn or improve the memos even when duty off. The experimental network infrastructure consists of a set of wireless terminals located in clinical departments. Only devices provided for the experiment can be accessed. The devices consist of SmartPad (nokia N90) and netbook (eeepc Asus 901).

Implementation

Different kinds of collaborative tools were examined in order to implement this augmented notebook: CMS (Content Management System), Wiki, social networks, blogs. Social networks (e.g. Facebook[6]) are originally designed to improve the social links between individuals, but they can now be implemented in a private sphere (e.g., Ning[7]) and offer many tools to share files or other kind of information, such as forums or "walls" of information. We didn't choose them as to perform a pervasive notebook we needed to structure our data. Blogs, highly structured chronologically were not retained as well.

CMS tools are designed to administrate and manage the online pages. They are effective to publish pages, to facilitate the design of the pages by using templates and to control the different validation steps before the publication of contents. A CMS, however, is not so suited to contextualize the information presented in the memos. We chose CMS to implement the general framework which gives access not only to the residents' notebook but also to external information, pertinent for the caregivers (publication databases, directory, dictionary of drugs, etc..). We used Joomla[8], which is an open source software that provides sufficient features.

Wiki tools effectively facilitate the collaborative construction of information. A wiki can easily build a network of linked

[5] http://www.vidal.fr/

[6] http://www.facebook.com
[7] http://www.ning.com
[8] http://www.joomla.fr

pages. Interesting mechanisms are implemented such as the creation and modification history that helps to control the information. It is possible to organize discussions around the concepts proposed in the pages; it is particularly interesting to secure the validity of the information provided in a collaborative way. We therefore propose to hold the notebook via a Wiki. There are many wiki engines available in open source. The MediaWiki[9] engine is used for the free online encyclopedia Wikipedia, it has proved to be robust. Its features meet fairly well our needs. Each resident's memo can then be viewed as a Wiki page, the title of the memo playing the role of the hyperlink. A discussion area on the pages is easy to implement. The concepts presented in the page may refer to internal or external links. This Wiki has additional features provided by an active community of developers. Among these features, the interface with LDAP for authentication, the possibility of exporting pages to PDF, the advanced text editor are of particular importance for our project. Structuring documents per category is proposed. Each category can be seen as a set of tags associated to that page. The Semantic MediaWiki[10] extension can annotate items or typed relations (links) between items. This Wiki has been chosen for the implementation of our prototype.

Results

Through the analyses of the pedagogical exchanges performed during the care activity, we identified a specific document: the notebook mainly used by residents. The computerization of this notebook opens up interesting prospects for pervasive learning. We have developed the infrastructure necessary to deploy a test in services. Firstly, we distributed mobile tools: Asus eeePC 900 or 901and Smartphone Nokia N90 to some of the residents working on the service in which we conduct our experiments. These tools didn't integrate the augmented notebook. The use of mobile tools was then very low, despite the number of encyclopedic knowledge available online. It confirms our hypothesis about the importance of the services offered. Then, we have developed a prototype of augmented notebook which provides contextual information according to the main axes of categorization identified. Next step of this work is the evaluation of the prototype. In particular, the collaborative aspects for the capitalization of knowledge will be explored.

Discussion

Many research opportunities are opened by this exploratory study. The capitalization of knowledge should help to identify general knowledge, or specific knowledge. Learners should become actors to build learning materials. It could reveal knowledge linked to teams (in such service, this drug is often used with the dosage xx/l) or to individuals. In particular, some habits could become explicit and such knowledge could save precious time when new people arrive and don't know yet the implicit rules. We must explore the duality between the collaborative notebook and the personal notebook, combining the contributions of a wiki tools very efficient to share and co-build information, with fair tools allowing to tag personals data.

Conclusion

The acquisition or the consolidation of knowledge can be based on other activities than the consultation of encyclopedic information; therefore residents store know-how information and examples on notebooks or USB storage. Improving e-learning through pedagogical engineering is obviously important, but there is still a room for new modalities for learning: modest, punctual but precise, which could provide small and contextualized documents. Our analysis of the learning resources that are used and exchanged during the care, highlights the difficulties that we face with in integrating learning in everyday practice. This work just sketches solutions but it provides a model of document able to capitalize applied learning knowledge. It might help us to introduce new digital material in a pervasive learning perspective.

Acknowledgments

We would like to thank the students U. Bechameil and S. Delasalle and our colleagues from the p-LearNet project for enriching discussions about pervasive learning as well as our funders: ANR telecom and the GIP UMVF.

Abstract

There are numerous advantages described of how imaging technology can support forensic examinations. However, post-mortem examinations of bodies are mainly performed to address demands which differ from those of traditional clinical image processing. This needs to be kept in mind when gathering information from image data sets for forensic purposes. To support radiologists and forensic clinicians using Virtual Autopsy technologies, an initial workflow study regarding post-mortem imaging has been performed, aiming to receive an improved understanding of how Virtual Autopsy workstations, image data sets and processes can be adjusted to support and improve conventional autopsies. This paper presents potential impacts and a current forensic Virtual Autopsy workflow aiming to form a foundation for collaborative procedures that increase the value of Virtual Autopsy. The workflow study will provide an increased and mutual understanding of involved professionals. In addition, insight into future forensic workflows based on demands from both forensic and radiologist perspectives bring visualization and medical informatics researchers together to develop and improve the technology and software needed.

Human engineering, Task performance and analysis, Forensic medicine, Radiology, Tomography, X-ray computed**,** Post-mortem imaging, 3D visualization, Virtual autopsy

Introduction

Thanks to new imaging technology cold human bodies can be virtually examined and the cause of death determined. New Magnetic Resonance Imaging (MRI) and Computed Tomography (CT) technology present new opportunities within post-mortems and forensic medicine. A recent addition to the autopsy workflow is the possibility of conducting post-mortem imaging. In its three-dimensional (3D) version, this is also called Virtual Autopsy (VA), where CT/MRI data from scans of corpses are post-processed with 3D Direct Volume Rendering (DVR) techniques [1-4].

Some of the most apparent potential advantages of VA, compared to conventional autopsies are:

- The VA is time saving and provides novel analysis opportunities. It can also improve the efficiency of the physical autopsy by improved prior knowledge of the case.
- The VA procedure does not alter evidence; the data sets can be stored indefinitely allowing subsequent re-examination by other pathologists.
- The VA can be an option when a conventional autopsy is rejected by family members due to religious beliefs, or threatens the health of coroners, pathologists, and medical examiners from highly infectious diseases.

There are several additional advantages and benefits of VA that, in the long run, will also make a significant wider contribution to healthcare and medicine. An interdisciplinary team of researchers and clinicians, further described below, works in a project to develop VA technology and procedures. To summarize, the mission of the *Advancing the State-of-the-Art for Virtual Autopsies* project is: To develop VA technologies and methodologies that enable widespread use of virtual autopsies in the standard forensic workflow. [5]

Methods and Materials

Previous research efforts have successfully shown the basic and technological benefits of VA [4, 6, 7]. This project aims to fulfill the mission by taking the next steps: to enhance the existing methods by addressing new research challenges and to prove that the full envisioned potential of VA is attainable. The needed advances encompass both technology and workflow issues in VA procedures. To address the required advancement of VA technology and procedure the work is organized into the following areas: Data Capture, Data Management, Virtual Autopsy Workstation, *Virtual Autopsy Workflow Studies*, and Demonstrator Integration (figure 1). The objective of the Data Capture area is to develop scanning procedures tailored for VA, for synthetic MRI, CT and Dual Energy CT. The Data Management research aims to extend and enhance the existing multi-resolution framework in a PACS

environment. The VA workstation area will develop visualization tools to increase quality and efficiency of the VA procedures at both the radiology and the forensics departments. The development of the VA Workstation will depend on the non-technical contributions, such as the VA Workflow Studies and the Demonstrator. [5]

Purpose of the VA workflow studies

VA workflow studies aim to develop collaborative procedures that increase the value of VA and exploit the novel visualization techniques and thus establish documented procedures for VA. In parallel, there is an integration project that puts together the results from previous innovations in a demonstrator system, the Virtual Autopsy Table [8], for dissemination use. The demonstrator and the workflow studies will mutually feed each other's development processes (Figure 1).

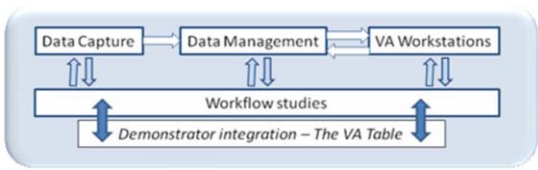

Figure 1-Project work areas' exchange of knowledge.

Methods for the VA workflow study

The technical work is a foundation for the VA deployment, but it is also important to use these tools in an optimal way. There are several aspects to consider; communication, such as instant interplay and asynchronous messaging between different professionals, documentation, the flow of data and documentation items, as well as physical scanning and transport of the deceased.

The workflow studies contain usage and process studies and result in documentation of current workflow and designs of future routines and procedures. The method used is based on a new multi-disciplinary method [9] for user needs analysis and requirements specification in the context of health information systems. This method origins from established theories from the fields of participatory design and computer supported cooperative work (CSCW). Whereas conventional methods imply a separate, sequential needs analysis for each profession, the "multi-disciplinary thematic seminar" (MdTS) method uses a collaborative design process [9]. Application of the method in previous research resulted in developed health information systems as well as new work procedures that were well adapted to the intended user groups. Vital information in the intersection points between different healthcare professions was elicited and a holistic view of the entire process was obtained. MdTS was perceived to efficiently identify in-context user needs, and transformed these directly into requirements specifications for further development [10].

Here, the initial work consists of field studies, observations and interviews, conducted by health informaticians and usability specialists, to understand current work situations and to capture users' tacit knowledge. This is particularly important in situations where different medical professions are, or will be, cooperating. The method further consists of multi-disciplinary work in inter- and intra-professional groups analyzing different topics, or themes, aiming to encompass the necessary knowledge of clinical work situations and procedures in the integrated work. The seminars contain both a holistic and a detailed perspective. In the detailed perspective seminars results from the holistic perspective are further analyzed, examining intersection points and specific details for each profession, items that are necessary for development of medical systems that actually support the integrated clinical work [9].

Materials for the VA workflow studies

There are many actors involved in a Virtual Autopsy procedure: the forensic pathologist, the radiologist, the police, and the court officials. Focus of the workflow studies are the staff of the National Board of Forensic Medicine and the staff at the Radiology Department of the University Hospital in Linköping, Sweden. Researchers working at the CMIV (Centre for Medical Imaging Sciences and Visualization) and the VITA division (Visual Information Technology and Applications) of the Department of Science and Technology at Linköping University and their industrial partners are involved in the study and subject for interviews and observations.

National Board of Forensic Medicine

The National Board of Forensic Medicine is a central government agency. It operates at ten different locations around Sweden and has 370 employees. The principal task of the agency is to produce reports required in legal cases, commissioned by the courts, the police and the prosecutors. There are four different fields of operation: forensic medicine, forensic psychiatry, forensic toxicology and forensic genetics. Experts in forensic medicine perform more than 5000 examinations per year, on both living and deceased persons, at six departments in Sweden, where Linköping is the one studied in this project. The department in Linköping performs around 900 autopsies per year related to unnatural death. Less than 3%, 20-30 of 900, are suspected murder cases. [11]

Östergötland county council

The Östergötland county council operates some forty care centers, four hospitals, of which the University Hospital in Linköping is the largest, and includes highly specialized medical healthcare, in some specialist areas working with all of Sweden as a catchment area.

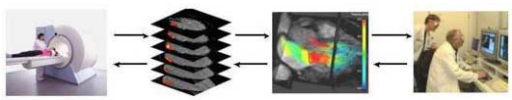
Intensive development work with medical healthcare has been ongoing for several years. Training and research are organized in close collaboration with the Faculty of Health Sciences, the medical faculty at the University of Linköping. [12] Staff from the radiology clinic is involved in this project.

CMIV

Center for Medical Image Science and Visualization (CMIV) is a multidisciplinary research center initiated by Linköping University, Östergötland county council, and Sectra Imtec AB. CMIV conducts focused front-line research within multidisciplinary projects providing solutions to tomorrow's clinical issues. The mission is to develop future methods and tools for image analysis and visualization for applications within healthcare and medical research.

Research within CMIV is based on earlier work within medical image science and visualization. Future directions will strengthen the interdisciplinary approach to enhance the possibilities of image-based diagnosis and treatment. At CMIV research is conducted within several medical problem areas, combining a number of technologies for novel application within clinical routine, medical research and dissemination of information.

Research activities within CMIV include the following four areas (Figure 2), with special emphasis on integration of these areas of expertise. [13]



Data Acquisition/ Image Reconstruction | Image Analysis/ Modeling | Visualization/ Simulation | Medical Application

Figure 2-Research activities within CMIV

The latest generation of CT, synthetic MRI and ultrasound scanners generate multidimensional data sets of rapidly increasing size. Obstacles associated with the handling and analysis of these large-scale data sets are of growing and immediate concern. Medical diagnosis is now facing serious data navigation and management problems. Focused research is required to solve these problems and to fully exploit the possibilities of the new technologies. [13]

VITA

The division for Visual Information Technology and Applications (VITA) contains five different research groups,

- Scientific Visualization,
- Information and Geo Visualization,
- Computer Graphics and Virtual Reality,
- Structural and Civil Engineering,
- Visual Learning and Communication.

The Scientific Visualization group is closely affiliated with the CMIV where the VA examinations take place. The Scientific Visualization research is conducted in the context of medical applications. Main research efforts regard volume rendering of large datasets, multimodal volume visualization and data visualization using augmented reality. The research groups are also affiliated to the Norrköping Visualization and Interaction Studio (NVIS) and share access to the laboratory and state-of-the-art equipment [14], such as the virtual autopsy table [8], Figure 4.

By using the latest technique within medical visualization, on the virtual autopsy table it is possible to study details of volume rendered 3D data sets of real scanned bodies. The user can interact with the 3D images, for instance remove certain layers of the body to look into specific details such as brain, skeleton, heart or the skin. The images are created with for example Dual Energy CT and new methods from the field of MRI and are post-processed by using different tools of image analysis and visualization [8].

Results

VA is currently used in Linköping as a complement to the autopsy procedure in cases of unnatural death [7]. To date approximately 300 cases have preceded a virtual autopsy. They are examined through a CT or MRI scan and the subsequent image analysis. Interviews, field studies and observations from both medical and forensic perspectives report an added value and future potential of virtual autopsies.

Although technological equipment and applications have passed the prototype state and are fully working, the organizational workflow is not yet optimized. This results in that the scanned cases are used mainly for research purposes and not yet smoothly inserted in the routine work of forensic pathologists.

Current Forensic Virtual Autopsy Workflow

In most cases the forensic pathologist investigates the crime scene together with the police and oversees the handling of the body, which is placed in a sealed body bag before being transported to the forensic department and placed in a cold storage. The following morning a full body virtual autopsy is performed using Dual Energy CT. Dual Energy CT is applied in all VA cases whereas MRI and synthetic MRI are applied in specific adult cases and for children, Using Multi Detector CT (MDCT) up to 25000 images can routinely be reconstructed [7]. The radiologist nurse walks through the images and makes short annotations of the findings. If there is additional information available about the body more detailed scans can be performed on specific body parts, e.g. head and thorax. Creating, storing and transfer of images are time consuming; often the pathologist has access to the images in the afternoon after the morning scan. The radiologist and the pathologist would perform a collaborative 3D DVR session in preparation for the physical autopsy and in immediate conjunction with the scanning. To save time however, as the DVD with the 3D images arrives at the forensic department later, in current procedure the radiologist summarizes the findings of the scans orally direct after the scanning is performed.

One advantage of the VA is that the captured MDCT data is stored, in case new circumstances arise. Compared to conventional post-mortems where you only get one chance, iterations of the procedure can answer new questions and re-examination of the VA images can put new light on the facts found during the physical autopsy.

The workflow of the forensic procedure is summarized in figure 3. The conventional physical autopsy is extended by adding the VA activities (shown in red rectangles) which enables an iterative approach. The possibility of a continuous interaction between radiologists and pathologists benefit the post-mortem examinations. Unfortunately current restrictions of the data transfer results in that the workflow often is serial and ends after the phone call between the radiologist and the pathologist. The potential to use the images to a greater extent is stated as high and the workflow will undergo further studies.

The interviewees agree that the technology however could revolutionize forensic medicine. Using the VA procedure, there are cases where completely new findings are detected. For instance, the brains of deceased children can be scanned in order to rule out abuse. Also, with new CT technology, small metal particles which are not visible in any other way can shine clearly and the tiniest fractures show up. Hitherto unrecognized signs of strangulation, fractures and foreign bodies are found and some suspected murder cases have been reassessed after having undergone a virtual autopsy.

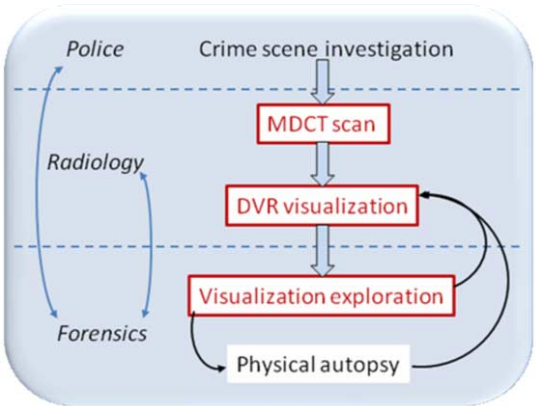


Figure 3-Overview of the forensic autopsy procedure. The VA activities are shown in red, enabling iterations. [7]

In short, the virtual autopsy is a newly developed procedure that will significantly enhance the autopsy, giving it the capacity to achieve more reliable results and by improving the VA workflow for the involved professionals.

Potential research impact

In some cases the virtual autopsy may replace the conventional autopsy procedure. Research on the unique aspects of post-mortem radiology must, however, be undertaken to identify cases and validate procedures. The interviewees foresee that novel visualization, interface and interaction design as well as data management techniques will be generated from this work. The contribution to medical and forensic fields is also imminent from establishing visualization techniques validated against histology and tissue examinations. VA technologies and methodologies will enable widespread use of virtual autopsies in the standard forensic workflow. Furthermore, VA will give a unique opportunity, in many medical research fields, to serve as the real "gold standard".

Potential impact on the society

The outcome of this project will have a significant impact on society at large. The decrease in the number of physical autopsies and some of its consequences can be counteracted, specifically in cases where religion and cultural requirements, in the multicultural society of today, prevent conventional autopsies. Since VA can also play an important role in improving forensics, and enable faster and more accurate crime solving, advancing VA technology and procedures further is of high value. Many aspects of VA can be directly transferred to healthcare in general, improving the quality of medical imaging and diagnosis for society as a whole. VA can also be used in non-forensic autopsies and solve the problem with the decreasing capacity for hospital autopsies.

Potential industrial impact

A major impact for industry is the possibility to commercialize and sell VA-related products. Given the tight collaboration with industrial partners that already have major international products in medical imaging; the commercialization will be easy to bring about. An additional positive impact from the PACS perspective is that VA constitutes a "worst case scenario" when it comes to large data set handling. The VA examinations are, in many ways, like any other diagnostic CT examinations, with the exception that radiation dose is not an issue. This means that a PACS that can handle VA is well equipped for the future challenges of traditional PACS tasks. This work furthermore widens today's applications for the MRI technique which will open a new market for the supply industry of MR scanners and its visualization techniques. Finally, when the applications improve, a second-hand market of CT and MRI equipment from the hospital domain could benefit the dissemination and use of VA worldwide in the standard forensic workflow.

Figure 4- Virtual Autopsy demonstrator: the VA table:

Discussion

The workflow analyses are ongoing; therefore we can not yet summarize all details. Although the potential impacts are clear, the technology is best used in conjunction with regular post-mortems. There are significant differences between living and dead bodies; for example on a deceased the arteries collapse and the veins get thicker, gas arises in different locations. Therefore it is important that the radiologist nurse and physician learn how to correctly interpret the VA images. Whereas other sites that have adopted the VA technology involve sub-specialities, as thorax and neurology, for examination of the VA images, this full-body examination procedure results in a coherent report and not disparate answers. Moreover, recurrent and iterative communication between radiologists and forensics in this workflow is unique and results in improved knowledge of how to interpret VA images. An

evolving profession will be the forensic radiologist, skilled in analysing radiology and 3D images of deceased bodies.

Future work will be to put more effort on developing intuitive user interaction tools and smooth workflows. Human interaction with the visualization is a crucial part of arriving at the goal of creating insight. A forensic pathologist does not want to, nor should he need to, interact with the system using technical constructs. The pathologist, and to a large extent also the radiologist, should be able to stay in their respective familiar professional domain. This means that a mapping must be established between the natural semantics of autopsies and classifiers that can identify the corresponding features in the data. Furthermore, the workflow must be adjusted for both radiologists and forensic pathologists.

Conclusion

The VA technology could revolutionize forensic medicine. Using the VA procedure, there are cases where completely new findings are detected. Although technological equipment and applications are fully working, the organizational workflow is not yet optimized. To bring the VA procedure into the standard forensic workflow, however, the specific demands of forensic examinations need to be adhered to. Virtual Autopsy workstation and image data sets need to be adjusted to support and improve conventional post-mortems. The future forensic VA workflow that is to be cooperatively designed and deployed is required to improve both the radiology and the forensic departments' collaborative and individual work situations.

In conclusion, virtual autopsy is a newly developed procedure that will significantly enhance the autopsy, giving it the capacity to achieve more reliable results and by improving the VA workflow for the involved professionals.

Furthermore, advances of VA resulting from this work are foreseen to play an important role to improve forensics in terms of enabling faster and more accurate crime solving.

Acknowledgments

Apart from the colleagues at CMIV (Centre for Medical Imaging Sciences and Visualization) and the VITA division (Visual Information Technology and Applications) of the Department of Science and Technology at Linköping University, we would like to thank the staff of the Department of the national board of forensic medicine and the radiology staff at the University Hospital in Linköping, Sweden. This project is financed by The Knowledge Foundation, The Vårdal Foundation, VINNOVA, Swedish Foundation for Strategic Research, and Invest in Sweden Agency as well as by its industrial partners; Sectra Imtec AB and Siemens Corporate Research.

An Analysis of Nursing Education's Immersion into Second Life, a Multi-user Virtual Environment (MUVE)

Patricia A. Trangenstein, Elizabeth E. Weiner, Jeffry S. Gordon, Ryan McNew

Frist Nursing Informatics Center, Vanderbilt University, School of Nursing, Nashville, TN, USA

Abstract

Second Life (SL) is a multi-user virtual environment (MUVE) using 3-D modeling to replicate real world settings and experiences. However, little is known of the extent to which nursing education is involved in SL activities. This study used four different search strategies to conduct a comprehensive review of print, blog, web and media sources. Twenty-nine unique nursing communities, groups or educational activities were identified. This study identified a number of barriers identified that made the analysis both difficult and time-consuming.
Two main categories emerged: explorers and developers. The explorers used SL for a support group, networking, and uncovering health-related sites. The developers were associated with land ownership and were involved in distance learning and simulation activities. Seven unique simulations for nursing education were identified. Given the number of registered users, the number of universities currently involved in SL, the availability of health-related sites for consumers, and the emerging interest in telehealth in SL substantial growth in the use of SL in nursing education is likely.

Keywords:

Nursing education, Computer simulation

Introduction

A variety of Learning 2.0 technologies have emerged over the last few years as adjuncts to both traditional and distance learning in nursing.[1] One of these technologies is a multi-user, virtual environment (MUVE). Some of the purported advantages of student engagement in MUVEs include active interaction, role playing professional skills, and increased competency in learning a new skill. [2] The degree of immersion and interactivity available in MUVES allows for a greater sense of presence which is believed to contribute to meaningful learning. [3, 4]

Presence is defined as "the subjective experience of being in one place or environment, even when one is physically situated in another".[5] In other words, participants feel as if they are actually in the virtual environment rather than where they are physically. In contrast, immersion refers to the sense of being enveloped by, included in and interacting with the environment. While involvement is "a psychological state experienced as a consequence of focusing one's energies and attention on a coherent set of stimuli or meaningfully related activities and events". [5} According to these authors, both immersion and involvement are required to experience presence.

At this time, one MUVE that is being used for a wide range of educational and healthcare activities is Second Life (SL). Second Life, developed by Linden Labs, has been available over the internet since 2003. Currently, there are over 16 million registered users with over 300 universities teaching courses or conducting research in SL. [6]

Upon entry into this virtual world, each participant creates a free, customizable avatar. Communication is via text messaging or by voice. Avatars navigate SL by walking, flying or teleporting. Real world entities can be replicated in SL through 3-D modeling and can provide simulated learning experiences that are impossible to achieve in the real world or are considered to be of high risk.

While nursing education has long used simulation part of its repertoire of learning activities, little is known of the extent to which nursing education is immersed in Second Life. This study surveys and categorizes the range of nursing education-related sites in Second Life.

Methods

To explore this area, four different searches were conducted. First, the term nursing was entered into the search engine in SL. The SL search engine used the key word "nursing" to search region names and descriptions, group names and descriptions, and individual avatar profiles. In addition to this search strategy, the author conducted additional searches in Google Scholar, Google and PubMed to identify additional nursing education activities through a comprehensive review of print, blog, web and media sources. These latter searches used the terms "Second Life" combined with "Nursing Education". Unique nursing educational activities were identified. Next, all relevant materials, including visits to SL sites, were reviewed to identify associated region or island names, sponsoring agencies or institutions, funding sources and descriptions of educational activities employed or proposed. Catego-

ries were developed that grouped the results based on their primary purpose.

Results

Table 1 displays the search results. Sixty-six percent (66%) of those were identified using the SL search engine. Of the 141 listings identified by SL only 21% were related to professional nursing. Ten (10) additional listings were identified by a Google search. Both Google Scholar and Pub Med did not identify any additional listings beyond what was obtained by SL and Google.

Table 1 – Search Results

Search Engine	Results	Unique Listings
SL	141	19
Google	6690	10
Google Scholar	92	0
PubMed	4	0

Of the 19 listings identified by the SL search, one (5%) indicated a region or island and 14 (74%) were group pages not directly linked to the corresponding region or island in SL. Descriptions contained in individual avatar profiles lead to an additional 4 unique listing (21%). Again, individual profiles were not associated with a SL region.

Initially, 32 sites were identified. Three were found to be members of a consortium and those sites were included with the listing for the consortium. Of the 29 unique institutions or groups identified as using SL for educational activities in nursing, the vast majority (83%) were American. Of the remaining 5 sites, 3 were located in the UK, 1 in Canada, and 1 in Australia.

The 29 unique listings were classified into 2 main categories: explorers and developers. In the larger, developer set (N=18, 62%) the group was associated with a region in SL. However, the 38% of those sites identified, were not linked to given region in SL. In addition, each entity in this latter group was identified in only one of the four searches conducted. Most (64%) were identified from SL group pages and 4 were identified through the Google search.

Those entities not associated with a region in SL, tended to be explorers of SL. They used SL for one of 3 reasons: support (N = 1), networking (3), or nursing educational activities (6). The one support group identified was Nursing Students of SL whose purpose was "to help with NCLEX/HESI questions, critical thinking scenarios, or advice for performing in clinicals". Other educational activities described by these explorers in SL included discovering healthcare resources in SL (Treasure Valley Community College/TVCC), possible use of a paramedic simulation in the curriculum (University of Nottingham/UK), or proposing to develop a virtual poverty simulation in SL for a community health clinical (University of Nevada)

Of greater interest in investigating nursing education's immersion into SL was a further analysis of the listings associated with regions or islands in SL. By purchasing land in SL, these groups had a greater financial commitment to, as well as a greater responsibility for developing and implement educational activities.

However, discovering the names of the respective regions in SL was difficult and often required additional searches in SL. Institution and region names are listed in Table 2 with their corresponding Second Life Uniform Resource Locators (SLurl), when available.

Table 2 – Institution and Region Names (SLurl)

Table 2 (continued)

12. HealthLink New York (http://slurl.com/secondlife/HealthLink%20New%20York/188/187/25)	HealthLink New York
13. Learning Commons for Nurses (http://slurl.com/secondlife/Teaching%2010/128/128/0)	Teaching 10
14. Second Health Imperial College of London (U. of Nottingham – UK) (http://slurl.com/secondlife/Teaching%2010/128/128/0)	UK Virtual Hospital
15. SLENZ/New Zealand Tertiary Education Commission (U. of Auckland) (http://slurl.com/secondlife/Kowhai/148/164/32)	Kowhai
16. Texas State Tech. College (http://slurl.com/secondlife/Kowhai/148/164/32)	TSTC-Commons
17. University of Michigan	Wolverine Island
18. U. of Texas Medical Branch at Galveston	UTMB Alpha - Main Campus

It was interesting to note that 50% of these communities in SL were found in only one of the 4 search strategies used. Most common was an individual or group page in SL, or a Google listing. Both Kansas City Medical Center and the Wisconsin Tecne were found in all 4 search strategies.

Given that land ownership in SL requires annual fees, probable funding sources or sponsors for these various SL communities were of interest. Nearly two-thirds (61%) of these communities were part of a wider university endeavor. Seventeen percent were supported or developed using grants. The remaining 4 communities were equally divided between government and consortia sponsorship.

Materials returned from the 4 search strategies that described nursing educational activities in these 18 SL communities were reviewed. Most referenced some type of distance learning activity that created a greater sense of presence. Most notable, was the YouTube video describing Duke University's School of Nursing distance learning for informatics students. [7] Students attended presentation in SL, gave poster presentation, and interacted with other students or communities in SL.

Four SL communities did not provide adequate descriptions of the nursing educational activities occurring within their region. Another one third (N=6) of these communities vaguely described simulated patient encounters or a virtual simulation lab experience. However, visits to these SL sites were either restricted to members only or these simulation areas could not be located on the respective regions.

The remaining 7 SL regions did provide more information that described unique nursing–related educational simulations. Table 3 lists these unique educational activities developed or proposed.

Table 3– Unique Nursing Educational Sims in SL

Site	Unique Uses
Ball State	Health and nutritional histories using volunteers and standardized client avatars.
Kansas University Medical Center	Healthcare Informatics/ Operating room for Nurse Anesthesia students proposed
University of Arizona	Border Crossing Sim
Vanderbilt University School of Nursing	Sims to teach nurse educators how to develop and implement simulations
Washington State Board for Com. and Tech. Colleges	Emergency Room Sim
Second Health Imperial College of London	Detailed Hospital Sim; Paramedic Sim
SLENZ	Post-partum Hemorrhage Sim

Discussion

Investigating nursing education's immersion into SL was both difficult and time consuming. Four different search strategies were needed to fully identify and describe participants and activities in this environment. The professional literature was sparse. Searching within SL resulted in twice as many sites for non-professional nursing listing. It was interesting to note that the SL search engine did not distinguish between "Nursing" (usually related to the profession of nursing) and "nursing" which was related to activities such as such as breast feeding and animal care. Attempting to locate relevant SL communities or activities would be a daunting task for nurse educators new to this environment.

The inability to locate and retrieve pertinent information related to nursing educational activities in SL, limits its adoption and likely underestimates nursing's immersion in this environment. A science-related wiki maintained by SL residents [8] includes a tag for nursing. However, only one site, the Ann Myer Medical Center, was listed that was related to nursing education. As with all wikis, updating and adding pages is a personal endeavor.

Another barrier to identifying nursing education's immersion in SL is the lack of any standardized template as to what to include in descriptions of regions or groups or in individual profiles. A consensus within nursing of users of SL as to a standardized approach to listing information would vastly improve search capabilities. A template similar to the one used

by the SL Health y wiki [9] could be adopted and might contain the following information.

- Group or SIM Name
- Purpose
- Contact Information
- Educational Activities Provided
- Target Audience
- Open to All or Closed (except to Members)
- Special or Unique Features
- Related Blogs, Wikis and Other Outworld Content
- Tags/Keywords
- Additional Comments

Furthermore, even if a SL nursing simulation or community was identified in this study, it was very difficult to uncover where in a given region the activity took place. This was due to either the community being closed to non-members or lack of information that directed visitors to nursing educational activities. In addition, many simulations could not be observed as synchronous participation by a group is required. Machinimas, such as those found on YouTube videos provide greater insight into select simulations.

It is not surprising that most of the SL communities identified in this study relied on institutional, governmental, or grant support, given that land ownership and development in SL is not trivial both in terms of costs and the learning curve. The resources needed to develop, maintain, and improve nursing educational communities is extensive. Therefore, it is likely that these or similar funding models will continue.

Using SL to explore healthcare resources is a valuable learning activity for nursing students. The SLHealthy wiki lists nearly 300 sites related to consumer health locations and groups or general health education resources. Many of these are already providing counseling and patient education. In addition there is growing interest in using SL for telehealth. [10-12] All of these reasons indicate that future nurses will likely need to be able to use navigate and interact with others in MUVEs such as Second Life.

Conclusion

Second Life is an environment that can provide valuable educational experiences in nursing. The degree of immersion and interactivity available provides a greater sense of presence, contributing to better learning outcomes.

Identifying nursing educational activities currently available in SL is very difficult. A number of barriers and possible solutions were identified. The difficulty in identifying educational activities in nursing in addition to the challenges of learning to navigate and develop simulations in a 3-D world and the technological requirements required may contribute to nurse educator's reluctance to consider SL as a viable educational tool.

However, since SL has only been available since 2003; the educational experiences identified by this study most likely represent the early adopters. Better identification of nursing education's immersion into SL can assist in the dissemination of this unique environment in nursing. Given the number of registered users, the number of universities currently involved in SL, the availability of health-related sites for consumers, and the emerging interest in telehealth in SL, substantial growth in the use of SL in nursing education is likely.

Trust – Can it be controlled?

Debra Box[a], Dalenca Pottas[b]

[a &b] School of Information and Communication Technology, Faculty of Engineering, the Built Environment and Information Technology, Nelson Mandela Metropolitan University, Port Elizabeth, South Africa

Abstract

Trust is an important component in the security of an information system. The advent of the electronic health record (EHR) and the health information system (HIS) have raised it to greater prominence. These systems and their intended benefits are rendered less effective through a low level of trust between the stakeholders. The potential reciprocal relationship between accountability and trust is investigated. A literature study examines both concepts and their interrelationship. The accountability and audit controls provided by the NIST SP 800-53 security guide and the ISO 27799 security standard are extracted, collated and expanded to strengthen the accountability mechanisms within an HIS security program. A dedicated set of accountability controls (NIM) which is specific to the healthcare environment is produced. It is proposed that through the strengthening of the accountability function of the HIS, its level of trustworthiness may be improved

Keywords:

Medical informatics, Accountability, Security measures.

Introduction

There has been a dramatic change in the management of health information using information technology (IT) during the last decade. The adoption of the electronic health record (EHR) together with the evolution of communication mechanisms such as the Internet have enabled the transfer and sharing of clinical information. These developments have arrived with an attendant increased risk to the safety of sensitive patient information [1].

The EHR provides discernable benefits in the administration of patient care and to medical research [2]. Its use allows easier access to the patient information. The sharing of these records facilitates government health-care decision making and medical research using de-identified patient data [3]. It is seen as superior to the paper version because the information is presented in a coherent manner, can be distributed to many locations and its access rules are explicit. It is not possible to ascertain who has viewed a paper record, but it is possible to record all and any access to an EHR [2].

The wealth of information contained in the EHR, however, poses additional security risks which have far-reaching effects. It contains all the information about an individual that a thief needs to steal their identity. Medical identity theft is a growing trend but healthcare providers are more concerned about protecting the clinical information. It is protected by layers of security but similar regard is not applied to Personally Identifiable Information (PII) [4]. This contradiction was noted in 1998 by Barber and is still an issue according to [4]. Healthcare practices who fail to protect the PII of their patients risk their reputation and harm such as the loss of public trust, legal liability or damages [4, 5].

This apparent security gap affects the confidence of the patient in the usefulness of an automated Health Information System (HIS). This concern about privacy hampers the truthful exchange of information between the patient and the clinician. It is seen as a major hindrance to achieving the full potential of an HIS [6].

The importance of security is highlighted by the global proliferation of privacy and data protection legislation such as the Data Protection Directive of the European Union, the Organisation for Economic Co-operation and Development (OECD) Privacy Guidelines, the Asia-Pacific Economic Co-operation (APEC) Privacy Framework and the Health Insurance Portability and Accountability Act (HIPAA) in the United States of America [5, 6].

Recent research in both Australia and the United Kingdom indicates that healthcare staff enjoy a high confidence level which results in minimal scrutiny of the HIS usage which brings a variety of possible security breaches through the improper use of access rights [7].

The healthcare environment is characterised by its co-operative nature and the trust placed in the judgement and activities of the healthcare professionals. It is an environment where security is not seen as a serious issue due to the professional status of the role players [8]. There are many factors that influence personal ethics and the fact that the healthcare personnel, using an HIS, are, in the main, members of professional bodies implies that a high level of professional trust exists. This type of trusting organisational culture acts as barrier to recognizing security threats and results in information security not being given the prominence it requires [3].

It is essential to build trust in an HIS because quality health care depends on accurate information [6]. The importance of good information within an HIS and its benefits cannot be understated. These include improved patient care and the creation of a culture of trust between the patient and

healthcare provider. As stated by Alshawi, Missi and Eldabi "after all, what is information if you cannot trust it?" [9].

It is proposed, in this research, that a high level of professional trust in healthcare environments may be controlled through a set of accountability measures. It is argued that trust and accountability are seen to exist in a reciprocal relationship and that the greater the accountability of an HIS may result in increased trust by both the users and patients. This leads to an examination of the security controls or measures themselves that are dedicated to accountability and the role they play in establishing accountability and enhancing trust. A resultant accountability control set specific to the healthcare environment is produced.

Method

A literature based approach was used to investigate the concepts of security management and control, accountability and trust. The literature study argues towards a reciprocal relationship between the concepts. The security controls that relate to the concepts of accountability and auditability were re-examined. Those controls that related specifically were extracted and collated. A resultant accountability and audit control set was produced, titled the NIM Accountability control set (NIM). This was achieved using the following method.

The following four source documents were identified as relevant to compile the NIM Accountability control set, viz:

- NIST SP 800-53. A guide to recommended security controls;
- ISO 27002, standard for IT security techniques and guide to information security management;
- ISO 27799, standard for health informatics and information security management using ISO 27002;
- Markle Foundation Connecting for Health – The Common Framework.

The NIST publications are used in this research because they are widely accepted and are freely available. They present generic guidelines that are applicable across a variety of organisational situations and their range of subjects is extensive. The ISO 277002 and ISO 27799 standards are used because they are internationally accepted and are well-known. The Markle Foundation Connecting for Health Common Framework is used because it represents an independent and unrelated viewpoint. It is the result of collaboration between various healthcare and IT professionals.

The NIST Computer Security Division has developed a variety of publications concerned with security programs and controls which encompass fair information practices, privacy principles, management and specifically auditing and accountability mechanisms. The NIST SP 800-53 covers the steps that address security control selection and includes tailoring the security controls. There are seventeen control families which have a two-character identifier unique to each family and are divided in to technical, operational and management classes. Examples include AC-Access Control, Technical Class to SI-System and Information Integrity, Management Class. The family of particular interest to this research is the AU-Audit and Accountability in the technical class [10].

The ISO/IEC in their publications ISO 27002 and ISO 27799, related to information security and health information security respectively, specifically address a security program and an ISMS and include monitoring and audit logging.

The Markle Foundation Connecting for Health Common Framework includes core privacy principles, trusted network design and accountability mechanisms [6, 11, 12].

The NIST SP 800-53 was identified as a natural starting point to define a control set for Accountability, because it specifically contains a family of controls dedicated to Audit and Accountability (AU). Thereafter, the corresponding controls in the ISO 27002 were identified, using a security control mapping tool provided by the NIST SP 800-53. It was noted that all the AU-Audit and Accountability controls, with the exception of AU-13 and AU-14, were covered. This rendered an ISO-27002-based control set dedicated to Accountability as defined by the SP 800-53.

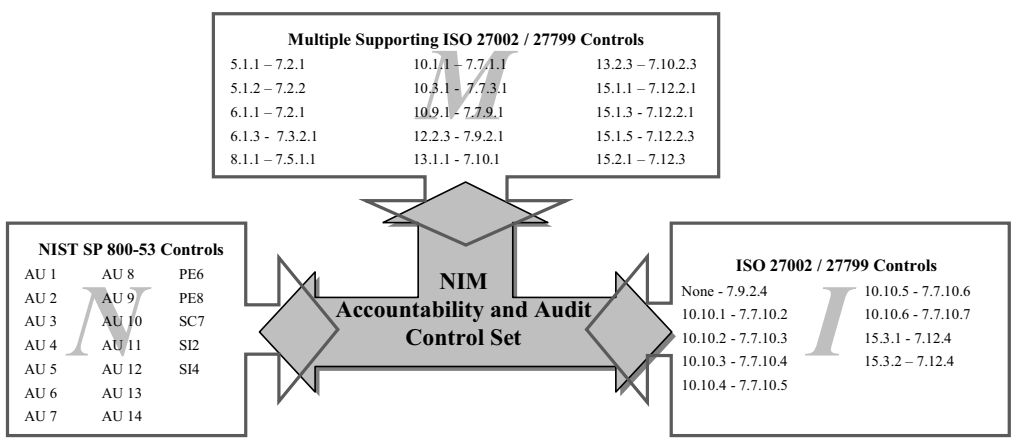

Figure 1 – NIM Accountability control set

The focus shifted to the ISO 27002. The controls dedicated to accountability were identified. These are presented in Figure 1 as Arrow I which contains the ISO 27002 controls that are directly related to accountability. The SP 800-53 security control mapping was used again, this time to map the ISO controls to the NIST controls. This mapping rendered some NIST controls not contained in the AU family. The complete set of identified NIST controls are presented in Figure 1 as Arrow N.

The focus of this research is the healthcare industry, therefore, the ISO 27001 controls needed to be mapped to the ISO 27799 health specific standard. This was achieved using the work of [13] in which a mapping between the ISO 27002 and the ISO 27799 was done. It includes the extent of coverage offered to the security issues by each standard. It was observed that the ISO 27799 includes additional guidance to accommodate the unique needs of health information security.

The activities of accountability exist within a security program and its ISMS and are, as such, directly and indirectly related to other security controls. The mapping between the NIST and ISO 27002 identified ISO-controls that are indirectly related to accountability. These are included in the resultant control set as multiple supportive controls and are presented in Figure 1 as Arrow M. The mapping between the ISO 27002 and ISO 27799 is reflected in the diagram.

The completion of these steps rendered a resultant control set for Accountability. The Connecting for Health Common Framework was consulted, as an independent source, to provide an unrelated analysis of the completeness of the accountability and audit controls.

Results

The NIST AU-family of security controls cover the entire gamut of audit logging and mentoring activities and their related controls are inclusive of a variety of activities including risk management and access enforcement [10].

The ISO 27799 Monitoring security clauses contain additional guidance to satisfy the special, healthcare security requirements for audit and logging that will ensure accountability and provide an incentive to users to conform to a level of acceptable use [13]. It was apparent that due to the unique needs of healthcare accountability it was necessary to include the new ISO 27799 security control - 7.9.2.1. Uniquely identifying the subject of care - into the NIM Accountability control set. There are many references to the need for distinctive identification needs within the EHR and its PII. Healthcare accountability is strongly linked to the unique identification of the users, their actions and the subject (the patient) of their activities.

There are many references in the Audit Record Content to the identification of the user and patient to enforce the concept of accountability through traceability. This raises the importance of uniquely identifying the user and patient interacting with the HIS [14], [12], [10]. This reinforces the decision to include the ISO 27799 security clause 7.9.2.1 in NIM Accountability control set.

The inter-relatedness of the accountability controls is demonstrated in Figure 1. Arrow N presents the identified NIST controls, Arrow I presents the ISO-controls that are directly related to accountability and Arrow M presents the multiple ISO-controls that support accountability. The NIM Accountability control set is represented by the multi-directional arrow.

The NIM Accountability control set is presented in Table 1. It represents the control set at the union of the Arrows marked N, I and M. It tabulates, in full, the controls identified through the mapping between the NIST SP 800-53, the ISO 27002 and ISO 27799 and includes the additional healthcare specific control.

Table 1 – NIM Accountability control set

Discussion

There are a variety of defined and generally accepted concepts in the area of information security and information security management. It is pertinent to inspect some to frame the proposition that trust can arguably be controlled.

The goal of information security is seen as the "preservation of confidentiality, integrity and availability of information" and includes such terms as the accountability of users, authentication, non-repudiation and reliability [15]. The goal of health information security is stated as maintaining information confidentiality, availability and integrity including authenticity, accountability and auditability [14]. There is a subtle difference between the two definitions and the healthcare security requirements are more inclusive. Additional healthcare considerations include the compliance with data protection laws and privacy legislation, maintaining organisational and individual accountability and maintaining public trust in the healthcare provider and the HIS in use [14]. Notably, accountability, auditability and trust are central to the definition of security in the healthcare context.

The ISO 27799 Section 7.7.10 Monitoring covers audit logging and monitoring and states that "Of all security requirements protecting personal health information, among the most important are those relating to audit and logging. These ensure accountability for subjects of care entrusting their information to EHR systems and also provide a strong incentive to users of such systems to conform to the policies on the acceptable use of these systems…" [14].

There are frequent references in the security literature to the concepts of trust and accountability. These concepts are examined to clarify their relationship. Trust is defined as, according to [16], the firm belief or confidence in the integrity, reliability, honesty etc. of another person or thing. It has the following synonyms: assurance, confidence, certainty and belief.

Trust, as a concept in IT security, is seen as result of good information security. It is not explicitly defined and is seen as an intrinsic concept.

Accountability, conversely, is frequently defined in a variety of standards, practices and guidelines. Its main aim is to ensure that activities are attributable to individuals [12]; similarly as the "property that ensures that the actions of an entity may be uniquely traced to that entity" [14] or as "the security goal that generates the requirement for the actions of an entity to be uniquely traced to that entity." [17].

The question posed by this research is – can trust be controlled by the use of appropriate accountability measures? There is an imperative to maintain organisational and individual accountability and the public trust in the HIS. These, it is argued, can be seen as a function of the implemented security controls that promote the accountability of the users for the data [5].

An HIS environment often relies heavily on the trust of its users who act as "guardians'' to protect its information. Guardianship can be implemented through using IT in monitoring and auditing the system activities [3]. Monitoring and auditing activities are typically associated with the concept of accountability. Therefore, accountability may be improved, through the application of appropriate mechanisms, such as monitoring and auditing. An improvement in accountability may lead to an increase in trust. This is due to stakeholders being sure that all activities are uniquely attributable to individuals, who can be held accountable for their actions. Therefore, it can be concluded that there appears to exist a reciprocal relationship between the level of trust placed in an HIS and the degree of accountability of its users.

Self-regulation is a key element of trust. However, relying on the trust or ethics of the users, who enjoy a professional status, is in-adequate and some control measures are necessary. Strong, user-identification procedures strengthens the ability of the HIS to prove accountability through its audit processes. It is possible to uniquely trace all activities within the HIS through examining the audit records.

The NIM Accountability control set is proposed to cover all the aspects of accountability within a healthcare environment and is specifically expanded to strengthen the identification of the user and patient. It is necessary to examine how the NIM Accountability control set may strengthen accountability and, therefore, trust.

The ISO 27799 text underlines both the importance of and inter-relationship of accountability and trust. The implication is that the stronger the accountability measures, the greater the resulting trust because all system actions are uniquely traceable to an individual. The rationale is that these mechanisms ensure accountability for the patient who has entrusted his personal information to the HIS and that it is used in an acceptable manner [14].

An audit log and the traceability afforded by the EHR are an important benefit provided by the use of an HIS. Privacy and accountability can be ensured through the audit and logging mechanisms which record all the access, activities and use of the EHR [2]. Strong privacy protection is seen to enhance the quality of the data and the subsequent health care that can be provided, by increasing the trust and the amount of truthful information shared by the patients, according to [18]. The inclusion of transparent and effective logging and audit control practices will promote trust among both the patients and participating institutions [12].

Accountability is established when the activities of the users of the HIS can be uniquely identified through a meaningful audit trail which is created for the actions of the users who can be held responsible for their actions. It is argued that robust audit controls may produce a greater level of accountability through enhanced traceability which, in turn, may promote the level of trust in the HIS.

The NIM Accountability control set contains a set of robust audit controls which are augmented to satisfy the health-specific accountability needs of health information security. The NIM Accountability controls are designed to provide an increased degree of accountability, for an HIS, when implemented. The reciprocal relationship between trust and accountability implies that the level of trustworthiness of the HIS, as perceived by its stakeholders, can be improved by the use of the NIM Accountability control set.

The use of the NIM Accountability control set may promote a tangible culture of trust within the healthcare environment.

This may help overcome the barrier of treating information security as a serious threat issue [3].

There is link between strong audit mechanisms that promote accountability which may lead to a reciprocal increase in trust by the users and patients of an HIS. This is the rationale behind the argument that trust may be controlled by implementing strong accountability control measures which influence the amount of trust placed in an HIS by its stakeholders. An HIS which employs a set of strong audit controls, as provided by the NIM Accountability control set, may improve its accountability and therefore, its level of trust.

Conclusion

The increasing reliance of healthcare management on IT and use of the EHR has brought benefits which carry an increased but unrealised security risk. This security gap has affected the confidence of the stakeholders in the operation of an HIS. It has raised the issue of trust in the provision of healthcare IT services. The research argues that a reciprocal relationship exists between trust and accountability. The viability of implementing accountability controls or measures, in healthcare security, to strengthen trust is examined.

A literature based approach is used and the NIST SP 800-53, ISO 27002, ISO 27999 and Markle Foundation Connecting for Health Common Framework were examined. A set of augmented accountability controls, the NIM Accountability control set, were identified from these documents.

An area of future research is the creation of dedicated security performance measures which will measure the effectiveness of the NIM Accountability control set.

The NIM Accountability control set is inclusive of the special needs of an HIS. It is proposed that when the controls are implemented they create greater user accountability which may result in increased patient trust in the use of an HIS, therefore, trust may, arguably, be controlled.

Abstract

This article reports on the experience of one organization between 2004 and 2009 to develop an effective people-process-technology system to better manage the quality of health care. The creation of this system started with creating a strategic plan for quality and then establishing a structure to implement the plan. The next phase consisted of establishing a number of simultaneous steps that ranged from identifying and leveraging the appropriate informatics tools to the oversight process, and from the implementation team to strategies for working with clinical groups. The outcome as of 2009 is a well established evidence-based quality process and team in place. There are over 450 evidence-based medicine quality sets. More than 52% of all patients are admitted on quality evidence-based medicine pathways and protocols. This article reflects a successful prescription for combining informatics and evidence-based medicine to improve the quality of health care.

Keywords:

Evidence based medicine, Informatics, Quality of health care, Medical order entry systems, Leadership

Introduction

There are many imperatives for organizations focusing on quality improvement. Health care delivery is not as good as it could be and progress toward a system that reliably delivers high-quality outcomes still has significant challenges [1]. Health care workers (clinical providers and ancillary staff) would like to improve, but achieving high-reliability, quality care cannot be achieved by simply working harder [2]. A new system of care must be created, but it is difficult to move from current practices without organizational leadership to sanction the needed changes and to ensure the importance of this direction [3].

Developing a new system of care is a significant change management/transformation process. This article reflects the experiences of one organization over five years (2004-2009) to improve the quality of health care through an organizational change process [4-6].

Vanderbilt University Medical Center (VUMC) is a comprehensive healthcare facility located in Nashville, Tennessee. VUMC consists of four hospitals: Vanderbilt University Hospital, Monroe Carell Jr. Children's Hospital at Vanderbilt, Psychiatric Hospital at Vanderbilt, and the Vanderbilt Stallworth Rehabilitation Hospital. It is home to the region's only Level I Trauma Center as well as the region's only Level IV Neonatal Intensive Care Unit. There are over 100 ambulatory specialty practices within the Vanderbilt Medical Group and the Vanderbilt-Ingram Cancer Center is Tennessee's only Comprehensive Cancer Center.

During this time period, Vanderbilt's Chief Medical Officer (CMO) had responsibility for the quality of patient care, for oversight and partnership in quality improvement efforts, and in developing systems to sustain high-quality care processes through time. To develop and implement an improved system, the CMO engaged the medical staff, resident physicians, nurses, nurse practitioners, dieticians, social workers, pharmacists, financial counselors, etc. to collaborate in on the goal of creating the most effective quality patient care delivery system possible [7,8].

Methods

In order to create a comprehensive quality effort, the CMO developed a strategic plan with input from multiple VUMC stakeholders. Based on this plan, quality committee structure included a new Quality Council and an Evidence-based Medicine (EBM) Committee, to better support quality-related goals and objectives.

One component of the quality plan was to identify all externally reported measures and develop internal methods for improving all of those metrics. To accomplish this, the following were included as key elements of the plan:

- assigning accountabilities
- developing internal metrics
- creating incentives for the organization
- working on motivation for those involved
- reinforcing our infrastructure to support these efforts

In addition to establishing operational accountability for quality-related items, infrastructure was needed to support achieving institutional goals. This infrastructure included support for determining best evidence applied to particular populations, determining the standardized practice that would be needed to deliver this care in a reliable fashion, and

electronic systems to support the delivery of desired care and also to monitor real-time status of patients with respect to desired care. To this end, an evidence-based medicine committee was established to identify opportunities for improvement, remove barriers to progress, and provide a forum to jump start moving from evidence to practice.

Pre-existing infrastructure was utilized as a platform on which to disseminate and implement evidence-based care pathways. Vanderbilt hospitals had used patient care pathways and order sets for a Clinical Provider Order Entry (CPOE) system for a number of years, but the order sets were not necessarily standardized, nor fully based on evidence. The informatics systems (such as CPOE) provided a platform to more uniformly implement and disseminate evidence-based care pathways to directly impact day-to-day care decisions. Thus, the Informatics organization was a significant component in creating a sustainable system of care that reliably delivers quality care.

With a quality strategic plan developed and a Quality Council in place, it was important to begin an effective organizational implementation process. A key component of the quality strategic plan was ensuring Vanderbilt's order sets and pathways were evidence-based. The initial goal was to begin to transform the organization away from expert-based care, where a lack of standardization can lead to unnecessary variability, to one of standardized, evidence-based care where every patient receives the care that he or she should receive for a given clinical situation, while still allowing appropriate variability to account for differences between patients. To kick-off the initiative, the organization established several simultaneous components to set the stage for success:

Ensured that the appropriate informatics tools and informational resources were available:

- Content creation tools and resources (e.g. order set creation).
- Content "vetting" tools that make comparing and contrasting current evidence with current practice simple and efficient.
- Expert assistance from an Evidence-based librarian to aid in evidence searches where answers are not found in off the shelf resources.

Created an oversight team which was responsible for:

- Approval Process
- Clinical sounding board to help prioritize the work
- For Vanderbilt, this group was the EBM Committee which consisted of the Chief Medical Officer, The Chief Nursing Officer, the Chiefs of staff for the various hospitals, Case Management leadership, and Informatics Leadership.

Established a support model for clinical teams:

- An integrated support team to facilitate this effort was essential. Clinical teams consisted of physicians, nurses, pharmacists, librarians, and informatics professionals we termed "Evidence-based Medicine (EBM) Specialists" to facilitate the work.

Created guidelines for facilitating change with clinical groups:

- Processes were established for contacting the teams, what information to share, sign-off sheets, communication strategies, etc.
- Created operational agreements to promote smooth functioning of work across business units (e.g. timely pharmacy review of orders to facilitate rapid development)

Identified areas of concentration:

- There were over 120 possible concentration areas. These were classified into current stages of "completeness." The eventual stages that evolved were: (1) Promised; (2) Preliminary Work; (3) Well along; (4) Ready for Oversight Group approval; (5) Ready for Case Management and Informatics Implementation; and (6) Completed. As we started "test-driving" this system a significant number of items from the "promised" category were eliminated to enable concentration on those topics that had the highest probability of success.

Alignment of informatics to actively support the initiative:

- CPOE – Content creation, and content clean up. New functionality to improve access to order sets (e.g. the creation of an "admission wizard" as a final common pathway to display order sets related to the admission service as a part of the admission process)
- Enterprise Data Warehouse – Data integration with other systems to track usage and outcomes related to pathway use
- Pharmacy Informatics – to develop clinical decision support to aid in the order creation process (e.g. creating a simplified renal dosing algorithm based on clinical indication for levofloxacin, rather than having the content duplicated across numerous order sets)
- Advanced Analytics – to aid in data analysis (e.g. opportunities for further work, analysis of impact outcomes)
- Content tools (e.g. "canned" evidence-resources such as Zynx Evidence)

The Process

The key in any successful program is not just to start but to think about the barriers, the desired end goal, and begin to design a process that people can understand and that can be used repeatedly. At the beginning of this initial phase, the needed products were purchased, the appropriate tools were created, and appropriate staff were engaged. This became a team effort. In order to identify efficient methods of developing evidence-based pathways and order sets, multiple development models were tried, with the idea that one of the models would prove superior to the others. Models that were tried included ones where multiple physician "leads" were involved, a model with a single physician lead researching evidence and creating the practice, and a model that utilized a team to facilitate the evidence discussion and content creation with the clinical team. The facilitative model proved most successful in terms of efficiency of time for the clinical

experts, as well as the ability to rapidly achieve consensus around a standard "Vanderbilt" practice. This model served as the basis for all ongoing work to support the EBM order set effort, and is still in place.

Developing and implementing content, however, is only part of the story. A major challenge is whether or not clinical teams view the content as their own, or whether they view it as owned by informatics or operations. If the former, clinicians are much more likely to use the order sets. Critical to achieving this view was the approach taken by the EBM Specialists while facilitating the clinical teams. The approach was one where the EBM Specialist asked the question "What to you defines good care for this patient population" and the resultant practices specified by the clinical team were then implemented. We found that by taking this approach, we mitigated fear by the clinical team that the EBM process would dictate care, and we also reassured the team that the organization would support what they considered to be best care. In other words, informatics, operations, and the clinical staff formed a partnership for success, with all parties focused on an end goal of reliable, high-quality care. In following this process, all evidence-based considerations were included, but were voiced first by the clinical team, thus establishing direct ownership of content by the team rather than informatics. The approach also consisted of a structure to support this ownership strategy [9].

The Clinical Teams

Each clinical work group consisted of physicians, nurses, a pharmacist, a librarian, and an EBM specialist. The EBM specialist facilitated clinical team meetings and built evidence packets that linked evidence directly to orders in current order sets (e.g. our current practice). The evidence packets focused helped clinicians focus discussion on desired practice. In addition to the evidence packets, a key feature of the teams was to assign a single physician lead. The lead was chosen strategically, and was specifically not a person who was viewed by peers to be a "techy" person. It was critical to find a leader who was clinically respected and whom others could identify with. Once selected, the physician lead served as the broker of agreements with other physicians to standardize practice where practice might vary but where standardization could prove beneficial. This was done outside of the team meetings in a one-on-one fashion and proved very successful. Previous to this, physicians often felt a need to justify practice differences, which lead to difficulty in coming to consensus. The "off-line" nature of the new model, greatly improved establishing a consensus, as well as fostered further "ownership" by the clinical team.

To more effectively facilitate arriving at a standardized "Vanderbilt" practice, evidence is presented to the clinical teams in a focused way. This allows the work group team to come to consensus on how they will treat a particular population of patients. The focus was not on "follow this guideline," but rather on "based on this evidence what would you like to do in taking care of these patients?" To accomplish this part of the process there were three key components:

1. Identifying the members of the clinical work group team, defining everyone's roles and structuring the team for more effective outcomes
2. Having evidence resources available that streamlined the looking at the evidence related to an orderable and order sets
3. Feeding back information on order set usage and performance to the clinical teams, so they can track to the kind of care they intended to deliver.

We were strategic about how the clinical teams were structured. For example, the physician lead is someone who needs to be respected by the other physicians in that group, someone whom other physicians would follow. The desire was to have other physicians trust and identify with the leader such that they would say, "Yes, that's a good way – I could do that as well." This physician then brokers any areas where there is disagreement among physicians or other members of the clinical team. Division chiefs or the department chairs were to identify the work needed, to help to prioritize, and identify the leaders. This was to ensure that the effort had upper level ownership. Residents and/or fellows were also included on the team. When needed, an Evidence-based Librarian completes more extensive searches.

Evidence Resources

For streamlined evidence resources, the EBM Specialists create "Evidence Packets" that list available evidence from a variety of sources, and organize the evidence around a template order set. Directly listing evidence for specific orderable items allows the clinical teams to focus their discussion, rather than having to deal with an entire corpus of evidence all at once. This process helps in developing consensus.

The CPOE System

Vanderbilt University Medical Center has a computerized provider order entry (CPOE) system. CPOE is an excellent mechanism to embed evidence-based guidelines and display to clinicians at the time of they are implementing orders. This is accomplished mainly through order sets that are lists of individual items that someone might want to use at a particular phase of patient care. For example, on admission to the hospital for congestive heart failure (CHF) exacerbation, there are a set of things that need to be initiated. A CHF admission order set is targeted to that particular phase of care to make the "right thing" easy to do. Later when the patient is moved to another phase of care another related order set is available and finally at discharge yet another order set is available. Making these order sets evidence-based was one of the avenues for affecting our inpatient care and we wanted consensus from the clinical teams about practice.

Reports to show actual performance with respect to desired performance

Feedback is provided for those items that clinical teams identified as key elements of the evidence-based care pathways. For example, one group explicitly added an evidence-based pain management section to their post-op order sets. This usage information could be provided to the clinical team that showed how often various pain management items

within the order set were being used. This allowed the clinical team to address potential issues with appropriate management of post-op pain.

Results

To date the process has been very successful. There are over 450 evidence-based order sets in the system with new ones being created all the time. Over 52% of all patients are admitted on EBM order sets. The basic process from four years ago continues and is built on a foundation of agreeing to a standard "Vanderbilt" practice that is based on evidence. Once agreement is reached, the order sets are created, utilization is monitored, and the data are provided to clinical teams to optimize use and performance within the desired practice. Data are reported to clinical teams to a) ensure that the order sets are being used; b) ensure that components of the order set are used in the manner that was planned; and c) to track to desired patient outcomes.

Monitoring is a critical component that enables the Evidence-based Medicine Specialists to serve in a facilitative partnership role with clinical teams helping them deliver correct and desired care to patients and drive that care toward desired outcomes. Utilization data is critical to promoting appropriate use and further promoting ownership of the content by the clinical teams. For example, a new order set may be created but after a few months it may not have been used. The reasons for this could be several, including the fact that people may not be able to find it in the system. Each of our order sets has synonyms associated, and it is possible that commonly entered terms that relate to a particular order set may not bring up the order set in the list of search results. For example, "Succinylcholine" is ordered for certain types of intubation protocols, but when typed in by a physician, order sets that pertain to these protocols were not showing in the search results. Adding Succinylcholine as a synonym resolves this issue, making the order set easier to find.

Order set usage data are important to ensure that the content is being used, but order set usage does not tell the story of *how* the content is being used. Order Set *Performance* is monitored to show the utilization of individual orders within an evidence-based order set. This can be viewed for a single patient (i.e. which elements did a single patient receive) and also in aggregate to see what percentage of the time certain elements are used across patients. For example, when the stroke admission order set was examined, orders for aspiration precaution were not utilized as often as the clinical team preferred. The patient population being evaluated had 100% of the patients on the clinical pathway but only 38% of those patients had orders for aspiration precautions. These data when presented to the clinical team caused them to investigate what elements of care workflow needed to be changed in order to ensure high performance with desired care. Discussion included whether or not this should be a standard of care for the unit and therefore did not need an order or whether they wanted an order "in the chart" for aspiration precautions to drive appropriate care. This case illustrates that with only simple order set utilization information, we could have been satisfied that 100% of the patients that came in with stroke were on the stroke pathway. However, after investigating the details of the performance with the desired care for these patients it was discovered that we were not at the 100% level and had additional work to accomplish this goal.

Our system allows us to know if an order set is being used, and also if we are performing as desired with respect to key evidence-based elements of the order set. However, once all is performed as planned, what does that mean for patient outcomes? This is a more difficult item to track. Looking at common outcome measures such as risk-adjusted observed to expected mortality, observed to expected readmission rate, and observed to expected length of stay is one major approach. Another approach that is being pursued is to have clinical teams and other groups define measures of clinical quality and build in capture of these data wherever possible, including using physician note templates, and automated capture from devices and other clinical systems such as bar-code medication administration systems. The plan is to aggregate these data and develop a more comprehensive picture of quality outcomes that extend across the inpatient-outpatient paradigm, and then associate performance and practice data with outcomes. This is the final piece in closing the loop for quality and is proving a challenge to accomplish. However, this is critical in ensuring that the desired care leads to desired outcomes. Each component of data feedback cycles back into the desired practice to inform whether or not changes are warranted. This basic approach for creation of evidence-based content in the form of order sets has been utilized for more complex evidence-based advisors that include complex logic within the order entry system as well as initiatives to reduce ventilator associated pneumonia, and other "hospital acquired conditions," such as pressure ulcers, falls, and reduction of adverse drug events. The Evidence-based Medicine Team is truly a partnership between IT and clinical teams to identify, establish, and implement standard practices and ensure reliable, high quality care that tracks to desired patient outcomes.

Discussion

It is easy to say that you would like to start an evidence-based medicine program so that the majority of patients are admitted to the hospital or treated in an ambulatory area using evidence-based practices. From a leadership perspective there are barriers that arise that make this difficult. The following are a few of the barriers.

Getting Started

Our first attempt with starting this effort was to hire a retired physician who had worked with evidence in the past to head this program. This was not successful. At this point an internal person from informatics with the leadership skills and the process knowledge to basically take what she called "going through the rainforest with a machete" to figure out where the roads actually could be or should be. She started a process that helped align people in the direction desired.

Agreeing on the resources

When starting this we did not know how many staff were needed, what type of electronic resources were required, etc. It

took several attempts at creating evidence-based medicine packets to know the needed resources. For example, library and pharmacy professionals needed to be included in the core team. The team needed to be staffed by nurses who were in the "bridge" role between the evidence based medicine information and the practitioners in the clinical areas.

The right leadership

The evidence-based medicine process needed the right leadership to be in charge of it. After an initial start it was determined that there was an informatics based physician who understood this process, had a personality to engage clinical and non-clinical staff, and had the style to create teams. That person was selected to lead this effort on an on-going basis and has demonstrated excellence in this area for a number of years.

Converting the doubters

When you live in an academic institution everyone is certain that they are the "world expert" and therefore evidence-based medicine is what they are creating or what they are doing. It was extremely important to show that the experts can make changes in their practices that would ensure and drive higher quality. To this end, the approach in achieving clinician ownership of order sets and pathways, coupled with ongoing support through data reports and iterative improvement established a new way of working that built momentum over time. People who started off on the sidelines saying "Evidence-based Medicine is cookbook medicine" began to say "Why didn't you work with me first?"

Conclusion

To have a successful link with informatics and evidence-based medicine requires leadership at the senior levels of the organization and at the process/operational level. It requires process metrics, measures of *performance*, and clinical teams that understand and respect feedback to enable the highest quality of patient care. Further, links to clinical outcomes are critical to ultimately assess the effectiveness of the implemented order sets and pathways. The implementation methodologies used, created a framework in which trust developed between clinical teams and informatics, and enabled true partnerships to flourish in which the pursuit of clinical excellence and excellence in patient outcomes is the goal.

The Trajectory of Scientific Discovery: Concept Co-Occurrence and Converging Semantic Distance

Abstract

The paradigm of literature-based knowledge discovery originated by Swanson involves finding meaningful associations between terms or concepts that have not occurred together in any previously published document. While several automated approaches have been applied to this problem, these generally evaluate the literature at a point in time, and do not evaluate the role of change over time in distributional statistics as an indicator of meaningful implicit associations. To address this issue, we develop and evaluate Symmetric Random Indexing (SRI), a novel variant of the Random Indexing (RI) approach that is able to measure implicit association over time. SRI is found to compare favorably to existing RI variants in the prediction of future direct co-occurrence. Summary statistics over several experiments suggest a trend of converging semantic distance prior to the co-occurrence of key terms for two seminal historical literature-based discoveries.

Keywords:

Literature-based discovery, Distributional semantics, Random indexing, Latent semantic analysis

Introduction

The field of literature-based knowledge discovery can be traced at its inception to the fortuitous discovery by Don Swanson of an implicit and therapeutically useful connection between fish-oil and Raynaud's Disease [1]. The idea underlying Swanson's approach to this problem is that two concepts may be meaningfully associated despite not yet having occurred together in the literature. The discovery of such implicit connections constitutes a literature-based knowledge discovery, and a number of computational approaches have been applied in an attempt to automate discoveries of this nature (for a review see [2-4]).

These approaches generally attempt to identify unknown connections by first identifying a "linking term" which co-occurs with the cue term. However, the explicit identification of linking terms imposes certain limitations on the discovery process. Firstly, the number of possible linking terms is generally large, and a combinatorial explosion in the size of the discovery search space occurs with the number of linking terms permitted on the path from cue to target. Consequently, automation of Swanson's discovery paradigm in this manner incurs I/O and computational costs that limit the possibilities for dynamic and responsive literature-based discovery tools. In this context, the development of methods to directly identify implicit connections, without the need for explicit identification of a linking term presents a desirable alternative. Such goals have led researchers in the field to explore methods of distributional semantics that directly identify implicit connections (without the need to explicitly identify a linking term), as an alternative [5, 6]. In our recent research, we have shown that Reflective Random Indexing (RRI) [7], a customized variant of the Random Indexing (RI) [8] approach to distributional semantics, is effective in identifying meaningful implicit connections.

However, a further limitation of existing approaches, including our own, is that they attempt to determine meaningful implicit connections by considering the distribution of terms or concepts in a corpus at a single point in time. From another perspective, the detection of meaningful implicit connections in a time-delimited set of documents can be viewed as the prediction of future explicit connections [9, 7]. One might hypothesize that changes in the strength of implicit associations over time would be important in predicting explicit connections in the future, as the associative strength between two concepts from disparate fields would be expected to grow as new connections are discovered between other concepts in these fields. In this paper we explore the extent to which changes in implicit associative strength over time are predictive of explicit connections in the future, in the context of two historical literature-based discoveries. In order to do so, we require a scalable model that is able to derive implicit connections from text, and is also easily incrementally updateable to accommodate adding new documents chronologically to the model without significant re-computation.

Both RI and RRI offer significant advantages in scalability over established methods such as Latent Semantic Indexing (LSI) [5] (for a computational details see [7]). In addition, both RI and RRI allow for incremental updates, as new documents are added to the corpus [8, 7]. As we have shown in our previous work [7], RI as originally implemented is ineffective in deriving meaningful associations between terms that do not occur together in any document. The reason for this is that RI produces a reasonably accurate reduced-dimensional approximation of the term-by-document matrix describing the

distributional statistics in the corpus concerned. Distance between terms is measured using the cosine (or normalized scalar product) between the vector representations of these terms in the reduced-dimensional space. Two terms that do not share any document between them will be represented as two vectors with no non-zero dimensions in common, and consequently their relatedness as measured by the cosine metric will be zero. RI does a good enough job of preserving the relative distances in the original matrix that there is a high probability of this being true in the reduced-dimensional matrix also [10]. In our previous work, we have addressed this limitation using RRI [7], however on account of its iterative nature the process for incremental updates using this method requires several steps.

Methods

To simplify the process of incremental updates for the purpose of exploring changes over time, we have developed a simple yet novel variant of RI which is also effective in deriving meaningful associations between terms that do not co-occur. The idea underlying this variant emerged from the observation that in the Singular Value Decomposition, which is used for dimension reduction in LSI, a reduced-dimensional approximation of the initial term-document matrix is obtained by finding the eigenvectors of the matrix AtA. This matrix is constructed by multiplying the term-document matrix by its transpose. Consequently a more consistent mapping between LSI and RI is obtained by adapting RI to reduce the dimensions of this symmetric matrix, in which each term is represented in terms of the extent to which its distribution across documents is similar to that of every other term. We will refer to this variant as Symmetric Random Indexing (SRI).

The procedure for dimension reduction of a term-document matrix using RI is as follows:

(1) Assign a *k*-dimensional (*k* in the order of 1000) zero vector to every **document**. We will term these elemental vectors.

(2) Set at random on the order of 10 of these zero values to +1, and the same number to -1.

(3) Assign a *k*-dimensional zero vector to every term. We will call these semantic vectors.

(4) Each time a term occurs in a document, add the elemental vector for this document to the semantic vector for this term (a weighting metric can optionally be applied here).

An advantage of RI is that the full term-document matrix is not ever represented in its entirety, which offers significant space advantages. As the elemental vectors are sparse, there is a high probability of their being orthogonal, or close-to-orthogonal to one another. Consequently, rather than assigning an orthogonal dimension to each document, as is the case in the full term-document matrix, a near-orthogonal elemental vector is assigned to each document, and semantic vectors for terms are projected directly into the reduced-dimensional space. The procedure for dimension reduction of the symmetric matrix AtA using SRI is as follows:

(1) Assign a high-dimensional (in the order of 1000) zero vector to every **term**. We will call these elemental vectors.

(2) Set at random on the order of 10 of these zero values to +1, and the same number to -1.

(3) Also assign a *k*-dimensional zero vector to every term. We will call these semantic vectors .

(4) Every time a term occurs in a document, add to its semantic vector the elemental vector for every other term occurring in the document, multiplied by the frequency with which this term occurs in the document (a weighting metric can be optionally applied here).

This procedure can be understood best by reviewing the process of matrix multiplication (Figure 1).

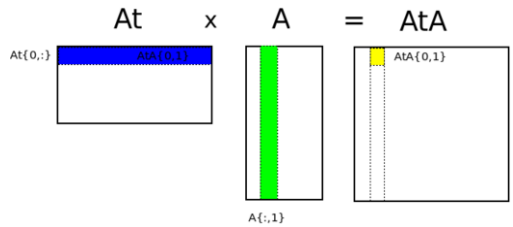

Figure 1- Matrix multiplication to generate AtA

A given cell, for example the cell {0,1} in the AtA matrix is obtained by taking the scalar product between the row At{0,:} and the column A{:,1} (Figure 1). To affect dimension reduction using random projection, we would like to assign a reduced-dimensional elemental vector to the column AtA{:,1}, thereby achieving dimension reduction by replacing each orthogonal dimension of the matrix AtA with a near-orthogonal approximation, in a similar manner to the process of RI. However, as the scalar product is a linear process, it is not necessary to calculate it simultaneously (Figure 2).

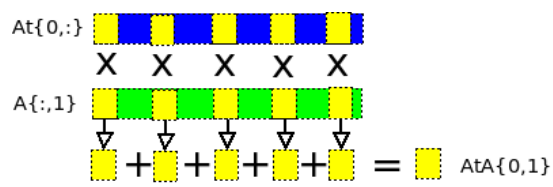

Figure 2-Components of the scalar product

Rather, we can calculate each linear component of the scalar product independently and multiply this by the elemental vector for AtA{:,1}. The sum of these linear components each multiplied by the elemental vector will equal the product of the elemental vector and the cell AtA{0,1}. In this way, we are able to create a reduced-dimensional approximation of AtA on a document-by-document basis, without constructing the full matrix. Consequently it is possible to derive implicit associations from large data-sets using this method. The space complexity of this model is $O(tk + ts)$ where t is the number of terms to be indexed, k is the dimensionality of the reduced-

dimensional space, and *s* is the number of non-zero values in each elemental vector. As with other variants of RI, time complexity is linear to the number of documents in the corpus.

In the experiments presented in this paper, we utilize SRI to derive implicit associations from abstracts in the MEDLINE corpus, and monitor the strengths of these associations as new documents are added incrementally to the model. In addition to the four steps of SRI described above, we use the log-entropy weighting metric to minimize the effect of disparities in local term frequency and emphasize the effect of terms that are focally represented [11]. In addition, we perform an on-the-fly equivalent of normalization of the document vectors to minimize the effect of differences in document length. Both of these customizations are common practice in Latent Semantic Analysis (LSA) [12], which has been successful in the derivation of meaningful implicit associations from smaller corpora in a number of applications [12]. In all cases, we generate vectors for those unique terms occurring 10 times or more in the corpus concerned, that do not contain any non-alphabet characters. In addition, we exclude terms on the stopword list distributed with the Arrowsmith system [13], which has been customized for the purpose of literature-based discovery.

Experiment 1: SRI and Implicit Associations

For the first experiment, we use SRI to derive a model of a time-delimited segment of the MEDLINE database. As in our previous research [7], this segment consists of the titles and abstracts of all citations added to MEDLINE between 1980 and 1985. For comparison with existing models, two 2000-dimensional SRI spaces are constructed, one with and one without the use of log-entropy weighting. For each of a set of 2000 randomly selected cue terms, the same set as employed previously, the 50-nearest indirect neighbors (NINS) are retrieved. NIN's are the terms most associated with a cue term that do not co-occur with it in any document in the corpus. Finally the proportion of these NINS that co-occur directly with the cue term in citations added to the 2008 release of MEDLINE after 1985 are evaluated. The assumption underlying this evaluation and similar methodologies [9], [14] is that an implicit connection at one point in time will be stated explicitly once it becomes discovered public knowledge.

Experiment 2: Trajectory of Historical Discovery

Having evaluated the ability of our model to derive meaningful indirect connections, we proceed to explore the trajectory of scientific discovery in the context of two of Swanson's seminal discoveries. For this experiment, we derive a 1000-dimensional space from all of the abstracts in the 2009 baseline release of MEDLINE (n=9,573,614), generating vectors for every unique term meeting the constraints described previously (n=333,214). We build this model incrementally, processing those abstracts added to MEDLINE every year, and evaluating the strength of association (as measured with the cosine metric) between the term "raynaud" and the term "eicosapentaenoic" which represents eicosapentaenoic acid, the active ingredient of fish oil. In addition, we keep track of the points in time when these two terms occur together in an abstract. As a control, we also assess the strength of association between the term "raynaud" and the term "kuru" which was selected by the authors on the account of their inability to conceive of a reason for these two terms to be meaningfully associated. On account of the stochastic nature of SRI and the small sample size, this experiment is repeated 50 times establish an average and to assess the statistical significance of the observed results. We perform the same experiment using the terms "migraine" and "magnesium", another implicit association identified by Swanson in his early experiments.

Results and discussion

Experiment 1

Figure 3 shows the results of the first experiment, presenting the proportion of the 50 NIN's extracted prior to 1985 that co-occur directly with their cue term after 1985.

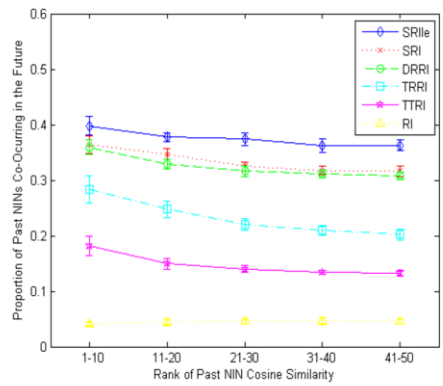

Figure 3-Comparison of RI variants. RI = Random Indexing as originally implemented [8], TTRI = term-term (or sliding window) RI [15], TRRI = term-based RRI [7], DRRI = document-based RRI [7], SRIIe = SRI with log-entropy weighting.

Each column in Figure 3 shows this metric for a range of rank, with the first column showing the proportion of the 10 nearest indirect neighbors that predict future co-occurrence. This column can be interpreted as precision at k=10, if future co-occurrence with the cue term is taken as a gold standard. SRI is compared to results obtained with other RI variants on this data set in a previous publication [7], which includes a detailed comparison of the methodological differences between these models. For the purposes of this paper we note that the SRI model is more effective in predicting future co-occurrence than any of the models evaluated in our previous work. As can be determined by the error bars on the graph (+-1 standard deviation) along with the sample size (n=2,000), most of the differences between SRI and other models are statistically significant, as are the changes in rank with decreasing cosine similarity. However, we note that SRI also favors NIN's with a higher global term frequency than other models, as illustrated in Figure 4. Terms with high global frequency are more likely to occur directly with cue terms by chance, and are generally less informative. Nonetheless, the results of this experiment show that log-entropy weighted SRI is able to predict future direct co-occurrence more effectively than any of the RI variants we have previously evaluated.

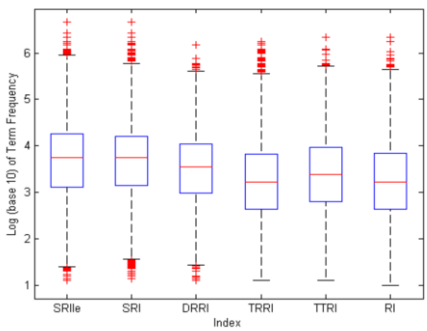

Figure 4-Boxplot of the global frequencies of NIN's.

This experiment proves SRI is able to predict future co-occurrence, which can be viewed as a measure of its ability to draw meaningful associations between terms that do not co-occur directly together in any document. When considering the ten NIN's, the precision of SRI with log-entropy weighting approaches 0.4. By comparison, in our previous research precision at k=10 on this data set ranged between 0.25 and 0.36 for RI variants, with one exception: a second iteration of the term-based RRI approach did produce a precision at k=10 of 0.4. However, repeated iterations make it more difficult to implement the incremental updates that are essential for the experiments presented here. All of these results exceed those obtained in a similarly-structured comparative study of discovery methods requiring explicit identification linking terms [9]. While these results are not strictly comparable due to the additional constraints and smaller size of the test set in the evaluation using linking terms, that the precision at k=10 of SRI in our experiment exceeds any published estimate for other methods in similar evaluations suggest it will make a useful addition to the set of tools currently employed for literature-based discovery. However, SRI tends to retrieve on average terms with higher global term frequency than other RI variants, suggesting that some of the predictions may be less informative than those produced by, for example, term-based RRI.

Experiment 2

Figure 5 illustrates the aggregated results of fifty runs of the second experiment. The figure show an increase in the association between "raynaud" and "eicosapentaenoic" that precedes the first time these terms co-occur together in a MEDLINE abstract, which is shown by a circular marker. We note that while the first observed co-occurrence occurs approximately five years after Swanson's discovery, the increase in associative strength begins before this. This increase in associative strength is also greater than that observed between "raynaud" and the control term, "kuru", and this pattern is consistent across runs. A similar pattern is observed in relation to the implicit association between "migraine" and "magnesium" (Figure 6).

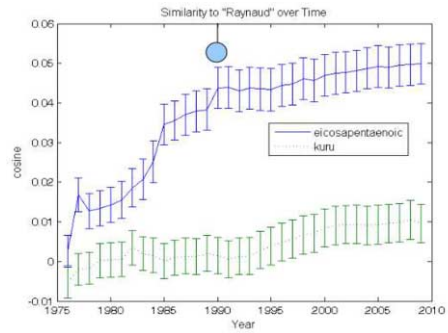

Figure 5-SRI associations between terms "raynaud" and terms "eicosapentaenoic" and terms "raynaud" and "kuru" between 1981 and 2009. Mean values over fifty runs depicted.

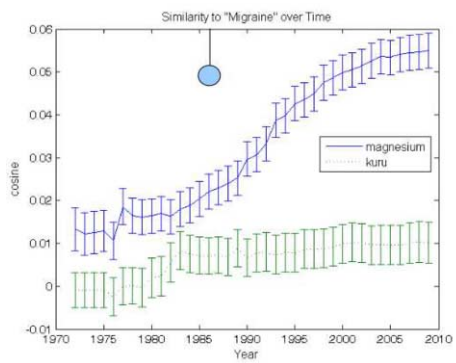

Figure 6-SRI associations between terms "migraine" and "magnesium" and terms "migraine" and "kuru" from 1981 to 2009. Mean values over fifty runs depicted.

In both cases, the increase in the strength of the implicit association precedes direct co-occurrence. This experiment provides some suggestive evidence that an approach incorporating changes over time may offer an advantage over approaches that view distributional statistics as a static snapshot in time. There is evidence from this study of a sharp rise in the strength of implicit association between the terms "raynaud" and "eicosapentaenoic", as well as between the terms "migraine" and "magnesium" that precedes both their first direct co-occurrence in an abstract and Swanson's seminal literature-based discoveries. However, as in all experiments simulating historical literature-based discoveries, there is the concern that findings related to a particular discovery may not generalize.

Limitations and future work

In our current research, we are investigating the extent to which trends in time, as measured using SRI, can be of use in the prediction of future co-occurrence from a large sample set. Results up to this point have been inconclusive: re-ranking of SRI-based NIN's according to the positive change in their cosine to the cue term over time does not appear to improve predictive ability. Furthermore, while terms with the greatest increase in association to a given cue term (Table 1) are often meaningfully related, this measure of relatedness does not

appear to be as predictive of future co-occurrence as SRI alone. Further research is required to develop methods that utilize the additional information provided by trends over time.

Table 1 – terms with the greatest increase in (direct) association strength (1980 and 1985)

thrombolysis	Schizophrenia
0.127: intracoronary	0.065: dimond
0.109: stk	0.055: casenotes
0.100: reocclusion	0.054: multiconditional
0.083: recanalisations	0.053: constructivist
0.077: reoccluded	0.049: schizoform
0.075: recanalised	0.048: balogh
0.074: recanalization	0.047: nonsimultaneity
0.067: thrombolysin	0.047: palau
0.065: reperfusion	0.045: murky
0.063: myocardial	0.044: schizoaffectives

While this work does demonstrate the effectiveness of SRI in deriving meaningful implicit associations, and provides some suggestive evidence that additional useful information is obtained by following trends in these associations over time, the methods used to measure changes over time are rudimentary. In our future work we will explore linear regression models and other more sophisticated approaches to measuring change over time to determine the extent to which these improve the ability to predict future co-occurrence. In addition, we will evaluate other factors we have not attended to here, such as the point in time at which future co-occurrence occurs.

Conclusion

In this paper, we present and evaluate SRI, a method which enables highly efficient updating of term vectors as additional documents are added to a database. The ability to track changes in the strengths of implicit associations over time is one of the advantages of the method. We find suggestive evidence that the additional information provided by this method may be of use in the prediction of future co-occurrence, and consequently it is of interest for literature-based knowledge discovery. The finding that this method is productive in deriving implicit associations has implications for information retrieval also, as it is both scalable and more conveniently amenable to incremental updates than similarly productive models.

Acknowledgments

We would like to acknowledge Dominic Widdows, for originating the open source Semantic Vectors package, some of which was adapted to the ends of this research.

Abstract

Translating legislation and regulations into access control systems in healthcare is, in practice, not a straightforward task. Excessive regulation can create barriers to appropriate patient treatment. The main objective of this paper is to present a new methodology that can define, from legislation to practice, an access control policy as well as a RBAC model, in order to comprise generic legislation and regulation issues together with the access control needs from the ends users of a healthcare information system. The methodology includes the use of document analysis as well as grounded theory and mixed methods research. This methodology can be easily applied within a healthcare practice or any other domain with similar requirements. It helps to bridge the gap between legislation and end users' needs, while integrating information security into the healthcare processes in a more meaningful way.

Computer security, Access control, Computerized patient medical records, Mixed methods, Grounded theory.

Introduction

Healthcare Information Systems (HIS) allow the collection, extraction, management and search of information and involve several people, processes and services within its environment, stressing therefore the need for information security [1, 2]. Both patient and healthcare organization concerned can be seriously damaged if no proper security is provided [3]. Access control constitutes the baseline for information security [4] and is one of the first interactions between humans and technology. In order to access information within a system there are usually 3 steps: identification – where a user says who he is (e.g. using a unique login or username); authentication where the user proves he is who he says he is (e.g. using a password or PIN number); and authorisation where access rights are given to the user. Authorisation can usually only occur after the first 2 steps are successful, and it checks if users meet all the requirements to exercise those rights and access the resources they requested. Access control is part of the authorisation process that checks if users may access resources they asked for. Current access control policies and models are usually not properly defined. Either they do not exist or do not integrate users' needs (i.e. healthcare professionals and patients), so when it comes to their usage, healthcare professionals can have many difficulties [5]. Also, recommendations and legislation are available in healthcare to protect sensitive medical information and to guarantee that this type of information is only accessed and used in specific and justified contexts [6-9]. These regulations tend to be generic and orient attitudes within the medical practice. However, to translate these orientations into practice is not straightforward. Many times this is not even possible. Research shows that excessive regulation can actually create a barrier that physicians have to surmount when treating patients [10]. The main objective of this paper is to present the development of a new methodology that can define, from legislation to practice, an access control policy as well as a RBAC (role-based access control) [11] model in order to comprise generic legislation and regulation issues together with the access control needs from the end users of a HIS. This methodology will try to bridge the gap between these two parties and help to reduce the barriers that are usually present in the integration and use of a HIS.

Background

One obstacle mentioned by healthcare professionals for the use and integration of EMR within healthcare is the lack of controls to provide for patient privacy [12]. Access control, which is one means of providing confidentiality, needs to be improved so that patient's privacy can be effectively protected. There are also other barriers that impede the effective integration of EMR within the healthcare practice. These barriers can be grouped in: time/cost, relational and educational [13, 14]. The relational barrier includes the perceptions that physicians and patients have about the use of the EMR and how their relationship may be affected by it. An example could be when the physician uses the computer during a consultation and the patient does not trust the information the physician is inputting and searching on the system because he usually does not know how that information can be used and what kind of protection is provided. The educational barrier comprises the lack of proficiency and difficulties that healthcare professionals have in interacting with the EMR in order to perform their daily tasks [15]. Healthcare professionals do not usually participate in the design and development of working tools (in this case the EMR) so they usually have to redes-

ign their practice workflow and processes, which is very challenging and consumes more time and costs [14]. Results from a systematic literature review on access control for both generic and the healthcare domain showed that although access control is a security service that has been widely studied and applied in healthcare systems such as EMR (Electronic Medical Record), the fact is that the most interested parties, the users (both healthcare professionals and patients), are not usually consulted when the access control policies are integrated into these systems, and when the system is integrated within their workflow environments. Healthcare professionals usually needed to change their workflow patterns and adapt their tasks and processes in order to use the systems [5]. This study [16] showed that EMR designers and implementers should monitor healthcare professionals' attitudes, opinions and experiences through the use of comprehensive evaluation methods such as focus groups and structured questionnaires in order to obtain substantial information to input into the design and implementation process. In this way the implemented systems are more likely to succeed. The use of both qualitative and quantitative methods (i.e. mixed methods) can elicit a wider range of information from the end users, thereby helping the designers and implementers to gain a deeper knowledge about the human needs from the EMR system. Further, the analysis of legislation and regulation documents that focus on defining the rules for access control can also be integrated within the same goal. The study and analysis of both generic and specific access control issues for the healthcare environment and the integration of these results within the healthcare access control policy should improve, not only the acceptance of EMR, but also the design of the access control component in order to reduce some of the educational and workflow problems that were found to be very common among the EMR systems in use. This type of research or methodology has not been published before and so the results cannot be compared to previous work.

Materials and Methods

Method Development

As there were not much research available on this subject the process started by analyzing published material on access control, both in generic and healthcare domains [5], as well as on the type of methodology to gather information that is not yet available. So in this case, literature reviews were performed in order to select the most appropriate methods for this purpose [16]. It was decided that there was the need to include both generic issues (legislation and regulations) as well as specific issues (end user needs – both healthcare professionals and patients).

1. For generic issues: a document analysis regarding legislation and regulations was performed to retrieve access control related issues;
2. For specific issues: grounded theory together with mixed methods was selected in order to collect data.
    a. After qualitative data collection, the analysis was performed according to Figure 1.
    b. Results from the qualitative analysis were used to develop the quantitative methods that were subsequently applied.
    c. The analysis of the quantitative data was done according to Phase 4 of Figure 1.
3. Generic assumptions were taken into account since there was not much information available aposteriori;
4. All analyzed data was then transformed into Access Control Rules;
5. Access control rules were standardized into IF THEN rules to comprise a generic Access Control Policy;
6. The generic Access Control Policy was transformed into a RBAC Policy;
7. A new extension of the RBAC model was developed in order to comprise the new RBAC Policy.

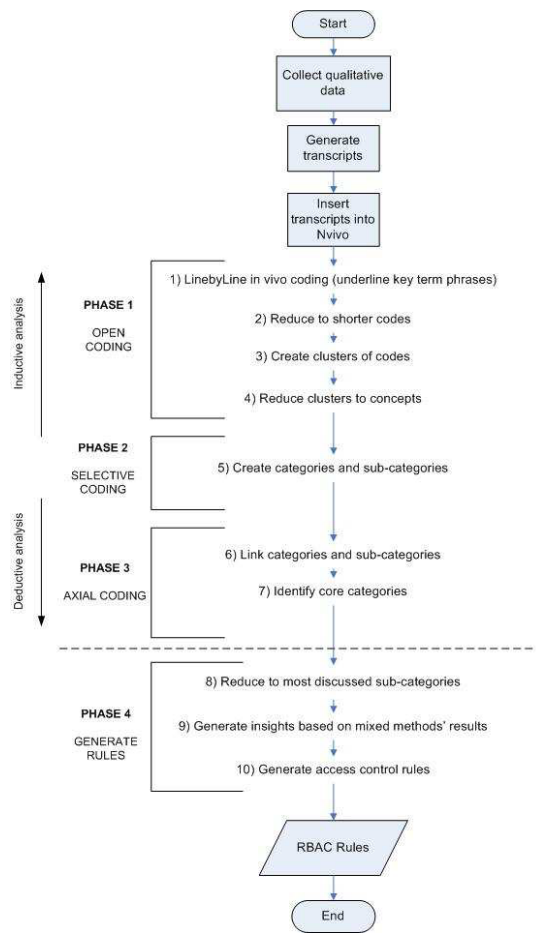

Figure 1 – Grounded Theory method used to analyze qualitatively focus groups' data.

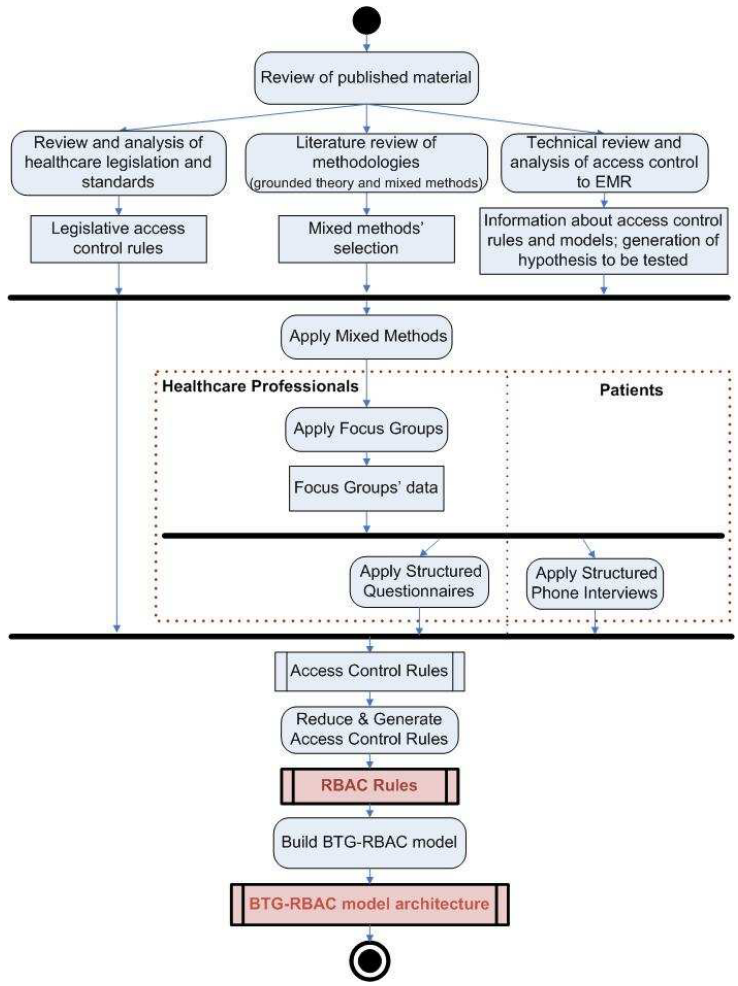

Figure 2 – Methodology description.

The method described in Figure 1 that is included within the bigger methodology presented in Figure 2 ("Reduce & Generate Access Control Rules") for the analysis of focus groups' data is the central part of this research. It describes how qualitative data was analysed and how the whole grounded theory process was done.

In more detail, the data generated from the qualitative research was collected and then transcribed and inserted within qualitative coding software (NVivo [17]). Phase 1 of this process included the line by line coding and grouping of codes of the whole transcripts; Phase 2 included a more focused or selective coding that allowed for the generation of categories and sub-categories from the codes in Phase 1; Phase 3 comprised the organization and ordering of the previous categories; and Phase 4 reduced the generated categories to the most discussed ones that were then included within the Access Control Rules' list.

Method Description

The methodology that was developed and can be used in a generic way by other researchers is described in Figure 2, with an activity diagram.

1. For generic issues: HIPAA [6], European Healthcare Recommendations [8,9] and the code of ethics for health information professionals were analysed; for specific issues, a technical review on access control was performed;
2. From the revised material assumptions were made for both healthcare professionals and patients regarding access control, these were used to confront with the results obtained;
3. A literature review of methodologies was performed. For grounded theory and mixed methods: focus groups (the main qualitative method) were applied first:
    a. Data was analysed according to Figure 1;

   b. Results from the most discussed categories were included into the subsequent quantitative methods;
   c. Structured questionnaires were applied to healthcare professionals;
   d. Structured phone interviews were applied to patients.
4. Access control rules were generated for both healthcare professionals and patients;
5. Each access control rule was separated into fundamental blocks of conditions and operations to be transformed into a RBAC rule, using the format as in [18];
6. A new access control model (the BTG-RBAC model) was developed in order to model the RBAC Policy generated from this method [19].

Results

In order to validate the presented methodology, a case study was performed. It used the BTG (Break the Glass) concept [19, 20] and instantiated every step of the method in Figure 2 as described below.

The first step of revise published material was previously performed and applied generically for every case study, and so it was used for this specific one.

1. **Document Analysis**: Portuguese Legislation - Law 12/2005;
2. **Generated Assumption**: There is the need for an override policy (e.g. Break The Glass);
3. **Mixed methods appliance and results** (Table 1):

Table 1- Description of the mixed methods applied.

Method	N	Data results
Focus groups	26 (4FG)	Access in emergency situations: requires different access(6 references);
Struct. questionnaire	27	A majority of respondents 74% (n=20) agreed with the existence of providing access in emergency situations depending on the situation and healthcare professionals
Struct. Phone interviews	200	YES: 191; NO: 3; no answer: 5; does not know: 1

4. **List of generated access control rules after applying the method in Figure 2**:

   A. Specific roles must be able to BTG and access (visualize only) information in emergency (or other unanticipated) situations
   B. It must be possible to define a fine-grained BTG (i.e. it may depend on roles as well as time and location restrictions)
   C. Logging and obligations must be provided at all times
   D. Access to genetic information must be managed and accessed only by medical doctors from the genetic specialty
   E. The number of healthcare professionals that are authorized to access information regarding DNA and biological products must be restricted in order to guarantee security as well as prevent losses, modification or destruction

5. **Access Control Policy based on RBAC-ACF [18]**:

Access control policies are often expressed through policy specification languages each of which may have different syntaxes. However, fundamental building blocks of any access control policy are: **subject, object, operation**, **condition**, **effect**, **obligation** and **purpose** [17].

A subject is a computer system entity that can initiate requests (e.g., user, agent, application process) to perform an operation or series of operations on objects. An object is a system entity on which an operation can be performed (e.g., a file, a table, a view). A condition describes the additional restrictions that must be evaluated in order to GRANT or DENY access to a particular subject for a particular data object. Effect is the outcome of evaluating a policy rule (e.g., GRANT or DENY). For these rules, the effect is always GRANT or allow because they are all described in the positive. Obligations are additional actions to be performed when the access control rule is triggered. The purpose has usually two objectives: business or data purpose.

The access control rules are defined as:

> Allow **[user/role/subject]** to perform **[operation]**
> on **[object]** provided **[condition]**
> Carry out **[obligation]**

The access control rule D was separated in two rules (D & E) in order to comprise both actions *access* and *manage*.

A. Allow **[specific users/roles]** to perform **[BTG (visualize only)]** on **[medical data]** provided **[emergency or unanticipated situations occur].** Carry out **[BTG obligations: logging, alert, email to responsible parties and proof of justification]**
B. Allow **[specific users/roles]** to perform **[definition of BTG operations with or without constraints]** on **[other users/roles]** provided **[they are authorized]**
C. Allow **[users]** to perform **[logging and obligations]** on **[medical data]** provided **[a BTG action is performed]**
D. Allow **[medical doctor(role)]** to perform **[access]** on **[genetic information]** provided **[medical doctor is from a genetic specialty]**
E. Allow **[medical doctor(role)]** to perform **[manage]** on **[genetic information]** provided **[medical doctor is from a genetic specialty]**
F. Allow **[users/roles/subjects]** to perform **[restrict access to a minimum required]** on **[DNA + biological products information]** provided **[they are authorized]**

6. The generated access control policy for BTG is comprised of 6 access control rules. Rules A to C can be modelled by the **BTG-RBAC model** [19], while rules D to F can be modelled by a generic RBAC model, and therefore, the BTG-RBAC model as well.

Discussion

This paper presents a new methodology that did not exist in the literature in order to ground security in the healthcare domain. It is a simple methodology to apply and integrate both generic and specific needs of the healthcare environment approaching this way legislation to the healthcare daily practice. This methodology can be applied not only in healthcare but also in similar domains with similar requirements in terms of security. It is flexible enough to be adapted according to the requirements of the system, both in terms of types of qualitative and quantitative methods chosen as well as the number of participants in each one of them.

Limitations of this work include the need for time and costs involved within the qualitative and quantitative methods setup, appliance and data analysis. Studies that do not involve end users of an information system may not benefit from this methodology.

In order to improve and refine the methodology presented in this study, it must be applied and tested with several other similar case studies and, if possible, in other domains besides healthcare.

Conclusion

The methodology presented in this paper can be used to generate, from legislation to practice, access control rules to be integrated within an access control policy for the healthcare practice. This methodology helps to bridge the gap between legislation and users' needs while integrating information security in a more meaningful way into the healthcare processes.

Can Signalling Theory and the Semaphoric Nature of Information Systems Explain Clinicians' Ambivalence to Informatics?

Derek Meyer[a], Benita Cox[b]

[a] *Division of Community Health Sciences, St George's, University of London, UK*
[b] *Imperial College Business School, Imperial College, London UK*

Abstract

Investment in information systems has traditionally been justified in terms of productivity or value-added gain. From this point of view the slow rate of adoption of IT in the healthcare sector appears paradoxical because the rapid increase in medical costs has created an urgent need for productivity improvements. Spence's market signal theory may explain why some information system investment decisions are made and may, in part, explains the reluctance of clinicians to embrace informatics. Case studies are presented where we argue that information system investment was made primarily to send a market signal. We call information systems that are used primarily to send a market signal, semaphoric information systems. Characteristics of semaphoric information systems are presented. It is postulated that the therapeutic relationship between doctor and patient is central to current models of healthcare, and that the semaphoric 'message' of the current generation of IT systems may be detrimental to this relationship. This suggests that clinicians will continue to be reluctant to embrace information systems until information systems are developed that can send signals that enhance the doctor-patient relationship.

Keywords:

Semaphoric, Doctor-patient relationship, Market signal, Economics, Clinical informatics, Consultation.

Introduction

It is generally recognised that clinicians and the healthcare sector have been slow to afford themselves of the opportunities offered by information technology. Yarbrough and Smith noted that "the proliferation of information technology has been a revolutionary force that has increased efficiency and effectiveness in many industries. However, health care organizations, particularly physician practices, are noticeably lagging in the adoption of such technologies" [1].

The semaphoric nature of information systems may, in part, explain this. A signal can be considered semaphoric if:

1. The signal reveals some quality of the organisation as a whole, or of the goods or services it produces. The signal recipient must regard the quality signalled to be of importance.

2. The costs involved in generating the signal are significant and do not in themselves increase productivity, and the risks of signalling are proportionally higher for dishonest signallers than they are for honest signallers.

Traditional evaluation methods of IT use quantitative and objective measures derived from accounting. These approaches are based on the principle that the purpose of information systems is to improve operational efficiency or productivity of the organisation [2-4]. The success of It investment is typically measured in terms of return on investment and improvements in efficiency, although the need to take a broader approach that includes organisational criteria based on the structured consideration of financial and non-financial concepts is also recognised [2, 5-8]. While there is considerable debate on how best to measure the benefit of information technology, it is clear that information technology has resulted in a substantial increase in productivity in many areas.

For clinicians this may be beside the point. Clinicians offer their professional skills for the benefit of patients, and the interests of the insurance industry or the taxpayer are secondary. From the clinical point of view it is the effectiveness, not the efficiency, of health interventions that is of primary interest.

We suggest that the economic theory of market signalling is applicable to information systems in general, and present case studies from non-medical fields to support this assertion. The application of this theory to clinical informatics systems suggests that the clinicians' conservative attitude to the current generation of health information systems is rational economic position, given the current structure of medical practice in the industrial world. Clinical information systems that are designed to overcome this before may gain a more enthusiastic endorsement from clinicians.

Market signalling theory

Akerlof [9] observed that information in the marketplace is distributed asymmetrically, with gaps in information between a seller and a buyer. Typically, while buyers have information

about the market as a whole, sellers have better information about the particular good on offer. As buyers only have information on the market as a whole and not the specific good, buyers will only offer average prices for the good. This will benefit sellers of inferior goods but will not be attractive to sellers of superior goods. Akerlof concluded that adverse selection would occur – sellers of superior goods would leave the marketplace.

Spence [10] developed this further by noting that sellers need not leave the marketplace if they could signal the superior nature of their goods to the buyer and thereby command a higher price. This signal would be cost-effective even if the cost of issuing the signal was significant and this investment did not itself increase productivity. Spence's worked showed that costly and unproductive signalling could occur in equilibrium, even if markets operate with gross inefficiencies introduced by costly unproductive signalling.

Attempts have been made to classify costly signals according to the way the costs are incurred [11]. For example, costs could be incurred as an up-front expense, or deferred and taken in the loss of future income. Costs could also be fixed or dependent on other factors, such as sales. While these distinctions may be important for some of the wide variety of market signal types, for the purposes of this paper costly signals will be classified as semaphoric if the investment required to generate the signal is both visible and unproductive, irrespective of how this cost is met. This expenditure can be used by the recipient as a sign of sincerity and gives the signal more credibility.

Characteristics of Semaphoric Signals

The above discussion has listed a large number of costly signals, and these signals differ from sending the market a signal through, for example, a press release. We term these semaphoric signals. They reveal some quality of the organisation as a whole, or of the goods or services it produces. The signal recipient must regard the quality signalled to be of importance. The costs involved in generating the signal are also significant and do not in themselves increase productivity, and the risks of signalling are proportionally higher for dishonest signallers than they are for honest signallers.

Information Systems as Semaphoric Signals

In the following cases we consider examples of investment in Information Systems where the justification for such investment cannot be conventionally supported but is made on the grounds of the value of its market signal. We call such systems 'semaphoric information systems'.

Real-time parcel tracking.

United Parcel Service (UPS) and Federal Express (Fedex) have both established themselves as major international players in the logistics market. Both offer a high quality service, and both enjoy high levels of customer satisfaction [12]. They have also both deployed semaphoric IS in the form of real-time parcel tracking.

While there are many similarities between these two organisations, there is a significant difference in corporate culture. UPS began as a bicycle messenger service and prides itself on reliability and dependability. "[The] press describe us as a plodding and disciplined company" said then UPS Chairman Jim Kelly [13], but dull and reliable were attributes that UPS were proud of. In contrast, Fedex was funded by venture capital, began with a purchase of a fleet of aircraft and established itself in the niche overnight delivery market.

Fedex pioneered web-based package tracking in 1995 [14]. It was a development that UPS did not immediately appreciate. "I thought … that the cost of supporting real-time package tracking would never be justified", admitted Jim Kelly [13]. Kelly was not alone in this view. "We don't want you to remember tracking an overdue package: if the package is overdue, the sooner you find it and forget about the whole thing, the happier we will be" suggests web design commentator Bernstein [15]. Nevertheless UPS quickly followed Fedex and introduced the service. We argue that the justification for doing so lay in their intention to send a signal to their customers of their reliability.

Ultimately, this signal was appreciated by UPS' customers despite their reputation for reliability. By 1996 UPS were receiving 1 million queries a month. By 1998 this hit 1 million queries a day, and by 1999 it had reached 2.5 million per day. By 2002 the figure had risen to 6.6 million tracking requests per day [16,17].

Signalling with Enterprise Information Systems 2: Clinical Trial Registries

The success of the pharmaceutical industry in developing medicines that have cured disease and alleviated suffering might have made them the heroes of the age, but is this the case? Fiona Godlee [18], in an editorial for the BMJ, wrote:

"If there's one group in urgent need of repositioning it is, as even members acknowledge, the pharmaceutical industry. … When your customers see you as 'manipulative, dark, menacing,' you could be said to be losing the battle for hearts and minds."

The pharmaceutical industry itself is highly regulated, and the medicines development process involves a rigorous process of clinical study design, conduct and reporting. As part of the regulated process all clinical studies are reported to the relevant authorities. Requirements and coverage of regulated systems is patchy and not always publicly available. The European Union clinical trial registry, EudraCT, in which studies are recorded as a part of the regulatory process is not openly accessible [19].

Information is disseminated via publication in peer review journals, where the results are open to careful scrutiny. While peer reviewed journal articles have been the standard method for disseminating scientific knowledge for decades this system has serious shortcomings. Some information may not be published and so not reach the wide range of interested parties such as prescribers and other medical practitioners. Peer review journals also have a built in time lag and give no assur-

ance of a complete disclosure of information, there is also a bias in published studies in favour of positive or promising results [20]. Trials are frequently reported several times, leading spurious weight to the findings [21] and it may be difficult to determine how many trials have in fact been done [22]. By 1999 both the British Medical Journal and The Lancet felt the case for a register of randomised trials was unanswerable [23].

The lack of trust in pharmaceutical companies, and the need for transparency to signal honesty, is appreciated by the industry, and in 1998 the Chairman of GlaxoWellcome Richard Sykes announced that a basic clinical trials registry would be set up. This would be an internet based application, openly accessible, in which variable amounts of information about clinical studies being undertaken would be recorded and published, and would cover all of GlaxoWellcome's completed Phase 2 to Phase 3 studies which are the studies required for registering a medicine. Protocols for completed studies were to be registered at regulatory approval. Sykes stated:

"GlaxoWellcome has taken the lead in disclosure of information, and I hope that the rest of the pharmaceutical industry will join this initiative. As knowledge based industry we understand well the value of information, and we want to create a climate of openness where the evidence for prescribing our products is clear" [24].

In 2004, Eli Lilly & company launched its clinical trials registry, which it claimed was 'the most comprehensive effort to date, by either a public or private entity, to publicly disclose clinical trial information' [25]. Novo Nordisk made a similar release of their register stating 'We're conducting our business in a transparent way, and offering information on our clinical trials activities should be seen in this perspective'[26]. By 2008 most major pharmaceutical companies had clinical trial registries publicly accessible via the internet.

Once Glaxo had signalled its honesty, other pharmaceutical companies were obliged to do the same because not to signal would imply something to hide.

While clinical trial registries appear to display the features of an semaphoric system, there is a further factor to consider. In 2004 Glaxo faced prosecution for failing to make public clinical-trial data that raised concerns about the safety and efficacy of one of their products used to treat children with depression [27], and this renewed calls for compulsory registration of clinical trials in a public registry. The International Committee of Medical Journal Editors instituted a policy that required that clinical studies be registered in order to be considered for publication [28]. In 2009 Section 113 of the FDA amendment act came into law [29], requiring registration of clinical studies for current and future trials.

The trend is clearly for clinical trial registration to become a regulatory and stakeholder requirement but ahead of this many large companies have developed their own publicly available registries, and advertise that they are exceeding the requirements and the timelines. This illustrates that some aspects of semaphoricism are not only non-optional as far as competitors are concerned, but may even become a regulatory requirement within a sector.

Discussion

The case studies described above lead to the following observations on the characteristics of semaphoric systems.

The signal reveals some quality of the organisation as a whole, or of the goods or services it produces. Real-time parcel tracking signalled reliability, while the Controlled Trials Registry signalled honesty and transparency. In the case of PowerPoint the quality was professionalism and preparation. These are all qualities that the signal recipient regards as being important.

The costs involved in generating the signal are significant and do not in themselves increase productivity. The cost of installing a real-time parcel tracking system provides information for customers but does not ensure trucks leave fully-laden or on time. However, a logistics company that has a highly efficient operation with good quality assurance systems will find the cost of implementing a real-time parcel tracking service less onerous than a logistics company that does not have these systems in place. The same is true for Clinical Trail Registries. Making clinical trial data accessible limits the company's ability to market its products, but an honest pharmaceutical company that has a solid evidence-based foundation for the efficacy of its products will find this less limiting than a company that does not have this evidence.

Implications for Clinical Information Systems

Adoption rates for clinical information systems are driven by a variety of factors, and the clinical maxim *Primum non nocere*, 'First do no harm', applies here. The negative effects of clinical information system manifest themselves in increasing demands on clinician's time and decreasing patient satisfaction.

The effect of clinical information systems on clinicians' time is controversial, and may vary between implementations and between individual users. Saving time is frequently cited as the motivating factor in adopting information technology (Hier et al. 2005; Ash and Bates 2005; Irani et al. 2009). Implementing information systems is a hazardous undertaking in healthcare and other sectors, and a large number of implementations fail. Systems which place burdens on the clinicians' limited time are less likely to succeed [30].

Several studies on the effect of the use of clinical information systems have, in general, found that the effects on patient satisfaction are neutral or slightly positive [31], and that computers can be integrated into the clinical consultation without a detrimental effect on patient satisfaction [32]. This is consistent with a review of earlier studies done between 1980 and 1997 [33]. While clinicians do express reservations about the effect of the computer on professionals' interactions with patients [34], the literature suggests that clinical information systems do not have a negative impact on patient satisfaction.

While this may be true of clinical information systems in general, it is not be true of all clinical information systems. While clinical decision support systems have been shown to improve patient safety and clinical decision-making, there is evidence that patients do not value the benefits of computerised decision

support systems and have less esteem for clinicians who use these systems[35, 36].

One explanation for this is that patients expect clinicians to be concerned, compassionate and knowledgeable, and expect clinicians to signal these qualities. It can be argued that computerised decision support systems send the opposite signal. They suggest that the clinician is not knowledgeable because they need to look up information, that the clinician is more concerned about recording 'hard' data and following protocols than about the patient's idiosyncratic needs, and the impersonal nature of the CDSS's knowledge base is contrasted unfavourably with human judgement, which balances compassion with necessity.

An awareness of the signals sent by clinical informatics systems may result in improvements in the design and structure of these systems. For example, a system that emphasises a primary care clinician's gatekeeper role, and demonstrates their knowledge of the availability and quality of locally available services sends a positive signal. A similar system which concentrates on patient workflow and requires the clinician to behave as a clerk in bureaucracy sends a different signal.

Conclusion

The rate of diffusion of information technology has been slower in the healthcare sector than it has in other sectors, this cannot be ascribed to an anti-technology bias. It has been noted that physicians are adopt new technology enthusiastically, have embraced PACS, video cameras and BlackBerries, and will be more than happy to adopt information technology solutions that will improve their own lives and the lives of their patients [37].

Information technology is not neutral. The adoption of new technology does send a signal about some quality of the organisation as a whole, or of the goods or services it produces. In the case of the clinical information systems, the 'organisation' is embodied in the person of the clinician, and clinical information systems send a very personal signal about their quality.

Developers who would like clinicians to adopt their information technology solutions need to be aware of the signals that technology sends, and to concentrate on developing systems that send appropriate signals.

Abstract

Changes have recently been passed in the Norwegian legislation, allowing for more exchange of patient information between health personnel. These legal changes came as a result of a long and still ongoing debate concerning the potential conflict between confidentiality issues and patient safety as health care is getting more fragmented. At the same time, an increasing number of patients now make use of their legal right to access their patient record. In this paper, we shed light on some of the reasons why patients request a copy of their record. We report the preliminary results from an interview study in which seventeen patients who have asked for a copy of their patient record following a hospital stay have been interviewed. In our interview study, securing transmission of information between health care workers is one of the main reasons for requesting a copy of the record. We will discuss how this finding might contribute to the ongoing debate.

Keywords:

EPR, Medical record, Patient access to records, Patient information, Communication, Confidentiality, Patient safety, Empowerment, Interview study

Introduction

An increasing number of patients now make use of their legal right to access their patient record in Norway, as in other countries [1-3]. This legal right can be seen as part of a larger trend in health care during these past several years to strengthen patient autonomy. Making health personnel's assessments and decisions more transparent is expected to contribute to patient empowerment and reduce the power imbalance between patient and providers. It is claimed that in order for patients to be true partners in the health care encounter, they must have access to their own personal clinical health information [4-6]. In Norway, the legal term has changed from medical record to patient record, to emphasize these changes. But in Norway, as in other countries, like for instance Canada, there has been some unwillingness on the part of health personnel to give up "ownership" and embrace the new role as custodian of the patient record [5]. Norway is likewise facing a shift from paternalistic attitudes in health care to a more consumer based approach. In this process health personnel have tended to be more skeptical of the benefits patients might receive from reading their own records. Like in other countries, Norwegian health personnel have been worried that reading their own record may worry, confuse or embarrass patients [7].

Changes have also recently been passed in the Norwegian laws regulating health registers and the work of health personnel, allowing for more information exchange inside the hospitals, between hospitals, and between hospitals and primary care/community services. These legal changes came as a consequence of a long ongoing debate due to strict legal confidentiality regulations in Norway and an increasing fragmentation of the health care system that has made efficient transmission of information between health personnel more and more important [8;9]. The debate concerns the potential conflict between confidentiality issues and patient safety, a conflict that does not seem to be completely solved by the recent Norwegian law changes. A similar debate has been going on in other countries, e.g. in England in connection with the creation of a national database of health records [10]. We conducted an interview study to explore why patients request a copy of their record and their experiences in connection with receiving such a copy. In this paper we are reporting some preliminary results from this interview study that contributes to the debate mentioned above.

Materials and Methods

In this explorative study we conducted in-depth interviews with former patients who have asked for and received a copy of their patient record following their stay at two Norwegian hospitals. EPRs (electronic patient records) have been in use for some years in these hospitals, but patients who want to read their record receive a paper copy by mail from the central

record archives. There is no electronic record access for patients.

Inclusion criteria

Men and women over 18 years old, who have requested and received a copy of their patient record at the hospital, speak/read fluent Norwegian, and have no known cognitive impairment were included in the study.

Participants

A convenience sample of the 17 first patients that volunteered for an interview - sixteen women and one man - between the ages of 28 and 67 were interviewed. They had different diagnoses (e.g. cancer and childbirth) and different lengths of hospital stay.

Procedures

The interviews took place either in the researcher's office or in the informant's home or work place depending on the patient's preferences 3-4 weeks after the informants had received the copy of their record in the mail. The interviews were tape recorded and then transcribed verbatim.

Analysis

The interviews were analyzed by qualitative content analysis [11]. The first author conducted the textual analysis by reading and re-reading sections of the interviews and identifying differences, similarities and patterns in the text. All interviews were divided into meaning units that were coded, condensed and abstracted. To address trustworthiness the co-authors who were experienced in the field and the method, checked and discussed analysis and interpretations to reach consensus. In the analysis of the manifest content of the interviews a main theme was constructed and grouped into sub-themes.

Results

A main theme coming out of the analysis is that informants wanted to have a copy of their record due to *"a wish to have control"*. This main theme consisted of several sub-themes that will be presented inn full elsewhere. In this paper we are focusing on one specific subtheme that seems to be relevant to the debate on patient safety vs. confidentiality issues. We have called this sub-theme "*transmission of information*".

Transmission of information

Patients who volunteered to be interviewed explained that they wanted a copy of their record to secure the transmission of information between health personnel, inside the hospital, between different hospitals, between hospital and GP or specialist outside the hospital. The informants discussed at length during the interviews that the documentation of care was poorly communicated and largely unused by health personnel. Informants felt that a large number of different health personnel they met during a hospital stay and/or at the outpatient clinic did not have a full overview of their situation. The informants took it upon themselves to be fully updated on their record content to make sure that the health personnel did not forget or misunderstand anything. To have a copy of the record gave some of the informants a feeling of control in this situation. They could choose to show a copy to who ever in the health care team that they thought needed it or tell them to read for example the admission note for a certain piece of information that they knew was documented there.

Informants were also concerned that important information would not be transmitted between different hospitals where treatment took place, so they took on the role as "messenger" or "postman". One informant described it like this: "*I did have questions that I wanted an answer to when asking for a copy of my record, but first and foremost my purpose was to pass on the record information to this other hospital where the birth was going to take place, to get help to decide whether a caesarean or a normal birth would be best.*" Later in the interview this informant said: "*... I find it strange that there is no common patient register… If I move to another part of the country, then it's only me that can pass on relevant information in case of complications with the birth… And what if I'm not sufficiently aware of things – is this safe enough?*"

Likewise there were examples in the interviews of how informants felt they had to take responsibility for the transmission of information from the hospital to their GP or specialist outside the hospital and the judgment of what information that would be relevant and necessary for these doctors to receive.

Informants pointed out that one does not normally get a copy or even a receipt of the correspondence between health personnel, like referrals and discharge summaries, as one would do in many other situations in the role as a customer or a client. This lack of confirmation made some of the informants unsure if the letter or referral that health personnel said they would send was actually sent and how their case was explained in that document.

One informant described that she received the referral from her GP and got the responsibility to find a specialist herself to make an appointment. She felt quite troubled about this task, as she did not know any specialists, and just had to look it up in the telephone directory without knowing who would be the best to see. She also commented that they all had limited calling hours that she had to find out. Although she was interested in what the referral said, she would rather not see this information, when it implied making all these phone calls.

Discussion

From the findings in this study we get a picture of patients requesting a copy of their record as representatives for the modern patient, conscious about their civil rights and free will, but also aware of their duty to take responsibility [12]. The patients' experiences can be seen as statements of the fact that the problem in health care today is not lack of information, but bad communication [13]. Bad communication might potentially threaten patient safety and the use of ICT in health care could lead to better communication and more efficient flow of information. It is certainly in the patients' interest that health personnel have the necessary information when they need it. Through the experiences of our informants, we get the impression that the hospital routines for transmission of information

might not be good enough. The patients are left with an unreasonably big responsibility, not only to transmit important information within the health care system, but also to decide who needs what information. In this way, the patient might be seen to be exploited as a customer to enforce cuts in public expenditure [12]. The investment in extra time and resources to improve continuity of care through better routines for information exchange is not a prioritized task within the system of financing that dominates Norwegian hospitals today. This illustrates how the role as the modern patient contains new opportunities for patients' empowerment, but at the same time expectations of self-responsibility that do not always seem reasonable [12] The informants in our study are surprised that transmission of information doesn't happen in a more smooth and automatic manner. Moreover, patients are often unsure if information is transmitted or not. They therefore take action to get the information transmitted, just to be on the safe side. This speaks for a more efficient transmission of information between health personnel and preferably electronic transmission. However, is a more liberal sharing of EPR content between hospitals and between hospitals and GPs the best way to go then?

Risk of information overflow

Patients feeling that they have to secure transmission of information between health personnel even inside the hospital, indicates that the EPR solutions that exists on the hospital level in Norway is not well enough organized to make it easy for health personnel to find relevant and necessary information. The EPRs are still to a great extent organized the same way as the paper records were. Consequently all the various information from a hospital stay will be spread out in many different folders and these are normally not easy to put together in one view.

To expand the electronic access to this record to other hospitals and the primary care as well might therefore turn into a new example of bad communication and information overflow. There is reason to believe that exchanging knowledge about the patient, as it is done in referrals and discharge summaries, is more efficient than sharing all the record content (giving electronic access to the whole record). This view is supported by other studies [14-16] and is also emphasized in a report from the Norwegian Centre for Electronic Patient Record [17]. The writing and reading of summaries calls for reflection on the patient's situation by the health care workers, in a way that sharing of information does not equally contribute to [17]. There is a certain risk that less effort will be put in the discharge summaries if other hospitals and the GP have full access to the hospital's EPR. This could in fact increase the time health personnel spend looking for relevant information, which is not in the patients' best interest [17].

Related work is going on in Norway to develop a "core record" (in Norwegian, "kjernejournal") similar to what already is in use in Scotland under the name of Emergency Care Record. In our view, this would be of much more help in most clinical situations than hospitals opening the whole record and sharing all information with each other. At the same time this would hopefully reduce the patients' burden to secure the transmission of essential information between health personnel.

The right information at the right time

Some patients in our study had experienced that it took so long (several weeks and even months) to get a copy of the record that when they received it, they no longer really needed it. This was certainly not an empowering experience and did not leave the patient with a sense of control. In Norway there is some pilot work going on to develop electronic access for patients to provider held electronic records. So far there has been focus on electronic access to the discharge summary after a hospital stay and the possibility to communicate with health personnel by secure e-mail (e.g. www.minjournal.no). The experiences of the informants in the current study, that it sometimes took unreasonably long time to receive a paper copy of the record, should be an argument to put more resources into the further development of electronic access for patients to provider-held records, such as EPRs in hospitals. Given the increasing number of patients requesting paper copies of their EPRs, the development of electronic access for patients to the EPR, from the patients' point of view, is long overdue. Access to the EPR is a fundamental patient right and this development should therefore not be delayed. As stated by Wiljer et al. (2008) health care organizations should create a culture of custodianship, rather than ownership, of patient data. This shift could be alleviated by creating models of shared control between health care professionals, patients and the public [6].

From a patient autonomy and empowerment view, a requirement for sharing the patient record between healthcare institutions (hospital-hospital and hospital-GP) should be that patients get electronic access to their own record as well. Similar to what was found by Whiddett et al. (2006) in a New Zealand study, most of the patients interviewed in our study did not know to what degree their information was shared between health personnel in the hospital [18]. In our view, they should not be ignorant about the information that is exchanged between health personnel and a log should be easily accessible to the patient listing who reads their record, where, and when. Patients should have the right to know when and for what purpose their data is used [19] as well as the ability to control the flow of their clinical data and also to delegate access to the data. In addition, the patients seem to be in the best position to discover documentation errors in a situation where so many different health personnel are involved in their care. This is also pointed out by others [1-3;20;21]. When patients in our study discovered information in the record that was not correct or information that they would not like everyone to see, the lack of an effective system both to shield and correct record information bothered them terribly. Lastly, judged by these patient experiences it would not only be extremely timesaving for the archives if electronic access for patients was the norm and that a paper copy of the record was only sent out on request, but it would be an important step towards real patient empowerment and autonomy.

Limitations

First of all, these are preliminary results based on analysis of the manifest content of the interviews. A limitation of our work is that the sample is self-selecting. Patients who have a story to tell about bad experiences with health personnel or the hospital as an organization might be more likely to volunteer for an interview than patients who don't have these kinds of experiences. One should therefore be careful to generalize these findings as typical for patients' experiences on this area. Other studies have found that women are much more likely than men to be interested to read their record [2]. Even if the low number of men recruited to the study may reflect the number of men requesting to read their record in Norway the unequal participation of genders is a limitation of the study.

Conclusion

From the experiences shared by patients in this interview study, we conclude that there is a need for improvement in the organization of content as well as flexible views in the patient record system. Improvements can also be made in the system for electronic transmission of referrals and discharge summaries, so that patients can be sure of what is communicated and do not have to bring a copy to be on the safe side. Ongoing work to develop a "core record" should consider findings presented here.

Better discharge summaries and a "core record" might in many cases cover the patient's need for written information too. A requirement for providing broader electronic access to records as the legal changes now allow would in our view be that patients have access to the same information as health personnel to avoid diffusion of documentation errors without anyone noticing it. This is in accordance with the conclusions of Powell et al. [10]. Better organization of the record content is needed to be able to limit health personnel's access to what is relevant and necessary information about a patient to avoid information overflow and to shield information that is not in the patient's best interest that everybody see. Thus we support the view of Wiljer et al. (2008) that providing electronic access to EPRs is a vital next step in promoting active involvement of patients in their care and improving the health system on a profound scale [6].

Acknowledgements

The authors would like to acknowledge the help of the staff at the central record archives of the two hospitals involved. They helped in planning the practical procedures for the study, and have in fact made this study possible for us by their continuous contribution.

This work was supported by South Eastern Norway Regional Health Authority, Grant 3b133.

Exploring Control in Health Information Systems Implementation

Maryam Ali, Tony Cornford, and Ela Klecun

Information Systems and Innovation Group, Department of Management, London School of Economics, London, UK

Abstract

Health information systems promise opportunities for improved healthcare. However, these opportunities may become challenges and obstacles to practice. This research reflects on the outcomes of implementing healthcare information systems in three English hospitals. In each case qualitative methods were used to observe and interview doctors, nurses and pharmacists as they carried out their daily healthcare routines. The changes that the implementation of health information systems brought for both the clinical encounter, as well as health care professionals' work flow, were explored. We argue that such technologies have become a central orchestrator of the clinical setting, to the extent that they often impose control on healthcare practices. Using a socio-technical approach we seek to understand how information systems technology and healthcare professionals can work together rather than apart, or around one another.

Keywords:

Information systems, Medical informatics, Medical records systems, Computerized, Hospital information systems, Electronic prescribing, Implementation, Healthcare practice, Workarounds.

Introduction

Health information systems are often implemented with anticipation for their delivering improved health care practices as part of a complex promise of reduced cost and enhanced quality, safety, and efficiency of healthcare [1,2]. However, beside these desired benefits, researchers acknowledge unexpected outcomes and changes in healthcare routines that may emerge as a result of the use of such technologies. Unintended adverse consequences are cited in studies of computerized provider order entry (CPOE) implementation [3-5]. Other literature has cited similar outcomes as 'workarounds' [6], while studies in the IS field consider issues of technology and control [7]. This research has confirmed such findings, and suggests that in addition to workarounds, health information systems impose degrees of control on clinical encounters and the professional's work practices including shifts in time and space. This control that emerges from health information systems has potentially important consequences for the way healthcare is performed and for healthcare outcomes.

This paper explores in theoretical terms these unexpected (or sometimes less expected) control-driven changes in healthcare practice. It draws on four studies we have been engaged in where the everyday work routines were to a degree controlled by a technology-in-practice [8]. The use of this technology, and the intentional and unintentional controls emergent from the technological systems in use, at times cause healthcare professionals' work practices to become obstructed, modified, or delayed. As a result and as often observed in other studies, health professionals adopt workarounds, which let them (to some extent) subvert the system's controlling features.

In the past, clinical encounters usually included a doctor or nurse and a patient. For centuries professionals have been reliant on some medical technologies too, e.g. to carry out physical examinations of the patient using a stethoscope, blood pressure monitor, or magnifying glass, alongside some technology for record keeping to make informed temporally coherent decisions (patient paper record or medical notes). The flow of the consultation was doctor-led and would be naturally dependent on the severity of the patient's condition, the completeness of his or her paper record, the time the doctor had to examine the patient, and the decisions made on how to move forward with a care plan. Today's clinical encounter continues to carry on most of these traditions, but increasingly, it is dependent on health information systems as new 'clinical leaders'. We argue that clinical encounters have changed (or are changing) significantly, from being clinician-led (by physician, nurse, or pharmacist), to technology/computer/information system-led encounters. These changes are characterised by new aspects of control. We define control here as 'the power to influence people's behaviour or the course of events' [9] through exercise of restraint, directing, auditing, or eliminating possible outcomes.

Our research stems from an interest in work practices [10]. Hence, we first present four changes in work practices: work obstruction, modification, disjunction and shifts in time and space. We present this along with examples from our field work in the results section. In the discussion, we explain two reasons for these changes; one is intentional and the other unintentional controls mediated by technologies-in-practice. We relate these findings to models of technology drawing upon ideas and constructs from sociotechnical theory. Finally, the potential implications as well as suggested areas for future research are presented in conclusions.

Methods

We follow here the tradition of information systems research that focuses on contextual, social approaches, and adopts an interpretive research methodology [11- 14]. Three healthcare institutions are considered here, drawing from our previous and

ongoing research including two London teaching hospitals and a district general hospital in England. The research we draw upon was carried out across four medical specialties; general surgery, cardiovascular surgery, elderly care, and cancer care. Qualitative methods were used to collect data [15], particularly semi-structured interviews, alongside observations. Interviews were tape recorded and subsequently transcribed, and hand-written notes were taken. Data collection was carried out during different periods in different settings, between 2005 and 2009. Further, research findings were indexed, interpreted and analysed against concepts from the sociotechnical approach [16].

We have studied the implementation and use of different health information systems in varied settings.

1. Electronic Prescribing Studies (completed):
    a. A pilot of a closed-loop electronic prescribing, automated dispensing, barcode patient identification and electronic medication administration record (EMAR) system introduced on one ward (general surgery) in a London teaching hospital [17]. We refer to this case as (1a).
    b. An integrated electronic prescribing, administration and records system implemented over time in English district general hospital. We refer to this case as (1b)
2. Electronic Patient Records Studies (on going):
    a. A study of a London teaching hospital's clinical information systems, which included a patient administration systems (PAS), electronic clinical letters, picture archiving and communication systems (PACs), a pathology results reporting system (OrderComms), and an electronic prescribing and discharge systems (eTTA). We refer to this case as (2a).
    b. A Study of a Clinical Data Repository, based in a large London teaching hospital which integrated many sub-systems. These included PACs, PAS (Patient Administration System including appointment scheduling and real time bed state), Clinical Letters, Proactive electronic document capture (i.e. discharge summaries), Order Communications (pathology requests and results), Nursing assessment (ePAN), Therapy activity recording, and Knowledge management tools. We refer to this case as (2b).

Results

A repeated observation made across these healthcare settings is that the clinical work flow is manipulated or orchestrated by the health information system. This characteristic of the technology-in-practice is described by us as 'control', though this word may have some over negative connotations. The control that is seen in action seems to result in four different types of outcomes (sometimes in combination). These we describe as; work obstruction, work modification, work disjunction, and work-related shifts in time and space. Each one of these themes are explored below, with examples.

Work Obstruction

We define work obstruction as a control that is a direct consequence of the technology-in-practice, and which results in the healthcare professional's work flow stopping, or being halted and she or he are not able to carry on their work as usual.

Health information systems often control when the clinical encounter begins and when it ends. Consultations would often begin and (or) end with the physician making the patient's electronic record available on the computer terminal, rather than by ensuring the availability of patient's paper record or the physical presence of the patient. An encounter could be seen to begin, for example, before the patient enters, as in an outpatient clinic where a doctor reads the electronic record for 5 minutes while the patient is waiting outside. At other times, healthcare information systems can pause or obstruct the physician from carrying out his or her chosen task as when a record is slow to download. This may be particularly the case when the technical performance of a system was poor, which meant the system would take a long time to load, would occasionally freeze, or cause the computer to restart. The physician may have the paper record at hand, but such an obstruction would still delay his or her consultation. This resulted in major frustrations, delays in the clinical start and end time, and, less often, cancelations (2a and 2b).

Pharmacists also reported their work being obstructed by slow computer terminals. Additionally, they also had difficulty finding a single available computer terminal to use for discharging their patients. Unlike the paper system which was fast and practical and always available to carry out the discharge task. This resulted in discharge from in-patient care being delayed, which ultimately made managing hospital flow of patients and bed management more complicated (2a).

Work Modification

The term work modification is used to describe a small temporary change in usual practice in order to get work done. Similarly, workarounds have been defined as "work patterns an individual or a group of individuals create to accomplish a crucial work goal within a system of dysfunctional work processes that prohibits the accomplishment of that goal or makes it difficult" [18] and do not include deviations, mistakes or shortcuts [6].

When pharmacists compiled discharge summaries, they often could not find the exact detail on the drop down menu which they used describe some drug specification. They resorted to using the closest description that the system would accept, and then finding a free text box (often the dietary information field, which was not limited in capacity) to clarify this in more detail (2a). Another example is of a hospital where there were eleven different clinical systems used by one department, and each of those systems required different sign-on details as a security measure. It was also programmed to 'time-out' every three minutes. Physicians commonly wrote the eleven different user names and passwords on a notepad on their desktop, in their personal diaries or agendas. In one instance, a surgeon had them listed on the back of one of his business cards. While this made the physicians' work flow possible, it allowed for a new

'security breach' in the confidentiality of patient information stored on all systems.

Another workaround was commonly practiced when dealing with random pop-up boxes that usually occurred when physicians were navigating PACs. Pressing 'cancel' several times was the quickest way to by-pass the 'glitch' and carry on their work. It became common practice to flag it up to junior colleagues during orientation and training (2a).

A third example is from nurses who printed patients' identification bar codes and stuck them on their bedside lockers or tables in order to be able to dispense medication when the patient was away from the bed. This was done as the drugs trolley only opened upon reading the bar code. This workaround subverted a safety feature intentionally included in 'computer logic'. Also, doctors used a subsidiary paper chart to prescribe certain drugs (i.e. warfarin, sliding scale insulin, variable dose heparin and intravenous fluids). This was a necessary work around. These drugs could not be safely prescribed through the system because their protocols did not fit easily into the structures embedded in the software –just regular doses of drugs at set times (1a).

Work Disjunctions

By work disjunctions we refer to situations when the information system has a direct or indirect effect on a healthcare professional's control over work flow, or by simply slowing down their ability to complete a task. For example, at one hospital notes regarding administering a drug in the future could not be made on the computer record, consequently the pharmacist would have to note it physically in other records. This meant that potentially important information might not be recorded or remain unnoticed (1b).

Work disjunctions are also caused indirectly by the increased structure that a health information system may impose. In the case of drug administration nurses had to follow the system's logic when dispensing drugs, and could not easily override it (unless in emergency). Initial evaluation showed that this feature might have lead to fewer dispensing errors but some procedures took more time, requiring additional work flows in some instances. Prescribing or administration that was not undertaken as part of regular drug rounds, e.g. when a nurse gives a "stat" (occasional or elective) dose, called for another work flow to log and administer. This involved the nurse walking to the computer and back twice to obtain the drug and then to record administration (1a).

Surgeons reported difficulties encountered when viewing heart ultrasound images, which forced them to change their physical space, and leave their consultancy suites, and in one incident, a live-surgery, in order to find a computer terminal that can load the images quickly enough (2a). Similarly, nurses using an EMAR system found that at times they had to queue to use the computer on the ward (1a).

Work Shifts in Time and Space

By shifts in time and space we refer to controls imposed by information systems that cause healthcare professionals to physically change their work location in order to carry out their work. We also refer to the flexibility that these systems bring, allowing professionals to manage their work from different locations and at different times than the usual ones.

When researching electronic prescribing systems, it was observed that doctors often prescribed away from the wards (e.g. from the doctors' mess). By accessing computer records, doctors could more easily deal with out of hours calls, sometimes avoiding going to the ward. This, as suggested by a doctor interviewed, should lead to more accurate prescriptions as compared to phone prescribing (a practice which sometimes took place at night). However, the availability of relevant data might mean that even less prescribing activities are done by doctors who actually see the patient. Thus, the potential implications of this shift are ambiguous (1a).

One related consequence was found in two healthcare institutions. There, before electronic prescribing was implemented, pharmacists would visit each patient daily and check their drug chart if available; now they could check through the computer and assess each patients' computer chart for changes and only visit those whose records indicated a pharmacy-related problem. This resulted in some (but not all) pharmacists choosing to do the majority of checking in the pharmacy and limiting their visits to the wards. When checking prescriptions, pharmacists had access to relevant data, for example test results more easily than in paper-based system and thus might be more likely referred to them. This potentially reduces errors and improves care. However, certain cues might be missed if patients are not seen in person, and less interaction was possible with other health care professionals. Computerisation of prescribing also meant that pharmacists could check prescriptions at any time with no need to have a set time or set amount of time and pharmacists were no longer tied to the ward timetable. This allowed a degree of flexibility and enabled them to prioritise work. Pharmacists reported that this has led to efficiency gains (1b).

The integrated nature of hospital information system has meant that doctors could potentially re-organise their clinics and conduct some aspects of care in different locations. For example, patients' notes could be accessed and tests ordered remotely. One senior doctor reported regularly accessing patients' notes and ordering tests remotely from home (1b).

Discussion

The view that ICTs do not have predefined 'impacts' is increasingly accepted in information systems, health informatics and medical informatics literature. Indeed, it is now widely acknowledged that ICTs have many unintended positive and negative consequences [3] and that these consequences depend on the organisational context, culture and the fit between the task, the clinical environment and the technology [19,20]. This suggests that we cannot study technology per se or unreflectively take findings from one setting and generalise them to another. Rather, we need to consider ICT as embedded in work (and social) practices and part of heterogeneous relations both potentially enabling and obstructing activities, i.e. as *technology-in-practice* [21].

> *... technologies are embedded in relations of other tools, practices, groups, professionals, and patients and it is*

> *through their location in these heterogeneous networks that treatment, or any other action, is possible in health care.* [21]

Furthermore, it is through the situated practices of everyday users and in particular circumstances that consequences of technologies are manifested and felt [22]. But different studies have shown that the models of care delivery underpinning information systems are often based on what ought to happen (e.g. according to formal rules and practices which are not followed), rather than on what actually happens, and on perception of care as a linear process with a clinician at the centre rather than as a collaborative, non-linear process undertaken by a multi-disciplinary group [23].

The difference in theoretical and practical perception of medical work practices leads to 'aberrations', including workarounds created to by-pass the system, parallel communication channels or duplication of work due to lack of coordination [20, 24, 11, 25]. Workarounds may be introduced because of work flow blocks associated with technology or organisational processes not effectively integrated with technology. Workarounds tend to distract staff and take them away from patient care and can result in errors [6, 26].

Our paper complements and builds on this literature by focusing on controls emerging from the systems in use. Other studies have identified different types of controls [27]. Our categorization of controls is derived out of the four changes in work practices described above. We classify these controls as:

(a) ***Intentional controls***: These may be in the form of *work flow control*, when for example technologies are seen as 'clinical leaders', controlling the flow of clinical encounters and other activities, such as prescribing of medications (orders). Increasing dependence on these new 'clinical leaders' means that when they break down activities might be halted. We identify *adherence* controls, when systems are designed to enforce different ways of working, e.g. adherence to local or national guidelines. These often overlap with *work flow controls*.

(b) ***Unintentional controls***: Such as in *accidental controls* imposed by pop-up boxes appearing apparently randomly due to arbitrary systems errors, inadequate hardware or faulty software. These controls may be caused by 'unintentional mismatch of practice' when computer systems do not reflect work practices they are supposed to support. This may be a result of poor analysis and design, changing work practices and organisational context, or practices that are difficult to model in the technical system (e.g., warfarin prescribing and administration). We term these *disjoint controls*.

Controls inherent in technologies-in-practice result in different outcomes and workarounds, such as work obstruction, work modification, and work disjunctions. Information systems also have profound implications for shifting time and space of clinical encounters and clinical work and these in turn may have varied implications for the quality of healthcare delivered [18]. This implies that workarounds are to be expected and that they are inherent in work systems, which (like computerised information systems) tend to be highly structured. However, information systems not only constrain but also enable work and may lead to emergent changes in healthcare practices and ambiguous consequences.

Conclusion

Our findings lead us to conclude that when implementing and evaluating information systems it is important to consider implications of control and structuring of work due to 'computer logic', and of work shifts in time and space. Deceptively simple decisions, e.g. of where to place computers, have consequences for the practice of healthcare, e.g. for communication with patients and between health professionals. Computers can become 'centres' where different professionals meet or catalysts for further compartmentalisation of work and distancing of different healthcare professionals from each other and from patients.

We give examples of when computerised systems facilitated prioritisation of work and shifting times and places, as well as when systems obstructed or structured work and imposed their own work flows. When controls embedded in computer systems break the flow of work it is likely that people will find workarounds to subvert the logic. Thus, when implementing information systems the following need to be carefully considered: (a) what controls (and values, norms and guidelines) we want to embed in information systems and what (potentially reengineered) work processes we want them to support ; (b) in what circumstances should workarounds be 'designed into the computer and work systems' (e.g. how exceptional, emergency situations should be dealt with,); (c) how to limit 'undesirable' workarounds (e.g. by reflecting existing practices in computerised systems and when appropriate limiting the number of intentional work flow stops, as well as by re-organising work and physical spaces to make adherence to work flows easier; and (d) what emergent changes these technologies-in-practice might bring about.

There is a substantial literature on organisational impacts of information systems and implications for healthcare practice. But as new systems are implemented in varied settings new research opportunities open up. In particular, research "unpacking" information systems, such as that outlined in this paper, that reveals embedded controls, values, norms and policies and their implications for healthcare promises to deliver important insights relevant to both practitioners and researchers alike

Ghost Charts and Shadow Records: Implication for System Design

Abstract

Ghost charts, sometimes referred to as shadow charts, are duplicate medical records. Governance documents in several countries suggest that ghost charts present a risk to patient safety, to the extent that they contain information which may not appear in an official hospital record. Although most would agree ghost charts should not exist, their existence is widespread. This paper reports on an in depth multi-method qualitative study of ghost charts undertaken in two ambulatory care settings in a Canadian hospital. The study was undertaken in order to inform the design and implementation of a clinical information system which it is hoped will eliminate the need for duplicate charts. Our research demonstrated that ghost charts filled a variety of needs only some of which are typically accounted for in electronic record design. We suggest that if the functions ghost charts fill are not addressed, their existence will persist. This work is significant in that few studies of ghost charts have been undertaken, and in the in-depth understanding it contributes to design requirements for electronic record systems.

Keywords:

Medical records, Duplicate, Electronic health records, Ambulatory care, Patient safety.

Introduction

A study of duplicate medical records (referred to here as ghost charts) was undertaken in order to develop in depth understanding of work practice issues related to the existence of duplicate paper based medical records (PMRs) in ambulatory clinical settings, in order to gain insights about the use of paper based charts that can inform the design of electronic records. Study objectives were a) to develop an understanding of the work practices regarding paper medical records in 3 ambulatory settings; b) to document how different clinical user groups interact with the PMRs including ghost charts, (e.g., what information do practitioners require? what information is shared with other practitioners, and under what circumstances? why is some information maintained in ghost charts?); c) to develop an in depth understanding of ghost charts, including what information they contain, what needs they fill on clinical units that are not met with the official clinical record, and underlying reasons for their existence; and d) to share insights gained from the study described here with stakeholders who will engage in decision making about electronic medical records. Material reported here is based on findings from observations and interviews in 2 clinical settings (a neurosurgery unit and a gastrointestinal (GI) clinic), and focuses on the functions that ghost charts fill. Additional findings pertaining to other aspects of the study (e.g., a detailed analysis of the contents of ghost charts compared to hospital records, in depth information about how charts are used during clinical encounters, and different stakeholders' views of health records) are beyond the scope of this paper and will be reported elsewhere.

Our hypothesis was that ghost charts meet a variety of needs for varied groups of workers who interact with charts, and the need they have for these additional charts is poorly understood—and this has implications for system design. When work is computerized, if system designers do not have a thorough understanding of how work is carried out (or, in other words, if the existence of ghost charts and the needs they meet are not acknowledged), then the resulting system will in all likelihood not meet staff needs. Hence, it is important to understand what role(s) ghost charts fill so that computer based systems can be designed in a manner that meets the needs of varied stakeholders who interact with charts. Our goal was to develop a better understanding of the roles ghost charts filled.

Background and Scope of Problem

The term ghost charts is sometimes used to describe a uniquely identifiable patient record that does not reside in an officially sanctioned hospital record location. Other terms used to describe the phenomenon of maintaining a patient care record independent of the main medical record include shadow charts, soft charts, duplicate medical records, working charts and clinical or clinic charts or records. Ghost charts are "duplicate record[s] kept for the convenience of a department or healthcare provider."[1] They exist in addition to health records (here referred to as hospital records), which are defined by the Canadian Health Information Management Association [2] as:

> a compilation of pertinent facts of an individual's health history, including all past and present medical conditions, ill-

[1] AHIMA FAQ [1] http://library.ahima.org/xpedio/groups/public/documents/ahima/bok1_017169.hcsp?dDocName=bok1_017169

nesses and treatments, with emphasis on the specific events affecting the patient during the current episode of care. The information documented in the health record is created by all healthcare professionals providing the care.

Although there is a paucity of written material about ghost charts—no doubt reflecting concerns about exposure to legal risk associated with acknowledgement of their existence-- informal conversations with a range of care providers as well as a review of reports written as part of the hospital accreditation processes[2] suggests that ghost charts are a common phenomenon, and their existence is not limited to ambulatory care settings [3, 5-9]. Several sources suggest that ghost charts emerged because paper based records are unwieldy in that they cannot be in two places at once, which leads to the need for ghost charts.[3] One article suggests the problem is most prevalent in multidisciplinary care [10]. Other explanations for the existence of ghost charts identified though grey literature searches include:

- the need for quick access to charts for patients with unscheduled visits is too challenging to manage through a central hospital records department, which providers responded to by keeping ghost charts [6, 7, 9, 11, 12;
- that patients visiting multiple clinics, often on the same day creates a situation where the "chart could be anywhere" so staff create ghost charts [6, 7, 9, 11, 12];
- that some staff have ongoing unscheduled contact with patients (e.g. calls regarding patient education, medication or symptom management that the clinic handles without requiring a formal appointment) and want/need the records handy as a quick reference [9, 12];
- that test results, specialist reports and other documents arrive as hard copy and are not integrated into the chart immediately, so ghost charts are created to keep this information together and ready at hand and are used in conjunction with the medical record, until such time as the medical record is updated [5, 8, 13];
- that staff make up their own charts because they cannot readily access the information they need in the formal chart [11 -13];
- that ghost charts can contain information useful to clinical management but that are not part of the formal medical record, or are not kept for a long period of time (e.g. because of "thinning policies" for medical record storage);
- that ghost charts have a reminder function – the chart is put aside as a reminder that staff are waiting for critical test results etc., rather than filing them away and relying on memory or the return of the result to trigger subsequent steps in treatment or scheduling [12];
- that ghost charts support continuity of care across transitions (details about how this is accomplished are lacking, but presumably relate to the ghost chart as a receptacle for more detailed information than would normally appear in the hospital chart, which is required to manage care across transitions);
- that research study records are often kept in a ghost chart accessible to researchers (which can occur in the context of formal research involvement or clustering of charts to support ongoing quality improvement or retrospective chart review research in clinical areas, which is particularly important in terms of intern and resident projects) [11];
- that some clinical areas "hang on" to charts or pieces of information from the chart for an extended time period (e.g., 6 months) for their convenience before submitting them to medical records [6].

Ghost Charts as a Problematic Phenomenon

Ghost charts present many challenges. Within the context of this research project, while our primary reason for studying ghost charts has related to the eventual computerization of hospital records and a desire to develop an understanding of the roles ghost charts are filling in the provision of care, it is important to note that computerization is often cited as a means through which ghost charts can be eliminated. A frequently offered rationale for the use of electronic medical record (EMR) systems is that they can integrate across physical sites or services where ghost charts have been in use [7, 9, 12, 13]. It should also be noted that ghost charts are generally viewed in a negative light, for a number of reasons related to problems associated with the practice of using ghost charts, and exposure to medico-legal risk related to the use of ghost charts. Each of these is discussed briefly below.

Problems Arising from the Practice of Using Ghost Charts

The practice of maintaining and using ghost charts has been identified as problematic in both the Canadian Council on Health Services Accreditation (CCHSA) and the Joint Commission on the Accreditation of Healthcare Organizations (JCAHO) standards [3, 14]. Ghost charts are considered substandard practice in that they are presumed to compromise patient safety. Current norms and standards for good practice in patient safety are predicated on the need for complete, accurate, reliable and accessible patient data and information, and ghost charts are seen as a threat to record completeness, accuracy and accessibility. Hence ghost charts are seen as under-

[2] For example,

- A 2007 accreditation report for Capital Health (Nova Scotia) cites the existence of shadow records in 11 clinical areas, including acute geriatric medicine, surgery and neurosurgery and cancer care, and noted that the physician groups had begun stand alone medical record systems in some areas [3].
- A Saskatoon accreditation summary notes the recommendation for "examination of multiple chart approaches with the intent to make all healthcare information available during the healthcare encounter."[4].
- An accreditation report for PEI written in 2007 indicated that the Emergency Department stored ECGs separately from patient charts [5].

[3] AHIMA FAQ [1] http://library.ahima.org/xpedio/groups/public/documents/ahima/bok1_017169.hcsp?dDocName=bok1_017169

mining informational continuity of care,[4] as well as practitioners' abilities to be responsive and effective.

Problems identified with ghost chart use include that some ghost charts contain more information than the official medical record, which may lead to gaps in information among care providers [6, 11], and that a lack of up to date information may lead to inappropriate treatment and detrimental consequences to the patient [3, 14]. In addition to potential problems related to informational continuity of care, concerns have been raised about exposure to medico-legal risk related to the use of ghost charts. For example, issues have been raised about confidentiality/privacy and compliance with Freedom of Information and Protection of Privacy (FOIPOP) [16] and the U.S. Health Insurance Portability and Accountability Act of 1996 (HIPAA) legislation [11]. In addition, an organization's obligation to release records under freedom of information acts may be thwarted by the existence of unofficial records [16]. Finally, ghost charts may not comply with policies governing controlled access to patient information under FOIPOP regulations. Discussions about ghost charts suggest that they can be seen as both an adjunct to medical care, and as a legal document, and efforts to computerize hospital records should be undertaken with both of these views of a chart, as well as the notion of supporting staff in carrying out their work.

Although our primary purpose in exploring the existence and use of ghost charts has been within the context of future computerization of ambulatory care clinics, we have considered regulatory, governance and legal aspects of charting, and materials pertaining to the governance of medical charts (including ghost charts). While issues pertaining to the governance and legal status of ghost charts warrants further attention than space here allows, a preliminary examination of governance instruments pertaining to charting practices suggests that the push for a single medical record is rooted in accreditation standards rather than governance tools coming from professional associations or legislation (with the exception of the Canadian Health Information Management Association definition cited above), and that guidelines pertaining to the specific contents of medical records are often vague. Legal issues seem to arise when there is a discrepancy between what is documented in ghost charts and hospital records (the "officially sanctioned" record, herein referred to as hospital records), or when a hospital record is ordered under a freedom of information and protection of privacy request, and only the contents of the hospital record are furnished, and the patient is aware that a ghost chart exists, but it is not furnished in response to the FOI request.

The reliance upon ghost charts by medical staff for patient care raises important legal and ethical issues about what constitutes adequate information for good patient care. One view is that ghost charts should not be used because comprehensive information is not available for the doctors to make their decisions and do their work if they rely primarily on the ghost charts (GCs) rather than the hospital record, which is the officially recognized chart. In contrast, it can also be argued that the ghost charts exist for a reason (usually several reasons), and provides doctors with more in depth information about their patients than what is contained in hospital records, and, that they facilitate a number of other activities which take place in the ambulatory care clinics (such as scheduling of procedures, telephone-based nursing consultations), and elimination of ghost charts may compromise the clinics' ability to carry out their work (e.g., the removal of GCs from clinics would interrupt the provision of telephone support and education to patients and their family members).

Although the existence of ghost charts is well known, concerns about exposure to risk (e.g., based on an argument that a practitioner may not have consulted all available information when treating a patient, or has failed to release information held in ghost charts in response to a Freedom of Information and Privacy Act request) and questions about whether or not patient care is compromised as a result of ghost charts (seen by some as a threat to informational continuity of care, which in turn is seen as an important aspect of patient safety) result in a situation in which publication of material about ghost charts—whether scholarly, operational or in the form of reports—has been limited.

Methods

The study described here is a multiple method single-case study using embedded units of analysis. In this context, the single case is a single hospital, and embedded units of analysis are ambulatory care clinics (one hospital bounds the case, and three different ambulatory clinics—referred to in research design terminology as units, serve as focus for in depth study). Methods of data collection have included participant observation, formal and informal interviews and chart review. In addition, interviews have been carried out with staff from facilities other than the facility which serves as the focus of our study, in order to determine what practices are in place in other facilities in which ghost charts exist. We have also consulted medical literature and grey literature (e.g., hospital accreditation reports, material that is not peer reviewed but was located through on-line searches) about ghost charts, and conducted a search aimed at identifying governance instruments which address ghost charts.

Methods of Data Collection

Suchman's [17] observation that planned work activities differ from situated actions, and her observation that often people are unable to voluntarily describe what they take for granted (e.g., tacit elements of their work) lay the groundwork for the use of observational methods of data collection, in which researchers observe work activities, and seek clarification of activities from staff whom they observe. Observational methods of data collection are used to develop an overview of work practices in clinical settings, and interviews—both formal and infor-

[4] Informational continuity reflects the idea that details about past events should be available to inform current care [15]. See Reid et.al. [15] for a more extensive discussion of continuity of care. Varied meanings of the term continuity of care are useful to keep in mind within the broader context of discussions about both the functions that ghost charts serve, and both the explicitly and implicitly stated goals of computerization of electronic health records.

mal—have been used to clarify issues as well as gain additional insights about the nature of work.

Observations have focused on i) the setting (describing activities in a given space); ii) people's use of ghost charts and hospital records in order to understand practices from the perspectives of different persons/professions (physicians, nurses, secretaries etc.); iii) objects, (with a focus on the artifacts that mediate the work); iv) tasks (identifying tasks that constitute the work); v) information (focusing on information flow between groups of workers, in different locations, over time).

Sampling

The two units reported on here were chosen for in depth study because they represent varied service provision models within a single provider agency. In addition, units chosen for study fall under a single director, who was able to ensure access to each of these clinical settings. All staff members—from clerical and support staff to nursing, allied health and medical staff—working on the units included in the study have been eligible to participate. Only staff members who choose not to participate (n=1) have been excluded from participation. Research participants have been staff (doctors, nurses, and administrative staff) who work in two of three ambulatory care settings. Future study will add a third clinic.

Findings reflect data collection which occurred between August, 2007 and February, 2008. Observational data which forms the basis of what is reported here were collected on days when clinics occurred, and on days when no clinics were scheduled. Interview data and observations which formed the portion of material reported here were collected on 31 different days, in sessions ranging in length from one and a half hours (for an interview) to 8 hours (for observations).

Results and Discussion

Through this research it has become evident that clinic charts serve an important role as a working document (e.g., information in ghost charts is required to schedule procedures, support telephone based patient education, coordinate appointments between multiple units, etc.), and the removal of ghost charts in the absence of new mechanisms for addressing the needs that ghost charts fill would be likely to significantly interrupt work flow and patient care on those units using ghost charts.

While some duplication of information (e.g., lab results) exists between the hospital record and the ghost chart, the hospital record is archival in nature and serves as a repository of information, while the ghost chart serves as an active or working document, and must be ready at hand in order to support activities such as patient education, complex appointment scheduling, etc. Information required for the ongoing treatment and management of in-patients resides in the hospital record. Information in clinic charts which is not duplicated in the hospital record pertains only or primarily to the service maintaining the clinic chart (e.g., nursing notes pertaining to patient education). It is required for smooth operation of ambulatory care clinics, and would normally be culled from the hospital record.

Medico-legal norms and FOIPA regulations create a demand for a single record. The contents of the hospital record are ill defined and the legal status of a single hospital record is unclear. The current governance climate which identifies a single record as the standard of care is not reflective of the working realities of out patient or ambulatory care clinics operating within an acute care facility, in which paper based records are the predominant form of record. If the ambulatory care clinics were not located on-site or were not part of a single governing institution, there would be no expectation of a single record.

Although they fill critical roles for a variety of staff involved in the chain of care, ghost charts are not without their problems and challenges. If the use of ghost charts is to be reduced, any computer based system introduced will need to support the tasks that ghost charts currently support**.** Challenges related to the maintenance and use of ghost charts are numerous (e.g., the volume of paperwork created by interim lab results). To some extent, these problems could be mitigated with the advent of an electronic system, however, whether they are or are not mitigated will depend in part on the design and implementation of that system.

Building electronic records that reduce ghost chart use will require undertaking in depth data collection and analysis aimed at determining who requires access to what information in hospital records, so that the often neglected aspects of record use (e.g., scheduling, phone consultations) are supported. Additional research aimed at ascertaining how best to present clinical information to varied specialties in electronic format may also reduce reliance on specialty-specific charts.

Calls for a single record are also based on a normally tacit assumption that the availability of all information pertaining to a patient leads to better provision of care by a specialist than the provision of a relevant subset of information that relates to the providers' specialty. One of the things we observed is that each clinical group prepared its own 'face sheet' that summarized specialty-specific information about a patient, and that such specialty-specific views of the patient were essential to clinical consultations. This practice—along with our observation of differences in content of charts related to specialty areas-- suggests that ghost charts play an important role in organizing specialty-specific views of patients for providers. Further research is warranted in order to determine if providers are more effective in diagnostic work when they must deal with more information about a patient, some of which may not be relevant to their diagnostic frame.

Subsequent Directions for Research

As our work on this topic progressed, we undertook observational data collection aimed at determining how doctors use charts during clinical encounters. In addition, we explored issues related to the flow of patient information into and out of the health records department. Although not initially planned, chart review has been added to the study protocol and is being undertaken in order to determine to what extent chart contents vary from clinical area to clinical area and within clinical areas, and to determine to what extent there is overlap in the

contents of ghost charts and hospital records. Results from this chart review will be reported at a later date.

Anecdotal information has suggested that ghost charts may also be used to protect privacy in some circumstances. For example, care providers addressing issues such as psychiatric or mental health illness, sexual or other assault trauma, or addiction issues may rely on ghost charts to protect patient privacy. Additional research and policy discussion will be required to determine under what circumstances such information should be visible to all care providers, and when additional privacy is warranted.

Conclusion

Any attempts to computerize patient records beyond a single clinical area or geographic location will need to take into account the functions that ghost charts fill in supporting unplanned care (e.g., phone consultations), the work of nonmedical staff (e.g., in scheduling procedures), and should strive to preserve specialty-specific views of the patients, and at the same time adequately protect patient privacy. Failing to account for these aspects of charts—arguably the reason ghost charts exist—will fail to eliminate the need for ghost charts.

Acknowledgments

Funding for this research was provided by the Social Sciences and Humanities Research Council of Canada, through an Initiative for the New Economy Collaborative Research Grant (ACTION for Health), Ellen Balka, Principle Investigator. Several members of the ACTION for Health research team contributed to data collection.

Why don't innovation models help with informatics implementations?

Rod Ward

Faculty of Health and Life Sciences, University of the West of England, UK

Abstract

This paper describes various models that have been postulated to understand and explain the acceptance and diffusion of technological innovation. The wide range of factors relating to the innovation itself, and, most importantly, the human and organisational factors which will impinge on these processes, is detailed. Attempts to apply the model to healthcare settings are explored. In particular a systematic review in 2005 which attempted to integrate the models and apply them in the UK's National Health Service will be critiqued. The strengths and weaknesses of the models are explored, particularly in relation to the minimal testing they have been subjected to. It is argued that the complexity of the theoretical models makes them difficult to apply and questions their efficacy in supporting informatics implementations. The need for a clearer understanding of the factors which make staff positively disposed towards informatics innovation, and those which are likely to make them resist them is made apparent.

Keywords:

Computers; Attitude of Health Personnel; Diffusion of Innovation; Organizational Innovation; Models, Theoretical

Introduction

The process by which new technological innovations are adopted and disseminated has been extensively studied for many years. Data have been collected from many settings internationally and within different academic paradigms [1]. However, many of the models of innovation development and diffusion are developed from a limited empirical evidence base and have only been tested by post hoc application to previously published reports and fail to demonstrate predictive capabilities. More recently these models have been applied to the introduction of Informatics applications in healthcare; however the components of the models which relate to human and organisational factors are often considered secondary to technological issues when it comes to real world use.

This paper will argue that complex theoretical models are not currently helping to predict the factors that will lead to the success or failure of informatics developments. The models have similar components, but each with slightly different emphasis, and have increased in complexity over the years.

Models

Many of the models that attempt to explain the factors affecting whether an innovation will be shared and adopted by other individuals and organisations have been based on Rogers Diffusion of Innovation Theory [2]. Rogers argued that each adopter's willingness and ability to adopt an innovation would depend on their awareness, interest, evaluation, trial, and adoption. This led to the proposal of a five stage model for the diffusion of innovation [3]:

- Knowledge - learning about the existence and function of the innovation;
- Persuasion - becoming convinced of the value of the innovation;
- Decision - committing to the adoption of the innovation
- Implementation - putting it to use and
- Confirmation - the ultimate acceptance (or rejection) of the innovation.

An alternative approach to Roger's work is the Technology Acceptance Model (TAM) that focuses on the factors and decision processes an individual will go through in any decision to accept and use a technology or other innovation. The model suggests that when users are presented with a new innovation, two key factors influence their decision about how and when they will use it. Perceived Usefulness is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance" and the Perceived Ease-of-Use: "the degree to which a person believes that using a particular system would be free from effort" [4]. The TAM can be seen as an extension of Ajzen and Fishbein's theory of reasoned action [5, 6], which suggests people's volitional (voluntary) behaviour is predicted by their attitude toward that behaviour and how they think other people would view them if they performed the behaviour. A person's attitude, combined with subjective norms, forms behavioural intention.

Several researchers have replicated Davis's original study to provide empirical evidence on the relationships that exist between usefulness, ease of use and system use; [6-11]. Davis, [12] using newly developed scales, demonstrated that perceived

usefulness was 50% more influential than ease of use in determining usage.

Malhotra and Galletta [13] argued for much greater emphasis on social influences, rather than the nature of the technology, and developed and tested constructs based around these factors which may be particularly significant in complex organisations in which many different players are likely to be in a position to influence the success or failure of the innovation, even if they are not involved in adoption decisions.

Further work has tried to integrate individual and organisational factors. Venkatesh et al [14] compared existing models in an attempt to identify and test a model that integrates elements across them. Based on their work in a variety of settings they produced a set of hypotheses to explore and explain the variables which impinge on acceptance and use.

- The influence of performance expectancy on behavioral intention will be moderated by gender and age. The effect will be stronger for men and particularly for younger men.
- The influence of effort expectancy on behavioral intention will be moderated by gender, age, and experience. The effect will be stronger for women, particularly younger women, and particularly at early stages of experiencing the innovation.
- The influence of social influence on behavioral intention will be moderated by gender, age, voluntariness, and experience. The effect will be stronger for women, particularly older women, particularly in mandatory settings.
- Facilitating conditions will not have a significant influence on behavioral intention.
- The influence of facilitating conditions on usage will be moderated by age and experience. The effect will be stronger for older workers, particularly with increasing experience.
- Computer self-efficacy will not have a significant influence on behavioral intention.
- Computer anxiety will not have a significant influence on behavioral intention.
- Attitude toward using technology will not have a significant influence on behavioral intention
- Behavioral intention will have a significant positive influence on usage

Application to Health Informatics

In 2005 a major systematic literature review was undertaken, in an attempt to draw together the research on the diffusion of innovations and apply them to health service organisations. A particular emphasis was placed on the relevance of the work to the United Kingdom's National Health Service which funded the work [1].

The review reaffirmed many of the well known themes such as the importance of the attributes of the innovation itself, of social networks and organisational cultures, but also pointed out the lack of empirical evidence demonstrating that work from product-based innovation in companies can be applied to process innovation in service organisations, such as healthcare providers. The review attempted to integrate work from a variety of paradigms into a single conceptual model. The model seeks to encompass the whole range of factors and was tested against purposively sampled case studies.

The Greenhalgh et al model[1] covers several key areas:

- **Innovations** which covers relative advantage, compatibility, complexity, trialability, observability, reinvention, fuzzy boundaries, task issues, the nature of the knowledge required to use it and support required.
- **Adoption by individuals** which explores general and context specific psychological antecedents to, and the nature of the adoption decision.
- **Assimilation by organisations** where there is a dynamic relationship between initiation, development and implementation.
- **Diffusion and dissemination** which covers network structure, homophily, opinion leaders and harnessing their influence, champions, boundary spanners and formal dissemination programmes.
- **The inner context** addressing organisational antecedents and readiness for innovation, discussing structural determinants of innovativeness, absorptive capacity for new knowledge, the receptive context for change and the resources available.
- **The outer context** which covers inter-organisational networks and collaboration
- **Implementation and routinisation** which includes structure, leadership and management, human resources, funding and communication issues.

The Greenhalgh model accepts the importance of interactions between different components, but argues that it is not possible to make "formulaic, universally applicable recommendations for practice and policy" based on the model. This makes it impossible to use to predict behaviours and outcomes. It also becomes difficult to test or use in implementation projects, and lacks any ability to how much effect will be brought about by different factors.

Greenhalgh et al. [1] sought to test the model with four case studies; integrated care pathways, General Practitioner fundholding, telemedicine and the electronic patient record. Telemedicine is subtitled "the maverick initiative" and was selected partly because it had previously been studied from a diffusion of innovations perspective (e.g. [15, 16]). It was highlighted as being an initiative that tends to be introduced by individual enthusiasts rather than as part of an organisational process. The importance of human actors and the processes between them is described as being more important than the hardware and software of the technologies concerned [1]. The

evidence for the effectiveness and cost-effectiveness of telecare is inconclusive and barriers to adoption are extensive, however small teams of enthusiasts, have devoted time and personal resources to development, often in the face of institutional indifference and made the projects successful. May et al [17] used telehealthcare as a case study in their examination of the processes surrounding health technology assessment. They suggest that although the technology is attractive to policy makers as a "technological fix" for some structural problems that affect access to health care, it is unstable in clinical practice, not widely used and there are doubts about its efficacy, acceptability to patients and cost effectiveness. They suggest that evaluating these sorts of technological developments involves debates about evaluation methodology and professional dynamics that conceal more fundamental difficulties in conceptualising a technology in play, and which are difficult to resolve in practice. May et al [17] produced a set of terminology about how these innovations are adopted including; Ideation, Mobilisation, Clinical specification and Specific application which are not dissimilar to the stages originally set out by Rogers in his diffusion model but do focus this on application to clinical settings.

The other case study by Greenhalgh et al. [1] with direct relevance to Informatics is their review of the electronic health record which they dub "the big roll-out". This major national initiative is seen in the context of the UK's National Health Service which is fragmented across multiple sites and sectors posing obstacles to clinical care, administration, research and public health initiatives. The strong "external mandate" from central government is seen as being in conflict with the response from staff, because of "high complexity, questionable relative advantage and low ease of use" Greenhalgh et al.[1, p208-210]. These problems are identified as being significant because of the critical dependence on simultaneous adoption by multiple users, and low absorptive capacity of many parts of the system. These findings are further reflected by the independent evaluation of the summary care record early adopter programme, which identified positive mediators, including organisational readiness and aspects of the implementation, and negative mediators including the concerns of the potential adopters of the innovation [18].

Weaknesses of the models

The Greenhalgh et al, [1] model could be seen as being rather un-dynamic and undifferentiated, avoiding ranking the importance of the various factors and really providing a checklist rather than a full exploration of the complex factors involved in the diffusion of new technologies. Although highlighting a wide range of factors they did not place these in any order of priority. The research team also postulated that power relations were critical to successful implementation, but suggested they were very difficult to explore systematically. They also bemoaned the lack of research on the complexities in spreading and sustaining innovation in service organisations as opposed to initial innovation.

The general complexities of identifying the factors that contribute to the diffusion of innovations are complicated within specific organisational contexts and interpersonal relations. West [19] showed how, in the UK, the networking behaviours of senior nurses and medical staff, and their cliques, were different. The differences influenced the way in which they gained and shared information with colleagues, and suggested that these were a result of the occupational socialisation within the different professions, which had led to the development of subcultures [20]. Similar work in the USA examining the implementation of an electronic medical record system found that the new working practices which were inherent in the electronic system required "clarification of clinical roles and responsibilities which was traumatic for some individuals" and that "no single leadership style was optimal – a participatory consensus-building style may lead to more effective adoption decisions, whereas decisive leadership could help resolve barriers and resistance during implementations: the process fostered a counter climate of conflict" [21]. These professional variations and the wide variety of roles played by individuals mitigate against finding models which can encompass all the myriad influences of adoption and dissemination of technologies within the healthcare domain.

Resistance to innovation

There is a need for clarity in looking at the "fit" between the technology and the task it is intended to support. System design (from IT people) may not match well with objectives and values of clinical staff [22]. The degree to which a "one size fits all" solution can cause local resistance in organisations and individuals who have been used to "locally grown" systems which have high degrees of customization and localization was also highlighted by Hendy et al [23]. They found this factor was a significant driver in the development of resistance to new systems by clinicians.

Nursing staff reactions and strategies when employed to use software driven algorithms for decision making in a variety of settings, are influenced by the inflexibility imposed by the system which hampered their work. The nurses often overrode the guidance given by the system because it was not seen as being individualized to the specific patient problem [24]. At NHS Direct, nurses using similar software felt it was sometimes unable to consider contextual or other relevant information. They described the software as "interfering with their consultation with the patient, leading either to dependence on, or avoidance of, the software" and it was seen as a limitation imposed by management on the nurses' practice [25]. These types of reactions are to some extent predictable, but are not included in the models and need to be taken into account by system developers and those with responsibility for new implementations.

The 'Design-reality gap' has been given as a label to identify some of the factors which may influence the outcome of eHealth systems taking into account the situation specific factors which are relevant [22]. The Information, Technology, Processes, Objectives and values, Staffing and skills, Management systems

and structures, and Other Resources (ITPOSMO) model is based on a continuum between reality as it exists, and what the design is trying to achieve and helps as a way of identifying the need to reduce the gaps on all dimensions [22]. This model attempts to take into account attitudinal and organisational factors as well as technology based ones, although the models use as a predictor of implementation effectiveness remains to be tested.

Implementation models which accept the importance of involving users require consultation with individuals who will be affected by the change, both on an individual basis and through representative organisations. These require recognition of professional autonomy and an understanding of the different values and assumptions which may be held by different groups such as managers and clinicians. Kaplan [2] illustrated this with examples of the introduction of a computerised records system within one health care institution. She argued that the focus of the project team on a system which provided an automated patient history, rather than providing tools which the physicians thought would facilitate their work caused "information overload and standardization, clerical task load increase, work organisation rigidity and expert autonomy negation" [2, p 44]. The same system was found by nurses to be "highly normative as it tried to impose a new reality, producing uniformity and predictability in thought and behaviour patterns in nurses". These could be summarised as "a failure to appreciate the nature of decision problems and a mismatch in motivations between developers & users" [26].

In 1997 Myers and Young reworked Broadbent et al's [27] application of Habermas' model of societal development to examine the work of the information services unit within a mental healthcare provider in New Zealand, which encountered opposition from clinical staff. Clinicians objected to the "hidden agenda" of time based costing which underpinned managerial attempts to introduce a new recording and communication system. The resistance appeared to be in reaction to a perception that computers were being used to "control professional people" [28].

The systems need to provide user interfaces and response times which are acceptable within a clinical environment where the pace of change in patients' conditions and the interactions with health professionals may be rapid. The effects of the interaction between health professionals and patients in face to face settings have been studied however the social effects of interaction at a distance, mediated by technology in the growing fields of telemedicine and telecare applications are still unclear. The "human factors" need to be taken into account at all stages of the design, implementation and use phases of informatics implementations and need to be included in the models which aim to explain them.

Conclusion

The factors influencing acceptance or adoption of a technology and its subsequent diffusion will be influenced by the application itself, but also by a variety of other factors which will form individuals' attitudes towards the application. It is the individuals within organisations who are the ultimate users and consumers of the technology, [29] and the true benefits and impacts of IT are contingent on the extent to which individual users appropriate and use IT in their ongoing work activities that, in turn, contribute to organisational productivity [30].

Adoption and diffusion models offer us some insights into the myriad of factors which may impinge on the success or failure of informatics innovation; however they also have their limitations. Often they focus on policy drivers and barriers to innovation and do not fully take into account the complex organisational and personal factors which impinge of development and adoption.

Further empirical work to test and refine the existing models is needed, but the more effective approach may be to simplify the models, focusing on the most important or significant factors in the hope of producing something which can be used to predict and support informatics implementations.

Abstract

Building qualitative clinical decision support or monitoring based on information stored in clinical information (or EHR) systems cannot be done without assessing and controlling information quality. Numerous works have introduced methods and measures to qualify and enhance data, information models and terminologies quality. This paper introduces an approach based on an Information Quality Triangle that aims at providing a generic framework to help in characterizing quality measures and methods in the context of the integration of EHR data in a clinical datawarehouse. We have successfully experimented the proposed approach at the HEGP hospital in France, as part of the DebugIT EU FP7 project.

Keywords:

Data quality, Medical informatics computing, Hospital information systems, Total quality management, Information storage and retrieval, Database management systems

Introduction

Clinical Information Systems (CIS) are built to record operational data about the patient, to record her/his pathway through the health institute and everything that relates to her/his care. CIS includes Electronic Healthcare Records (EHR) data and other sources, such as laboratory systems data. Besides, Clinical Data Warehouses (CDW) are built to aggregate a great amount of data reliable for healthcare decision-making: decision support, monitoring, alert or data mining [1]. Today, building CDWs [2] is the right opportunity for health institutions to enhance the quality of their information systems.

CIS and CDW are different entities since the requirements of clinicians do not necessarily meet the ones of research physicians or organizations. In many health institutes, one issue is to feed automatically CDWs with heterogeneous data from CIS. Since CIS are not built to specifically structure and store clean aggregated data, quality is often not accurate enough in CDWs, which sometimes lead to wrong decisions [3].

We believe it is necessary to assess data quality within the CIS prior to its storage and use within a CDW. Therefore we propose a methodology to assess data quality of a CIS, then we introduce a framework and tools to control and enhance the information quality based on three dimensions: *concepts*, *terms* and *objects*.

This work takes part in the European DebugIT[1] project [4,5] which goal is to build a technical and semantic information technology platform able to share heterogeneous clinical data sets from different hospitals for the monitoring and the control of infectious diseases and antimicrobial resistances in Europe. The Georges Pompidou European Hospital in Paris (HEGP) is one of DebugIT's partners; a dedicated CDW named Transmed has been developed locally for this project. This CDW is fed with medical data including antibiotherapy and antibiogram data, recorded over the last decade within the HEGP EHR system.

In the following, we present an Information Quality Model and a methodology that we experimented to improve information quality in the context of importing HEGP operational EHR data into Transmed. Results are then presented and discussed.

Background

Data volumes have been growing massively along with inconsistencies and erroneous data. Data quality started to be studied in the late 60's by statisticians [6]. Then, at the beginning of the 90's, computer scientists considered the issue of defining, measuring and improving data quality. ISO defines quality as "the totality of features and characteristics of an entity that bears on its ability to satisfy stated and implied needs" (ISO 8402-1986, Quality Vocabulary). Wang [7] proposes to define a piece of data as of good quality if it matches the intended use in its context. However, that concept being broad enough to be an axiom, it is not narrow enough to be able to characterize precisely data quality. Redman [7] has proposed to specify that axiom into four dimensions: *accuracy*, *perfection*, *freshness*

[1] Detecting and Eliminating Bacteria UsinG Information Technology

and *uniformity*. Other quality factors were introduced in order to assess data quality criteria depending on semantic [8, 9], process [9] or goal [10, 9]. Wang [7] also introduces a Total Data Quality Management (TDQM) methodology based on Deming wheel[2] that defines a quality improvement process. Likewise, the data warehouse communities have introduced various methods to measure, enhance and monitor the quality of data in CDWs [11, 12].

Besides the evaluation of the quality of data, many frameworks were introduced for evaluating information models quality [13, 14]. However, it remains difficult to assess quality of information models only with metrics [15]. Moody *and al.* proposed eight quality factors as metrics candidates. They also introduced subjective measurements of the information model quality by grading from 0 to 5 each of the 7 factors known as: *correctness, implementability, completeness, understandability, integration, flexibility and simplicity.*

In healthcare, data quality works have also been studied. A recognized need is growing for a secondary use of qualitative electronic health records for research (epidemiologic, public health). Nevertheless, it remains challenging to rely on good quality data [16]. Causes of insufficient data quality in medical records have been classified between systematic or random errors types [17] at different stages of the recording process. Kerr [18] introduced a framework to measure data quality based on the CIHI[3] recommendations. It led to setup a framework composed of 69 quality criteria grouped into 24 quality characteristics that groups into 6 quality dimensions: *accuracy*, *timeliness*, *comparability*, *usability*, *relevance* and *privacy & security*. These works propose methods and measures to assess data quality, yet we believe they have been essentially focused on data accuracy.

Beside this, the healthcare domain has built over years reference knowledge sources that could help in data quality assessment, namely, the standardized information models and domain terminologies or ontologies [19]. Reference terminologies have gained general acceptance over the research community [20], as they are key resources to interoperability and decision support. In addition to reference terminologies, "interface terminologies" are defined as "systematic collections of clinically oriented phrases aggregated to support clinician's entry of patient information in computer programs". Methods to compare the quality of interface and reference terminologies were introduced in [21].

Materials and Methods

Information Quality model

The clinical information contained within the CIS can be defined through 3 main dimensions: 1) data, or instances of real world objects, are physically stored information into CIS data stores, 2) information models are representations of concepts or relationships (among other properties) used to organize and structure information and 3) terminologies store referential data in various forms: terminology (list of terms), thesaurus (index and synonyms), classification (with generic relationships) or vocabulary (with definitions). We propose to classify the quality measures proposed in the literature, given those three dimensions defined as *objects*, *concepts*, and *terms*.

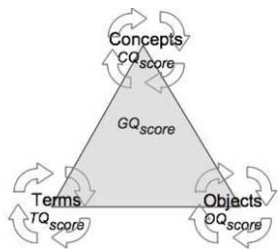

Figure 1- The Information Quality Triangle

The three information quality dimensions are the vertexes of our Information Quality Triangle (IQT) depicted in figure 1. For each vertex, there are methods and scores to measure information quality. Each score is then aggregated into a global score that would be defined as an information source score prior to data integration.

Material

The main data source in our experiment is the EHR system of HEGP. It stores 10 years of EHR data in various domains. We have focused our work on data domains that concerns infectious diseases, and particularly the laboratory results related to antibiotic resistance tests and antibiotic prescriptions.

The EHR dataset is composed of a volume of 1 200 000 patients, 1 600 000 admissions, 3 200 000 antibiograms, and 24 000 drugs/substances.

Most of the *object* quality criteria are measured using Talend© Open Studio[4] open source software as well as developed stored procedures in SQL[5].

Our domain is modelized with the help of the 6 following HL7 information models of the January 2009 version of the HL7 ballot:

- A_Encounter universal (COCT_RM010000UV01),
- Result Event (POLB_RM004000UV01),
- Composite Order (POOR_RM200999UV),
- Common Observation (POOB_RM410000UV),
- Adverse Reaction (REPC_RM000022UV),
- BillableClinicalService Encounter (COCT_RM290004UV06).

This covers the conceptual scope of the DebugIT project. The information model includes 61 classes and 262 properties.

[2] Plan-Do-Act-Check iterative problem solving process
[3] Canadian Institute for Health Information: a pioneer on health care information quality domain

[4] http://www.talend.com/products-data-quality/talend-open-profiler.php
[5] Structured Query Language

To standardize the EHR vocabulary, we have first focused on two consensual resources in use within DebugIT: 1) ATC: The WHO drugs and substances international classification and 2) NEWT: organisms taxonomy database.

Perl routines have been developed at the University Hospitals of Geneva (HUG) to map free text terms to terminologies' entities. The drug names mapping is performed in several steps, until a successful candidate is found, consisting mainly in removing letters (the French version of the drug names often adds a final "e") or part of the term. For instance, the term *ac.fus* is not found by exact matching. When searching only for the second part (*fus*), the system returns several possible answers, but only one is an antibiotic: *fusidic acid*. The bacteria names mapping follows a similar approach. Moreover, when no candidate is found for a species, we attribute the parent taxon, the gender, to this term.

Quality method

We applied the TDQM 4 steps approach to score quality of each vertex [7]. They can be grouped into two functions, assessment (*audit* and *qualification*) on the one hand and enhancement (*standardization* and *surveillance*) on the other hand.

The *audit* consists in scoring the source for each vertex using defined criteria. Table 1 reports the criteria used at each vertex to build the overall score of the IQT. Each object quality score is composed of various criteria scores measured using computerized algorithms. Concept quality score is based on the subjective rating of information model quality proposed in [16]. Terminology score measurement is a statistical distance between the reference and the interface terminologies.

Table 1 – Criteria and Methods for auditing the data at each vertex

Vertex	Criteria	Method
Concept	Domain	Subjective Rating of Data Model Quality
Objects	Completeness	Total number of records filled compared to total number of records
Objects	Accuracy	Data format
Objects	Uniqueness	An algorithm that searches for uniqueness
Objects	Consistency	An algorithm to check consistency, for example check if Start Date of Prescription < End Date
Terms	Consistency	Distance to reference terminologies

The criteria are measured according to a reference for each of those dimensions. From the *object* dimension level, the reference is a set of rules (for example the date of death is after the date of birth). From the *concept* dimension, we state as a reference the HL7 version 3 information models specialized from the reference information model (RIM)[6], which proposes a conceptual representation for electronic health records. As for the *terms*, we use as reference the NEWT and WHO-ATC standards in order to normalize the terms of our domain of study.

The *qualifying* process aims at scoring the source information based on the IQT and the measures of the *audit* phase. Criteria scores are precise and accurate, though the qualifying of a source of information can be quite subjective. We use grades to score each IQT vertex of our information source, varying from A to D. For each quality domain, we made the average percentage of every criterion and split them every 25% to the corresponding grade. The meaning of the global scores can be qualified as following:

- A: The information quality is excellent. The information source carries enough semantics and organization to be queried without needs to be adapted.
- B: The information quality is good though it requires some work to improve one of the vertexes of the IQT.
- C: The information source quality is narrow. It could be usable only after some consequent work to improve information quality.
- D: The information quality of the source is low. The time and/or effort to improve it would be too high to consider this information source as a potential source for a CDW project.

Then, we enhance the quality within the *standardization* phase and we make sure the quality is controlled over time in the *surveillance* phase that helps to ensure the information is controlled over time within the destination CDW.

Results

For each step of the methodology, we present the results of our experimentation for the three vertexes of IQT.

Audit

For the *objects*, Table 2 shows result samples for three criteria on a limited number of objects.

Table 2 – Object Criteria Scores

Object	Criterion	Score	Comments
Discharge Date	Completeness	69,9%	Helps calculating the length of stay
DrugUCD	Consistency	75,6%	The UCD is a French classification code
Patient ID	Uniqueness	100%	The patient ID has unique values

As for the *terms*, Table 3 shows a sample result obtained against NEWT taxonomy for the Bacteria names, and against a local referential for sample location and type built by a medi-

[6] The RIM is a pictorial representation of the HL7 clinical data domains. See (http://www.hl7.org/implement/standards/rim.cfm)

cal expert. The measured distance is a percentage of correct terms within the EHR system compared to the standardized terminology.

Table 3 – Terminology Distance Scores

Terminology (Standard Referential)	Distance to Standard Referential
Bacteria Names (NEWT)	85,53%
Sample Location (local)	93,11%
Sample Type (local)	36,77%

For the *concepts*, we obtained the scores shown on Figure 2 with the help of a domain expert and a data modeler. Each axis represents the empirical evaluation of the source information model rating from 1 (poor) to 5 (excellent). Many examples illustrate the weaknesses of the EHR information model compared to HL7 version information models. In the field of lab results, the HL7 version 3 model "Result Event" (POLB_RM004000UV01) proposes a specific class to manage clusters of tests to be made on a given derived specimen (aliquote), which allows better management of the microbiological lab test results compared to the implementation done in the HEGP CIS. In the field of medication order, from a vocabulary perspective, a table named C_SPECIALITE records in fact drug prescriptions. A strength of the EHR information model is that it integrates a repository of shared data elements that are linked to national and local referential terminologies. This helps for integrating the EHR into the CIS.

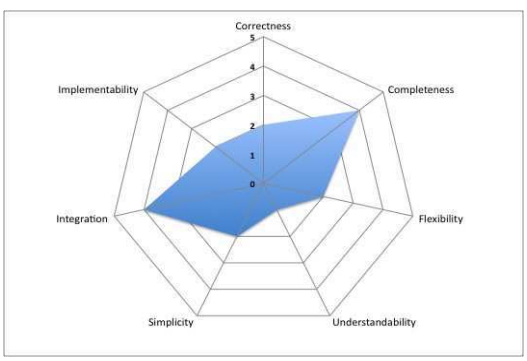

Figure 2- The EHR IM Quality subjective rating

Qualifying

The overall Information Quality Triangle of our information source for the restricted domain chosen is shown in Table 4.

This qualification phase can be considered as the validation method to our IQT. Each score is calculated given the scores found at each vertex. For example, the average of scores of the *concept* vertex being 2.42, the score is C. The *global* score of our source EHR system reflects its overall quality in the context of our evaluation.

Table 4 – Source EHR system scores

Vertex	Score
Object	C
Term	B
Concept	C
Global	**C**

Standardization

The standardization process was made during the loading of our clinical data warehouse for research. It was made at two different levels. At a first stage, we built an information quality firewall between the EHR and the CDW. Using the open source software Talend© Open Studio, we setup procedures to standardize the objects using a CTS[7] based information model. We built ETL scripts to correct objects based on a dictionary of 'dirty' and preferred terms stored into the CTS information model. At a second stage, we implemented two PERL scripts in order to map the local terminology preferred term with the standardized term. Up to 76% of the drug names present in the CDW were normalized successfully. Concerning pathogen normalization using NEWT, 99% of the pathogen names identified by an antibiogram were mapped to a NEWT term, which was manually validated.

The CDW physical information model was standardized using HL7 version 3 information models. The OMDF[8] platform was used to specialize the HL7-based conceptual models and generate the MySQL scripts in order to implement the CDW HL7-based information model corresponding to our domain.

Monitoring

We setup the necessary scripts to monitor the future load of data using Talend© Open Studio. We also setup the necessary alert routines that notifies of any unknown new concept loaded into the CDW in order to keep controlled clinical data warehouse information.

Discussion and Conclusion

The contribution of this work is three fold. First, this work enabled the HEGP hospital to provide a first attempt of measuring the distance between standardized information models and reference terminologies against its CIS after 10 years of production (it could also result in enhancing the information quality of their CIS). Secondly, it enhanced the quality of information within the CDW, which allowed building pertinent and coherent monitoring trends illustrating antibiotic resistance profiles over 10 years of data. Finally, it enabled the HEGP hospital to interoperate with other health institutes within the DebugIT project. Controlled vocabularies are a necessity to share data across Europe.

[7] Common Terminology Services: HL7 specifications for managing terminologies within clinical information systems
[8] Open Medical Development Framework: https://gforge.spim.jussieu.fr/projects/omdf-hl7/

We have introduced another method based on the literature work to assess information quality of electronic health records that takes into account a 'formal' framework to measure information quality, given the health care domain specificities: the IQT. We think this methodology abstract enough to be generalized. For instance, the use of an ontology could be preferred to the use of an information model to conceptualize a domain. In that case the conceptual vertex of the triangle could be an ontology.

We have successfully experimented this methodology in the context of the European project DebugIT. Not all of the experiment is automatized since it still requires the help of medical experts, but it does not invalidate the proposed methodology. The translational clinical data warehouse we built contains controlled objects, terminologies and concepts. We believe it is a first step to interoperability that cannot be avoided in the healthcare domain. It would be interesting to validate our approach on other EHR systems in order to better evaluate it. We also would like to investigate the use of our quality scores within a clinical decision support system.

Acknowledgments

This work was supported by grant from FP7-ICT-2007-1- « Patient Safety » (DebugIT project).

Understanding Effective Clinical Communication in Medical Errors

Saif Khairat[a], Yang Gong[a,b]

[a] *MU Informatics Institute,*
[b] *Department of Health Management & Informatics, School of Medicine*
University of Missouri, Columbia, MO, USA

Abstract

Clinical Communication failures are considered the leading cause of medical errors [1]. Minimizing communication problems among clinical team members could directly reduce medical errors and hence, increase patient safety and improve health care quality. Our main focus is, through knowledge representation approach, to develop an understanding of communication problems applied to health care settings. This will serve as the foundation to our long term goal of building an ontology-driven educational tool that will be used to educate clinicians about miscommunication issues and as a means to improve it.

Keywords:

Clinical communication, Knowledge representation, Model, Human-computer interaction, Medical errors.

Introduction

Medical Errors in health care are estimated to cost more than $5 million per year in a large teaching hospital [1]. The causes behind those errors are various; however, clinical communication is listed as the main cause of medical mishaps [2-5]. According to a report by the Institute of Medicine (IOM) [6], preventable health care-related injuries cost the economy from $17 to $29 billion annually, of which half are health care costs. On the societal level, the massive cost of medical errors affects the health care industry as well as the U.S. economy at large. In 2006, the IOM stated that at least 1.5 million preventable adverse drug events occur annually in the United States as a result of medication errors [7]. This remarkably high cost of injuries has a significant impact on individual's well being as well as the society. By understanding the causes of medical errors and efficiently evaluating possible solutions, preventable medical errors can be minimized and hence, improve patient safety and reduce health care costs.

In this research, we define communication as the exchange of ideas, messages or knowledge between two or more entities through oral and written forms, or signals. In health care, professionals carry dialogues using traceable mediums such as Electronic Medical Record (EMR) systems, paper chart or emails; and untraceable channels like face-to-face discussions. Communication problems arise when the instructions are incomplete or incoherent and therefore, incorrect tasks are performed which lead to medical errors. However, communication failures, whether traceable or untraceable, are hard to catch.

In 2003, a research was conducted to observe communication patterns between physicians, nurses and pharmacists, also known as clinical-to-clinical communication. Results suggested that through the use of technology and EMR to enhance communication better communication can be reached [8]. The use of technology to reduce medical errors is necessary however, the need to understand how and why medical errors occur as a result of miscommunication is essential. In another study carried out in Denver, some of the causes behind miscommunication were attributed to the complexity of health care structure and differences in education and training among health professionals [9]. Those results provide the necessary background for diagnosing the causes behind miscommunication between health professionals.

The role of communication in healthcare

The clinical communication space, which resembles total information transactions clinician time, accounts for the major part of the information flow in health care [10]. According to the Joint Commission on Accreditation of Healthcare Organizations, problems related to communication represent 60% of sentinel events reported [11].

A study carried in Australia shows that in a 16,000 in-hospital deaths, communication errors were found to be the leading cause, twice as frequent as errors due to clinical malpractice [4]. Results show that poor communication can lead to negative outcomes such as misunderstandings and medical errors and thus, poor patient safety [12]. Therefore, the need for better communication skills among health professionals is a must.

Clinical Information Systems

Computer-based systems, such as Clinical Decision Support Systems (CDSS) and EMRs, have facilitated evidence-based and patient care by reducing serious medication errors [13] and enhancing the delivery of preventive care services[14] [15]. However, about 34% of computer-based systems have shown insignificant progress in clinical practice [15]. One of

the major reasons for this inefficiency is, as the use of Health Information Systems (HIS) and Computer Information Systems (CIS) increase, new medical errors are introduced. The types of errors produced by both systems differ for each type; HIS mainly keeps track of administrative issues and CIS concentrates on patient-related data such EMRs. However, many errors from both systems can be related to miscommunication. Therefore, the communication model proposed addresses communication limitations in both HIS and CIS.

A previous study shows that there are two categories of errors that occur during human-computer interactions. The first is errors submitting and retrieving information to and from an information system and secondly, errors in the communication and coordination processes that (CIS) is supposed to support [16]. In order to improve clinical communication, human-computer interaction has to be considered as a major component of the communication process. We believe that CIS should facilitate communication between clinicians, ensure correct clinical data flow and most importantly, improve health care services to the maximum effect.

Methods

To our knowledge, there is no communication model that represents clinical communication. This research aims at developing a communication model that fits health care. Initially, we analyzed general communication models through identifying the strengths, limitations, overall applicability in health care for each model. Then, using literature reviews and domain experts, we identified medical error cases to indentify miscommunication factors. Table 1 shows a sample of selected cases, the scenario, and communication factors we identified. The table distinguishes between general communication models and the proposed model by displaying the coverage level of each model. Through the previous steps, we developed a communication model that can better represent communication in clinical settings.

A need for a communication model

As the largest industry in the United States in 2006, the health care industry provides about 14 million jobs [17]. This shows the diversity in education, training and culture among employees. Therefore, a communication model that articulately demonstrates the communication framework among clinicians is essential. We believe that a communication model is a significant step towards improving the concept of communication in health care. By demonstrating a communication model, there will be more opportunities to raise questions and to encourage more research in this field. The model will show the complexity of the process and hence, display the order and coherence of procedures. Moreover, a practical model will open more research doors to new discoveries and better approaches about enhancing clinical communication which is our ultimate goal.

We expect the model to go through cycles of modifications and refinements as more cases are reported. However, our research does not stop at the model; in fact the model is just the beginning point in a roadmap to increase patient safety. Using the model, we plan to build ontology of possible clinical miscommunication causes which would help healthcare professionals understand medical incidents and increase their awareness of effective communication. The cases collected enable classification of communication factors at a lower level taxonomy. The communication model classifies the communication barriers and hence, provides higher level categorization of the communication model. Both, cases studied and the proposed model will provide a vision towards building a communication ontology which is exhaustive and complete.

Proposed Model

To build the model, we used previously reported error cases, where miscommunication is the main cause behind the error. Through studying the relevant literature and analyzing reported cases, we believe that to build an inclusive model there needs to be two main subcomponents to clinical communication; Human-Human and Human-Computer communication.

We define human-human interaction in health care in the following scenario: a communicator tries to send a message through a given means of communication, while delivering the message some noise is usually introduced. The noise can occur due to external and/or internal factors.

External factors include interruption during communication and incoherent messages. Internal factors can be multitasking or assumptions made by a recipient. Those noise factors usually introduce distortion of some sort in the true meaning of the message and hence, it affects the overall efficiency of the communication process. The message is received by recipient but, the message is usually different from what was originally sent by communicator. Therefore we introduce a distortion variable 'Y' to the message; this variable can hold negative or positive values. A negative value means the message received is incomplete. A positive value means the message received had either more or different details than what was intended. Upon receiving the message, the recipient sends a feedback to the sender to ensure that the meaning received was the meaning intended by the sender. In some cases the message sent is the same message received however, miscommunication can still occur due to factors such as differences in training, cognitive factors. However, the feedback process is also viable to noise introduction and thus, more distortion could be added to the process.

As for human-computer interaction, the user submits a request through the interface; requests vary from entering data to a request to retrieve information. Upon receiving user's query, the computer system takes legitimate action to perform the requested set of actions. Once data has been extracted and formatted, the system displays the information to the user in a meaningful manner through the Graphical User Interface (GUI). Medical errors occur due to miscommunication between the user and the information system. Factors causing communication breakdown include GUI issues, user skills to enter or retrieve the right information, knowledge represented by the system and how it is interpreted by user, and miscellaneous factors represent access problems and ways to work around error messages.

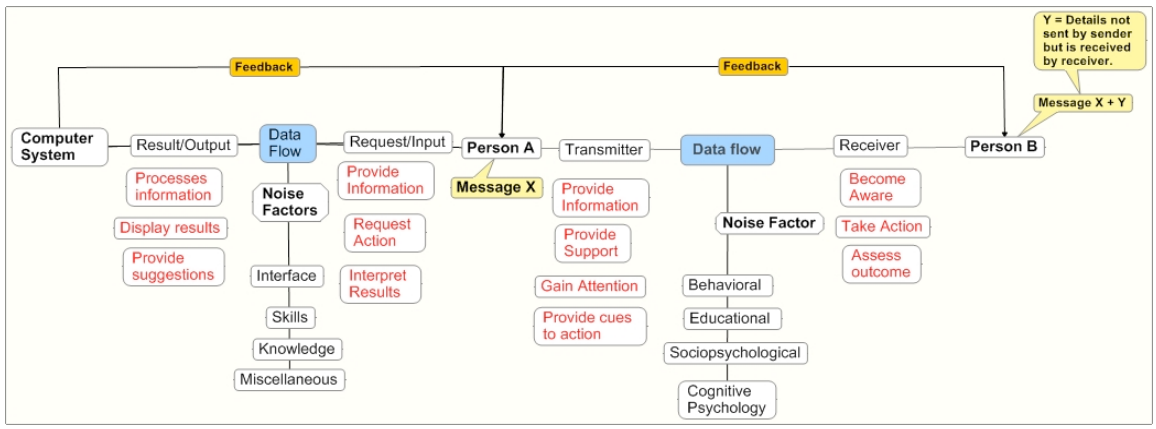

Figure 1- Proposed Communication Model with an emphasis on human-human and human-computer interaction

Comparing Communication Models

Table 1 shows 5 medical error cases we chose from the pool of cases. The cases were chosen carefully to represent the wide range of variability in miscommunication cases and they demonstrate our initiative to validate the model we proposed. We compared the proposed communication model against major communication models in other fields. Among those models were Shannon's, Schramm's, Riley's [18], Berlo's, Ecological, and Coorientation model [19-21]. The table displays a summary of each incident, factors leading to communication breakdown, factors covered by general communication models, and factors covered by the proposed model. The specific aim of this study is to provide a communication model that expresses the strengths and weakness of the communication process between clinicians.

Results

General communication models cover major communication aspects such as feedback, message medium and noise. However, the 5 cases show that in healthcare there are specific characteristics to communication. There are factors that are not expressed in general models. The model proposed, besides including more factors, has categories that are inclusive and well displayed which will facilitate future research.

Based on communication literature reviews, fragmented keywords were identified as communication factors for each case shown in the third column of the table 1. Then, factors from literature review were mapped with the current communication model to identify which factors, if any, are covered by which model, as shown in column 4. In some cases, some models do not have any overlaps with factors from the review. Another mapping was conducted between the literature factors and the model proposed, shown in last column. The proposed model includes taxonomy of the communication problem and hence, includes a higher level classification of the factors. For example, in case 1 the factor of lack of experience is mapped in the proposed model under educational factors. The proposed model has an advantage over current communication models in Human-Computer communication. The new model expresses Human-Computer interaction in more details than other models. Through real cases, the factors suggested have played an important role in communication between clinicians and computer systems.

Table 1 demonstrates the challenge in applying general communication model in health care. Through the five cases we studied in this paper, it can be concluded that other models can represent some of the problems but not all. The same cases show the ability of our proposed model to represent communication scenarios in health care. Therefore, we believe the results from this study support our model as an initial representative model to health care communication that requires more work to maximize cases covered by the model.

Discussion and Future Work

One of the obstacles to understanding clinical miscommunication is the scarcity of data. The absence of a mandatory reporting system has resulted in many medical errors occurring and not being reported. With the exception of Veterans Health Administration [27] and the Department of Defense, there are no nationwide reporting systems that mandate error reporting. Some of the reasons why such a system has not been implemented yet are the lack of anonymity, lack of knowledge on what to report, fear of blame, and most importantly lawsuits [28]. To our knowledge, very little research has been conducted to minimize clinical miscommunication. Researchers have explored the causes of miscommunication and ways to improve it [8, 9, 28-30]. We believe this research provides a new approach for physicians, nurses and other clinicians to improve communication within a single team.

Table 1- Medical Error Cases Analysis Guided by the Proposed Model

Case	Story [Reference]	Factors in communication literature	Factors in current Models	Factors in proposed Model
1	• Surgeon asks the anesthesiologist to give 10,000 Heparin. • The anesthesiologist hears the dose to be 2,000. Consequently, the Activated Clotting Time was low. The surgeon finds out the wrong dose of Heparin was given. The correct dose is given to the patient and a full recovery was achieved. [22]	• Assumptions • Ask Questions • Lack of Experience • Feedback	• Feedback (Shannon, Coorientation) • Experience (Schramm)	• Behavioral • Educational • Feedback
2	• Benny, 14-month old kid was admitted to the Care Unit. The nurse documents a verbal order as 0.7mg of Digoxin. • According to Benny's weight, the appropriate dose is 0.07mg. • When Digoxin was administered, Benny went into Cardiac Arrest and was announced dead. [23]	• Clinical Background • Training • Experience • Knowledge • Memory	• Culture (Berlo) • Social system (Ecological, Berlo, Riley) • Experience (Schramm)	• Educational • Cognitive Psychology
3	• A 47-year-old man was admitted and diagnosed with Pneumocystis jiroveci pneumonia (PCP). Two Biopsies were performed. • The intern finds a third biopsy in the hospital's EMR. The intern questioned her memory. • The team realized the third biopsy had been accidentally entered into this patient's record. • Dermatopathology department physicians and staff didn't have access to the hospital's EMR. [24]	• Human memory • Error Entering information to the system • Incorrect assumptions • Access to the system	• Experience (Schramm) • Feedback (Shannon, Coorientation)	• Behavioral • Cognitive Psychology • System skills • System knowledge • Miscellaneous
4	• An 85-year-old woman was admitted with a reported fall. • The surgery team decided that the patient is a candidate for nonsurgical treatment and noted in the EMR that the patient is able to weight-bear without pain. • The intern read the surgeon's note and found these comments ambulating odd. The team had evaluated the wrong patient. [25]	• Clinicians Feedback • EMR feedback • Memory	• Feedback (Shannon, Coorientation)	• Behavioral • Educational • System knowledge • Miscellaneous
5	• A 75-year-old woman admitted to the emergency department (ED) with chest pain. The patient could not recall of some of her medications. The physician printed the medication list from the EMR. • The patient developed a heart rate under 40. • On reviewing the patient's outpatient, the physician found a note stating the plan to discontinue some medications. [26]	• System design • System Interface • Usability skills	• Missing human-computer interaction	• System interface • System skills • System knowledge

The current communication model needs to be further verified and tested, through the analysis of more cases, in order to develop a more inclusive model. Case acquisition will come from literature databases such as Ovid database and Agency for Healthcare Research and Quality (AHRQ). Also, live observational study at the Critical Care Unit at the University of Missouri Hospital has been planned in an attempt to further identify the patterns and trends in clinical communication. The choice of Critical Care Unit is based on the fact that critically ill patients receive more services in short time spans which can be more error prone. Furthermore, critical care patients are prescribed twice as many medications as patients outside of the ICU which mean that the rate of preventable and potential adverse drug events is twice as high in ICUs and hence, higher chances of miscommunication occur in ICUs [3].

This ongoing project aims to utilize the data collected with domain expertise to build fully developed and exhaustive clinical communication ontology, which is in consistency with the early work [32]. Our effort would help healthcare professionals understand medical incidents and increase their awareness of effective communication. This ontology can serve as a classification methodology to communication problems in HIS. Also, as this ontology can be integrated with knowledge base systems to enhance clinical decision support systems. The long term plan is to utilize the built ontology to build an educational tool, that provides clinicians with the necessary information they need about clinical communication, its factors, and ways to improve it.

Abstract

Clinical practice guidelines are used to disseminate best practice to clinicians. Successful guidelines depend on literature that is both relevant to the questions posed and based on high quality research in accordance with evidence-based medicine. Meeting these standards requires extensive manual review. We describe a system that combines symbolic semantic processing with a statistical method for selecting both relevant and high quality studies. We focused on a cardiovascular risk factor guideline, and the overall performance of the system was 56% recall, 91% precision ($F_{0.5}$-score 0.81). If quality of the evidence is not taken into account, performance drops to 62% recall, 79% precision ($F_{0.5}$-score 0.75). We suggest that this system can potentially improve the efficiency of the literature review process in guideline development.

Keywords:

Natural language processing, Machine learning, Clinical guidelines

Introduction

Clinical practice guidelines are produced by medical professional societies, governmental agencies, and the biomedical research community to assist clinicians in providing quality care [1- 3]. As part of the guideline creation process, queries are issued to MEDLINE® to retrieve citations relevant to critical questions supporting the guideline. Cited studies must be of high quality (typically, randomized clinical trials and systematic reviews) according to the evidence-based medicine (EBM) paradigm [4]. Currently, domain experts find such studies by reading large numbers of citations for each question posed, a process that is both resource- and time-intensive.

To reduce the amount of manual effort expended during guideline creation, we recently proposed an automatic method based on SemRep [5, 6] semantic processing for discriminating between relevant and nonrelevant MEDLINE citations for critical questions [7]. Although we suggest that the system can help streamline guideline development, it is unable to identify high quality clinical evidence. Others, however, have developed machine learning techniques for automatically recognizing such evidence [8- 10]. In this paper, we describe a system that combines our symbolic processing [7] with a statistical method [10] for selecting studies that are both relevant to questions and of high scientific quality. Retrieved citations are ranked: those which are both relevant and of high quality are put in the highest rank, while those which are nonrelevant and not of high quality are in the lowest. We tested the system on a class of questions for a guideline on cardiovascular risk reduction being produced by the National Heart Lung and Blood Institute at the National Institutes of Health.

Background

SemRep

The SemRep natural language processing system extracts semantic predications from biomedical text using linguistic analysis and domain knowledge in the Unified Medical Language System® (UMLS)® [11]. Processing begins with a partial syntactic analysis based on the SPECIALIST Lexicon [12] and MedPost part-of-speech tagger [13]. Simple noun phrases in this structure are then mapped to Metathesaurus concepts by MetaMap [14]. In final processing, underspecified dependency rules identify some of these augmented noun phrases as arguments of semantic predications asserted in the sentence. Such predications must be sanctioned by a relationship in the UMLS Semantic Network.

For example, from sentence (1), SemRep extracts the predications in (2), in which the arguments ("sibutramine," "Obesity," and "Patients") are concepts from the Metathesaurus, and the relations TREATS and PROCESS_OF are from the Semantic Network.

(1) Second phase of a double-blind study clinical trial on sibutramine for the treatment of patients suffering essential obesity

(2) sibutramine TREATS Obesity
Obesity PROCESS_OF Patients

Predications such as these are used to identify relevant citations for guideline questions.

Relevance

Analysis demonstrated that the distribution of predications representing the semantic components of questions is different in relevant and nonrelevant citations. We therefore wrote rules that match questions to predications [7]. For example, pertinent semantic components of questions in the cardiovascular guideline are risk factor, disorder, population, and action, and the question in (3) has the rules in (4) associated with it.

(3) What is the evidence that diabetes mellitus can be decreased in children?

(4) <Diabetes> PROCESS_OF <Children>
<Diabetes> NOT PROCESS_OF <Adults>
X TREATS <Diabetes>

These rules match SemRep semantic predications in the following way: "X" matches any argument, while items delimited by brackets in the rules represent variables to be matched to a specified domain of Metathesaurus concepts serving as arguments of predications. For example, "<Diabetes>" matches concepts such as "Diabetes Mellitus," "Diabetes Mellitus, Insulin-Dependent," and "Diabetes Mellitus, Non-Insulin-Dependent," while "<Children>" matches "Child," "Youth," "Boys," and "Girls."

If predications matching the rules in (4) are found in the SemRep output for a retrieved citation, it is relevant to the question; otherwise, it is nonrelevant. It is important to note that this processing does not answer the question (e.g. [15-19]), but merely identifies citations which can be used to determine an answer. The word *evidence* in the question implies that only high-quality evidence is sought.

Quality of the Evidence

The evidence-based medicine paradigm categorizes types of clinical evidence and ranks them according to their strength (quality) to avoid research bias. The Oxford Centre for Evidence-Based Medicine [20] proposed an influential categorization which states that the most rigorous scientific studies are systematic reviews and randomized clinical trials. The second component of our combined system identifies such studies, using machine-learning techniques trained on MEDLINE citations annotated by hand for high-quality evidence [21, 22]. An array of features, including text words, semantic features, and MEDLINE metadata are used by several classifiers augmented with boosting and ensemble techniques to mark each document encountered as either reporting high quality research or not. The classifier achieved an F_1 score of nearly 0.70 in making this determination in test documents [10].

Materials and Methods

Our technique for combining symbolic relevance processing with the statistical method for identifying high-quality research is tied to a particular guideline question. A PubMed query is issued to retrieve citations for that question. Relevance and quality of evidence processing are then applied independently to the retrieved citations and the results are combined so that each citation has a score both for relevance (1 or 0) and for quality of evidence (also 1 or 0). Citations are ranked into four disjoint groups based on these scores:

A. Relevant to the question and high quality of evidence (1,1)
B. Relevant to the question but not high quality of evidence (1,0)
C. Nonrelevant to the question but high quality of evidence (0,1)
D. Nonrelevant to the question and not high quality of evidence (0,0)

Citations in A have the highest probability of being true positives and those in D the lowest. We hypothesized that we could exploit the A group to retain only systematic reviews and randomized clinical trials in the list of relevant citations recommended to the guideline developers. To test this hypothesis we first calculated recall and precision on the A and B group combined and compared these metrics to those computed on the A group alone.

In constructing a reference standard for evaluation, we selected four questions from the guideline on cardiovascular disease risk reduction and issued a PubMed query for each. All queries were limited in PubMed to: Only items with abstracts, Humans, Meta-Analysis, Randomized Controlled Trial, and English. A further limit was imposed appropriate to the target population of the question. Questions, queries, and additional limits were as follows:

Question 1: What is the evidence for the effect of sibutramine on weight loss and maintenance in adults?

Query: sibutramine

Additional limits: All Adult: 19+ years

Retrieved citations annotated: 91

Question 2: What is the evidence that obesity can be decreased in children?

Query: Obesity/therapy[majr]

Additional limits: All Child: 0-18 years

Retrieved citations annotated: 100

Question 3: What is the evidence that hyperlipidemia can be decreased in children?

Query: Hyperlipidemia/therapy[majr]

Additional limits: All Child: 0-18 years

Retrieved citations annotated: 88

Question 4: What is the evidence that diabetes mellitus can be decreased in children?

Query: Diabetes Mellitus/therapy[majr]

Additional limits: All Child: 0-18 years

Retrieved citations annotated: 100

Retrieved citations were then annotated by the first and second authors as being relevant (or not) and high quality (or not). Limiting their analysis to titles and abstracts, relevant citations were those considered to be informative in answering the question. System output for Group A and for combined A and B were compared to the reference standard separately, and recall, precision, and F_1-score were calculated. We also calculated a weighted $F_{0.5}$-score (1.25*P*R)/(0.25*P +R), which calculates precision twice as much as recall, since guideline developers value precision more highly than recall.

Results

For evaluation, a citation had to be marked as both relevant and high quality in order to be considered a true positive, and, of the 379 total citations processed, 138 were so marked in the reference standard. We first consider overall results for all questions for Groups A and B combined. These two groups include all citations returned as relevant by the system, and are equivalent to not exploiting quality of the evidence processing. The system missed 52 (out of 138) of these, yielding recall of 62%. Of the 108 citations returned, 22 were false positives (either nonrelevant or not high quality), resulting in precision of 79%. The F_1 score was 0.69 and the $F_{0.5}$ was 0.75. The $F_{0.5}$ scores for the individual questions in Groups A and B combined range from 0.59 to 0.90. (See Table 1.)

Table 1- Questions and performance metrics for combined Groups A and B, N=Total number of citations. R = Recall, P = Precision

Question	N	R	P	F_1	$F_{0.5}$
Question 1	91	50%	82%	0.63	0.73
Question 2	100	52%	61%	0.56	0.59
Question 3	88	86%	90%	0.88	0.90
Question 4	100	76%	84%	0.80	0.83
Overall	**379**	**62%**	**79%**	**0.69**	**0.75**

As noted, citations in Group A are marked as both relevant and high quality by the system. In system output for Group A, 61 relevant citations were missed, resulting in overall recall of 56%. For all questions, the system marked 85 citations as belonging to Group A; of these, 8 were false positives, in that they were not both relevant and high quality, resulting in precision of 91% and an $F_{0.5}$ score of 0.81 for this group (an improvement of 6% over results for Groups A and B combined). The $F_{0.5}$ scores in Group A range from 0.67 to 0.92 for the individual questions. Although precision was higher in Group A alone than in A and B combined, lower recall caused the F_1 score to remain constant. (See Table 2.)

Table 2-Questions and performance metrics for Group A. N=Total number of citations. R = Recall, P = Precision

Question	N	R	P	F_1	$F_{0.5}$
Question 1	91	45%	96%	0.62	0.78
Question 2	100	42%	78%	0.55	0.67
Question 3	88	82%	95%	0.88	0.92
Question 4	100	72%	91%	0.81	0.87
Overall	**379**	**56%**	**91%**	**0.69**	**0.81**

Discussion

As shown in Tables 1 and 2, recall was always lower than precision and this is mostly due to SemRep missing predications. However, there were also mistakes made by the machine learning system when assigning high quality citations. Since it is hard to determine the real cause of machine learning errors, we give a SemRep example. (6) was the only predication generated for (5), which occurred in a relevant citation.

(5) This study demonstrates that plant stanols reduce LDL-C levels in children with hypercholesterolemia

(6) Hypercholesterolemia PROCESS_OF Child

The citation in which (5) occurred was not marked as relevant, primarily because "plant stanols" does not occur in the Metathesaurus, and thus SemRep could not extract the predication for stanols reducing LDL-C levels. Moreover, an inference based on domain knowledge would be required to determine that reducing LDL-C levels is related to decreasing hypercholesterolemia (hence making this citation relevant), and this is beyond the current capability of SemRep.

Our preliminary evaluation suggests that combining relevance assignment with quality of the evidence processing has promise in supporting guideline development. Although recall in the combined A and B group was 6% higher than in Group A alone, precision in Group A was 91% as compared to 79% for group A and B combined. The $F_{0.5}$-score rose from 0.75 (A and B) to 0.81 (group A). Guideline developers strive for high precision because of the added expense of reading additional citations. Although preliminary, our findings support the claim that considering citations only in group A sacrifices very few citations that are both relevant and based on high-quality studies. Additional strategies exploiting groups A, B, C, D might help guideline developers in other ways. The ranking inherent in this partitioning could be used to prioritize reading and conserve resources.

Group D (nonrelevant and not high quality), the lowest rank, may be useful for reducing the number of citations to be read during guideline development. Considering all questions, the system assigned 56 (out of 379) citations to this Group. Eleven of these were both relevant and high quality, as opposed to 77 out of 85 in the A group. It is unlikely to be worth developer time to read citations in Group D.

Group C presents a trade-off between sacrificing true positives and effort spent. The system assigned 215 citations to this

(nonrelevant but high quality) group. Of these, 41 were true positives according to the reference standard. This is a considerably high number; however, in order to find the true positives, developers would have to read 215 citations, which may not be cost effective.

Another consideration is that for some questions, developers are interested in case-controls, observational, and even serialized case report studies. For such questions, an appropriate partition would be A and B for true positives and C and D for true negatives.

This study is limited in that the evaluation was based on a small sample of four questions and was not conducted in the context of actual guideline development. Further, the method was tested on only one class of question and it remains to be seen how the incorporation of quality of the evidence processing will extend to other question classes.

Conclusion

In the context of clinical practice guideline development, we describe a system that combines symbolic semantic processing with a statistical method for selecting studies that are both relevant to guideline questions and of high scientific quality, the most valuable research for guideline developers. Evaluation revealed that exploiting the combined processing allowed us to improve overall performance by 6%. Finally, we described how this combined system might be useful to support guideline development.

Abstract

Information technology has the potential to greatly streamline healthcare and reduce the chance of human error. However, there is a growing literature indicating that if systems are not designed adequately they may actually increase the possibility of error in the complex interaction between clinician and machine in healthcare (i.e. they may lead to technology-induced errors). In other domains the study of error has been guided by a variety of theories, models and frameworks for understanding human error. In this paper we argue for the need to consider and extend this work to the study of technology-induced error in healthcare. Insights from the software engineering, human factors and organizational behaviour literature will be described, including a set of models and frameworks that we have been using to guide our work in detecting and preventing technology-induced error in healthcare.

Keywords:

Technology-induced error, Evaluation, Theory, Models, Frameworks, Software engineering, Organizational behaviour, Human factors, Socio-technical theory

Introduction

The evaluation of health informatics applications is becoming an increasingly more important activity as the number of health information systems (HISs) that are being implemented in healthcare settings continues to grow. Historically, summative evaluation methods were used to determine if a HIS led to improved clinical outcomes, reductions in costs, or reductions in medical error rates (thereby improving patient safety) [1]. However, in recent years, researchers have also found that formative evaluation is essential to identifying other issues associated with a technology's use (such as socio-technical issues and technology-induced errors) [2,3,5]. No where is this more apparent than in the use of evaluation to study technology-induced errors. In the literature technology-induced errors have been defined as those sources of error that "arise from: (a) the design and development of technology, (b) the implementation and customization of a technology, and (c) the interactions between the operation of the new technology and the new work processes that arise from a technology's use" [4, p.154]. Unintended consequences are unexpected results of use of technology that "lack a purposeful action or causation" [6, p. 415]. Technology-induced errors are one type of unintended consequence arising from the use of HISs by clinicians [3,4,6]. Researchers have used many evaluation methods and approaches to identify the presence of technology-induced errors [2,3,6]. The evaluation methods used in the study of technology-induced errors range across a continuum of approaches from purely qualitative to mixed method and then exclusively quantitative approaches [7]. These methods have been used to evaluate technology-induced errors arising from the use of HIS software and devices at varying points in the software development lifecycle through to HIS implementation in healthcare organizations (including the customization of software applications, the selection of devices and the long-term maintenance of applications and devices in clinical settings) [7]. Although many evaluation methodologies have been used to identify sources of technology-induced error such as interface features and functions [2], database content [2,6] and workflows emerging from interactions between software, devices and organizational settings [6,8], these evaluation methodologies have only been able to identify specific types of errors at specific time points: (a) in software development [2], (b) prior to organizational implementation of software and devices [8], and (c) after organizational implementation of software and devices [6]. For example, some researchers have been able to identify potential sources of technology-induced errors during the software development lifecycle [2]. Other researchers have identified sources of unintended consequences after a system/device has been implemented in a real-world setting and the system/device is being used at point of care [see 6]. It is interesting and worthy to note that some of the same unintended consequences or technology-induced errors that have been identified by researchers studying applications and devices both before and after a system/device has been implemented in an organizational setting [3,6].

Therefore, there is a need to develop a more holistic understanding of technology-induced errors and how they propagate throughout a system [4]. This holistic understanding needs to take the form of models, frameworks or theories that span the entire software development process through to organizational implementation and maintenance of software and devices. Such theoretical work will help us to understand where errors come and how those errors are propagated throughout the HIS development, implementation and maintenance process [4]. Therefore, there is a need for researchers to describe the differing types of technology-induced errors and their unintended consequences (arising

from technology use) [4,6]. There is also a need to better understand the implications of software errors that arise during software design, development and implementation upon future clinician work at point of care (as has been done in other industries) [2,4,8].

Some researchers have suggested that error models can be imported from other industries (i.e. aviation, banking, nuclear power) [2,6,9]. Other researchers have indicated healthcare has unique features that do not allow for theories and models developed in other industries to be easily applied in healthcare settings [10,11]. For example, researchers have found that healthcare work is variable, dynamic, complex, emergent, involves a high degree of ambiguity, is inter-professional in nature, is highly professionalized, requires a high degree of coordination and is not easily deferred (unlike work undertaken in other industries such as banking, mining) [10,11]. Furthermore, some researchers have found [10], healthcare places additional pressures upon its workers (e.g. physicians and nurses) to provide continuity of care. As a result, models of error cannot be easily imported into healthcare due to the unique features of the setting and in some cases these models require modification or extension. This is consistent with other industries where theories, models and frameworks from other domain areas are imported and then modified in response to empirical testing for their applicability in another domain (e.g. theory from sociology and psychology has been applied, modified and extended through empirical testing in the management and aviation industries) [see 10, 13].

Therefore, there is a need to empirically validate models of error from other industries for their applicability to healthcare and the field of health/biomedical informatics. These models need to be empirically validated, falsified, extended and customized for healthcare and in some cases researchers need to develop new models for describing technology-induced error that are specific to the healthcare industry as has been done in other industries [10,12,13]. Such work is necessary in order to diagnose potential errors involving technology before they occur in real-world settings. Many of these frameworks, models or theories specific to health/biomedical informatics that have been published are still in their infancy from a theoretical, conceptual and empirical perspective. Research is needed to empirically test these models and more research is needed to determine if these models can predict error. Such developed and empirically tested models will allow health informaticians to engage in "targeted" testing of software, hardware and interactions between applications/devices that may lead to technology-induced errors in order to eliminate them before the application/device is introduced into a real-world environment. The authors of this paper intend to take the first step in this process by outlining the frameworks, theories and models that are currently being used in health/biomedical informatics that conceptualize technology-induced errors.

Health informaticians need to begin the process of developing frameworks, models and theories. Frameworks, models and theories once developed and tested could be used to prevent and predict future sources of technology-induced error (from software development through to the implementation and maintenance of systems). The authors of this paper conducted a search of Medline using the key phrases "technology induced error and framework", "technology induced error and model", "technology induced error and theory", "technology-induced error and framework", "technology-induced error and model", "technology-induced error and theory", "unintended consequences and framework", "unintended consequences and model", unintended consequences and theory", "e-iatrogenesis and framework", "e-iatrogenesis and model", "e-iatrogenesis and theory". Two authors reviewed each of the titles of the published articles and proceedings that were returned on each of the searches. If the title or abstract of the article or proceeding referred to a framework or model or theory and technology-induced error or unintended consequences or e-iatrogenesis then the full article was reviewed by two authors to determine if a framework, model or theory was indeed described (i.e. 191 citations were returned 6 were identified by the authors using the above mentioned criteria and the articles were downloaded and reviewed). All articles in Medline from its inception to the end of 2009 were searched using the above strategy. We also included models of technology-induced error that were published in health informatics texts up to and including 2009 to inform the work. The frameworks, models and theories from the health/biomedical informatics literatures that were identified and will be discussed in this paper. The frameworks, models and theories were grouped by the authors into four paradigms: software engineering, human factors, organizational behaviour, and multi-theory model and framework approaches.

Software Engineering Approaches

Software engineering has a long and established tradition of research documenting testing methodologies that can be used to empirically evaluate software applications, devices and interactions between applications/devices as they contribute to worker error rates. More specifically, the software engineering literature identifies that inadequate programming, requirements specification, design, customization, and beta testing can lead to software errors once an application is implemented in an organization. Many publications and texts provide details about the differing types of general software testing methodologies - arguing for the need to conduct testing early in the software development process in order to reduce costs associated with addressing software errors after an application has been implemented (i.e. the later an error is discovered in the software development and implementation process, the higher the costs associated with correcting the error(s) that arise from the software once it has been implemented). It must be noted that a strength of the models and frameworks from this literature are the empirical research supporting and the breadth and the applicability of these models to many industries where software/devices are being used to improve the effectiveness and efficiency of work processes [4].

The strength of the software engineering literature is also its weakness. Much of the literature is based on research done in industries where transactions are simplistic in nature (as compared to healthcare) and there are few urgent or life threatening decisions that have implications for individuals

(i.e. patients). Additionally, requirements specification approaches are tacit in nature and users' beliefs about their work practices are not easily elicited during the requirements specification process. For example, findings from the empirical literature indicate that [18, 20]: a) a work process does not always occur in the way that users think it occurs, b) the way users carry out activities may vary by user, and c) rules and procedures that involve an application/device may be "broken" by users or not followed.

Lastly, unlike other industries, health/biomedical informatics has been slower in its evolution and application to real-world settings. There are many reasons for this. In some cases there is an inability for healthcare to obtain the necessary funding to support software development and the complexities of designing and developing applications for the healthcare system. In addition to this, testing approaches from the software engineering literature have limitations as they do not take into account the challenges of providing services in urgent care healthcare settings (i.e. hospitals) where the stresses that an application/device must effectively respond to are significant -especially when a patient's healthcare is complex, urgent and requires intervention by multiple and differing health professionals. It is because of these limitations that health/biomedical informatics researchers have identified the need to develop frameworks, models and theories that attend to the complexities of patients and the organizations (i.e. hospitals, home care agencies and physician offices) that attend to them.

Human Factors Approaches

A variety of models of human-computer interaction can be applied to the problem of reducing technology-induced errors in healthcare. Eason [13] in an influential paper provides a framework where human-computer interaction can be considered in terms of levels, ranging from Level 1 interactions between individual users, to Level 2 interactions involving use of computer systems to carry out work tasks, to Level 3 interactions at the more complex layer of social and organizational interaction. This framework has proven useful in providing a rational and efficient approach to identifying where technology-induced errors may arise [15]. For example, in conducting analyses of systems such as medication order entry, at Level 1 certain interface features may induce users to make data entry errors (e.g. unclear or inconsistent user interface operations). Moving up to Level 2, the use of a system may be problematic once it is implemented in a real-world healthcare setting, where the user interaction (e.g. in entering a medication) may be interrupted during medication administration tasks involving patients. Finally, at Level 3 the system may introduce problems and errors if it interferes with the complex communication among healthcare workers.

A second influential error model referred to in the literature has been Reason's model of human error. Reason's [9,14] approach distinguishes between a "sharp end" and a "blunt end" where error may arise in complex human-computer interaction. It is at the sharp end that errors are made by humans, however, the origins of such errors may be at the blunt end of the continuum, that is, at the end involving the complex organizational processes, policies and environments that may eventually lead to error at the sharp end. In a paper by Keay and Kushniruk [15], Eason's framework [13] and Reason's model [9,14] of error were integrated with Eason's Level 1 interactions corresponding to Reason's sharp end, and Eason's Level 3 interactions corresponding to Reason's blunt end. In more recent work, Borycki et al. [16] have extended and elaborated Reason's model to include consideration of sources of error specific to healthcare informatics and technology-induced error that blends work in human-computer interaction and human error with theory from the organizational behaviour literature (and which is described in the next section).

Organizational Behaviour Approaches

Health/biomedical informatics researchers have suggested that there is a need to blend in works from the organizational literature to address the limitations of the software engineering and human factors literatures in developing theories, models and frameworks that can act as an aid to the study of technology-induced errors in healthcare organizations. Borycki and colleagues [16] have proposed a framework that can be used to diagnose technology-induced errors that draws on the organizational behaviour literature. The framework borrows from Reason's work in the human factors literature [9] and Orlinkowski's [17] work at the intersection of the organizational behavior and the information systems literatures. In this framework the researchers recognize that HIS are developed against a policy and regulatory backdrop that influences organizational functioning (e.g. hospital and vendor), vendor systems design and development of HIS and the procuring organization's (e.g. hospitals) selection and day to day operation of a system/device. The framework identifies that systems are designed using a model organization. Software requirements approaches and modeling techniques are used to gather data and describe organizational processes. These approaches and modeling techniques serve as the foundation for HIS design and development. In the organizational behavior literature, it is recognized that organizations are imperfect and that all model organizations do not have ideal processes [17], these processes may be error prone [9] and processes can be undertaken in varying differing ways [18].

Vendors who develop software based on the work processes found in a model organization [4,17] may inadvertently design and develop HISs that integrate errors into their software applications. In addition to this, vendors in the process of programming, designing and developing a HIS may introduce new types of errors (i.e. programming errors, errors arising from inadequate requirements specification and design). The model also recognizes that the organizational acts of procuring, customizing, implementing and maintaining such systems may introduce new opportunities for errors: those arising from a policy and regulatory backdrop, the model organization, the vendor, and the adopting organization's own customization and implementation processes. Lastly, when a new HIS is introduced during an implementation, users do not use the technology as vendors and healthcare organizations intended the technology to be used [16,17]. Each of these

layers – those at the policy and regulatory level, the model organization, the vendor and the adopting organization each have an opportunity to introduce new types of technology-induced errors and when the "holes" line up in the defensive layers of the complete system the "trajectory of accident opportunity" occurs) [9]. Borycki et al.'s [16] extension to health informatics recognizes that the causes of error can be located on the blunt end with the policy and regulatory environment and the model organization on which a design is developed to the sharp end where healthcare workers use the HIS at point of care in the procuring or adopting organization.

Another model that draws on the organizational behaviour literature is Leavitt's diamond model from the 1970's [19]. Leavitt's model may allow one to track the trajectory of accident opportunities, and inversely, it may also be useful at exploring the events of an accident in order to trace out the root cause of errors (i.e. the blunt end). Leavitt's model for organizational change is based on the principle that any change in one of the four elements, 'task', 'actors', 'structure', and 'technology' (in a later extension of the model also a fifth element, 'organizational environment') will propagate to the other elements of the organization in a domino reaction until a new, steady state is reached. Such changes may lead to new events taking place, new procedures, or unforeseen problems with a new technology, and so on. That is, compensating reactions will result as a consequence of introducing a change agent (also implying that changes will be visible in places where the change was originally introduced to the organization). In Brender [20], Leavitt's model for organizational change is integrated with Mumford's socio-technical work (participatory design, also from the 1970'ies) as a methodology for testing objectives fulfilment and hence for revealing the complementary reasons for why an organization does not achieve what it had anticipated from the systems development/change effort, while enabling root cause analysis of identified problems.

Diffusion theories from varying literatures have been a source of inspiration for many researchers from many domain areas (e.g. management, health/biomedical informatics) [6, 22-24]. Roger's text entitled "Diffusion of Innovations" [22] has provided insights to some researchers as to the varying factors that affect a technology's diffusion [6,22]. For example, Roger's [22] provides an overview of how communication channels influence an innovation, identifies the main attributes of a technology that influence its diffusion through a social system and identifies the intended and unintended consequences associated with the use of a new technology. Ash et al. [6] extend work documented in Roger's text [22] to healthcare. Ash and colleagues document the intended and unintended consequences associated with using a physician order entry system and develop a thematic hierarchical network model for the consequences of using physician order entry. The researchers use ethnographic observational and interview data and derive their model from the qualitative findings of their study [6].

Multi Theory, Model and Framework

Lastly, an Interactive Sociotechnical Analysis Framework [21] has been developed by researchers in health/biomedical informatics. Harrison and colleagues [21] draw upon multiple theories, models and frameworks to develop their model. Their work has its origins in the socio-technical, ergonomic, social constructivist and the technology-in-practice literatures which have long empirical tradition. The framework identifies there are relationships between health information technologies, clinicians, workflows and organizational environments. The developers of the framework suggest that new health information technologies (HIT) change existing social systems, interact with existing technical and physical infrastructures, the social system mediates HIT use, HIT use changes the social system and these interactions between the HIT and social system lead to technology redesign. The authors cite several empirical works to support their development of the framework.

Theories, Models and Frameworks: Diagnosing Technology-induced Errors

In our work in predicting and preventing technology-induced error in healthcare we have blended the use of many of the approaches described above [2,4,7,8]. For example, we have conducted usability and laboratory-based simulation studies explicitly targeted at Eason's level 1 interactions, involving think-aloud studies of users interacting with health information systems in isolation [2]. In our work we have been extending frameworks and models by applying simulation methods (involving video observation of health professionals interacting with systems to carry out simulated and real work tasks) corresponding to Eason's Level 2 interactions [8]. Likewise, Reason's model of error has led us to conduct analyses targeted at both the sharp and blunt ends of the error continuum. Using one strategy we have started with the occurrence of an error (at the sharp end) and then traced the error back to possible blunt end causes. In addition, we have also conducted preventative analyses of error, by beginning at the blunt end of organizational factors (and using the framework outlined by Borycki et al. [16] that extends Reason's work to healthcare informatics) and then progressively moving to the sharp end to assess the potential impact of organizational and policy choices on error at the human end.

Discussion

In this paper we have described a number of approaches to the study of human error that can be applied and extended to the prediction and prevention of technology-induced error in healthcare. We must ensure that the information systems we deploy in healthcare do not inadvertently add new forms of error. However, due to the complexity of healthcare processes and work activities, the potential for information technology to cause technology-induced error is a growing concern. In this paper we have argued that an eclectic approach to considering technology-induced error that draws on theories,

models and frameworks from a range of disciplines is needed. This will lead to a more principled and effective deployment of applications/devices.

Abstract

In order to understand the nature and causes through which Health Information Systems (HIS) can affect patient safety negatively, a systematic review with thematic synthesis of the qualitative studies was performed. 26 papers met our criteria and were included into content analysis. 40 error contributing factors in working with HIS were recognized. Upon which, 4 main categories of contributing factors were defined. Analysis of the semantic relation between contributing reasons and common types of errors in healthcare practice revealed 6 mechanisms that can function as secondary contributing reasons. Results of this study can support care providers, system designers, and system implementers to avoid unintended negative effects for patient safety.

Keywords:

Health Information System, Patient safety, Medical Errors

Introduction

Health Information System (HIS) is strongly recommended for improving patient care quality [1]. Evidence concerning the effect of these systems on patient safety is very important. After many years of applying IT systems in healthcare services and despite many advances in the development of safe technology, there are still growing concern about the impact of these systems on patient safety [2]. Results from various studies in this area show how HIS can cause or contribute to medical errors. These studies, however, have mainly reported upon specific HIS and/or specific settings, making it difficult to generalize their findings. In order to learn more general lessons, there is a need to classify reasons for the unintended side effects of HIS and their related mechanisms. Such an understanding can benefit patient safety and increase positive impact of IT applications in healthcare. Thus the critical question here is: How can HIS cause or contribute to error producing conditions in inpatient settings? In this study, factors behind the unintended negative effects of HIS were presented and classified in order to support care providers, system designers, and system implementers and to provide them a better understanding of error mechanisms and consequences in healthcare practices.

Methods

We performed a systematic literature review to answer the research question. PubMed, EMBase, and Cocharan Library were searched for the relevant literature 1995 to September 2009. To select the relevant literature, the terms "patient safety", "medical error" or "medication error" were electronically searched in abstracts and titles of the literature. These terms were in turn combined with: information technology, information and communication technology, computerized provider order entry, computerized physician order entry, electronic patient record, electronic medical record, radiology reporting system, and laboratory reporting system.

Primary search refinement

The search hit 911 items. The result of the search was refined by manually examining the titles and the abstracts of the selected papers at the same time. The items that were related to patient safety concerns and the possible role of HIS in their creation were primarily selected. The literature that could not be judged based on their title and abstract, were examined by their full text. More refinement of selected literature was performed considering the research question. Trying to answer the "How" question, we needed to use in-depth qualitative studies for our review. The process of search refinement is presented in Figure 1; and the important primary exclusion and inclusion criteria provided in Tables 1 and 2.

Secondary search refinement: assessing quality of qualitative studies

There is yet much debate on whether or not to apply qualitative rigor to assess the quality of qualitative studies. In this review, however, we took the view that the quality of qualitative researches should be assessed to avoid drawing unreliable conclusions. In the literature, different sets of criteria have been proposed as rigour of qualitative studies. We developed our criteria by combining the commonly used

set of qualitative research criteria [3-6] with those which have commonly been considered in evaluating quality of IT evaluation studies [7]. In this study, qualitative literature was included if the authors could answer all of the presented questions in Table 3 (the secondary inclusion criteria) with *yes*. More literature was included by examining the reference lists of the literature resulted from the secondary search refinement.

Table 1- Important primary exclusion criteria

- Related to dental care
- Non-English papers
- Reviews (point of views), commentaries
- Conference proceedings Telemedicine or Telehealth related publications
- Papers related to ethical and legal issue on using IT for improving patient safety
- Papers without abstracts, except one case which was included into our study (they were either reports, point of views, news, editorials, or interviews).
- Related to primary care and outpatient setting.
- Systematic reviews which were not addressing related issue to our research question (in case the subject was relevant their reference list were searched to include appropriate studies)
- Simulation studies
- Merely quantitative researches were excluded on the ground that qualitative researches are more appropriate to understand a phenomenon in depth and to answer our "How" question.

Table 2- Important primary inclusion criteria

Original papers reporting empirical researches in inpatient setting were included if:

- They had qualitative research methodologies[1].
- Studies with mixed qualitative and quantitative method.
- Studies on voluntarily error reporting by the system users
- Case reports and case studies were included if they presented enough information about the system being studied and the error happened in using the system.

Data analysis and thematic synthesis

Campbell *et al.* [9] extracted what they called the 'key concepts' from the qualitative studies they found about patients' experiences of diabetes and diabetes care. In a similar attempt to a systematic review of qualitative studies, Thomas et al.[10] extracted all result sections of the included papers into qualitative data analyses software and analyzed the data based on an already prepared scheme of coding. In this study, we extracted the concepts from the included studies' findings that were reported about the direct, indirect, or potential role of HIT on medical errors. Following Thomas et al.'s method, we then assigned the extracted concepts into Atlas-ti 5.5.9 software for further qualitative data analysis. In case it was necessary, we used more information of the included literature to clarify the context of different pieces of extracted information.

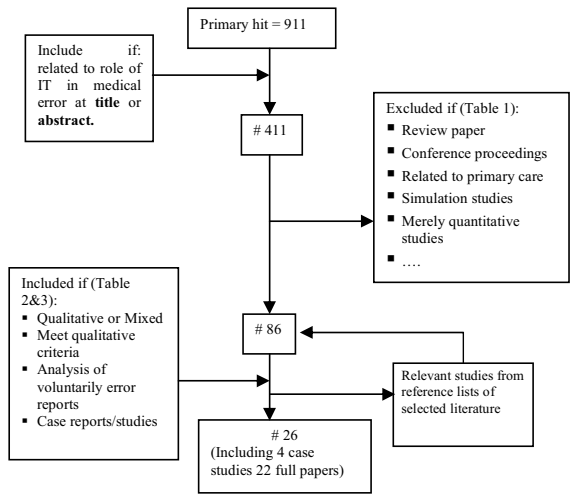

Figure 1- The search refinement process.

Table 3- Secondary inclusion criteria

1. Is there explicit theoretical framework and/or literature review?
2. Are aims and objectives clear?
3. Is the context of study clearly described (e.g., organizational setting, the evaluated system's detail and other systems in use)?
4. Is the study sample (e.g., system users) and how it recruited clearly described?
5. Is data collection method clear?
6. Is it possible to identify study findings from those of the other studies' in the paper?
7. Is the data analyses method clearly described?
8. Are attempts made to establish the reliability or validity of data analysis (e.g., reflexivity, triangulation, member checking, saturation in the field, and an audit trail)?
9. Are sufficient original data included to mediate between evidence and interpretation?

The extracted texts were coded for two types of contributing *reasons* (primary and secondary) of medical errors. More than 150 codes were created for the primary contributing reasons. In the process of thematic synthesis, the primary contributing reasons were reviewed frequently until 40 contributing *factors* (denoting the categories of similar primary contributing reasons that could be collected under specific causal themes) and 4 contributing *categories* (denoting the categories of family codes that could be organized under major causal

[1] Qualitative study was defined based on Strauss and Corbin [8] as "any kind of research that produces findings not arrived at by means of statistical procedures or other means of quantification".

themes of contributing factors) were created. The data was also coded with respect to identifying reported secondary contributing reasons (i.e., *mechanisms* through which primary contributing reasons were reported to produce error in healthcare practice). More contributing mechanisms were recognized by analyzing the semantic relation between the contributing factors and the common types of error in healthcare practice (i.e., mistakes, slips, and latent errors). In this study, we did not investigate the frequency and severity of the errors.

Results

Four case studies and 22 qualitative or mixed method studies were analyzed [11-36]. Four major categories were recognized out of 40 contributing factors: workflow problems, communication problems, technical problems, and user-related problems. Some of the contributing factors were reported to produce error directly (direct mechanism of error). The majority of the contributing factors however worked through *contributing mechanisms*. Figure 2 represents the semantic relation between the contributing factors at different levels with common medical errors.

Contributing categories

Workflow Problems

Working with HIS could hamper or block the normal flow of care work and as a result caused error in healthcare practice. Such workflow problems in working with HIS were reported due to increasing workload of care providers [11, 12, 20, 21, 25, 29-31, 35], or slowing down time intensive care work [11, 20, 21, 23, 25, 26, 28, 29, 31]. The use of information systems was reported to change inappropriately the structure of healthcare work and/or to increase the steps required to fulfill a healthcare task inappropriately [20, 21, 25, 35]. Many studies reported on HIS applications' failure to support intermediary tasks and shared responsibilities between care providers [16, 20, 25, 35]. Moreover, HIS reportedly failed to support non-routine and complex care processes [21, 31]; or it supported only a part of a care process and as a result created coordination problem between the automated part and paper-based part of the process [13, 25, 28, 29, 31, 34]. The workflow was also disrupted whenever a system forced its users to perform unnecessary extra-checks on one single part of a care process [11, 31, 32]. Extending the functionality of the software designed for one healthcare professional group (e.g., pharmacists) in order to support another group of professionals (e.g., physicians) also caused workflow problems [25, 35]. In the literature, many workflow problems were reported because of mismatches between the components of a process designed into HIS and the component of the process in the real care practice. Such mismatches were reported between HIS and its users in the way a care time [11, 20, 21, 26, 28, 35], a care unit [20], and a care process sequence [12, 25, 26] were defined. In addition a problem was reported when a system was not updated with new changes in healthcare practice [21]. Many recent studies have also reported the role of unsafe compensating strategies being adopted by care providers (i.e., workarounds) in order to improve problematic workflow as potential contributing factors for medical error [16, 17, 21, 25, 27-29, 31, 36].

Communication problems

HIS can contribute to or cause error by generating problems in the process of communication and information exchange between care providers. Working with information systems was reported to interfere with the communication between care providers [12, 18, 25, 28, 29, 35], or between the care providers and the patients [26, 35]. Information systems could also produce problems in the process of information mediation due to, for example, lack of feedback mechanisms between communicating care providers [12, 28, 29, 31, 34]. In addition, communication problems occurred in cases where HIS restricted appropriate registration of patient information, for example because of an insufficient /inflexible coding scheme [17, 21, 34]. Problematic information presentation was frequently reported as an important error contributing reason in the literature. Problems of this kind were reported due to fragmented presentation of data over different screens [20, 30] or over different patient care information systems [28-30], due to presenting too much information for systems users [28, 29], and because of problems in finding and retrieving already stored information [21, 29]. Moreover, interoperability problem between care providers as well as data loss were reported to happen in situations where care providers had to work with electronic and paper-based systems at the same time [28, 29, 33, 34]. Likewise, communication problems were reported in case patient information was not updated in information systems [17, 29, 35].

Technical Problems

Many studies have reported technical shortcomings with HIS that could directly or indirectly lead to error in healthcare practice. These problems were frequently reported to be in the form of a software glitch [13, 14, 18, 33] or due to applying outdated hardware [12, 33]. Problems in the design of user interface were also frequently reported in the literature. They were reported to be either in the form of inappropriate screen layout, forms, fonts, and colors [11, 18, 20, 24, 31], or inflexible data entry options [20, 21, 23, 35], or look alike on-screen forms [18]. Such design flaws could for example facilitate juxtaposition errors. Likewise, design problems such as inappropriate/insufficient order set [18, 20, 23], using inappropriate terminology in the system [18], unclear log in/off processes [20, 35], and unspecific alarms [21, 31] were also among the frequently reported error facilitating technical problems. Problematic ergonomics of HIS was reported as a contributing factor to erroneous practice [11, 21, 35] as well. Shortage of technical support in working with HIS, for example in case of networking problems or problems with system accessibility [21, 35], or when the system is down or has crashed [20] were of commonly recognized error contributing technical shortcomings in the literature. Moreover, working with nonintegrated or partially integrated information systems were reported to produce medical error [17, 19, 20, 30].

User-related problems

Some of the error contributing reasons were related to the way users worked with HIS and are hence called user-related

problems here. These problems were frequently reported to occur if users were not trained and educated enough with respect to the proper way of working with IT applications [12, 18, 21, 30, 31]. Another frequently reported problem of this kind was recognized to be system entry mistakes by users [11, 13, 14, 17, 20, 24, 33]. Users' cognitive ability to handle complex care processes was reported to be reduced or hampered if for any reason they developed negative emotions towards the IT systems [12, 21, 30-32]; or because they developed over-dependence to HIS [12, 21]; or because their social relationship with their colleagues and/or patients was intruded by HIS [11, 26, 31]. Users' role in error producing conditions dominated whenever they had to work with information systems in an interruption-driven and/or hectic environment [15, 22, 28]; or they had to work with paper-based and electronic systems at the same time [20, 29, 33]. User-related problems also reportedly took place if they did not comply with policy and procedure in working with HIS [13, 21, 26].

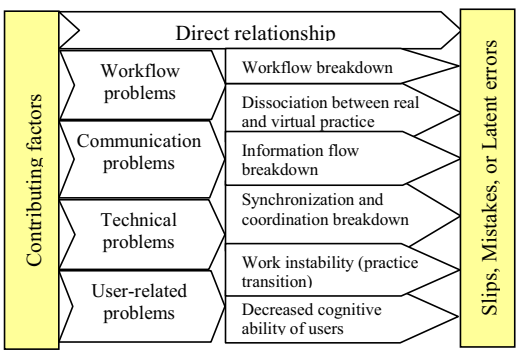

Figure 2- Semantic relation of medical errors with error producing mechanisms. Note that there is no one-to-one relation between the primary and secondary contributing factors.

Contributing mechanisms

Six error contributing mechanisms were recognized upon the contributing categories. The first mechanism, *workflow break down,* will be triggered if the construct of healthcare work is broken down as the result of applying HIS. The second mechanism works whenever *dissociation between real and virtual practice* happens. There should be a one-to-one connection between the components and stages of a care process designed into an information system (virtual practice) and the components and stages in real practice. The virtual-real connection is dissociated if for example patient information is not updated in the system or a wrong digital ID is allocated to a patient. The third mechanism will function if by using HIS *information flow is broken down* and the right information is not delivered to the right care providers at the right time and in the right place. The fourth mechanism will be initiated in case using HIS *hampers coordination and synchronization* between healthcare providers throughout the healthcare work. The fifth mechanism will be instigated if working with HIS *decreases the cognitive ability* of the care providers to cope with healthcare situations (e.g., due to increasing cognitive load). The sixth mechanism will work in case a care practice has developed a fragile and context specific configuration (*work instability*) as a result of interaction between a system and its users. In such a condition any unexpected change in practice can lead to error.

Discussion

The overview provided in this paper can benefit safe system design, implementation and use. The contributing factors and mechanisms are not specific for one system or one implementation site and hence important. More research however is required to point out where and how specific hands-on should be applied to decrease the unintended errors.

Abstract

Background: We have used routinely collected clinical data in epidemiological and quality improvement research for over 10 years. We extract, pseudonymise and link data from heterogeneous distributed databases; inevitably encountering errors and problems. Objective: To develop a solution-orientated system of error reporting which enables appropriate corrective action. Method: Review of the 94 errors, which occurred in 2008/9. Previously we had described failures in terms of the data missing from our response files; however this provided little information about causation. We therefore developed a taxonomy based on the IT component limiting data extraction. Results: Our final taxonomy categorised errors as: (A) Data extraction Method and Process; (B) Translation Layer and Proxy Specification; (C) Shape and Complexity of the Original Schema; (D) Communication and System (mainly Software-based) Faults; (E) Hardware and Infrastructure; (F) Generic/Uncategorised and/or Human Errors. We found 79 distinct errors among the 94 reported; and the categories were generally predictive of the time needed to develop fixes. Conclusions: A systematic approach to errors and linking them to problem solving has improved project efficiency and enabled us to better predict any associated delays.

Keywords:

Computerized medical records system, Data quality, Databases, Semantics, Controlled vocabulary, Computers.

Introduction

Internationally, routinely collected clinical data from primary care electronic patient record systems (EPR) is used for research and quality improvement [1]. However, many of the research databases only draw their data from a single vendor; thereby circumventing many of the difficulties due to variation in the way that national and international standards are implemented in different brands of EPR system. By way of contrast the Primary Care Data Quality (PCDQ) programme has worked with large datasets drawn from different vendors some using different classification systems and generating their own local codes to supplement standard taxonomies: truly heterogeneous distributed databases [2]. The largest PCDQ study drew data from 2.4 million patient records [3]; current studies work with databases of just under 1 million records drawn from six different brands of EPR system but extracting several hundred variables [4].

The difficulties in extracting data from heterogeneous distributed sources are well known [5] and standard methods and toolkits for measuring the validity and utility of electronic patient record systems have been proposed [6]. The difficulties arise because of the different architectures of the heterogeneous distributed systems, the local autonomy of these systems, problems in representational diversity of the same clinical concept, and the potential lack of precise semantic meaning. None of the classification systems within the UK have definitions, making it possible for meaning to vary between professional groups and over time [7]. There may be a trade-off for vendors between achieving functionality and strict adherence to guidance on requirements of EPR systems. Difficulties can then arise because standards are not strictly implemented.

We frequently encountered data extraction problems, which we historically reported in terms of what data were missing from our response files rather linking our problem to the underlying cause. We carried out this study to see if we could develop a system of solution-orientated error reporting, which improved our problem solving and predicted likely time to resolution.

Method

We carried out a literature review on the standard bibliographic databases to identify structured approaches to data extraction techniques from heterogeneous distributed databases. We narrowed our search to clinical data and databases. We tried to identify any current approaches to identifying and resolving data extraction errors apply prospective and retrospective statistics with dynamic validation as data are being extracted [8].

Our literature review initially focussed on the UK National Health Service methods of date extraction. We also looked for proprietary tools for data extraction provided by EPR vendors. We found two generic approaches to enable enquirers to execute queries and extract data from different types of general practice computer systems using a common query lan-

guage. The two alternatives are the MIQUEST (Morbidity Information and Export Syntax) HQL (Health Query Language) data extraction tool and the proprietary Apollo SQL interface. PCDQ uses the MIQUEST data extraction tool.

We then collected information about the experiences of five data collectors during 2008 and 2009. Interviews with the collectors, observations, documentation reviews and test data extraction queries were used as information gathering techniques. The study exports included detailed descriptions of errors, frequencies of occurrence and comments on specific issues, system installations and system versions. A post-hoc exploration process was carried out.

We constructed an initial list of the errors encountered and classified the errors according to their effect on the data collection process. This included; information about whether the query would execute at; the stage each query would run to, and whether it produced partial or no results at all. We then reviewed and categorised the observed data collection issues based on their impact.

We subsequently redefined the data collection issues to create a briefer but nevertheless descriptive functional IT component approach to facilitate problem solving.

Finally, we reclassified the improved list of errors based on our need for a system which enabled understanding of whether certain groups of errors could be resolved by the collection team or not; and finally whether they were vendor specific. This led to the creation of a taxonomy of errors for our data collection problems.

We then created an on-line resource for the PCDQ data collectors. The on-line problem reporting form was designed to capture the key information needed to diagnose the IT component which was responsible for any errors.

The studies carried out during the development of our taxonomy were ethically approved, and only used pseudonymised data.

Results

Errors during the Data Collection Process

We identified 94 problems with the data extraction from the four major UK GP electronic patient record (EPR) suppliers: EMIS PCS, EMIS LV, INPS Vision and iSOFT Synergy. These four EPR systems account for over 90% of GP EPR market for England [9].

Problems of different levels of severity and impact were identified and initially mapped to a set of groups in a purely clinical use driven approach. The frequency of the type of problems encountered is summarised in Table 1. Errors were reported in the following categories: (A) MIQUEST – the data extraction tool did not work, or the query code failed at some point, (B) The MIQUEST specification was differently implemented on one of the brands of EPR systems. For example the word "CHOSEN" returns different response files, (C) Clinical System and database would not return information, (D) Supporting Software and operating system, (E) Hardware and Infrastructure, (F) Generic/Uncategorised and/or Human Errors.

We documented the cumulative frequencies for each issue based on each individual collector's recordings and assigned them to any category they applied to.

Multiple mappings

This type of direct mapping did not allow for an optimised approach to error solving. We found that 56 of the 94 errors (60%) could be assigned to multiple categories as shown in Figure 1; a limitation of our initial categorised reporting.

Table 1 - Stage Process Categorisation Frequencies

Category(/ies)	Frequency	Number
B	21%	20
D	11%	10
D or E	11%	10
B or D	9%	8
B or D or E	9%	8
A or B	7%	7
A or C	6%	6
A or B or C	5%	5
E	4%	4
C	3%	3
B or C	3%	3
C or D	3%	3
B or E	2%	2
B or F	2%	2
F	1%	1
C or E	1%	1
C or D or E	1%	1
Total Errors: 94		

Post processing of the error list

We initiated another round of result interpretation to identify the generic functional IT standings of each specific issue and generate a list with strictly targeted errors that could be classified to one of our newly defined categories.

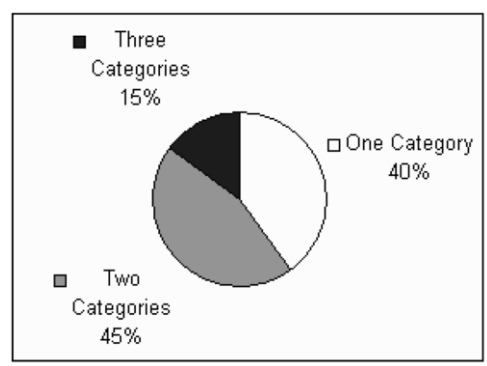

Figure 1 - Frequencies for Multiple Categories

Taxonomy of errors

We then investigated whether the errors identified could be mapped to a single root cause – recognising that this may involve careful analysis as to which IT component was responsible for the error encountered. We connected each of the redefined issues to the respective group described in Table 2. The new definition allowed for identifying the point of contact as well as an estimate on the delay for solving individual cases.

The list was structured from the data collectors' experiences in the field, response time average and contact points.

Table 2 - Component Oriented Approach

Code	Description	Resource Responsible	Delay Estimate
A	Data Extraction Queries and Process	Collector	Up to 2 weeks
B	Extraction System (Translation Layer/Proxy)	Extractor / Vendor	From 1 month
C	Top Level System and Database (Original Schema)	Software Vendor	From 1 month
D	Underlying Software, Networking and OS (System and Communications)	Technician	Instant to 1 month
E	Hardware Layer and Infrastructure	System Vendor	From 2 weeks
F	Human Errors	Technician / Extractor	Up to 2 weeks

We completed our direct mapping of each individual case to one category through several iterations; based on comments and feedback from collectors, IT resources and documented processes. This enabled us to summarise all the errors into the categories and export metrics as in Table 3.

This process, involved merging a total of 15 error descriptions with closely related ones. This created an accurate assignment to the various categories of secondary level processing.

Of the 79 final individual error types, category C (Clinical EPR System) was most frequent and found in 30 of these 79 problem categories – requiring input from the vendor. This was followed by D (Network and Operating System) and B (Data Extractor Specification) with 16 and 14 occurrences respectively. Categories A (Query Content), E (Hardware) and F (Other Human Errors) had 6 and 7 error types recorded for each. Around 40% (30/79) of the problems could be solved by phoning software support for the particular brand of EPR system, 20% by actions from the data collector, and 10% by senior team member. 30% could not be resolved by the team in the expected timeframe and required some external input. The majority involved external resources and required changes to the underlying hardware or technical intervention with the onsite systems; albeit usually delivered remotely by the vendor.

Table 3 - Taxonomy of Errors and Frequent Cases

Category Most probable errors	Issue Count Occurrences
A	7
Query code incompatible with current data	6
Query execution order and ID conflicts	5
B	14
Query timer issues	12
Unable to interrupt query execution	9
C	30
Uninterruptible response copying process	49
Query response filetype / output format	12
D	16
DB size and other filesizes incorrect	32
Client login without sufficient rights to Extractor	10
E	6
Disk space limitations	11
Query execution taking too long	10
F	6
Query execution/queue removed by third party	11
Malfunctioning/Non functioning Report server	6
Total individual cases: 440	**Distinct Issues: 79**

An online structured system for the initial reporting of errors was implemented. We used a project management platform and divided the tracking mechanism into several sub-systems for different projects (QICKD [4], IAPT (an evaluation of Improved Access to Psychological Therapies), Osteoporosis, and Diabetes studies) but with the same underlying format for cross reporting. A set of optional and required fields, allowed for immediate connection to a predefined taxonomy.

Practical examples of errors and solution orientated reporting

We report exemplar errors in each of the seven areas and the action taken and time taken to solve them:

(a) Data extraction queries and process problems: One brand of EPR vendor creates its own local codes to plug what it perceives as gaps in the standard (Read code) hierarchy. Unless queries collect these local codes this data area is deficient. Smoking data provides a good example - where sometimes local codes have accounted for >10% of the data. The solution took under two weeks, involving query re-writing and exploring with clinic doctors how these patients were represented in the EPR system.

(b) Extraction system errors: The INPS Vision and EMIS PCS systems can take several minutes to extract large response files during which the session cannot be interrupted. We prevented this by logging in another session on the same workstation on the proviso that login details are held. We asked that these details be provided so that restarting the extraction would require less time. Interference from support staff would often take hours or require a revisit.

(c) Top level system and database errors: Systems are not designed to handle large-size result files. EMIS LV in particular, is negligent for not having sufficient free database and

disk space which is an essential prerequisite for data extraction. This often resulted in system crashes if it was utilised for clinical purposes at the same time. We made sure at least 100MBytes are free, to avoid interruptions and system restarts that would take 30 minutes or more.

(d) System and communication errors: Due to insufficient user privileges, execution of queries is sometimes impossible. We used accounts with >Level 4 access to MIQUEST. Also, the interface would sometimes incorrectly indicate the current load. We were proactively ensuring that we had enough resources than the stated, to prevent having the support staff sort it for us with a 15 minute to 1 hour addition to the collection.

(e) Hardware and infrastructure errors: iSOFT Synergy and Premiere are both vulnerable to complex query sets when an external reporting server is not being used. We found that even in cases where a reporting server was installed, we had to use the live clinical system because of poor maintenance and data that were not up-to-date or incorrectly linked.

(f) Human errors: Experience has shown that human errors were also commonplace even in some instances where communication had been successful. On occasion, queries had been removed from the system by practice staff unknowingly, where researchers had scheduled set execution times or where practice staff needed to execute internal queries or maintenance tasks (the data extraction tasks get lower priority than the system maintenance processes).

Discussion

Principal findings

Data extraction techniques are widely used to answer research questions from routinely collected clinical data. Problems are faced during data extraction. Most appear to be associated with the way specific data extraction engines have been implemented by the different EPR system vendors. The adoption of this error taxonomy would enable consistent reporting to system manufacturers and potentially improved efficiency in data collecting.

Implications of findings

Our system imposed a much more analytical approach to error reporting and handling from data collectors. Errors were assigned to all categories. Although the incidents were not equally distributed, they were correctly proportioned based on the influence of each individual category (and system element) to the overall extraction and anonymised patient record collection process. The process allowed us to be more accurate, fast and proactive. For example, the common error of queries being randomly interrupted was originally handled as a query writing issue. Statistically, and based on our classification and findings, there are less chances of this error feedback because of a syntax or vocabulary error and the failure output is almost directly connected to automated backup processes on the reporting server or other maintenance issues. On another example, the traditional way of handling long-running queries was to generate subsets even in cases where the practice systems had a specific (in most cases easy to resolve) issue. With our process, we would classify the error, check the most probable causation and proceed with the collection without rescheduling a visit which involved writing vendor-specific subset queries in-between, using valuable study time and resources. Also, the taxonomy helped us provide feedback to the EPR vendors (and MIQUEST) as in a recent example, new data together with the inclusion of post-collection validation error information pointed to a vendor bug with a false return of text data type ACR values instead of numeric ones, resulting in gaps inside the collected data. This was flagged, the developers were notified and a fix was introduced prior to our next collection. We found that the duration of this process was less than our estimate for rewriting the queries, deploying and executing them as well as any changes to our analysed flat-file generation mechanisms for converting the inconsistent data type.

We followed a set of principles for our own research projects and found that early steps and precautions also allowed for minimised error frequency. For example, the use of mechanical processes for query writing, code execution and system maintenance minimised errors in categories A and F (we followed the commonly used reusable code principle via component based engineering for our processes), whereas documented solutions to usual problems on software-level (for categories B, C and D) allowed for error solving by the collectors themselves. Finally, articulating the least acceptable hardware features and specifications before a data provider joined a study minimised the impact of any issues with the infrastructure (category E).

The error classification through the taxonomy we implemented makes error reporting a solution-orientated approach. It allows for the flagging of the nature of any obstacles combining precautions as well as immediate action thenceforth. Problems which were frequent 12 months ago no longer feature on our error list, these include but are not limited to: Some human errors, disk space issues where feedback would be inaccurate, crashes on the server because of lengthy or problematic queries and shared folder issues where the mapping of local drives needs to be set up by staff with sufficient privileges.

This process provided team members the confidence to approach vendors or explain the limitations of hardware or software to healthcare providers participating in research.

Comparison with literature

We identified a dearth of literature on error reporting. Though much is written about how data from EPR systems are expected to have a central role within healthcare commissioning, and quality improvement [10].

There are generic IT approaches to problems with data extraction: namely the resolution of possible data conflicts occurring in the database integration process; incompatibilities between databases, differences in data types; and copies of the same information stored in different databases [11]. There are examples of logging mechanisms able to identify errors either in extraction itself or the underlying EPR system data (for example, the miscoding of family history as heart disease resulting in apparently 25% of practice population as having this diagnosis) [12]. The above reveal the need for a structured error handling process. The literature recognises the problems with heterogeneous distributed databases as well as the cost and

effort for overcoming them without a standard well-defined and designed process [5,11].

The UK national data quality programme PRIMIS+ discussion board illustrates how data extraction problems extend widely; but does not incorporate any sort of error taxonomy [13].

Limitations of method

We found that on rare occasions the translation of an issue that can be connected to multiple categories has a slight change on its meaning (not on its effect, however) when redefined for our functional approach.

Also, for a number of problems we had to analyse feedback from the data collectors several times, in order to define the most appropriate category definition and the course of action that required the least effort (in terms of man-hours or external resources involved).

Based on our need for immediate logging of the problems and comments about them, we had to update the list as the extractions progressed and collections were rescheduled.

The design of the online system for error reporting allowed us to propagate knowledge on the effect and effort in resolving issues across several projects by setting principles and user-access rights for different teams in several locations connected to the same central repository. An approach that can widely be used for cross-platform access with direct assignees, minimising the time spend for both administering and providing solutions in timely manner.

Call for further research

Based on our findings, the implementation of a shared reporting system adopted by the individual EPR system vendors can help the secondary use of routinely collected data by allowing for faster solutions and therefore interpretation and use of the output data.

Conclusion

This approach has enabled us to achieve higher levels of successful problem reporting and solving. Its method could be replicated in other projects. We recommend the use of this taxonomy for error reporting for any type of study whether using primary or secondary care data.

System vendors should be more aware of the potential impact of non-standard interfaces. Better structured systems, which more strictly implemented standards, would reduce the time spent in crisis managing problems when extracting data. A national or international system of error reporting would allow sharing of workarounds is urgently needed. Adoption of a standardised method of solution-orientated error reporting would help EPR vendors identify and address errors in data extraction from their systems.

Acknowledgments

Biomedical Informatics students Saqba Arif and Shaista Somani for their experiences during the data collection process.

Toward a Human-Centered Voluntary Medical Incident Reporting System

Yang Gong

Department of Health Management and Informatics, School of Medicine, MU Informatics Institute, University of Missouri, Columbia, MO, USA

Abstract

Voluntary medical incident reports are a valuable source for studying adverse events and near misses. Underreporting and low quality of reports in local organizations, however, have become the impediments in identifying trends and patterns relating at the local, regional and national level. Human factors on usefulness and ease of use have shown their important role in acceptance of voluntary reporting systems. To understand and identify the obstacles of quality reporting, we employed a set of human-centered analysis methods to examine one-year voluntary medical incident reports of a University Hospital. We found about 30% of the reports labeled as "miscellaneous" and "other", and their real incident types or error descriptions were identified through an in-depth recoding. Human-centered analyses show that the pre-defined reporting categories could serve well for the voluntary reporting need if reporters' tasks were better represented on user-friendly interfaces. We suggest that a human-centered, ontology based system design for voluntary reporting is feasible which could help improve completeness, accuracy, and interoperability among national and international standards.

Keywords:

Medical incident, Reporting system, Human-centered, Interoperability.

Introduction

Medical incident reporting system, where error data are collected in a properly structured format, is suggested a useful mechanism for the detection of patterns, discovery of underlying factors, and generation of solutions[1]. Such a system as a source of adverse event repository would allow patient safety researchers to categorize, trend, and analyze data, increasing knowledge about medical mistakes and generating common solutions. Voluntary incident systems are a valuable, major source for this purpose. However, there is a clear dissatisfaction with the current voluntary systems [2-5]. Incomplete and inaccurate reports are misleading and not usable for further analysis.

Despite a large amount of studies suggest instituting a "just culture" that encourages learning, non-punishment [6-15], few studies have investigated the system difficulty and inefficiency regarding ease of use, ease of understanding and their relations with the level of details in reporting[10, 16-18]. To date the research addressing the inefficiency of medical incident reporting system has been limited and fragmented, with findings not always broadly disseminated. Although general rules of human-centered design have been introduced in many other fields, currently there is a lack of design framework for medical voluntary incident reporting systems to effectively collect, catalog, and analyze the reports.

Human factors, an important role in voluntary incident reporting systems, greatly affect the reporting rate, completeness and accuracy of the incidents [19, 20]. For example, classification and definition used in incident reporting systems determine whether an event is recognized or ignored [21, 22]. The people, who report, are generally working under time critical and multi-tasking conditions, and often do not have either the time or sufficient information to create a complete and meaningful report of the incident. If "other" or "miscellaneous" is offered as an option, it is often chosen [23]. It is critical to know what the needed categories are and how they would promote the quality of reports, users' acceptance in voluntary reporting systems.

To understand the current status of voluntary reporting systems in term of completeness, accuracy and degrees of expressiveness, and to identify the technical barriers toward a human-centered design, we proposed to study a set of voluntary reports acquired from the University of Missouri Health Care System (UMHC). UMHC is one of the most comprehensive health-care networks in Missouri, with approximately 500 staffed beds and 19000 patient admissions annually, offering the finest primary, secondary and tertiary health-care services. In 2002, in response to the Institute of Medicine report[24], UMHC developed a web-based voluntary reporting system, the Patient Safety Network System (PSN), which collects adverse events, near misses reported from 5 facilities located in mid Missouri[25].

Goals, Operators, Methods and Selection rules (GOMS) have been widely applied to model user's behavior and system evaluation. As a theory of Human-Computer Interaction (HCI), GOMS models can be classified as predictive, descriptive, and prescriptive[26]. GOMS model can be used to predict the time it will take a user to perform the task. GOMS can be used to describe the way a user performs tasks on a system and can be used to prescribe because it can serve as a guide for developing training programs and help systems. Keystroke-Level Model (KLM) is a simplified version of GOMS.

KLM aggregates all perceptual and cognitive function into a single value for an entire task[27].

In particular, we are interested in those incident reports with wrong or mislabeled categories and uncovering the underlying reasons of incorrect category selection. This process may help us develop a new set of incident type or event categories to better serve reporting needs and be compatible with the Common Format(AHRQ) and International Classification of Patient Safety (WHO)[28, 29]. This paper demonstrates our process and results regarding consistency and reliability of the voluntary incident reports. Base on the analysis, we have proposed our recommendations for upgrading institutional voluntary reporting systems through a human-centered, national/international standard compatible design, and for effectively maintaining historical data.

Materials and Methods

We obtained a total of 2919 de-identified, unique (duplicate copies were combined) voluntary incident reports generated in a 12-month period during 2005-2006 from the Office of Clinical Effectiveness (OCE) at UMHC. The reports are stored in MS Access and password protected on a secured server. The PSN is a web-based electronic reporting with tutorials and explanations on harm scores usage provided on the same webpage. Regardless of the choice of anonymity, each reporter must complete a factual and objective report in the PSN system immediately following an adverse or near-miss event. The OCE periodically holds a peer review process, which identifies the basic or causal factors with focuses primarily on systems and processes, not individual performance.

In this system, adverse events/incidents are defined as "any potential deviation from policies, procedures and standards regarding patient care, or a clinically related adverse or unexpected event causing injury or the potential for injury to any person"[30]. This could include an unexpected adverse outcome related to the natural course of the patient's condition or an outcome unrelated to the patient's condition. Near-miss events are defined as "an adverse event that could have resulted in an accident, injury or illness to a patient but did not through chance or timely intervention."[30]

Data Structure & Reporting Flow

The voluntary report database contains one table with 26 required fields. Each case has been automatically assigned a unique event ID. Of the data fields represented on user interface, Five (up to seven) fields, including patient age, report date, event date, patient unit ID, patient unit ID, are typed in by reporters. Report data and event date can be either typed in or selected from a calendar. Most fields require reporters to select from pre-defined menus displayed as drop down lists, radio groups, check boxes, etc. The fields displayed in predefined menus include harm score, incident type, error description and brief description. Event description is a short narrative to support the selected harm score. The harm score is a subjective rating of severity from 0(no clinical changes) to 5(death). Each harm score corresponds to a different number of items provided to reporters as a reference for evaluating the severity of events[30]. For a typical reporting process, one has to go through "answer initial questions", "event common questions", "event details", and "report summary", totally four interfaces to complete a report. For all reports, reporters may choose to report them anonymously or retain their IDs. After submission, hospital administrators, service medical directors or departmental managers review the reports and fill in the solution, review, and additional information fields. Therefore, all reports we studied were previously reviewed and responded by domain experts.

Procedure

First, we conducted a systematic content analysis on all the reports using a comprehensive coding interface which aggregates event information on one page and offers a coding space for researchers [23, 31]. Content analysis is an effective method of identifying key concepts and building up the conceptual hierarchical structure of concepts [32]. Content analysis is especially necessary in such a voluntary reporting process because there might be a great variety of term usage in reporting a case. Similarly, the selections of harm score, incident type or error description may lack consistency due to individual's understanding and therefore affect usefulness of the reports for patient safety research [33]. The content analysis was conducted by two data analysts who completed the work independently and performed a cross checking for achieving a higher consistency among harm score, incident type and error description.

Second, we further conducted an in-depth analysis on a selective type of cases (346 patient fall cases) to reveal the factors which might have caused the inconsistency and incompleteness of the reports. We selected fall cases to examine for two reasons. (1) according to the hospital policy, all falls are required in the PSN system [30]. Therefore, this type of incident has a mandatory nature within a voluntary reporting system. (2) Patient fall, as a typical category in voluntary reporting systems, represents the quality and taxonomy granularity in the current system. Fall cases are usually more frequently reported in incident reporting systems than in patient charts. This is in consistency with other group's study [5]. In our study, fall is defined as a sudden, unintended, uncontrolled downward displacement of a patient's body to the ground or other object (such as bed or commode) at a lower level. The fall excludes the falls resulting from a purposeful action or violent blow [34].

Third, for exploring the feasibility of transforming the hospital on-site reporting categories into a compatible format recommended by WHO International Classification of Patient Safety(ICPS) [29] and AHRQ Common Formats [28], we developed a prototype using a set of questions with a step-by-step structure for fall incident reporting. The reporting categories were mapping results between the PSN fall terminology and the national/ international standards. We then compared the estimated execution times of two interfaces between the PSN and our prototype by using KLM, which predicts task execution time from a specific design and specific task scenario. Following Kieras's method [27], two experienced reporters conducted KLM analysis of reporting a typical fall case based upon two interfaces.

1. Choose one or more representative task scenarios.

2. Have the design specified to the point that keystroke-level actions can be listed for the specific task scenarios.
3. For each task scenario, figure out the best way to do the task, or the way that you assume users will do it.
4. List the keystroke-level actions and the corresponding physical operators involved in doing the task.
5. If necessary, include operators for when the user must wait for the system to respond.
6. Insert *mental operators* for when user has to stop and think.
7. Look up the standard execution time to each operator.
8. Add up the execution times for the operators.
9. The total of the operator times is the estimated time to complete the task.

"Click mouse", "move mouse", "move hand to mouse/keyboard", "time needed for mental preparation", "type keys" were calculated. System waiting W (how long the system takes to respond) was not considered as the system speed was great.

Results

Our content analysis shows the majority non-anonymous reporters were registered nurses (66.2%). Other reporting professionals such as unit clerks, physical therapists contributed a total of 5.0% in the reports. Figure 1 shows the percentage distribution. The inter-coder reliability was good and reached at 82% between two data analysts (κ=0.83).

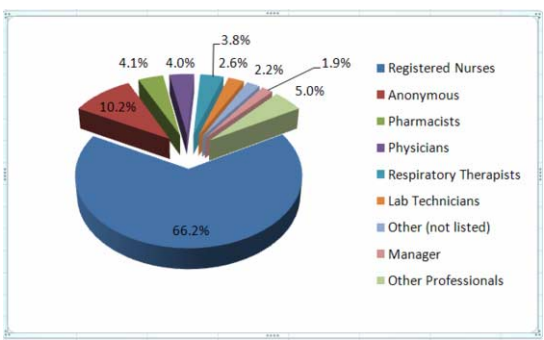

Figure 1- Distribution of Reporting Professionals in the PSN system

The incident type leads each reporter to further describe the error using predefined error descriptions and a free text entry. The major incident types are miscellaneous (32.8%), medication/IVs (23.7%), procedure/test/treatment (16.5%), fall (11.9%), equipment/device (5.9%), skin impairment (0.9%). The Error Description field is a pre-defined list designed for quickly summarizing the incident, where the major data entries were "other" (41.3%). We noticed that the field only allows reporters to select one item associated with the Incident type.

The big portion of "miscellaneous"(32.8%) in the incident type field and overwhelming percentage of "other" (41.3%) in the error description field indicate the reports lack of accuracy, completeness and affect the utility of the reporting system at large. There were 25.3% of the reports labeled with both "miscellaneous" and "other" in the two fields simultaneously. This means that the reports were completely not categorized by the original reporters. To investigate the case, investigators need to carefully examine all pieces of information and summarize out the exact category for the case.

We indentified 360 (12.3%, n=2919) fall cases among the unique 2919 medical incident reports after all the cases were cross checked and rectified for the "miscellaneous" and "other" cases. We then examined the PSN terminology used in fall reporting, which includes fell from bed/stretcher/table, fell while ambulating, sitting at side of bed, sitting in chair, toileting, transferring, unwitnessed, and other. Over one third of the cases (36.1%, n=130) belongs to unwitnessed case. This "unwitnessed", as an index for aggregating cases, does not provide more information than "miscellaneous" or "other" of other fields. As a result, we successfully revealed "unwitnessed" from reporter's free text description and replaced it with detail-oriented categories (a table not included due to space limits). We assigned "unwitnessed" as a secondary category attached to fall locations.

As shown in Table 1, the prototype with structured step-by-step questions greatly reduced the time needed for mental preparation, typing, and the total action though mouse clicks and mouse & hand moves are slightly increased. This implies that the prototype may increase reporting speed, yet it is subjected to more rigorous user testing with both new and experienced users.

Table 1- Comparison of KLM Analysis Results between the PSN system and Prototype

Action	Standard Operator	PSN system		Prototype	
		Count	Second	Count	Second
Click mouse	B (0.1 Sec)	30	3.00	34	3.40
Move mouse	P (1.1 Sec)	30	33.00	34	37.40
Move hand to mouse/keyboard	H (0.4 Sec)	11	4.40	19	7.60
Time needed for mental preparation	Tm (1.35 Sec)	139	187.65	90	121.50
Type keys	0.28 Sec/key	143	40.04	87	24.36
Total		353	238.09	264	194.26

As a result of mapping between the PSN categories and the national/international standards, seven major categories for fall were created. They are (1)sitting in chair; (2)fell while ambulating; (3)sitting at side of bed; (4)transferring(with assistance); (5)toileting; (6)location + unwitnessed; (7)fell from bed/stretcher/table, and (8)special (not included in the above situations). All the major 7 categories were clearly mapped between ICPS and Common Formats. This compatible taxonomy was used to successfully code 95.6% fall cases. Only 4.4%, coded as "special", cannot fit well in all the other six major categories.

Discussion

The content analysis revealed the overall status of the PSN reports in terms of consistency, accuracy and degree of expressiveness. "Miscellaneous" and "Other" cases were unmatched (mismatched) reports of incident types and error descriptions in the database. Through analyzing the short event summary, which contains the justification of harm score selection, we found that those "miscellaneous" or "other" cases usually can be coded by the categories existing in the system. This may because (1)those reporters were not experts in classification and may select the "safe" categories such as "other", "miscellaneous" due to their time limits or unfamiliarity with the classification for incident type or error description. (2) Only seven major incident types were available in the system and reporters selected "other" or "miscellaneous" when the incident could not properly fit into the description. For example, a patient fall with bleeding may be reported for both "bleeding" and "fall", since the system did not allow reporters to select more than one categories, which might result in "miscellaneous" or "other". (3) In addition, there were a few cases not fit into any existing categories, for example, an "organizational management" delay. In such a case, "other" or "miscellaneous" might be the best choice. If predefined categories do not match reporters' mental model of incident type, it may result in underreporting, incomplete or inaccurate issues. Moreover, reporters may also wish to capture varying levels of details. Therefore, each high-level category (broad concepts) ideally should contain more details through low-level categories (narrow concepts). This strategy may guide reporters to identify an optimal granularity as well as build an interoperable system at the local, regional, and national level. The reasons abovementioned direct designers of voluntary incident reporting systems to better understand the reporters' cognitive characteristics, term requirements on the interface level.

A human-centered design should fully consider both new and experienced users. In such a system, new users will not feel confused even without reading the tutorial whereas experienced users are able to find accelerators to expedite the reporting speed by using short-cuts, default values or preferred interfaces. According to the KLM analysis results, our prototype holds promise in reducing time needed for mental preparation and total steps. For example, (1) the current system requires users choose between "anonymous" and "un-anonymous" radio buttons. Since most reporters use "anonymous" reporting (no release of their work ID), new designs should offer a check box for "un-anonymous" and thus simplify the interface meanwhile make "anonymous" a default value. (2)Auto-completion features would increase the efficiency of pull-down menu selection, which is not offered in the current system. This is especially true when hundreds of names are listed in the menus. (3)Since most cases were reported with 24-48 hours, some convenient time/date stamp buttons (e.g. today, yesterday) could be very useful for reporters to click, rather than manually typing in the day and time or selecting from a calendar, which is laborious and prone to typos. (4)A holistic view that contains all entries of an individual report on a single page would be easy for reporter to conduct final editing and confirmation, rather than forcing reporters to flip pages back and forth to verify. (5)A navigational bar as an indicator of progress towards the completion of a quality report should be offered. This will improve system transparency to users and allow user to estimate if time slot is adequate to finish a report.

Designers for voluntary incident reporting system should notice the balance between efficiency and expressiveness of data entry. Current voluntary reporting systems are mainly template based, which increases data entry speed. Meanwhile, it may have the unintended effect of homogenizing incident descriptions with a loss of detail. For example, rather than asking reporters to recall an entire incident and type a long, time consuming free text description. A set of procedure-based questions, with conditional skips according to previous answers, would guide reporters better through the entire recall process. Moreover, an additional free text box would be offered in case any information not included in those questions deemed valuable for reporting. We suggest an intelligent interface for voluntary reporting based on existing data repository that can predict term requirements and offer intelligent guesses during data entry.

To further our study, we will employ heuristic analysis, user testing to examine the feasibility of our prototype, and apply an ontological approach to maintaining historical data without disrupting current users or altering the meaning of historical data. This pilot study based on an institutional voluntary reporting system contributes to a human-centered framework for voluntary reporting and promotes its migration towards a unified, interoperable reporting format.

Limitations

Accessing to medical incident reports generated in other institutes would definitely increase generalizability of the results. Collaborations between institutions are highly needed. Some inaccurate, incomplete data may be further rectified and analyzed through reviewing the corresponding patient charts. Due to the anonymous and retrospective nature, we are not able to interview the original reporters.

Acknowledgments

The author expresses heartfelt thanks to Lei Hua, Yanyan Shen, Zhijian Luan and James Richardson who assisted in data analysis at different stages. Special thanks go to the Office of Clinical Effectiveness at the University of Missouri Healthcare System for their support in conducting this research.

Abstract

Hospitalized patients receive countless doses of medications through manually programmed infusion pumps. Many medication errors are the result of programming incorrect pump settings. When used appropriately, smart pumps have the potential to detect some programming errors. However, based on the current use of smart pumps, there are conflicting reports on their ability to prevent patient harm without additional capabilities and interfaces to electronic medical records (EMR). We developed a smart system that is connected to the EMR including medication charting that can detect and alert on potential pump programming errors. Acceptable programming limits of dose rate increases in addition to initial drug doses for 23 high-risk medications are monitored. During 22.5 months in a 24 bed ICU, 970 alerts (4% of 25,040 doses, 1.4 alerts per day) were generated for pump settings programmed outside acceptable limits of which 137 (14%) were found to have prevented potential harm. Monitoring pump programming at the system level rather than the pump provides access to additional patient data in the EMR including previous dosage levels, other concurrent medications and caloric intake, age, gender, vitals and laboratory results.

Keywords:

Adverse drug events, Infusion pumps, Patient harm

Introduction

Ninety percent of hospitalized patients receive intravenous medications (IV) [1] and many are delivered by infusion pumps which can provide from 0.1 to 9999mL volumes over a wide range of infusion rates [2]. The pumps are usually programmed by nurses who enter the dose and rate for the specific drug that may be used for adults or premature infants. Function keys on the pumps are used to set dosages as mg/hr, ml/hr, mcg/hr, mcg/kg/min, units/hr, etc.

Adverse drug events (ADEs) were the most common cause of patient harm reported by the Harvard Medical Practice Study [3] and medication errors are the leading cause of ADEs [4]. The Institute of Medicine reported that one medication error occurs per hospitalized patient per day [5]. Patient harm occurs more rapidly and is more severe when ADEs are caused by IV medications [6]. Intensive care patients are at especially high risk for pump programming errors due to the potency and narrow safety margins of the drugs they receive and the fact that many are given via infusion pumps. Old infusion pumps provide dose calculation functions and free-flow protection. Still, 35% to 60% of ADEs involve pumps [1, 2] and most were the result of incorrect programming [2,4,7-9]. New smart pumps have drug libraries of acceptable dosages and infusion rates and provide soft and hard alerts when the pumps are programmed outside of acceptable ranges. [2,10]. Despite the obvious potential of smart pumps to prevent patient harm, there are conflicting reports of their ability to do so without additional capabilities and interfacing to electronic medical records (EMR) [10,11]. We report the development and use of a "smart system" on our EMR to reduce ADEs by enhanced notification of infusion pump programming errors that can be used alone or in addition to smart pumps.

Materials and Methods

Background

Intermountain Medical Center in Salt Lake City, Utah, USA is a 456-bed teaching hospital affiliated with the University of Utah School of Medicine and replaced LDS Hospital in November, 2007 as Intermountain Healthcare's Level One trauma facility. The key feature of the hospital information system is the integrated EMR that contains most clinical information including bedside charting of administered medications. The coded data in the EMR facilitates the development and use of clinical decision support programs to analyze the data and constantly monitor patient care. In 2005, we started the development of a computerized system connected to our EMR to help reduce ADEs caused by infusion pump programming errors.

System Description

The infusion pumps in the ICUs at Intermountain Medical Center currently do not have the smart pump capabilities. We developed an application using a USB to RS232 converter that we connected to the RS232 ports of each pump (Figure 1). The USB side of the converter is connected to a USB hub which is connected to the bedside computers. A program on the bedside computers queries each pump every second and any initial drip rates or changes are sent to a central server. A Java program

(DIAServer) on the central server allows nurses to associate each administered medication to a specific patient and pump in the EMR. When a drip rate change at the pump arrives at the server, the program queries an oracle table to see if it is a monitored medication and if so, checks the table to see if the rate violates the initial or change limits. Maximum initial and rate change limits were defined by a committee of critical care pharmacists, physicians, and nurses for 23 high-risk drugs commonly used for ICU patients. If the rate violates the limits, the program waits 30 seconds to allow the pump programmer to recognize and correct the error. If the rate continues to violate the limits, a message is sent to another JAVA program (AlertServer) on the central server to activate an alert of a potential pump programming error. That program also constantly listens on a TCP/IP port for messages sent from the bedside and nursing station computers which "check-in" with the server every 10 minutes. The server contains a table with the nursing units, room numbers, and IP addresses of each computer. If a computer has not checked-in during the previous hour, that computer is marked as "out of service" and removed from the table and a message is sent to the pagers of the on-call staff to determine the status of the computer. As computers are brought back online, a message is sent to the server. This process ensures that when alerts are sent, the AlertServer program can determine which unit the patient is in and send the message to all the computers in the same unit over the TCP/IP connection.

Another Java program loaded on the bedside and nursing station computers runs as a service in MS Windows. When this program receives the "activate" alert message from the server, it sends a Java frame to the terminal that fills the whole screen. The background of the frame alternates between blue and black every three seconds (Figure 2). The room number and pump number are displayed large enough to be seen from 20 to 25 feet away. There are two ways to turn off the visual alerts sent to all the computers in the unit; 1) fix the dose rate at the pump to within the limits, 2) close the alert window on the computer. If clinicians simply close the alert window on the computer, they have to acknowledge and terminate the alert (overridden alert). The alert also creates a log which is stored and sent via email to the clinical pharmacist. The log includes the patient's encounter number, time of the alert, medication, dose rate, previous dose rate, device number, order number, bag number, and room number. The program also logs how the alert was turned off and the clinician's comments and name.

Pump Use

The pump alerts were implemented in the ICUs at Intermountain Medical Center on November 1, 2007 right after it first opened. When a nurse hangs a medication bag for a patient and programs the pump the first time on the

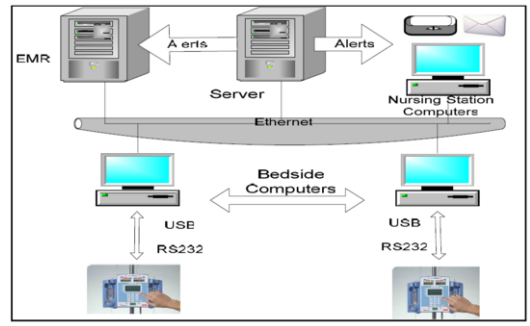

Figure 1 – Diagram of the enhanced infusion pump alerting system.

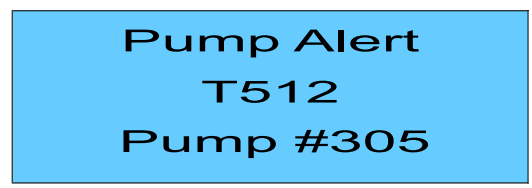

Figure 2 –Example of visual alert sent to every computer in the same unit as the patient.

first bag of the first order, the "initial start" rules are evoked. Any subsequent changes to the pump for that drug are monitored by the "rate change" rules. If the pump is turned off for 60 minutes, the initial start rules are used. While some pumps allow multiple infusions through a single pump, only one infusion per pump is allowed in our ICUs.

Evaluation

A critical care clinical pharmacist (RC) followed up on every pump alert in the 24 bed shock/trauma ICU (STICU) from November 1, 2007 through September 15, 2009 and determined the cause and potential outcome. Pump alerts were classified in the alert log as "fixed" or "overridden" by the nurse. Fixed alerts were those where the programming error was acknowledged and the pump was reprogrammed so the dosage was within acceptable limits. Overridden alerts were acknowledged by the nurse but not changed at that time. Overridden alerts were followed up and discussed with the programming nurse to obtain more information. Alerts were classified as "potential harm" if the clinical pharmacist determined the initial pump settings would have resulted in an incident report of a potential ADE.

Results

During the 22.5 month study, 3,865 unique patient encounters were in the STICU for a total of 13,648 patient days (average 3.5, range <1 - 183 days). Fifty-six percent of the patients were male and 4% were less than 20 years of age, 22% from 20-40, 32% from 41-60, 30% from 61-80 and 12% were older than 80. Most of the patients were admitted due to sepsis, acute respiratory distress syndrome, stroke, trauma and other

critical illnesses. Those patients received a total of 434,163 (average = 112) doses of over 500 different types of medications.

For the 23 different drugs monitored by the alert protocols, the patients received 31,102 different doses of which 25,040 (81%) were delivered via an infusion pump (Table 1). A number of doses of propofol, furosemide and labetalol were given as bolus doses and not via a pump. For the other 20 monitored drugs, all were given via a pump. Of the 25,040 pump doses, 970 (4%, 1.4 alerts per day) generated an alert due to pump settings that were outside of the acceptable ranges. Follow up for each alert found that 137 (14%, 10 per 1,000 patient days) were judged to have prevented potential patient harm. All of the alerts judged as patient harm in this study were the result of obvious infusion pump programming errors. For all but two of those alerts, the pump settings were fixed at the time of the alerts. For two overridden alerts, nurse follow up found that while the nurse overrode the alert they changed the doses to within the acceptable ranges within a few minutes. As seen in the table, the number of generated alerts was usually associated with the total number of drug doses administered. Thus, the more a drug was used, the greater the chance a pump's settings would be incorrect. Of the administered doses, dopamine generated the highest percent of alerts (30%), but none were judged to have caused potential harm. In contrast, only 2% of the fentanyl doses generated alerts, but 71% were judged to have prevented potential patient harm.

The number of alerts generated and the number of alerts resulting in potential patient harm varied during each month of the study (Figure 3). Likewise, there was no pattern as to which bag number was associated with the alert or the potential harm. There were only 33 alerts resulting in potential patient harm when the first bag of the drug was programmed (range 1-53). Thus, 104 of the 137 were the result of catching incorrect dose rate changes.

Discussion

Unlike prescribing and dispensing errors that can be detected and prevented by pharmacists or nurses, incorrect pump programming provides little time to discover and correct the error. This study showed that many doses of high-risk drugs are administered to patients who may be the least capable of tolerating additional harm. The drugs we found to cause the most alerts and potential patient harm are consistent with another recent study of smart pumps and ADEs [11]. Some drugs like fentanyl, norepinephrine, insulin and dopamine generated more alerts in this study because they were titrated more frequently and resulted in more dosage changes to the pump. An insulin drip protocol used in our STICU checks blood glucose levels every 2 hours and could result in a rate change every 2 hours. Dopamine generated a lot of alerts because it is titrated often and alert follow up found that some nurses felt that if they were not getting a patient response soon enough, they would increase the dose for a few minutes to get a response. These types of alerts provided opportunities for process control and nursing education.

Table 1 – Generated alerts and potential harm identified by the enhanced notification of infusion pump programming errors in STICU from Nov. 1, 2007 – Sep. 15, 2009.

Medication	Administered Doses* No.	Generated Alerts No. (%)	Potential Harm No. (%)

** Doses administered via an infusion pump.*

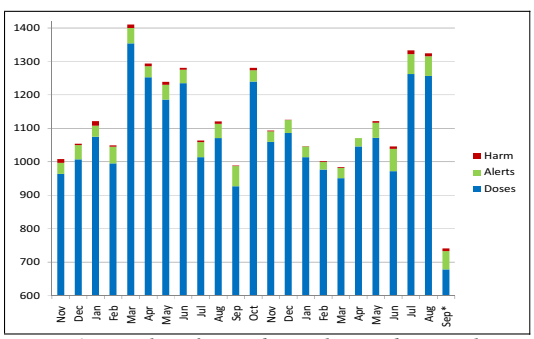

*Figure 3 – Number of pump doses, alerts and potential patient harm during the 22.5 month study. *Only 15 days.*

However, amiodarone is a drug that should only have the dose changed once or twice during the course of therapy. Many of the amiodarone alerts were caused by nurses giving bolus doses through the pump. Giving bolus doses through pumps is considered dangerous, is discouraged and we also educated nursing when it was detected.

The fact that the number of alerts and corresponding bag numbers varied throughout the study indicates that a variety of patient factors and work related distractions often result in pump

programming mistakes. Thus, the potential harm comes from the mechanism of the drug and the often non predictive series of events that lead to the programming errors. Fentanyl caused the most potential harm because of its narrow safety limits and propensity to cause respiratory arrest. A typical alert resulted when a physician wrote an order for extubation and to change the fentanyl drip down from 100mcg/hr to 75mcg/hr. Upon extubation, the patient experienced some complications that required additional treatment and delayed the fentanyl dose change. The nurse then quickly turned the fentanyl drip down to 75mcg/hr. Thirty seconds later all the screens in the ICU begin to flash with a pump alert for that patient. Several nurses and a pharmacist responded to the alert and found the pump running at 75mLs/hr or 750mcg/hr. With the 30 second delay built into the program and the time to respond to the alert, the patient received an extra 8.5 mcg of fentanyl. Before the pump alerts, this likely would have gone unnoticed long enough to require re-intubation and/or caused other physiological harm to the patient. In addition to respiratory arrest, many of these drugs, dopamine, norepinephrine and epinephrine can cause cardiac arrest, a neurological coma (insulin) or serious bleeding (heparin).

As shown in the table, most of the pump alerts did not result in patient harm. This is also consistent with other studies that found medication errors associated with infusion pumps were frequent, but most would not have resulted in patient harm [1,10,11]. One of those studies reported that current smart pumps would fail to generate meaningful improvement in patient safety until they can be interfaced to electronic medical records, computerized provider order entry and bar coding [11]. One of the first studies on the use of smart pumps did not find a statistically significant difference in ADE rates or severity when smart pumps were used [10]. Nurses could bypass drug libraries and override soft alerts. Nurses were found to only use the drug libraries between 31% to 75% of the time due to the extra time required to use the library. Conversely, a study at a pediatric hospital showed that ADEs dropped 75% when smart pumps were implemented [12]. However the direct role of the smart pumps is unclear since standard drug concentrations and improved medication labels were introduced at the same time and ADE rates were dependant on voluntary incident reporting. A study at Vanderbilt reported that smart pumps appeared to prevent errors involving heparin [13] and another study suggested that smart infusion pumps should be the standard for safety in intensive care [14]. The fact that the smart pump libraries automatically switch to the appropriate concentration and measurement units should reduce the potential for error by eliminating the need to make unit conversions. Moreover, a benefit of smart pumps and our smart system is the ability to examine the alert logs and monitor overrides and potential harm. Constant overrides can indicate the need for logic changes or further education and potential quality intervention. One of the reasons we had such a high alert rate with dopamine was because of how the alerts were initially set up. The dose increase limit was originally >= 5 mcg/kg/min. The cardiovascular group always increased by 5, so changing it to > 5 mcg/kg/min reduced those false alerts.

Advantages of a Smart System

Since the smart system logic occurs at the patient level and not at the pump, any coded patient data in the EMR can be included. We have an insulin alert that checks for concurrent total parental nutrition (TPN) in a different pump. If the TPN is turned off and the insulin is continued, an alert notifies nurses of the calorie and insulin inconsistency. In addition to concurrent drug therapy alerts, logic can include patient age, gender, renal function, weight, pregnancy status, vital signs such as blood pressure for patients on propofol, laboratory prothrombin times for patients receiving heparin or glucose results for patients receiving insulin. Smart pumps currently only have access to the current medication and acceptable dosage ranges, but not drug specific rate increase limits. Most of the potential patient harm detected in this study was due to dose rate increases rather than programmed dosages outside of initial dosages ranges.

It takes extra time to switch smart pumps to dose-checking mode and then access the drug library. Nurses find shortcuts for tasks they view as extra work or don't understand the potential patient harm [10]. In a smart system, no extra nursing time is required at the pump and the initial and rate change settings are always monitored. Likewise, adding or changing alert logic in a smart system can be done in the single knowledge base that monitors all infusion pumps in the hospital. This replaces the need and cost of having to have each pump reprogrammed. However, newer wireless smart pumps allow the logic changes to take place at one location and then sent to multiple infusion pumps.

Since pumps may be used in different types of nursing units, some smart pumps prompt the programmer for the specific care area the patient is in. The smart system automatically checks the room of the patient preventing the potential incorrect programming of the unit. For example, there are two vasopressin dosage settings in our logic. The STICU and the cardiovascular ICU use vasopressin differently. Thus, the smart system automatically selects the correct ranges. Likewise, the dose limits for heparin and insulin in our smart system are based on very specific unit protocols and require additional data from the EMR.

When smart pumps detect that cardiac drugs are running out, they can be programmed to go into Keep Vein Open (KVO) to reduce the drug rate, but keep the vein open. But, if not detected, the drug will eventually run out. Our system goes into KVO and also sends a unit-wide alert if it is not detected within 45 seconds.

Another benefit of our smart system was improved nurse charting of medications in the EMR. On occasion, nurses would delay the medication charting of the changes of the drugs on a pump. Nurses soon found with the smart system, if they did not chart a change in drugs before hanging and programming the new drug, the new dosages would usually generate an alert. Initially, nursing acceptance of unit-wide alerts was questioned. Nurses soon recognized the value of the alerts as potential harm was detected and prevented. Nurses now accept the alerts and appreciate the backup. Due to the visibility of the unit-wide alerts, nurses are not more prone to be careless and become dependent on the alerts.

Limitations

We installed the pump alerts in the new STICU when it first opened, and did not have any baseline ADE data for

comparison. However, our goal was to catch and reduce pump programming errors and not ADEs in general. Also, some of our drug limits could be considered as liberal. The current logic is set up to catch the obvious programming errors and giving bolus doses through the pumps. Thus, some additional patient harm was not detected by our alerts.

While the 30 second delay built into the logic increases nurse acceptance by allowing them to catch and correct an obvious error before the alerts are generated, it also exposes the patient to some degree of potential harm. While we detect the "nurse catches", we did not include them in the permanent alert log. Thus, we cannot report how often nurses caught their own errors within the 30 second delay.

One study found that 59.8% of their smart pump alerts were underdoses [15]. We only monitored and reported programming errors due to pump settings greater than acceptable limits (overdoses). Thus, we did not include underdoses for drugs like heparin that can also result in patient harm by not achieving the intended therapeutic drug levels. Likewise, we only monitored 23 different high-risk drugs in this study. There are seven additional drugs commonly administered via pumps in our ICUs that we could add, but we do not expect a large decrease in potential harm relative to the increase in alerts. The potential for "alert fatigue" should always be included in discussions to implement decision support of patient care.

Conclusion

We found our smart system prevented a number of pump programming errors from resulting in patient harm. Nurse and physician acceptance is extremely high and the system is being enhanced and installed in other hospitals.

Acknowledgments

We thank Drs. Terry P. Clemmer and James F. Orme for their encouragement and support during this project.

Abstract

With the rapidly growing use of electronic health records, the possibility of large-scale clinical information extraction has drawn much attention. We aim to extract adverse drug events and effects from records. As the first step of this challenge, this study assessed (1) how much adverse-effect information is contained in records, and (2) automatic extracting accuracy of the current standard Natural Language Processing (NLP) system. Results revealed that 7.7% of records include adverse event information, and that 59% of them (4.5% in total) can be extracted automatically. This result is particularly encouraging, considering the massive amounts of records, which are increasing daily.

Keywords:

Adverse effect, Side effect, Drug trial, Natural language processing (NLP)

Introduction

The use of Electronic Health Records (EHR) in hospitals is increasing rapidly everywhere. They contain much clinical information about a patient's health, including the frequency of drug usage, related side-effects, and so on, which facilitates unprecedented large-scale research. Nevertheless, extracting clinical information from the reports is not easy because they are written in natural language. This study specifically examines adverse effects and event information buried in EHR.

Why is Adverse Effect Information needed?

For each approved drug, adverse effects are investigated through multiple phases of clinical trials. Clinical trials usually target only a single drug. Consequently, it is difficult to capture detailed effects resulting from multiple drug administration.

Real patients sometimes take multiple medications (e.g. prophylactic administration), leading to a gap separating the clinical trials and the actual use of drugs by patients. For ensuring patient safety, it is extremely important to bridge that gap.

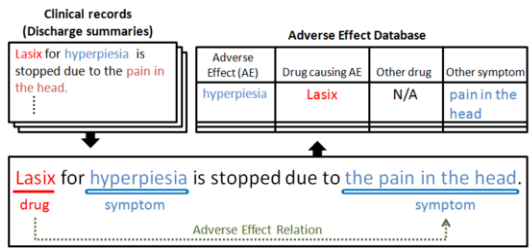

Figure 1- Proposed approach

Adverse Effect Extraction

For such situations, we have started a project to extract adverse effect information from clinical records. As the first step, this paper presents examination of the following two questions.

(1) How much adverse information is included in records? To investigate this, we manually checked the information included in hundreds of records

(2) How to extract the information? Manual checking of all records takes too much time. Therefore, we attempted automatic extraction. We regard the adverse effect extraction task as including two sub-tasks (STEP 1) "term identification" and (STEP 2) "relation extraction."

STEP 1: Term identification: First, the system identifies drug and symptom expressions in records. This task is almost equivalent to the Named Entity Recognition (NER) task in NLP. We use a state-of-the-art NER method: conditional random fields (CRF) [1].

STEP 2: Relation identification: Then the system identifies which effect is related to which drug (adverse effect relation between a drug and an effect). We use both a pattern-based method and machine learning (SVM[2]) based method.

Through STEP 1 and STEP 2, a pair of a drug and an adverse effect is extracted along with other information (other drugs and symptoms) and is stored in a database (Fig. 1).

Although experiments described in this paper are related to Japanese medical reports, the proposed method does not depend on a specific language or domain.

Specific Research Questions

The specific goals of this study were the following:

1. To investigate how much adverse effect information exists in the clinical records (described in Section 2; *Materials*)

2. To investigate the accuracy with which the current technique (automatically) was able to extract adverse effect information (described in Section 4; *Experiments*)

Materials

This section introduces the materials (clinical records) used for this study, and reports summary data related to the adverse effects contained in the material.

Clinical Records (Discharge Summaries)

The materials of this study are 3,012 discharge summaries[1], which are reports generated by medical personnel at the end of a patient's hospital stay. The summaries were gathered from all departments of the University of Tokyo Hospital[2]. Because it costs much time to survey all summaries manually, we split the summaries into two sets: SET A, which contains keywords related to adverse effects (a keyword set is presented in Table 1); and SET B, which contains no keywords. Consequently, we obtained SET A consisting of 435 summaries, and SET B consisting of 2,577 summaries. Regarding SET A, we manually checked all of them. For SET B, four annotators checked small parts (randomly sampled) of them. Cases of ambiguity were resolved through discussion. We regarded even a suspicion of an adverse effect as positive data.

Quantities of Adverse Effects in Summaries

The results are presented in Fig. 2. For SET A, 53.5% (=233/435) of summaries described adverse effects. For SET B, 11.3% (=6/53) summaries described adverse effects. The ratio of SET A: SET B was 435:2577 (SET A=14.5%: SET B=85.5%). To sum up the results, we estimated that at least 7.7% (=0.145×0.535; only SET A) of summaries contain a description of adverse effects. Even considering that the result includes merely a suspicion of adverse effects, the summaries are a valuable resource for assessing adverse effects.

Annotation for Machine Learning (SET A Only)

To use a machine learning method, we also added tags to records. This annotation is limited to SET A because the other set (SET B) included few descriptions of adverse effects. The annotation includes information of two types: (1) term annotation, and (2) relation annotation.

(1) Term Annotation: Term annotation includes two tag types: (a) an expression for a drug, and (b) an expression for an effect. The definition is presented in Table 2. We annotated 1,045 drugs and 3,601 possible effects.

(2) Relation Annotation: Adverse effects were annotated. We represent the effect as a relation between a drug <d> and a symptom <s>, which is represented as a "relation" attribute. Table 3 shows several examples, wherein "relation =1" indicates an ID of a drug – adverse effect relation, which is a unique number in the text. We annotated 460 relations.

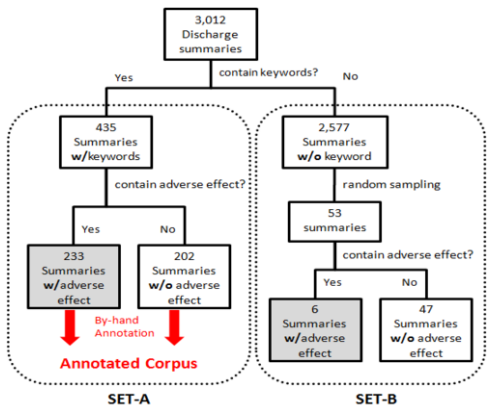

Figure 2 - Data Configuration

Table 1 - Set of Keywords

Stop, stepped, Change changed, adverse effect, side effect

Table 2 - Markup Scheme (Tags and Definitions)

Tag	Definition (Examples)
s (symptom)	An expression of disease or symptom: e.g. *endometrial cancer, headache*. This tag covers not only a noun phrase but also a verb phrase such as "<s>*feel a pain in front of head*</s>".
d (drug)	An expression of medication of administration of a drug. Some examples are *Levofloxacin, Flexeril*

Table 3 - Annotation Example

<d relation="1">*ridora*</d>*resumed because it is associated with an* <s relation="1"> *eczematous rash* </s>
<d relation="1">*ACTOS(30)*</d> *brought both* <s relation="1">*headache*</s> *and* <s relation="1">*insomnia*</s>

* If a drug has two or more side effects, then they share the same ID. For example, *ACTOS* has two symptoms in the following:

Methods

The prior section explained that 7.7% of the records contain adverse-effect information. This section describes the standard two-step NLP used to extract information automatically.

[1] That amount roughly corresponds to summaries accumulated in one month at the University of Tokyo Hospital.

[2] All private information was removed from them. The definition of private information was referred from the HIPAA guidelines.

STEP 1: Term Identification

First, terms in records are identified. This task is similar to Named Entity Recognition (NER). Therefore, we use a state-of-the art NER method (conditional random fields (CRFs)), which has been shown to provide high performance for many tasks, such as part-of-speech tagging [1], text chunking [3], information extraction [4], and named entity recognition [5]. The detailed manner is described in a previous report [6].
In learning, we use standard parameters[3] and features as presented in Table 4. The only difference between the previous studies and this method is the dictionary feature.

STEP 2: Relation Identification

Then, the system decides which drug caused which symptom. For this identification, we compared two methods; a pattern based method, and a Support Vector Machine (SVM) based method.

Table 4 - Features for Term Identification

Lexicon & Stem	Target word (and its stem) and its surrounding words (and stem). The window size is five words (-2, -1, 0, 1, 2).
POS	Part of speech of TW and its surrounding words (-2, -1, 0, 1, 2). The part of speech is analyzed using a POS tagger[4].
DIC	A fragment for the target word appears in the medical dictionary MedDRA/J [7] consisting of covered 47,665 terms (lower level terms), and a drug name list (30,085 terms), which comes from drug package inserts [8].

Table 5 - Relation Identification Algorithm

```
1: procedure Relation_Identify (D, S, K, n)
2: for each drug d in D do
3:     for each symptom s in S do
4:         for each symptom k in K do
5:         pattern_based_identifier (d, s, k, n)
```

* *D* is a set of drugs in the target record; *S* is a set of symptoms in the record; *K* is a set of keywords shown in Table 1; *n* is the parameter of the pattern (window size)

Pattern based relation identifier: The procedure is presented in Table 5. The system judges whether each extracted term pair (*d* and *s*) has an adverse effect relation or not. The judgment is based on heuristic-rule-based patterns (Table 6).

Table 6 - Patterns for Relation Identification

*d*s*k*	*s*d*k*	*k*s*d*
*d*k* s*	*s*k*d*	*k*d*s*

"*" represents a wildcard for *n* words, where *n* is a parameter of window size

[3] *f*=3 *c*=1.5 window size=3
[4] http://chasen-legacy.sourceforge.jp/

For example, given the example in Figure 3, the pattern "*d*k*s*" identifies an "*ACTOS-edema*" relation. Although the pattern is simple, it might suggest the difficulty of the task.

SVM based relation identifier: The SVM based method utilizes features as shown in Table 7 instead of patterns. The features come from words from a drug and a symptom. For example, we regard "*but stop for relief of the*" as a "word chain" feature in the Figure 3. For training, we regard a pair of a drug and a symptom sharing the same relation id as a positive sample, and the other pairs as negative samples. We utilized an RBF kernel, which has two parameters (C and gamma). We checked the performance with various parameter settings.

Table 7 - Features for Relation Identification

Symptom Lexicon	A symptom term
Drug Lexicon	A drug term
Word Chain	A series of words between a symptom and a drug.
Distance	A distance (the number of characters) between a drug term and a symptom term.

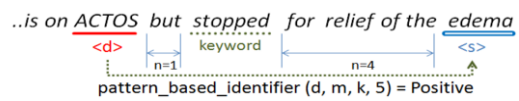

Figure 3 - Relation Extraction Example

Experiments

We investigate performance of two types: (1) term identification, and (2) relation extraction. The experimental design is portrayed in Figure 4.

Experiment 1 (Term Identification)

Experimental Setting: We collected 435 Japanese discharge summaries, as described in Section 2.

Evaluation: We conducted experiments in a ten-fold cross validation manner. The performance is evaluated in the precision, recall, and *F*-measure attributable to the standard NE manner.

Results: Table 8 shows that we obtained all scores of more than 80%. This accuracy is higher than the Japanese NE task result (shown in IREX [10]) in which the best system's accuracy is *F*-measure of 0.68. That result indicates that the term identification in records is easier than the other tasks.

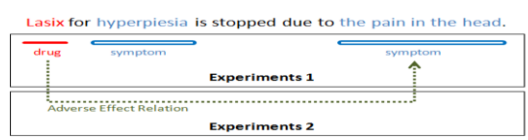

Figure 4 - Experimental Design

Table 8 - Term Identification Results

	Precision	Recall	*F*-measure
s (Symptom)	0.855	0.802	0.828
d (Drug)	0.869	0.813	0.840

Experiment 2 (Relation Identification)

Experimental Setting: Because this experiment specifically examines relation identification performance, we adopt an oracle setting, wherein terms in a text are identified correctly.

Evaluation: The evaluation manner is identical to that in Experiment 1; ten-fold validation, precision, Recall and *F*-measure. We compared two methods: pattern-based (PTN) and SVM based (SVM). We checked the performance of various parameters. The F-measure curve in SVM is shown in Figure 5. We checked the possible combinations of two parameters and picked up the highest f-measure points (Table 9).

Results: Both PTN and SVM F-measures were lower than 0.65, indicating this is difficult task. Especially, SVM obtained a significantly lower performance than PTN (p=.05). One of the reasons is the amount of training data (especially positive data) is too small to capture the complex phenomena.

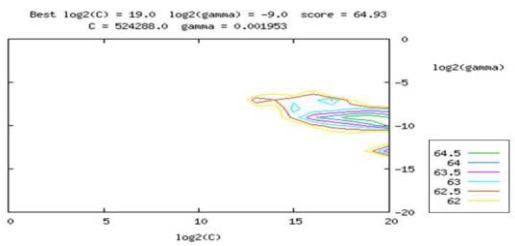

Figure 5 - F-measure in Various Parameters (C & gamma)

Table 9 - Relation Identification Results

	Precision	Recall	F-measure
PTN	0.411	0.917	0.650
SVM	0.576	0.623	0.598

Discussion

The experimental results revealed two salient facts.

1. How much information related to adverse effect is included in discharge summaries?

From the material, we infer that about 7.7% of the summaries contain information related to adverse effects.

2. To what extent are adverse effects extracted automatically?

The overall accuracy is estimated using the combined accuracies in experiment 1 and experiment 2: (accuracy of syndrome identification) × (that of drug) × (that of relation identification). Table 10 shows the result. Although the accuracy is insufficient (see precision 0.30), the proposed method (both SVM and PTN) could control the balance of precision and recall (Figure 6), which enables several practical applications appear promising: automatic mining under a high-precision setting, or pre-processing for human checks under the high-recall setting.

Table 10 - Results of Overall Accuracy

PTN	Precision	0.301 (=0.855 × 0.869 × 0.411)
	recall	0.597 (=0.802 × 0.813 × 0.917)

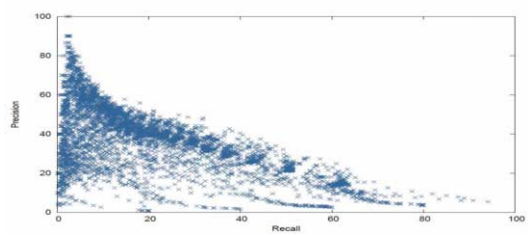

Figure 6 - Precision & Recall curve in SVM

Remaining problems

Training data: Compared with term identification, relation identification has low accuracy, which degrades the overall accuracy. Usually, the relation identification is solved using a machine learning approach (see a series of shared tasks [8]), we use that approach only slightly because adverse effects are rare events in records (the positive data are few).

Future studies should (1) increase training data to incorporate machine-learning techniques, or (2) apply another technique that works with small samples, such as active learning.

Variants: Another problem is orthographic variants. A typical example is "*WBC decrease*", "*WBC depression*" or "*reduced WBC*" that share the same concept, but which have different expressions. Such variants engender serious problems in the symptom-aggregating process. In the future, normalizing techniques are highly desired.

Demonstration System

The presented system is available on the web (Figure 7). The annotation guidelines and sample corpora are also downloadable.

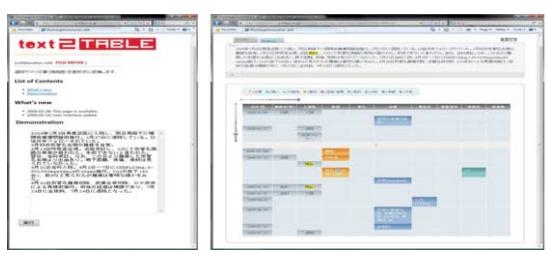

Figure 7 - Demonstration System

Related Work

Adverse Event/Effect Database

To date, several adverse effect databases are manually maintained, such as ARRS and GPRD.

The Adverse Event Reporting System (ARRS) is a famous adverse event database that is designed to support the FDA's safety program for all approved drugs. Reporting of adverse events from the point of care is voluntary in the United States. The current version of AERS contains 4,000,000 reports. The General Practice Research Database (GPRD) is a large database of medical records (over 3.6 million patients in the UK).
Compared with the large databases described above, the data in this study are few and have low reliability. However, the automatic technique is highly desired considering the rapidly growing use of new medicines. We believe that the proposed automatic approach will be useful.

Related Natural Language Processing Studies

1. *Term Identification*
Recent term identification uses machine-learning techniques such as Support Vector Machine (SVM) [2] and CRF [1]). Because of such trends, such techniques are also used in a clinical context [11,12]. We use the same approach as that in a previous study [11]; it effectively works with our corpus.

2. *Relation Identification*
Relation identification has drawn much attention from various fields: Information Extraction (IE) fields such as MUC [13] and ACE [14], semantic relations (such as Semantic Relation tasks at SemEval2007 [15]) and Protein–Protein Interaction ontology. In all fields described above, machine-learning-based approaches using annotated corpora are popular.
This study deals with low-frequency phenomena (adverse events). Therefore, machine-learning approaches suffer from a paucity of positive data. As described in the *Discussion* section, we must solve this problem.

Conclusion

The method described in this paper extracts adverse drug events from texts in records. First, we annotated 435 discharge summaries with adverse effect information. Then, using the corpus, we investigated how much the current NLP system extracted the information. The results revealed that 7.7% of the records contain adverse event information; 59% of them (4.5% in all) were extracted (recall 59%; precision 30%). This result is encouraging, especially considering the massive and continually accumulating amounts of records. In the future, a high precision method is highly desired.

Abstract

Quality assurance is a major task with regard to Electronic Health Records (EHR). Currently there are only a few approaches explicitly dealing with the quality of EHR services as a whole. The objective of this paper is to introduce a new Meta-Model to structure and describe quality requirements of EHRs. This approach should support the transnational quality certification of EHR services. The Model was developed based on interviews with 24 experts and a systematic literature search and comprises a service and requirements model. The service model represents the structure of a service whereas the requirements model can be used to assign specific predefined aims and requirements to a service. The new model differs from existing approaches as it accounts for modern software architectures and the special attributes of EHRs.

Keywords:

Electronic health record, Service, Quality, Requirements, Meta-model

Introduction

The idea of comprehensive Electronic Health Record had its origin in the early 90s and was first - amongst others - discussed by Waegemann (see e.g. [1]). Since that time a great number of projects and efforts were dedicated to the development of this basic idea. This fact has still not changed but the recent past shows that more and more of the research that was conducted is introduced in real life environments. Particularly Scandinavian countries are on the cusp of introducing EHR systems or at least parts of it (e.g. Denmark [2, 3]).

The success of such an EHR introduction is – apart from the mere technical questions – strongly dependent on the definition and fulfillment of a variety of different requirements on a functional and non-functional level. The definition respectively the coordination of such requirements is extremely difficult. This is due to several factors such as different norms and standards, legislation, different strength or heterogeneity of stakeholders within a country etc.

The general question in this context is: How can the quality of EHR services be defined? Basically, quality can be defined as the degree to which a set of inherent characteristics fulfills requirements (technocratic definition) [4]. But the actual definition and characterization of EHR quality poses a problem, as the large heterogeneity in existing requirements or tacit knowledge makes it difficult to define a consolidated set of characteristics that has to be fulfilled.

As the conceptual design and prototypical implementation were in the center of interest till the recent past, there aren't many initiatives so far that focus on the quality neither of EHRs nor on quality of EHRs as a whole. Quality approaches such as the ones from CCHIT [5] or EuroRec [6] have a very strong functional focus; the IHE again solely focuses on interoperability. Other more generic approaches such as FURPS+ [7] or the ISO 9126 [8] do not account for the specific requirements of EHRs.

The paper presents a Meta-Model to describe and structure quality requirements for EHR services. The model serves as a basis during/after requirements engineering as well as for potential quality certifications. It should increase, amongst others, transparency and comparability between systems and aims at an increase of the quality of requirements description and structure. Furthermore, potential users should be supported during the selection process of different EHRs. The approach also accounts for the particular characteristics of modern EHRs such as service oriented architectures, heterogeneous requirements, different vendors or interoperability.

Methods

The Meta-Model for quality requirements that is described in this paper was developed as part of an extensive research project that started in 2007 with the aim to support transnational quality certification of EHR services. The Meta-Model is part of a comprehensive framework including a large requirement repository (> 1200 EHR specific requirements), a language to formally represent the structural model, a thesaurus and a model to categorize requirements, a process model etc. To develop the model an expert survey and literature analysis in the middle of 2008 was conducted.

Data collection - Literature analysis

To collect all relevant publications for the data analysis PubMed, IEEExplore, Google and ACM Digital Library were used. The search was targeted towards publications on software quality and software certification with regard to electronic medical records in general.

The following initial list of keywords or keyword combinations was used: software, quality, software engineering, certification, software model, Health Record, Standards, EHR certification and EHR quality. This initial list of keywords was obtained by selecting relevant MeSh-Terms. Through the analysis of the documents found during the process further keywords and document sources were discovered and subsequently used. In total 400 sources were found of which 63 sources were relevant for this work.

Data collection – Expert survey

The expert survey was designed as qualitative problem-centric interviews. 50 Experts from the domains of legislation, standards, norms, data security, industry and science were initially selected. An expert was defined as a person that works in the field of clinical information systems for more than 3 years and is actively involved in the development (design/implementation) of Electronic Health Records. In total, 26 experts all over Europe (special focus on German-speaking and English-speaking countries) were questioned about general as well as detailed requirements regarding quality certification of EHR services. We applied the concept of theoretical saturation to both, the literature analysis as well as the expert survey, meaning that we stopped the research as the analysis of interviews and documents did not yield fundamentally new results.

Data analysis

Documents that were retrieved were analyzed by two independent reviewers. In the first step documents were roughly judged regarding quality and content. This was done by selecting scientifically published (peer-reviewed conferences, journals etc.) documents only and analyzing their abstract. Reviewers afterwards discussed their results to match all discrepancies in selection that occurred.

Selected documents as well as the results from the expert survey were analyzed in detail. Techniques of qualitative content analysis as described e.g. in [9] or [10] were used to derive quality requirements for EHR services.

Results

The following paragraphs describe the different elements and sub-models of the Meta-Model as well as general Meta-Model constraints. The Meta-Model is divided in two interdependent sub-models, a service model and a requirements model. This separation better reflects/distinguishes the structure of a service from its requirements. The service model is therefore used to describe the structure of an EHR service, whereas the requirements model is used to structure the requirements of EHR services. It is important to notice that the Meta-Model is not aiming at the definition or selection of specific requirements for an EHR service, but rather as a method to structure requirements.

Initial Situation and Model Constraints

To be able to represent EHR services, their structure and requirements using a Meta-Model the actual complexity of EHR services with regard to their structure had to be reduced resulting in different constraints, definitions and relations.

Summarizing these results a service is defined as an application program that runs on a (hardware) device using different communication means and transmitting various content by these means. Services may use other services to provide certain functionality. For this purpose services communicate with other services bi-directional, exchange information and compute information. Infrastructure neither communication infrastructure nor devices are of interest with regard to the current Meta-Model. Also Services that are needed to execute EHR services (e.g. operating system) are not part of the Meta-Model.

Service Model

The Service Model is used to describe the EHR service with its basic structural components aiming at the later, structured assignment of requirements. The Service Model defines an EHR service as the sum of the services that it consists of respectively that it uses to provide certain functionality. It is not regarded as a monolithic entity (see Figure 1). Such an approach is particularly important for the representation of applications that are based on service-oriented architectures where services may use different and sometimes even changing services in different physical or logical locations to provide functionality.

The root element of the Service Model is a certain service. Different structural elements and sub-elements (such as Application-Logic-Element, User-Interface-Element etc.) are assigned to this root element depending on the components a service consists of. All possible Elements that may be assigned are displayed in Figure 1. These structural elements are used as containers to assign different elements from the requirements model and subsequently specific requirements (see Requirements Model below). All structural elements of the service sub-model are categorized either as external or internal visible from the viewpoint of the service.

When a specific service is modeled using the service model not all of the structural elements need to be used. This is solely dependent on the requirements that are modeled for a service (see chapter Example of use). Figure 1 describes the Service Model and contains all structural elements defined (see also Figure 2).

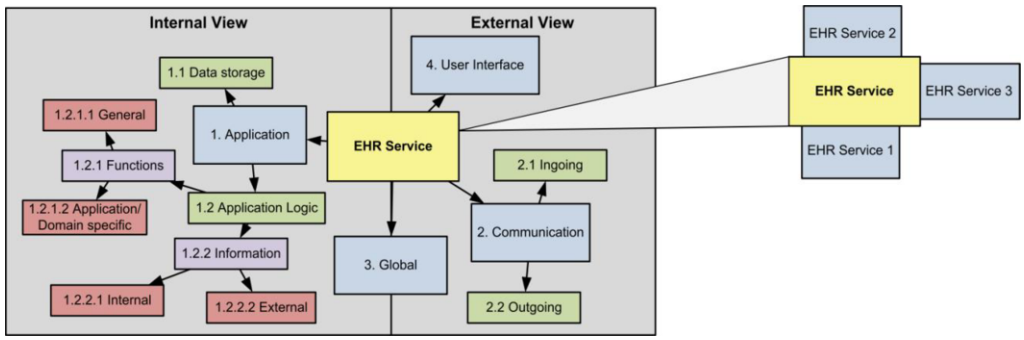

Figure 1 - Service Model

The EHR Service consists of / uses different services to provide its functionality (in this case three). The Arrows define a hierarchical order within the structural elements of the model. Colors represent the hierarchical layers. All structural elements are either part of the internal or external view except the Global-Element

Requirements Model

Whereas the service model describes the structure of a service, the requirements model describes and structures specific requirements that were selected for a certain EHR service. The basic idea of the Requirements Model is to define requirements on different levels of abstraction and to link dependent requirements.

The model consists of four basic elements: quality objectives, generic requirements, implementations and metrics. These elements are mainly determined by the content they represent and their sensitivity with regard to change during lifetime of a service. See Figure 2 for the elements of the Requirements Model and their relationships.

Quality objectives

These elements mainly have two functions they define long lasting objectives regarding the quality of a service and they are used to group generic requirements and other quality objectives. Quality objectives can be assigned to more than one other quality objective if applicable. A Quality objective needs to have at least one generic requirement to be assigned.

Generic Requirements

A generic requirement is used as a container for actual requirements that are assigned to an EHR service.

The main purpose is to describe a certain requirement with the objective of stating what has to be implemented / fulfilled by the service. One or more implementation elements can be assigned to a generic requirement. If a generic requirement has no implementation elements assigned then it is necessary to assign at least one metric.

Implementations

Implementation elements contain rules or references to certain existing rules such as standards or norms which describe how generic requirements must be implemented. Every implementation element must link to at least one metric element.

Metrics

Metrics are again rules or references to rules that in this case describe procedures how requirement elements respectively implementation elements can be checked for their fulfillment. Metrics do always have a certain type. So far a metric may be of one of the following types: value, presence, rate and combined type.

Sensitivity regarding the change of Requirements

As all elements were described regarding content and structure so far it is also of major importance to reflect the elements against the background of change during the lifecycle of an EHR service.

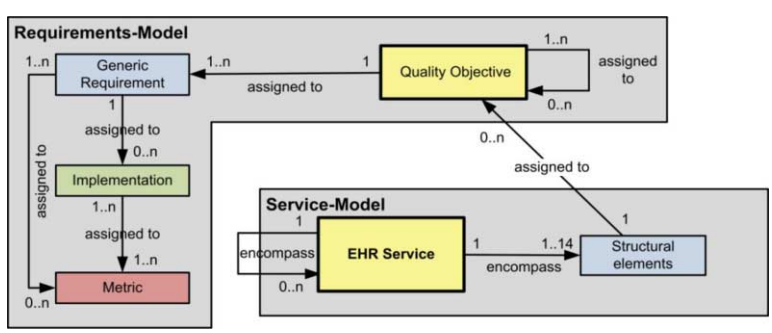

Figure 2 – Summary of all Elements and Interdependencies

With regard to requirement changes quality objectives are intended to face much smaller changes over time therefore they are highly suitable to describe medium and/or long-term aims. Generic requirements are subject to greater changes and represent medium-term aims. Implementations are suitable to describe the current state of the art and subsequently short-term aims. Figure 3 illustrates this matter schematically.

The requirements model, the service model and their interdependencies are summarized graphically in Figure 3.

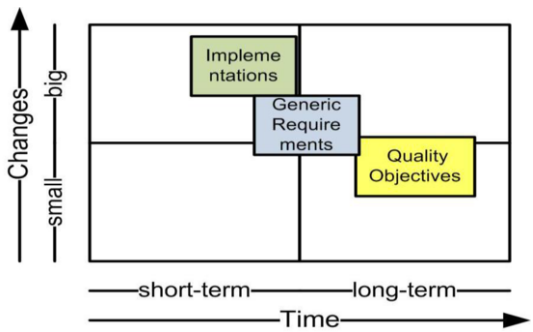

Figure 3 - Requirement Model Elements in Dependence of Time and Change

Example of Use

To illustrate the use of the Meta-Model a brief example is shown in Figure 4 and Table 1. The EHR service that is modeled is a Diabetes Diary which features a glucose meter import service, a web portal for additional data entry / display and a chart service to plot the results gathered as well as other services not mentioned here (see Figure 4). The services that compose the diary are not offered by the same organizations. The diary and the web portal belong to organization C, the chart service is offered by organization A and the Import service by organization B who also offers the glucose meter.

The import service which is displayed in the figure in detail as part of the diary does not make use of all structural elements of the service model. As the import service doesn't have a user interface or doesn't store data the corresponding structural elements are not modeled for the service.

Other services offered by the diary do have a user interface such as the web portal service. Therefore the structural element 'User Interface' is modeled for the portal service. Table 1 contains exemplary and randomly selected user interface requirements for such a service taken from the requirements repository which was also established as part of this project. The requirements are structured according to the requirement model (QO – Quality Objective; GR – Generic Requirement; IP – Implementation). Table 1 points out that all requirements used have a unique, service-independent ID to identify them.

The unique and service-independent identification is especially important for the comparison and consolidation of different services and their requirements.

Table 1 – Exemplary and randomly selected requirements for the User-Interface-Element of the Portal Service
(Legend: QO – Quality Objective GR – Generic Requirement; IP – Implementation)

Requirements Web Portal Service User Interface
QO - The interface should be user friendly (UI57)
GR - The user interface should be context sensitive (UI12)
QO - Forms should be user friendly (UI32)
GR - Forms should be structured (UI39)
GR - The user interface should be consistent (UI19)
IP - Icons should be unambiguous and conform to industry standards (UI86)
IP - The fonts should be consistent and easily readable (UI124)
IP - Screen item placement should be predictable (UI432)
GR - The user interface should be customizable (UI213)
IP - Font size should be customizable (UI17)
IP - Icon placement should be customizable (UI83)

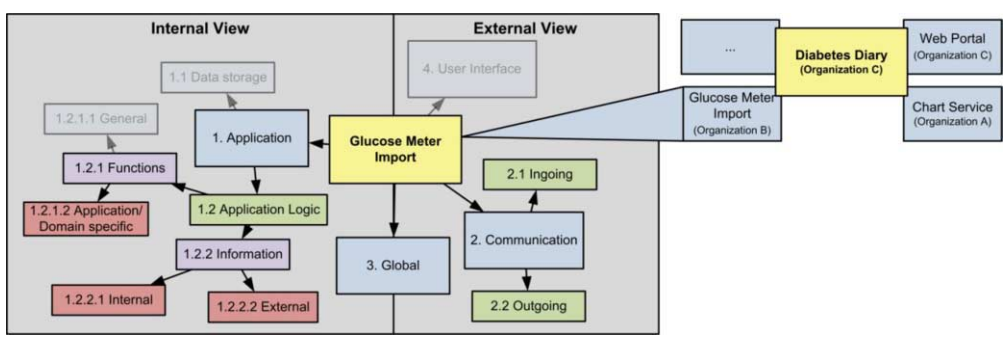

Figure 4 - Brief Example for the Service Model of a Diabetes Diary Service
Structural elements colored in grey (e.g. User Interface) are not used / applicable for this service

Discussion

SeReM^2 as presented in this paper is a Meta-Model that supports quality assurance as well as requirements engineering during the lifecycle of an EHR service. In comparison to existing EHR specific certification approaches such as the ones from the CCHIT [5] or EuroRec [6] or general software quality approaches e.g. Dromey [11], Boehm [12], FURPS+ [7] or the ISO 9126 [8] our approach features significant differences/advantages.

Complex structures and increased transparency

In general it is easier to represent complex service structures especially those based on service-oriented architectures. Interdependencies of different services that provide certain functionality are transparent.

It is not necessary to mix requirements of different services. Composed services can clearly be separated in terms of their requirements but not completely separated.

The afore mentioned approaches do not regard a service as the sum of different other services and therefore do not or only in a limited way offer these possibilities.

Better maintenance and comparability of requirements

Due to the classification of requirements in different levels of granularity the change process during the lifecycle of a service is better supported. Requirements can be discussed and changed on different levels improving the integration of different stakeholders in the definition and maintenance of requirements.

Comparison of different services and their requirements is supported as requirements are more structured. This is particularly true as requirements are split in different levels.

Existing approaches mainly categorize requirements but do not differentiate within requirements.

Selected further advantages

The model supports the inheritance of requirements for different services. This is the basis for requirements patterns for specific services such as web portal service. The model can be used to represent both, the requirements and the attributes of a service.

Limitations and drawbacks

So far the Meta-Model was used to model and structure requirements for a system run by the TILAK (Tyrolean Federal Hospitals) which is used by general practitioners to retrieve doctor's letters, laboratory and radiology findings. It is also used as a basis for the development of an EHR certification approach within ProRec Austria and is used to model requirements for the selection of specific EHR services by the Wiener KAV (Vienna Hospitals Association). So far all tests were successful but to fully proof the model more tests especially with complex systems are indicated.

At the moment there is also little tool support to implement the model for real system. The majority of the modeling tasks have to be carried out manually.

The approach does not support the user with guidelines regarding the categorization and actual structuring of specific requirements.

Exploiting UMLS Semantics for Checking Semantic Consistency among UMLS concepts

Halit Erdogan[a], Esra Erdem[a], Olivier Bodenreider[b]

[a] *Faculty of Engineering and Natural Sciences, Sabancı University, Turkey*
[b] *US National Library of Medicine, NIH, Bethesda, USA*

Abstract

Objectives: To quantify semantic inconsistency in UMLS concepts from the perspective of their hierarchical relations and to show through examples how semantically-inconsistent concepts can help reveal erroneous synonymy relations. Methods: Inconsistency is defined in reference to concepts from the UMLS Metathesaurus. Consistency is evaluated by comparing the semantic groups of the two concepts in each pair of hierarchically-related concepts. A limited number of inconsistent concepts was inspected manually. Results: 81,512 concepts are inconsistent due to the differences in semantic groups between a concept and its parent. Four examples of wrong synonymy are presented. Conclusions: A vast majority of inconsistent hierarchical relations are not indicative of any errors. We discovered an interesting semantic pattern along hierarchies, which seems associated with wrong synonymy.

Unified medical language system, Semantic consistency.

Introduction

Capsule of adrenal gland is an anatomical concept found in the Foundational Model of Anatomy (FMA) and the NCI Thesaurus. In the FMA, it is defined as a subclass of *Capsule*. Once integrated in the Unified Medical Language System (UMLS), *Capsule of adrenal gland* (C1181304) appears as a child of the concept *capsule (pharmacologic)* (C1181304), for which "*Capsule*" is also a name. Of course, *Capsule* is an ambiguous name used by both anatomy and pharmacology specialists. In fact, a search for "capsule" in the UMLS yields 4 concepts (Table 1). Surprisingly, none of these concepts pertains to macroscopic anatomical structures.

The issue here is both the absence in the UMLS of a concept for the membranous layer surrounding an organ and the wrong association in the UMLS Metathesaurus of this meaning with the pharmacologic concept *capsule (pharmacologic)*.

We stumbled upon this error while exploring the UMLS Metathesaurus for creating lists of drug form terms in preparation for the i2b2 Challenge in Natural Language Processing for Clinical Data on Medication Extraction[1]. We were surprised to find anatomical concepts such as *Capsule of adrenal gland* in the descendants of the concept *Solid Dose Form* (C1378566).

Table 1-Four concepts for Capsule in the UMLS

Name	CUI	Sem. Type	Sem. Group
capsule (pharmacologic)	C0006935	Biomedical or Dental Material	CHEM
Capsule Dosing Unit	C1706433	Quantitative Concept	CONC
Capsule Shape	C1704652	Qualitative Concept	CONC
Microbial anatomical capsule structure	C1325531	Cell Component	ANAT

Quality assurance in biomedical terminologies is an active field of research [1]. Various research groups have investigated quality in the UMLS, addressing issues including terminological cycles [2], ambiguity of concepts [3, 4], concept categorization [3, 5]. Consistency across hierarchies has been addressed by [6], while [7] have studied the consistency of Metathesaurus relations against Semantic Network relations. More recently, the semantic groups have been used for analyzing the consistency of Metathesaurus relations [8]. Most closely related to our work is a study of the validity of concepts associated with multiple semantic groups [9]. Our current work uses the same approach to assess the validity, not of single concepts, but of pairs of hierarchically-related concepts.

The objective of this paper is to quantify semantic inconsistency in UMLS concepts from the perspective of their hierarchical relations and to show through examples how semantically-inconsistent concepts can help reveal erroneous synonymy relations. The specific contribution of this paper is to leverage the semantic groups for identifying inconsistencies and to consider not only the semantics directly ascribed to a concept, but also the semantics it inherits from its ancestors.

[1] https://www.i2b2.org/NLP/Medication/

Background

The Unified Medical Language System® (UMLS®) [10] includes two sources of semantic information: the Metathesaurus® and the Semantic Network. The UMLS Metathesaurus was assembled by integrating some 150 source vocabularies. It contains more than 2 million concepts, i.e., clusters of synonymous terms coming from multiple source vocabularies identified by a Concept Unique Identifier (CUI). More than 36 million relations are recorded between these concepts. Several types of relationships among concepts are recorded in the Metathesaurus: parent / child of (PAR / CHD) and broader / narrower than (RB / RN) essentially correspond to hierarchical relations, while the other relationships are associative. More than 7.5 million hierarchical relations are represented in the Metathesaurus.

The Semantic Network is a much smaller network of 135 Semantic Types (STs) organized in a tree structure [11]. Each Metathesaurus concept is assigned at least one ST. Groupings of STs, called semantic groups (SGs), represent subdomains of biomedicine such as "Anatomy", "Chemicals & Drugs", and "Disorders" [12]. Each ST belongs to one and only one SG.

Version 2009AA of the UMLS was used in this study, after removing cycles from hierarchical relations in the Metathesaurus.

Methods

Computation

We say that a UMLS concept is *inconsistent* if the following two conditions hold for the concept:

- it belongs to two different semantic groups (except CONC) either directly or via its ancestors;
- it does not have any inconsistent ancestor (i.e., the inconsistency of the concept is not due to inheritance, it is original).

Therefore, to compute all inconsistent concepts, we need some method to find all the ancestors of a concept and their semantic groups, and check the inconsistency of each ancestor.

A naïve method to find all the ancestors of a concept and their semantic groups can be described as follows:

1. for each concept, compute all its ancestors;
2. for each ancestor, check that it is not inconsistent;
3. if no ancestor is inconsistent then check for each pair of ancestors whether they belong to different groups; else quit.

However, there are over 2,000,000 concepts in the Metathesaurus and some of them have too many ancestors (over 800); and thus it may not be practical to generate all of them at Step 1 above. Note that, to check the inconsistency of each ancestor at Step 2, we can apply the three-stage method above recursively: for each ancestor, find its ancestors and their semantic groups, and check the inconsistency of its ancestors, and so on.

Considering that a slight modification of the UMLS graph or a slight modification of the definition of inconsistency requires a new sequence of computations from the very beginning (that is, we may not reuse the previous results), we need to find more efficient methods that do not require programming efforts from the user and that can handle recursion.

We introduce a new method for computing inconsistent concepts: first, we divide the set of all UMLS concepts into smaller sets (e.g., of size 20,000); then, for each set, we compute in parallel all ancestors of its elements in the whole UMLS graph that are not inconsistent. Therefore, we compute the inconsistent concepts, as we compute their ancestors and check their inconsistency.

We have realized this method using a computational methodology, called Answer Set Programming (ASP) [13, 14]. The idea is to define the ancestors of concepts, and the inconsistent concepts by means of (possibly recursive) rules, and then call an existing ASP system (e.g., the ASP solver CLASP) to find inconsistencies based on these definitions. Figure 1 shows a sample ASP definition of inconsistency for a set of concepts. Since recursion is allowed in ASP, we can define hierarchical relations (e.g., descendant); we do not have to enumerate all descendants in advance. Furthermore, since ASP has default negation (not), we can define original inconsistencies without generating all paths to their ancestors.

Evaluation

One of us (OB) performed a detailed review of 200 inconsistencies involving the semantic groups "Anatomy" and "Chemicals & Drugs", groups in which the "capsule" error was originally observed. In addition, we performed a casual inspection of the four major groups of inconsistencies in order to identify categories of inconsistencies.

```
% define the ancestors C2 of a concept C1 in set n
descendant(C1,C2) :- childOf(C1,C2), set(n,C1).
descendant(C1,C2) :- descendant(C1,C), childOf(C,C2).

% define the concepts C with some inconsistent ancestor C1
descendantOfInconsistent(C) :- descendant(C,C1), inconsistent(C1).

% identify the groups G (except conc) that a concept C belongs to,
% such that C is not a descendant of an inconsistent ancestor
groupOfConcept(C,G) :- hasCategory(C,T), hasGroup(T,G), set(n,C), G != conc.
groupOfConcept(C,G) :- not descendantOfInconsistent(C), descendant(C,C1), hasCategory(C1,T), hasGroup(T,G), G != conc.

% a concept is inconsistent if it belongs to two different groups G and G1
inconsistent(C) :- groupOfConcept(C,G), groupOfConcept(C,G1), G<G1.
```

Figure 1- Defining inconsistencies in ASP

Results

Quantitative results

We identified 334,396 inconsistent concepts. Out of these concepts, 81,512 concepts are inconsistent due to the following reason: the semantic group of the parent differs from that of the source concept, and no ancestor of the concept is inconsistent. For example, the concept *Anti-purkinje cell antibody* (C0443893) is one of these 81,512 concepts: its semantic group is "Chemicals & Drugs", whereas its parent *Purkinje Cells* (C0034143) belongs to the semantic group "Anatomy"; furthermore, no ancestor of *Anti-purkinje cell antibody* is inconsistent.

The distribution of the number of inconsistencies by semantic group of the source concept is listed in Table 2. Two semantic groups, "Disorders" and "Physiology", represent less than 25% of all UMLS concepts, but concentrate 80% of the inconsistencies. This map of inconsistencies can be further refined by looking at the semantic group of the parent of inconsistent concepts in reference to that of the source concept. The number of inconsistent *child_of*[2] relations by semantic group of the source and parent concepts is listed in **Error! Reference source not found.**. For example, 10,732 inconsistent *child_of* relations involve a concept from the semantic group "Disorders" as the child and a concept from the semantic group "Anatomy" as the parent. Note that the number of inconsistent *child_of* relations is slightly higher than the number of inconsistent concepts, since a given concept can be involved in several inconsistent *child_of* relations.

Table 2-Distribution of the number of inconsistencies by semantic group of the source concept

	SG (source)	# conc	%
ACTI	Activities & Behaviors	750	1%
ANAT	Anatomy	809	1%
CHEM	Chemicals & Drugs	3482	4%
CONC	Concepts & Ideas	--	
DEVI	Devices	2463	3%
DISO	Disorders	30704	38%
GENE	Genes & Molecular Sequences	158	0%
GEOG	Geographic Areas	22	0%
LIVB	Living Beings	995	1%
OBJC	Objects	1084	1%
OCCU	Occupations	134	0%
ORGA	Organizations	236	0%
PHEN	Phenomena	4257	5%
PHYS	Physiology	34366	42%
PROC	Procedures	2052	3%
	Total	*81512*	*100%*

[2] We use a generic *child_of* relationship to represent the various kinds of hierarchical relations in the Metathesaurus (child and narrower than).

Wrong synonymy relations

Including the "capsule" error, four errors of the same type were identified by manual review of pairs of concepts with inconsistent *child_of* relations, two of which involve the semantic groups "Anatomy" and "Chemicals & Drugs".

Capsule. The concept *capsule (pharmacologic)* (C1181304), presented in the introduction, belongs to the semantic group "Chemicals & Drugs". Its parents include anatomical concepts such as *Membranous layer* (C2338391), as well as drug concepts (e.g., *Pill* (C0994475)). Analogously, mixed semantics is found among its children, with anatomical concepts such as *Capsule of adrenal gland* (C1181304) and drug concepts including *Oral Capsule* (C0991533). In order to address the wrong synonymy in *capsule (pharmacologic)*, a distinct concept should be created for the anatomical capsule, with a semantic type from the semantic group "Anatomy".

Retina / Retinol. The concept *Retina* (C0035298) from the semantic group "Anatomy" has two types of parents. On the one hand, there are concepts from the semantic group "Chemicals & Drugs", such as *All-Trans-Retinol* (C0087161) and *Aldehydes* (C0001992). On the other, there are concepts from the semantic group "Anatomy", including *Wall of eyeball* (C0929391). Except for some lexical resemblance, it is unclear what caused this error. However, there seems to be a wrong synonymy issue, because three of the children of *Retina* are also from the semantic group "Chemicals & Drugs" (e.g., *Retinal | bld-ser-plas* (C1972646)), while most children are anatomical concepts (e.g., *Retinal Neurons* (C2350331)).

Two additional examples of wrong synonymy involving other semantic groups than "Anatomy" and "Chemicals & Drugs" were identified in this study.

California plant / state. The concept *California* (C0006754) belongs to the semantic group "Geographic Areas." Its parents include *Pacific States* (C0524818) from the same group and *Geraniaceae* (C0996910) from the semantic group "Living Beings." (*Geraniaceae* is a family of plants comprising, among others, Geranium). Analogously, the children of *California* include other geographic areas (e.g., *San Francisco* (C0036152)), as well as plants (e.g., *California macrophylla* (C1891810)). This is another example of wrong synonymy. A distinct concept should be created for the plant family *Geraniaceae*, with a semantic type of Plant, from the semantic group "Living Beings."

Transdermal / Skin Patch. The concept *Transdermal Patch* (C0991556) from the semantic group "Chemicals & Drugs" has two types of parents. On the one hand, there are several drug concepts, including *Patch drug form* (C0994894). On the other, parents such as *Lesion* (C0221198) belong to the semantic group "Disorders." Moreover, the same mixed semantics can be observed among the children of *Transdermal Patch*, including the drug *Nicotine patches* (C0358855) and the clinical finding *Café-au-Lait Spots* (C0221263). The issue here is probably wrong synonymy related to "patch". A distinct concept should be created for the clinical finding *Skin Patch*, with a semantic type from the semantic group "Disorders."

Other types of inconsistencies

In addition to wrong synonymy, several other types of inconsistencies were observed. In contrast to wrong synonymy, the other inconsistencies could be expected, since the UMLS is **not** an ontology of biomedicine, but rather a terminology integration system, which, by design, does not impose a semantic model to the terminologies it integrates [15].

Many terminologies such as the Medical Subject Headings (MeSH) organize their concepts for a particular purpose rather than based on ontological principles. For example, the hierarchical organization of MeSH descriptors supports information retrieval. In other words, MeSH hierarchical relations often reflect "aboutness" rather than subsumption [16]. One such example is the relation from the Japanese version of MeSH between *Orphan Drugs* ("Chemicals & Drugs") and *Drug Industry* ("Organizations").

The absence of formal distinction between types and roles in the semantic network can lead to inconsistent usage. For example, *Sheep milk* is considered food ("Objects"), while its parent concept *Milk* is considered a body substance ("Anatomy").

We also found cases where concept categorization (i.e., the semantic type assigned to the concept) is arguable or inconsistent across similar concepts. One such example is *Animal Disease Models*, categorized as a disease model ("Disorders"), while its parent concept *Animal Model* is (wrongly) categorized as an animal ("Living Beings").

Finally, differences in granularity between hierarchically-related concepts are at the origin of some of the inconsistencies. For example, *Iodothyroglobulin* ("Chemicals & Drugs") and *Thyroid colloid* ("Anatomy") are definitely related, but their relationship – between molecular and macroscopic structures – is mereological in nature (part-whole) rather than taxonomic (is a).

Our casual review of four large sets of inconsistencies revealed that inconsistencies in these groups were essentially homogeneous within a group. We examined inconsistencies from the pairs of semantic groups with the largest number of inconsistent relations (10-20,000 per group). These are DISO-ANAT, DISO-PHYS, PHYS-PROC and PHYS-CHEM.

Most inconsistencies from DISO-ANAT come from the integration of the clinical synopses from OMIM in the UMLS. In a clinical synopsis, disorders are grouped under anatomical structures (e.g., *Mouth Neoplasms* under *Oral cavity*). The corresponding relations, i.e., *Mouth Neoplasms* to *Oral cavity*, have been integrated as *child_of* relations in the UMLS, leading to this type of inconsistency.

Inconsistencies from DISO-PHYS generally correspond to pairs of hierarchically-related concepts in which the parent represents a quality being observed in a clinical observation (e.g., *Texture of hair*), categorized with a semantic type from the semantic group "Disorders" and the child one possible value for this quality (e.g., *Coarse hair*), categorized with a semantic type from the semantic group "Physiology."

Inconsistencies from PHYS-PROC and PHYS-CHEM are related to the hierarchical organization of concepts in LOINC, i.e., how LOINC groups laboratory tests and clinical observations into classes, resulting in links between observations (from the semantic group "Physiology") and chemical analytes (e.g., class of sodium plasma tests) or procedures (e.g., class of observations related to organ transplantation).

In these four groups, the large numbers of inconsistencies are generally not indicative of errors, but reflect the fact that, although used to form hierarchies, these relations are not hierarchical in nature (i.e., not is-a). Consistency checking based on the semantic groups assumes that the *child_of* relations are subsumption relations, which is not the case here.

Discussion

UMLS semantic framework

With its multiple layers, Metathesaurus concepts, semantic types from the Semantic Network and semantic groups, the UMLS provides a unique framework for checking semantic consistency. Semantic consistency between the Metathesaurus

and the Semantic Network requires valid relations between concepts, valid relations between semantic types and accurate categorization of the concepts with semantic types. In contrast, inconsistency is indicative of a problem with at least one of these elements, but further analysis is required to pinpoint the problem causing the inconsistency. Additionally, semantic consistency between the Metathesaurus and the semantic groups (through the semantic types) is predicated upon the validity of the disjunction axioms added to the Semantic Network by the semantic groups.

As we have argued in the past [7], taking advantage of the UMLS semantic framework in the editing environment used by the Metathesaurus editors would help expose semantic inconsistencies at the time of editing and would likely reduce the number of such inconsistencies in the Metathesaurus release. Using the semantic groups rather than the semantic types for consistency checking seems appropriate in the context of terminology integration (as opposed to ontology development).

Lessons learned

One of the lessons learned from this analysis is that the approach we propose for identifying inconsistencies lacks specificity. In fact, we showed that a vast majority of inconsistent hierarchical relations are not indicative of any errors, but simply reflect the use of hierarchical relations for knowledge organization purposes.

Interestingly, we discovered that the four instance of wrong synonymy we identified exhibit a pattern of "semantic rupture" along the hierarchical structure of the terminology. By semantic rupture, we mean that, along one hierarchy, the source concept belongs to a given semantic group, its parent concept does not, but one of the parents of the parent belongs to the same group as the source concept. For example, in the "capsule" example presented earlier, the source concept is *Capsule of adrenal gland* ("Anatomy"). Its parent is *capsule (pharmacologic)* ("Chemicals & Drugs"), one parent of which is *Membranous layer* ("Anatomy"). We hypothesize that such pattern of semantic rupture might be a good marker for wrong synonymy and we plan to test it in future work.

Empirical Analysis of the Reduction of Medical Expenditures by eHealth

Yuji Akematsu, Masatsugu Tsuji

Graduate School of Applied Informatics, University of Hyogo, Japan

Abstract

This paper aims to examine reduction of medical expenditures by utilizing the system of Nishi-aizu Town, Fukushima Prefecture. The town office has been implementing it since 1994 and keeps receipts on medical expenditures of its approximately 4,000 residents paid by National Health Insurance for 5 years from 2002 to 2006. We select (1) users; and (2) non-users of the e-health system, and by comparing their medical expenditures, we examine: (i) difference in medical expenditures between two groups; and (ii) negative correlation between medical expenditures and the length of usage of the e-health system. We find that total medical expenditures of users are larger than those of non-users, whereas by restricting to lifestyle-related illnesses such as high blood pressure, cerebral infarction, strokes, and diabetes, medical expenditures of users are found to be smaller than those of non-users. The results we obtained here provide the rigorous economic foundation of the e-health system.

Introduction

Medical expenditures in Japan have been increasing steadily, amounting to 32.4 trillion yen (US$ 324 billion) in FY (Fiscal year) 2006. More than half (51.1%) of all expenditures are for persons over 65 years old. Japan is aging rapidly; the current percentage of the elderly (over 65) is more than 20%, and is expected to increase further in the near future. In order to cope with this situation, various policy measures have been taken, including requiring patients to bear more of their own medical costs. Japan has a well-organized universal public health insurance system; due to increasing medical expenditures and deficits in the medical insurance budget, however, the percentage of costs reimbursed by public health insurance has been falling. The elderly have thus been forced to pay more of their medical expenditures.

Another measure to reduce medical expenditures is to focus on prevention of diseases: the healthier people become, the fewer medical costs are required. One example is to enhance consciousness toward health and efforts to prevent illness. To this end, the government has taken initiatives such as the "Health Japan 21 Project." Recent campaigns against Metabolic Syndrome are another example, as this condition is thought to increase risks of hypertension or hyperlipidemia. The campaigns against Metabolic Syndrome include recommending regular physical exercises and monitoring of diet and nutrition. Prevention of illness through health maintenance is an important measure to reduce medical expenditures.

This paper focuses on the utilization of IT (Information Technology) to maintain health. We examine the e-health system, which monitors the health condition of the elderly at home by transmitting users' health-related data, such as blood pressure, ECG (Electrocardiogram), and blood oxygen, to a remote medical institution via a telecommunications network (see [4]). At present, more than 100 Japanese local governments are using such systems, using a total of more than 12,000 devices – more than any other country. The system is equipped with a simple device that records an elderly person's condition or a patient's illness in graphs that are then used for diagnosis and consultation. Reports sent by the medical institution also help users to enhance their daily health consciousness and maintain good health. These positive effects have been identified through field surveys in [4-6].

The e-health system in Japan has already passed the experimental stage, and is entering the diffusion stage. The government expects the e-health system to reduce medical expenditures and enhance the provision of public health and welfare. The authors have been conducting research on economic evaluation of the e-health system, by estimating the system's benefits in terms of WTP (Willingness to pay) and comparing benefits with costs (see [2, 3, 5-7]). Without confirmation of the e-health system's cost-effectiveness, the system's future sustainability cannot be guaranteed.

In this paper, we make an attempt to prove a statistically significant relationship between medical expenditures and the introduction of the e-health system by examining the case of Nishi-aizu Town. Reasons for this region's selection are: (i) the town has been making full use of the system since 1994; (ii) Nishi-aizu is the second town in Japan to introduce the e-health system, and since then the system has been the core of its health, welfare, and medical services; (iii) the authors conducted field research on this town in 2000, 2001 and 2006; and (iv) data on Nishi-aizu's medical expenditures is readily available. The town office has medical receipts paid of National Health Insurance for its 3000 residents for recent five years from 2002 to 2006 (for Nishi-aizu Town, see [1]).

The paper format will be a section explaining the basis of Nishi-aizu e-Health system, and then a section explaining how we construct the data for a survey analysis, and the method of analysis. The next section provides characteristics of sample, which based on our survey data. After that, the results of survey are presented, followed by rigorous statistical analysis by making use of Ordinary Least Squares method (OLS). Brief concluding remarks are stated in the final section.

Data and Methodology

Selection of Sample

As stated earlier, this paper examines the relationship between medical expenditures of Nishi-aizu's residents and the e-health system. According to the Japanese medical insurance system, which is organized and operated by the Ministry of Welfare and Labor, all people must be covered by one of several social health insurance systems. This paper focuses on people in Nishi-aizu who are covered by "National Health Insurance," since data on medical expenditures through this system are handled by local governments. National Health Insurance is not only for self-employed individuals such as farmers or owners and employees of small- and medium-sized firms, but also people who already retired.

One of the purposes of this paper is to compare medical expenditures between two groups such as (i) users and (ii) non-users of the e-health system from medical receipts of Nishi-aizu Town. Samples of two groups are selected according to the following way.

1) User group

We selected 412 users from the list of registered users in the town according year they registered. The total number of users and that selected as the sample is shown Table 1. Then we send questionnaires to them and 311 replies were received. Finally, after checking the replies, 199 replies remain as significant. The rate of valid reply is 48.30%.

2) Non-user group

We selected 450 residents who are covered by National Health Insurance out of total 3,528. Questionnaires were sent to 450 and we received 239 replies. Again by checking the replies, we had 209 significant replies. The rate of significant reply is 46.44%.

In sum, the total number of residents selected as the sample becomes 408. We checked their receipts from those stored in the town office, and total number of receipts of 3,528 residents who are covered by National Health Insurance is 160,000 for five years. It took 8 days for 18 students to picks up those of 408.

Receipt Data

The receipts of National Health Insurance of each month are kept at the town office, in which the data such as name and address of medical institution, birth date, name of disease, date of initial-visit, medicine, and score (amount) of medical treatment are described. In this paper, we use the following data: (i) name of resident, (ii) birth date, (iii) either regular outpatient treatment or hospitalized patient treatment, (iv) name(s) of major disease(s), (v) date of initial treatment, (vi) number of days needed for treatment, and (vii) cost of medical treatment.

Table 1 – e-health users

Year start using the system	Total number of users: Male	Female	Total	Users selected as sample
1994	9	11	20	20
1995	13	11	24	24
1996	8	14	22	22
1997	30	36	66	66
1998	13	15	28	28
1999	4	6	10	10
2000	8	11	19	19
2001	3	3	6	6
2002	6	7	13	13
2003	91	88	179	95
2004	53	69	122	95
2005	6	6	12	12
2006	2	0	2	2
Total	246	277	523	412

Characteristics of Data

The age distribution of users and non-users is shown in Table 2. As for users, more than half are age of 70s, while for non-users more than one third. Most of samples are age of 60s, 70s and 80s.

Table 2 – Age distribution of users and non-users

	User	Non-user	Total
40 - 49	2	0	2
50 - 59	14	23	37
60 - 69	45	67	112
70 - 79	92	76	168
80 - 89	46	37	83
Over 90	0	6	6
Total	199	209	408

According to Table 3, about 45% of users and 40% of non-users replied they have some kind of chronic diseases. The former has the higher rate than latter because suffering chronic diseases is strong incentive to use e-health service. This coincides with the property of other regions.

Table 4 indicated years of using the e-health system, and except less than one year, the numbers of users are not different in terms of years of use.

Table 3 – Having chronic diseases

	User	Non-user	Total
Yes	90	81	171
No	72	90	162
No reply	37	38	75
Total	199	209	408

Table 4 – Years of using e-health

Years of use	Number of user	
Less than 1year	6	3.0%
1-3	38	19.1
3-5	45	22.6
5-7	35	17.6
7-10	39	19.6
Over 10	36	18.1
Total	199	

Table 5 shows the relation between age and years of use. The longer the use, the older the users become. This is rather natural, longer use implies those users become old. Table 6 indicates the frequency of using the e-health service. Nearly 40% of users use it every day, while 24% use 3-4 times a week. More than 70% use at least one a week.

Table 5 – Years of using and average age

Years of use (years)	Average age (years)
Less than 1	71.3
1 - 3	68.9
3 - 5	70.3
5 - 7	74.8
7 - 10	74.0
Over 10	76.4

Table 6 – Frequency of using

Almost everyday	76	38.19%
3 - 4 times a week	47	23.62
1 - 2 times a week	20	10.05
1 - 2 times a month	23	11.56
Not use	25	12.56
No reply	8	4.02
Total	199	

Hypotheses and Model Specification

According to data discussed in the previous section, at first the following four hypotheses are presented.

- Hypothesis 1: Users of the e-health system have lower medical expenditures of lifestyle-related illness than those of non-users.
- Hypothesis 2: Users of longer practicing the e-health system have lower medical expenditures of lifestyle-related illness than those of non-users.
- Hypothesis 3: Users of longer practicing the e-health system reduce medical expenditures larger than those who use it shorter years if they extend usage one more years.
- Hypothesis 4: The e-health system there has more effect to people who have diseases than those who do not.

We tested these hypotheses based on the model as follows:

$$y_{it} = \alpha + X'_{it}\,\beta + u_{it}$$
$$u_{it} = \lambda_t + v_{it} \qquad (1)$$

where y_{it} denotes the medical expenditures of life-style related diseases, X_{it} indicates each characteristics such as sex, age, education, employment (dummy variable), number of family living together, income, and chronic diseases (dummy variable). We utilized the panel data analysis with one-way fixed effect model where λ_t denotes the year dummy, because the system of calculating medical expenditures is changed every 2 years. Also, individual effect, or dummy might cause serious multicollinearity with each characteristics, so we control only time effect.

Results

Hypothesis 1

Table 7 shows the result of estimation of hypothesis 1 by taking medical expenditures restricted to lifestyle-related illnesses as a dependent variable. The explanatory variables are Sex, Age, Education, Employment (dummy variable), Number of family living together, Income, Chronic diseases (dummy variable), and Use dummy (e-health user). Variables which provide significant effect at the 1 % significant level are Sex, Age, Income, Chronic diseases, and User dummy; and number of family living together at the 5% significant level. The results of this estimation can be interpreted in the following way, in which one medical score is equivalent to 10 yen (US$ 0.1).

- Medical expenditures of e-health users are smaller than those of non-users by 15,688 yen (US$ 156.88) per year. This amount is 21.2% of average annual medical expenditures.
- Medical expenditures of residents with chronic diseases are larger than those without it by 33,440 yen (US$ 334.40) per year.
- Medical expenditures increase 2,197 yen (US$ 21.97) per year when they become one year older.
- Higher income residents have lower medical expenditures than low income group.

Table 7 – Result of estimation (Hypothesis 1)

	Coef.	Std. Err.	
Sex	1467.36	473.55	***
Age	219.67	29.12	***
Education	309.45	315.10	
Employment	95.86	501.79	
No. of family living together	289.24	126.34	**
Income	-19.09	4.08	***
Chronic Diseases	3344.00	476.34	***
User dummy	-1568.79	478.90	***
Constant	-10517.63	2378.58	***
Number of Obs.	1545		
R2 adjusted	0.0819		

***, **, and * indicate the 1%, 5%, and 10% significant level, respectively.

Hypothesis 2

Next, we present the second result by making use of OLS. In this estimation, we take medical expenditures of lifestyle-related illnesses as a dependent variable, and as for independent variable, sex, age, education, employment (dummy variable), number of family living together, income, chronic diseases (dummy variable), and years of e-health use. The estimation result is summarized in Table 8. Variables which provide significant effect at the 1 % significant level are (i) sex, age, income, chronic diseases, (ii) number of family living together at the 5% significant level, and (iii) years of e-health use at the 10% significant level. Again these results can be interpreted in the following way:

- Medical expenditures of lifestyle-related illness can be reduced by 1,133 yen (US$ 11.33) per year, if they extend using the e-health system one more year. The amount of reduction is 1.5% of average annual medical expenditures.

Table 8 – Result of estimation (Hypothesis 2)

	Coef.	Std. Err.	
Sex	1542.36	474.40	***
Age	223.57	29.65	***
Education	302.22	315.90	
Employment	127.48	503.50	
No. of family living together	257.77	126.99	**
Income	-19.24	4.09	***
Chronic Diseases	3315.44	477.95	***
Years of e-health use	-113.32	66.18	***
Constant	-11250.42	2411.04	***
Number of Obs.		1545	
R2 adjusted		0.0780	

***, **, and * indicate the 1%, 5%, and 10% significant level, respectively.

Hypothesis 3

The elasticity, which is is a rate of decrease according to the 1% of increase of years of use, becomes larger, as shown in Table 9. In other words, for users who utilize e-health for more years, additional one year use decreases more medical expenditures than for those who use it for less years.

- This implies that elasticity increases according to years of its use, and the years one uses the system, the larger the reduction in medical expenditures becomes. This is an amazing result and verifies effectiveness of the e-health system.

Table 9 –Elasticity (Hypothesis 3)

Years of e-health use	Elasticity
Non-user	0
0 – 2	-0.01323
2 – 4	-0.04161
4 – 6	-0.07279
6 – 8	-0.09959
8 – 10	-0.12806
10 – 12	-0.15044
Over 12	-0.18321

Hypothesis 4

Nishi-aizu Town distributed the devices according to the following criteria:

(i) Senior people with diseases

(ii) The senior who are recommended by doctors

(iii) People other than the above categories who have chronic diseases or recommended by doctors.

The town office recognizes effects of its e-health system, and especially, it expects the effect to people with chronic diseases. Here we attempt to verify whether the e-health system there has more effect to those than people who do not have chronic disease.

The result of this estimation is indicated in Table 10, which implies that variables such as sex, age, and income are significant in the estimation for people without chronic diseases, while variables such as the number of family and user dummy in addition to above variables of people without chronic diseases. Especially, the dummy variable for people without chronic diseases is not significant, which means that there is no significant difference in medical expenditures between users and non-users. For the estimation of people with chronic diseases, its p-value is less than 1 %, which indicates that there is great difference between two groups. In other words, we cannot identify the difference between two groups for healthy people, while the system has great effect to people with chronic diseases. Our estimation shows that the difference in medical expenditures is 37,942 yen (US$ 379.42). According to this result, the principle of distribution of the device to people is verified.

Table 10 – Result of estimation (Hypothesis 4)

	Without chronic diseases		With chronic diseases

Conclusion

This paper analyzes the relationship between medical expenditures and the e-heath system, which connects senior people at home and medical or health institutions by transmitting vital data via the telecommunications network. Even though the e-health system is simple, it contributes to promote health of senior people. This paper aims to verify empirically whether and how much it contributes to promote senior people's health by examining the system of Nishi-aizu Town, Fukushima Prefecture in Japan. The town office keeps receipts on medical expenditures of its approximately 4,000 residents in a paper form paid by National Health Insurance for 5 years from 2002 to 2006.

First, we can estimate from OLS that users' average annual expenditures per person related to lifestyle-related illnesses is smaller than that of non-users by 15,688 yen (US$ 156.88). This amount is about 21.2% of average expenditures of non-users. Second, if users utilize the system one more year, then the above expenditures decrease about 1,133 yen (US$ 11.33) per year, which is about 1.5% of the average expenditures. We also find that the amounts of the above decrease become larger, if the experience of using the system is longer. Finally, the e-health system there has more effect to those than people who have diseases.

Nishi-aizu Town used to suffer high death rates due to life-style-related illnesses, and it introduced the e-health system as a part of projects such as "Promoting Total Care", and "Challenge to 100 Years Old." The efforts of residents as well as staff engaged in these projects for nearly 20 years achieved medical expenditures significantly smaller than the national average. It should be noted that behind this success lies close collaboration of networks of health, medicine, and welfare. Nishi-aizu's experiences thus establish a model to reduce medical costs and improve health of the residents of other regions.

The increase in medical expenditures is common phenomena all over the world. There are two measures to cope with this; the utilization of IT in medical area and prevention from being illness (or maintain health). The e-health system can solve these issues. The results we obtained here provide the rigorous foundation of the e-health system.

Abstract

We propose a business rule management system that is used to optimize the dispatchment on a mass casualty incident. Using geospatial information from available ambulances and rescue helicopters, a business rule engine calculates an optimized transportation plan for injured persons. It automatically considers special needs like ambulances equipped for baby transportation or special decontamination equipment, e.g. to deal with an accident in a chemical factory. The rules used in the system are not hardcoded; thus, it is possible to redefine them on the fly without changing the program's source code. It is possible to load and save a rule set in case of a catastrophe. Furthermore, it is possible to automatically recalculate an already planned operation if it becomes clear that the rescue vehicles assigned are needed by a person with life-threatening injuries.

Keywords:

Mass casualty incidents, Online systems, Decision support systems

Introduction

Even though mass casualty incidents occur only rarely, they present a major challenge for medical personnel. While the number of injured complicates a fast decision on how to treat individual persons, dispatchment has to be done quickly in order to save lives. Thus, efficient means to support humans in managing mass casualty incidents are sought for.

In Germany, the EMS (Emergency Medical Service) is organized municipally [1]. Every municipality has its own infrastructure. Often they are using central PSAPs (Public Safety Answering Point) to dispatch rescue operations. These headquarters answer the emergency calls and assign vehicles and personnel provided by different local organizations such as hospitals or private emergency medical services. To improve communication among these headquarters and different organizations, special networks like the "Trauma Network North-West" have been founded [2]. These networks make it easier to organize transports of injured people to hospitals in neighboring areas. However, the methods used by this network only suit a limited number of patients.

In the case of mass casualty incidents, the patients are brought to a special place to conduct triage. After being prioritized, seriously injured persons are transported first [3]. This simplified system is not good enough because it does not consider special needs of the patient. A baby for example needs a specially equipped ambulance and a hospital that is able to treat it appropriately [4]. Besides, the available transportation should be used in the best way possible.

The requirements to a dispatchment system are similar to decisions done in business environments. We hence suggested using rule based systems to support the assignment of injured people to available vehicles or helicopters and their transfer to hospitals.

This paper is structured as follows. In the next section we show the project background. Then we outline the technical implementation and present results from the evaluation. Finally, we give a conclusion and sketch future work.

Project Background

The Trauma Network North-West is a union of 43 hospitals in north-western Germany and the Netherlands. Its main goal is to improve trauma care. In the TEAM project, emergency physicians are equipped with mobile devices to get a quick overview of the time needed by an ambulance to the nearest trauma centers. Furthermore, they are able to request a rescue helicopter, and see, if it is on the way and when it will arrive. Thus, they are able to decide which transport would be best for the injured. After selecting a hospital, his decision will be shown to an agent at the next PSAP who is able to accept or decline this suggestion [5].

The described procedure works well for one or two injured people, but in a case of a mass casualty incident, the emergency physician does not know all the circumstances to properly decide which transport would be best considering the whole situation. In such a case, only the agents at the PSAP are able to decide properly about transfers and destination hospitals. However, they do not have much time to decide on dispatching plans. Since a fast transport to hospitals can sig-

nificantly increase survival rates [6], agents need the means to work out plans without much delay or effort.

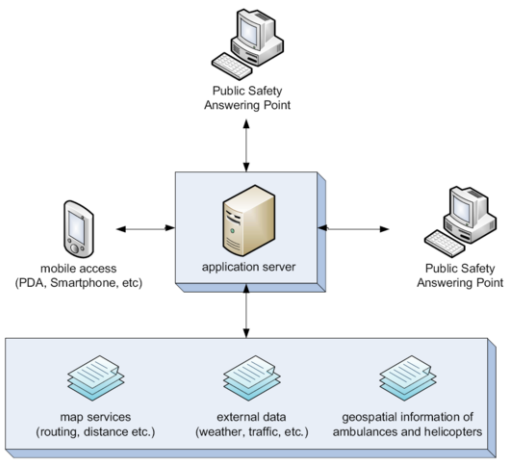

Figure 1- The technical architecture of the system.

Implementation Details

Technical Details

The software used on the server is written in Java and deployed to a central Tomcat application server. It is platform-independent and flexible [7]. Furthermore, the business rule system Drools [8] is included to provide the rule-based decision functionality. The rules can be edited with Guvnor, a web based rule editing tool [9]. The whole system is accessible online using a standard web browser. No proprietary software is needed on the client device.

External services are included in different ways. For example the "Rescue Track", a system to get geospatial information from rescue helicopters, is included as a XML-web-service (see Figure 2). In addition to its current location, its status is transferred via two-way radio [10]. The dispatchment system is able to recognize if the helicopter is available for another mission or if it currently carries a patient. Additionally, the estimated time for the helicopter to be available again can be provided by the system.

Also the mapping service which provides the geospatial information is included externally. It is possible to reconfigure the system to use a local installation easily [11].

In general, one of the advantages of external web services is their exchangeability. If a service is broken or discontinued, it is possible to get the needed data from another provider. This change can be done automatically in case of a failure or manually if it becomes clear that another service is able to provide more actual or detailed data. For that purpose multiple sources of external services can be provided in the system.

In addition to using the clients at the PSAP, it is possible to get access to the system with mobile devices such as PDAs or notebooks. This is useful to get a fast overview in a mass casualty incident at the accident site.

Rule Management

As outlined before, rules are edited by a special editing tool. (see Figure 3). The rules are written in a DSL (domain-specific language [12]) which is leaned against usual language and may include technical terms of the considered domain. A benefit value is allocated to every transportation possibility. This value is made up of the hospital's care level, the characteristics of the ambulance or rescue helicopter and the duration of the transportation. The rules are used to manipulate this value.

The screenshot in Figure 3 shows a rule that recommends an ambulance with special baby equipment for a patient with an age below two years. This rule causes ambulances with this equipment to be rated higher. Therefore, such an ambulance is rated higher if it is available. It however would less likely be assigned to an injured that is older than two years. The system tries to keep special equipment available if the medical conditions of patients that currently need help allow it. This means that it prefers available ambulances without special equipment that can transport an injured as fast as the one with the (not required) equipment could.

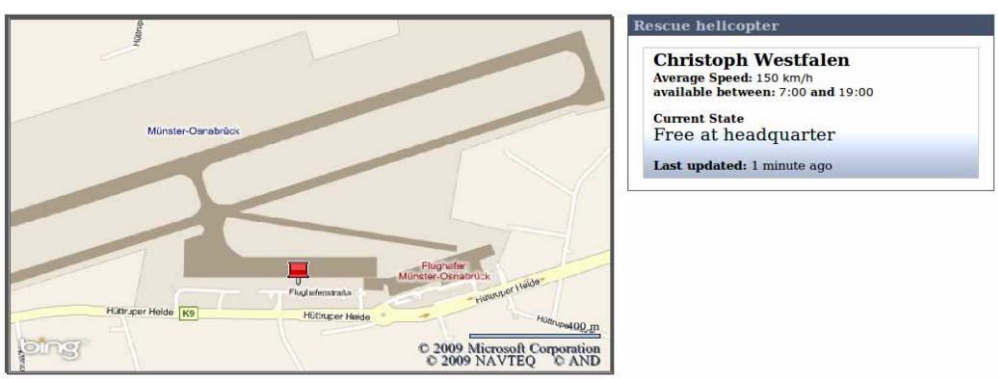

Figure 2- The rescue helicopter at its base.

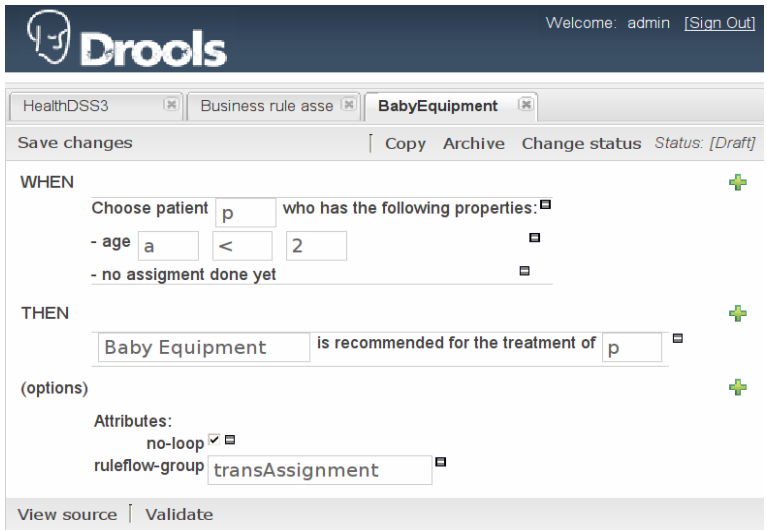

Figure 3- An example rule to assign an ambulance with special baby equipment.

In case of conflicting rules, the first rule that fits to the given situation is fired. Thus, there is no possibility of a deadlock situation. If no specialized rule fires, general rules will apply to ensure transportation for all patients.

Using this technique simplifies the creation and maintaining of rule sets to a level at which no knowledge in programming is needed. Furthermore, every user is able to validate them and to see how they work. The understanding of the rules is very important to create trust in the system. The rules can of course not be changed arbitrarily; we however suggest that a system that can be changed by authorized personnel in order to cope with new situation is suited for the complexity and criticality of disaster management operations.

New rules or entire rule sets are activated and deactivated with one mouse click in case of a mass casualty incident or disaster situation. This ensures that the dispatchment in these cases follows special rules, e.g. that vehicles for non emergency patient transfers are used as ambulances to deal with many injured.

Evaluation

To evaluate the execution time of the dispatchment program, two different rule sets have been run on a 1,6GHz Intel Core2Duo processor with 1GB of DDR2 RAM. Even with sophisticated rule sets the dispatcher gets an optimized result within about one second.

As shown in figure 4 using hard-coded rule preparation may increase performance significantly. But even without them calculation time grows only linear with the number of transportation possibilities. By using high performance hardware it is possible to decrease the calculation time to an acceptable minimum. Also the parallel execution of several calculations could be realized in a future version of the program.

Other factors for the execution time are external web services. If they are, for instance, used to calculate the time required by every transport possibility, they are called hundreds of times for one calculation and may slow down the dispatchment to an unacceptable rate. Therefore, the most important web services such as distance and routing calculation should be provided locally.

At all stages of the development, test runs were made by medically skilled personnel to verify the system. The results are promising and show that the dispatching system presented is able to enhance the dispatching system currently used.

Nevertheless, the presented system is in prototype stage. Further evaluation is needed before installation in time- or life-critical environments.

Conclusion

We presented a system for the dispatchment of casualties. By using a business rule management system it is possible to dispatch nearly every mission from an accident with only one injured to a mass casualty incident. The PSAP operators are able to get an optimized dispatching plan within seconds after a new emergency call is answered.

While the evaluation of the system is very promising, the system can be extended. For future purposes it is planned to include live GPS data from every vehicle involved in emergency services. This would allow even more precise routing and a better assignment of vehicles and injured.

To increase the performance of distance calculation between two positions it is possible to set up and run a local routing server. It is also conceivable to use the linear distance for the first optimization and then the real routing and traffic information for the few realistic transport possibilities only.

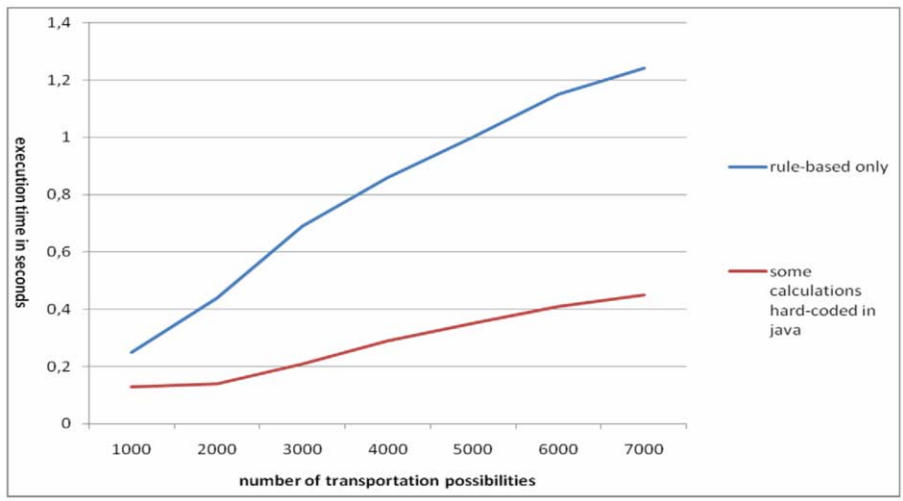

Figure 4- A partial hard-coded rule set may decrease execution time.

This would speed up calculation without losing precision. Furthermore, the local mapping web service can be extended to provide an intelligent visualization and a more sophisticated routing mechanism which includes the current traffic situation [13, 14].

In the next development step, the system will be included into the dispatching system of the Trauma Network North-West. In that project an emergency physician is able to suggest a destination hospital on a mobile device. Afterwards the PSAP agent receiving his request has to accept or decline it. The new dispatching system will assist the PSAP agent to rate these suggestions according to several characteristics like the current load of rescue vehicles and emergency physicians.

If the emergency physicians are equipped with mobile terminals in case of a mass casualty incident, they may be used for other purposes like an electronically health card [15]. Eventually, medical personnel could be equipped with multi-purpose mobile devices that allow for an even better treatment of injured.

Acknowledgements

We would like to specially thank the employees of the Fire Brigade Muenster [16], who allowed us to get a live view of their dispatching system and organization during normal operations and in a case of a mass casualty incident exercise.

[c] *Infection Control Program, University and Hospitals of Geneva, Switzerland*

Abstract

This article deals with data on nosocomial infections acquired in the Geneva University Hospitals. Goal of the work is to derive a model from a hospital-acquired infection (HAI) prevalence survey of year Y and apply them to a prevalence survey of years Y+1, Y+2. This analysis permits to evaluate the effectiveness of preventive measures taken after the prevalence survey in year Y. It also analyzes the robustness of the SVM algorithm on time-variable attributes. The model build on the dataset of year Y gives better results than in a previous study. The application of the model on the Y+1 and Y+2 prevalence surveys shows simultaneously improvements and deteriorations of 5 performance measures. This highlights the effectiveness of prevention and reduces the risk of HAI after the prevalence survey of year Y. We introduce a new method to detect redundancy in a dataset with the SVM algorithm.

Keywords:

Hospital infections, Program evaluations, Machine learning.

Introduction

A hospital is a facility providing medical care to sick people. Independent of the reason for admission, a patient may acquire new infections inside a hospital due to the presence of microorganisms. These hospital-acquired infections (HAI) usually appear 48 hours after the patient admission. The infectious agents can be transmitted from other patients or by health care workers during medical procedures. In Switzerland, 70'000 hospitalized patients per year are infected and 2'000 deaths per year are caused by HAI. Many prevention and surveillance programs are carried out to prevent and/or reduce the risk of HAI. A prevention program, for example, includes hygiene measures permitting to isolate or eliminate infectious agents such as washing hand before any contact with patients, the use of gloves, use of masks, disinfection, sterilization, etc. A surveillance program aims at detecting infections. *French et al.* proved that a repeated prevalence surveys is a valid and realistic approach for infection control and surveillance [1]. The prevalence of infection is the number of infected patients divided by the total number of hospitalized patients at the time of the study [2]. The infection prevalence rate can also be used as an indicator of the quality of patient care.

However, the HAIs are not always documented in the electronic health record (EHR) of the patients and the infection control practitioners have to carry out a survey to obtain the prevalence rate. For this purpose, the EHR of all hospitalized patients admitted for more than 48 hours are analyzed. If necessary, additional information is obtained by interviews with nurses or physicians in charge of the patient. This survey is performed during one to three months on a yearly basis at the University and Hospitals of Geneva since 1994. This survey is labor intensive and it cannot be carried out all year long.

In a previous study, we extracted the most important features of a HAI database allowing the prediction of an HAI infection [3]. Fisher's linear discriminant was used to evaluate the predictive power of these features and it provided good results. However, maximum margin classifiers such as support vector machine (SVM) are more appealing with respect to generalization performance from a theoretical viewpoint. A maximum margin classifier looks for an optimal hyperplane separating the training dataset so that the distance of training points to the optimal hyperplane is maximized. This supposes that the training data are separable. Finding the optimal hyperplane is equivalent to resolving the following optimization problem:

$$\min\left(w^T w\right) \textit{ subject to } y_i\left(w^T x_i + b\right) \geq 1 \qquad (1)$$

In the relation (1), w is a vector perpendicular to the hyperplane, b is a scalar value, $\left\{x_i \in \mathbf{R}^d, y_i \in \{-1,1\}\right\}_{i=1}^{N}$ are the training points, N the number of examples and d the number of variables. If certain conditions hold and using the Lagrangian formulation, the previous problem is equivalent to its dual (2), which is a quadratic optimization problem and which can be solved using several techniques.

A SVM is a maximum margin classifier using only points on both sides of the margin or support vectors (points x_i for which the Lagrangian multipliers $\alpha_i > 0$) to build a model.

$$\max_{\alpha \geq 0} \sum_i \alpha_i - \frac{1}{2}\sum_i \sum_j \alpha_i \alpha_j y_i y_j x_i^T x_j \quad st \sum_i \alpha_i y_i = 0 \qquad (2)$$

For non-separable training datasets, penalty variables ξ_i are introduced to soften the constraints of the maximum margin formulation (1). The penalty variables are drawn as follows: $0 < \xi_i \leq 1$ if the points are on the correct side of the hyperplane and $\xi > 1$ if the point is on the wrong side. A cost variable *C* is also introduced to control the trade-off between the width of the margin and the points within the margin. The goal of the SVM classifier is then to maximize the margin while minimizing the total sum of the penalties and thus the equation (1) becomes:

$$\min\left(w^T w\right) + C\sum_i \xi_i^p \; st \; y_i\left(w^T x_i + b\right) \geq 1 - \xi_i, \xi_i \geq 0 \qquad (3)$$

However, the dual problem is often solved because the duality theory provides a convenient way to deal with constraints. The dual optimization problem can also be written in terms of dot products permitting the use of the kernel functions. The kernel trick allows applying the maximum margin algorithm to a transformed version of a non-separable dataset (feature space) via a mapping function ϕ. The related dual problem can be expressed as:

$$\max_{\alpha} 2\alpha^T e - \alpha^T\left(G(K) + \frac{1}{C} I_n\right) \quad st\, \alpha \geq 0, \alpha^T y = 0 \qquad (4)$$

In the previous relation, e is the n-vector of ones, $\alpha \in \mathbf{R}^N$, *G(K)* the Gram matrix and defined by $G_{ij}(K) = [K]_{ij} y_i y_j = k(x_i, x_j) y_i y_j$, I_n is a diagonal matrix of 1 and $\alpha \geq 0$ means $\alpha_i \geq 0$ for all i=1,…,n. The transformation function ϕ is integrated in the definition of the kernel matrix *K*. One kind of such kernel is the Gaussian kernel or RBF kernel expressed as $K(x_i, x_j) = \phi(x_i)^T \phi(x_j) = e^{-\|x_i - x_j\|^2 / 2\sigma^2}$. For such a kernel, the misclassification cost *C* and the kernel parameter σ need to be optimized.

Many researchers consider SVM as one of the best classification algorithm due to its theoretical foundation based on structural risk minimization implying a better generalization performance [4]. However, SVM can provide bad results used with wrong parameters. The usual way to find the parameters of SVM is to scan a range of possible values of the parameters, evaluate the classifier with a data splitting methods such as cross-validation or bootstraping and then select those providing the best performance. A better method is to evaluate the SVM with the leave-one-out procedure during grid search. This process is expensive with respect to computation time and a more efficient way to choose the SVM parameters is to take advantage of the underlying theory especially the bound of the leave-one-out error.

For the SVM with an RBF kernel and in the case of non-separable training data, *Vapnik* showed that the leave-one-out error is upper bounded by $4R^2\|w\|^2$ (the radius margin bound) [4]. *R* is the radius of the smallest sphere containing all $\phi(x_i)$ and is a solution to the following optimization problem:

$$\max_{\beta} 1 - \beta^T K \beta \quad st\, \beta_i \geq 0, e^T \beta = 1$$

This bound of the leave-one-out error can be used to estimate the parameter σ of the RBF kernel and the soft margin parameter *C*. The reader is referred to [5] for a survey of SVM error bound estimation. To obtain the radius margin bound for non-separable training data, we perform the following change:

$\tilde{w} = \begin{bmatrix} w \\ \sqrt{C}\xi \end{bmatrix}$ and $\tilde{\phi}(x_i) = \begin{bmatrix} \phi(x_i) \\ y_i e_i / \sqrt{C} \end{bmatrix}$ as the i-th training data. The kernel function becomes:

$\tilde{K}(x_i, x_j) = K(x_i, x_j) + \delta_{ij}/C$, where δ_{ij} is the Kronecker symbol. The new radius margin bound is $\tilde{R}^2\|\tilde{w}\|^2$ where $\tilde{R}^2$ is the objective value of:

$$\max_{\beta} 1 + \frac{1}{C} - \beta^T\left(K + \frac{1}{C}\right)\beta \quad st\, \beta \geq 0, e^T \beta = 1 \qquad (4)$$

The relation (4) can be solved using optimization techniques such as the gradient descent algorithms [6]. The use of the radius margin bound to estimate the parameters of the SVM is attractive thanks to the speed of its resolution.

Even if preventive measures are taken along the year to reduce and/or prevent the risk of HAI, many signs and symptoms and/or risk factors remain reliable to diagnose an infection (e.g. antibiotics treatment, fever, use of devices such as catheter or urinary tract, etc.). The goal of this paper is to evaluate the robustness of the SVM with respect to generalization performance i.e. its capacity to predict future unseen prevalence surveys. For this purpose, we predict the presence of an HAI on patient enrolled in the 2007 and 2008 prevalence survey from a model build on the 2006 data. This evaluation can also provide an insight of the effectiveness of the preventive measures taken between two prevalence surveys. A longer-term objective is to build an automated prevalence survey tool using information within the hospital data warehouse.

Materials and Methods

Datasets and software

As introduced in the previous section, we use a 2006 prevalence survey to build the HAI model and the 2007 and 2008 prevalence surveys for evaluation. We use three versions of these datasets as did in a previous study [3]. The first dataset, called S, contains all features from the prevalence database: demographic information; admission diagnostic according to the McCabe score and the Charlson index classification; patient information at the study date (ward type and name, status of Methicillin-Resistant Staphylococcus Aureus portage, etc); and information at the study date and the six days before (clinical data, central venous catheter carriage, workload, infection status, etc). After a first data cleaning and binarization, this dataset contains 60 features and 1384 cases including 166 positive ones (11.99%). The second dataset, called S1, contains 20 features obtained after application of 2 feature selection

methods (information gain [7] and SVM RFE [8]). The third dataset S2 is obtained from S1 but without the fever and workload features as the values of these features are not systematically gathered in clinical practice. We also highlighted in our previous study the redundancy or the negative interaction of these two features with the others making the learning with the dataset S and S1 challenging. The 2007 (resp. 2008) prevalence survey contains 1528 (1467) unique cases including 153 (156) positive cases. The ratio of positive cases turns around 10% and 12% for the 3 years.

We use libsvm with L2 implementation (i.e. $p=2$ in relation (3)) and having a radius margin bound resolution implementation using gradient descent algorithm [9]. The software is executed on a linux machine having quad-processor of 2.33GHz frequency and 3Gb of memory.

Model selection and evaluation

We implement the same strategy as in our previous study: 105 random training and testing splits are created for S, S1 and S2. The number of splits is taken arbitrarily. The SVM parameters are obtained on 5 random training sets. The gradient descent algorithm is applied to each of the five training sets using 4 initialization points. For each of the initialization point, 3x5 cross-validations are performed and provide 60 couples of the SVM parameters. As the datasets present imbalance ratio on positive and negative cases, we arbitrarily correct the imbalance by taking equal numbers of positive and negative cases before performing cross-validations. The radius margin optimization may converge to the final SVM solution from each initialization point but we take the results having less absolute value of covariance on the 2 parameters.

The evaluation of the model on 2006 data is done on the 100 remaining training/testing splits i.e. 100 models are created with the best parameters and are evaluated on the corresponding test set. The mean of f-measure, precision, recall or sensitivity, specificity and accuracy over the 100 test sets is used as performance metric. The 2007 and 2008 prevalence data are also evaluated with the 100 models. The prediction of a case is the mean prediction over 100 models using a majority vote.

Results

Four initialization points are considered for model selection: $init1 = (e,1)$, $init2 = (e^2, e^2)$, $init3 = (e, e^{2^{-10}})$ and $init4 = (e^5, e^5)$ where e denotes the exponential function. The 60 SVM parameters of the dataset S (respectively S1 and S2) are obtained in 81 (respectively 56 and 53) seconds. Table 1 provides a summary of the obtained parameters with respect to their mean, median and standard deviation. The last line of Table 1 provides the absolute value of the covariance of the SVM parameters. All initialization points converge to the same value of C and $Sigma$ but the initialization point *init4* (respectively *init3* and *init4*) provides less covariance of the SVM parameters for the dataset S (respectively S1 and S2).

These best parameters are used to build 100 models on the 2006 prevalence dataset; the results are depicted in Figure 1 and more details can be found in table 2. The horizontal bar on the top of figure 1 indicates if the results obtained with S, S1 and S2 are not significantly different based on the Mann-Wilcoxon mean test. This is the case for precision, specificity and accuracy of S and S1 and the Sensitivity of S1 and S2.

The evaluation of these models on the 2006, 2007 and 2008 data based on the features used is summarized in table 2. The mean of the f-measure, precision, sensitivity, specificity and accuracy of the models are reported. Confusion matrices are also reported for an intuitive reading of the results (A1, A2, A3, B1, B2, B3, C1, C2, C3). The numbers in the confusion matrix is the rounded mean of true positive, true negative, false positive and true negative obtained over the 100 models.

Discussion

As we have seen in the previous section, the use of the radius margin bound is attractive for SVM model selection with respect to its computational efficiency. A cross-validation procedure can take days if the step of the variables is thin. The computational efficiency of the radius margin bound allows us to carry out more experiments with several values of the ratio between the positive and negative examples.

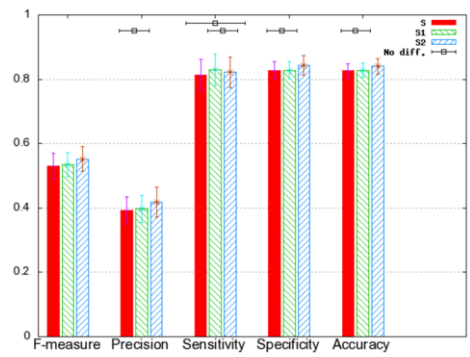

Figure 1 – Performance metrics of the models on the 2006 prevalence survey data.

For the 2006 dataset, the down-sampling methodology penalized the precision at the expense of recall. The obtained results are better than those from a previous study especially with the dataset S [3]. We have seen in the relations (1), (2), (3) and (4) that the SVM formulations are independent of the features present in the dataset. This was illustrated by the equivalence of the precision, sensitivity and accuracy between the datasets S and S1. The sensitivity of the three datasets S, S1 and S2 are equivalent and the other performance metrics of S2 are improved. From these results, we propose a new method to detect redundancy in a dataset using the SVM algorithm: if the removal of a subset of features keeps the recall unchanged while the other performance measures are improved then the subset of features has a negative interaction with the others. Many experiments are needed to confirm this proposal.

	ACCURACY		84.02%	ACCURACY		91.56%	ACCURACY		90.59%

With respect to our longer-term objective and with the features existing in S2 we can expect to have 41.87% true positive cases, which represent 82.13% of all infected patients when we build the model with the 2006 data. When the models were applied to datasets from 2007 and 2008, the "profile" of the performance changed: the sensitivity goes down considerably while the other performance measures increase. For the 2007 data, with the features in S2 we retrieved 61.32% true positive cases representing only 57.52% of infected patients. This drastic change of the performance measures can be explained as a consequence of the effectiveness of the prevention measures of the hospital. In other words, the prevention measures did not reduce the prevalence rate (around 10% from 2006 to 2008) but changed the signs and symptoms importance in our datasets and/or the risks of contracting the infections. A quick measure of the information gain followed by a chi-square filtering on the 3 datasets, as in [3] while we created the dataset S1, highlights a change in the order of the attributes and the appearance of new important ones. In machine learning this phenomenon is called "concept drift" [10]. Usually, the concept drift makes the model built on old data inconsistent with new data. If we want to use SVM to achieve our long-term objective, we need to take into account concept drift and implement, for example, an incremental method proposed in [11] i.e. exploiting the models build on previous prevalence survey datasets to predict actual cases.

Another important point in the analysis of the data warehouse data to support an automated prevalence system is the number of features to be extracted from the data warehouse, which was the topic of our previous study. A McNemar test (with Bonferoni's adjustment) was carried out in order to compare the performance obtained on the datasets S, S1 and S2 of years 2007 and 2008. This test indicates that the features present in S provide the best performance followed by S2. This indicates that if all the information of S can not be acquired for a new patient we have to use only those present in the dataset S2 (and not S1).

Conclusion

This study allows evaluating the robustness of SVM in a situation where the distribution of the features is changing over time. The sensitivity decreases and the other metrics increase when we apply a model build from datasets of the year Y on datasets of the year Y+1 and Y+2. This situation allows highlighting the effectiveness of the preventive measures taken after the prevalence survey in year Y. The use of the radius margin bound to select the SVM parameters was effective and allows us to carry out more experiments with respect to the manipulation of the ratio of positive and negative cases. We propose a new method to find redundant subsets of features in a dataset. We also found that the features present in S or S2 are necessary to build models. However it would be better to investigate the performance obtained using a dataset S3 including only common features obtained after the application of the information gain followed by a chi-square filtering on the prevalence datasets from the year 2006, 2007 and 2008. In the future, we plan to create models focusing on precision rather than the recall by using an asymmetrical misclassification cost. The main challenge is the adaptation of the radius margin bound for asymmetrical misclassification cost.

Abstract

Evaluating the burden of diseases treated in hospitals in terms of (co)morbidity and financial impact is a long standing problem. Proposed solutions often rely on very sophisticated medical registration systems that are less suitable for developing countries. The authors have developed a simple prototype method for calculating financial impact and comorbidity of clinical conditions treated in a Sub-Saharan hospital environment (CALCO method) using disability weights. The developed method has been tested for 4 major clinical entities (tuberculosis, nutritional deficiencies, perinatal complications and malaria) on a dataset of 8.309 electronically registered admissions between Februari 1st 2009 and September 1st 2009 at the Kigali University Teaching Hospital. Results suggest that the method consists an acceptable instrument for estimating the financial burden of diseases treated in the hospital and that the proposed algorithms provide a useful formal method for quantifying hospital-bound comorbidity. The CALCO method might find its use in future implementations of Performance Based Financing (PBF) programs in Africa.

Keywords:

Cost of Illness, Comorbidity, Financing, International Classification of Diseases

Introduction

In 2009, the Kigali Health Informatics Research Institute (KHIRI), a department of the Kigali University Teaching Hospital (CHUK), began working out a set of pathology grouping codes in an attempt to enable efficient evaluation of clinical activity in a typical sub-Saharan hospital. This collection of grouping codes [1] was called the KHIRI Pathology Grouping Set (KPGS) and is a bi-classified grouping system, based on ICD-10 [2,4] and ICPC-2 [3] classification standards, completed with a clinical thesaurus [6]. The code structure has been derived from ICD-10 chapters. KPGS is somehow similar to the well known concept of Diagnosis Related Groups (DRG), which has proven to be useful for health management mainly in the Western world. However, the usability of these sophisticated, expensive and complex systems in developing countries with different cultural, demographic and health environments [5], is at least questionable. The KPGS classification can therefore be considered a simplified African implementation of DRG's, addressing clinical conditions that better match local African health management requirements. [1,5,6]

The CHUK is using today the KPGS classification of clinical conditions for documenting a number of important health facility management parameters: length of stay, episode of care based co-morbidity, care delivery costs related to specificic clinical conditions etc. The Kigali University Teaching Hospital is a national reference hospital; a large number of patients are being admitted at the health facility with complex health conditions involving multiple diseases or clinical concepts. At present, no formal structured registration has been put in place to qualify the actual burden of different clinical conditions linked to one and the same episode of care. Therefore, every documented clinical condition for an episode of care is being considered of equal severity by the actual hospital information system. This means that if the hospital management wants to calculate disease related costs based on care deliveries linked to a specific episode of care, the only method being available today is to distribute costs equally over all diseases linked to the considered episode of care. Such an approach appears of doubtful use in approximating the real financial burden of disease and can therefore not be used for practical (disease related) management needs (e.g. predicting cost/income evolution related to major changes in incidence of specific diseases and modulating human resources assignment to hospital departments based on the typical disease profiles of the patients treated in those departements)

Being able to quantify the average (financial) burden of diseases would greatly improve the way care delivery costs can be distributed over different diagnoses that have been associated to one and the same episode of care. In that approach, severe diseases would get more admission days, care delivery costs (drugs, consumables, clinical acts) and overhead costs attributed to than mild or even insignificant diseases, reflecting much better the real cost distribution in complex multi-pathology clinical situations.

Materials and Methods

Purpose of the study

The purpose of this study was to:

1. Assign weight-scores to clinical conditions reflecting their importance in terms of financial burden and comorbidty.
2. Evaluate the usability of the assigned weight-scores for quantifying comorbidity related to clinical conditions
3. Evaluate the usability of the assigned weigt-scores for enabling realistic distribution of care delivery costs over associated diagnoses for hospital admissions

Study concept

This is a comparative retrospective study in which disease related cost of care information is studied including episode of care identification, length of stay (LOS), cost of provided care deliveries and diagnostic codes under ICD-10, ICPC-2 and KPGS classifications.

Materials

Since the 3th quarter of 2008, discharge diagnoses and detailed information about provided care deliveries are being systematically encoded for every in-patient in the CHUK hospital information management system (OpenClinic®). For the purpose of this study, we will use a dataset extracted from the hospital information system covering all hospital admissions between February 1st 2009 and September 1st 2009 (n = 8.309).

Methods

Step 1: Elaborate a method for attributing weight scores to all 167 KPGS codes in use at the hospital site. A weight score should ideally reflect the (financial) burden of a particular disease or clinical condition

Step 2: Develop a method for distributing care delivery costs/income proportionally over all clinical conditions linked to an episode of care based on corresponding weight scores (estimation of direct disease-related costs)

Step 3: Develop a method for distributing overhead costs proportionally over all clinical conditions linked to an episode of care based on corresponding weight scores (estimation of indirect disease costs)

Step 4: Develop a method for calculating the (financial) burden of diseases treated at the health facilty in a defined period of time

Step 5: Compare the results of financial burden of disease calculations based on a sufficiently large dataset using 3 different methods (evaluation of the developed method)

1. The method of equal distribution of care delivery costs over all clinical conditions linked to an episode of care
2. The newly developed CALCO method of weight score based care delivery cost distribution
3. The method of manually distributing care delivery costs over all clinical conditions linked to an episode of care. This is done by a clinician and is referred to as the 'golden standard'.

Results

Step1: development of a weight-scoring method

This method has been based on elements of the work of Murray and Lopez on the concept of Disability Adjusted Life Years (DALY's). The DALY is a metric that is used to quantify the burden of diseases, injuries and health risk factors in a single measure. It is based on years of life lost from premature death and years of life lived in less than full health:

$$DALY_x = YLL_x + YLD_x \quad (1)$$

Where:

$DALY_x$ = DALY for clinical condition x

YLL_x = Years of Life Lost due to premature death caused by clinical condition x

YLD_x = Years Lived with Disability caused by clinical condition x

= [Incidence$_x$] x [Average disability duration$_x$] x [weight$_x$]

The weight reflects the seriousness of the clinical condition on a scale from 0 (perfect health) to 1 (death) and therefore has been considered an excellent candidate for weight-scoring KPGS clinical conditions. The concept has been introduced by Murray and Lopez for the purpose of their Global Burden of Disease (GBD) study in 1990 and was reused in the WHO GBD study in 2004 [7] assigning a score to a total of 107 GBD-clinical conditions (diseases and injuries). For every concerned GBD-clinical condition, a link has been made to corresponding ICD10 codes, enabling mapping on KPGS-clinical conditions used at the Kigali University Teaching Hospital:

- 76 of the 167 KPGS codes could be directly mapped onto a GBD clinical condition. In these cases, the GBD weight-score was transferred to the corresponding KPGS code.
- 21 KPGS codes cover symptoms or circumstances influencing health and have not been assigned a weight-score
- The remaining 70 KPGS clinical conditions had no equivalent in the GBD study. They have been assigned weight scores by clinicians referring to a table of sample-scores as shown in Table 1.

Table 1 – Sample scores table

Score	Sample clinical conditions
0,00	Mild anemia, mild hearing loss
0,05	Upper respiratory infection, migraine, skin diseases
0,10	Sleeping disorders, moderate hearing loss, low back pain
0,20	Serious hearing loss, reumatoid arthritis
0,30	Tuberculosis
0,40	Neuropsychiatric disorders
0,50	HIV, mental retardation
0,60	Meningitis
0,70	Major depression, metastatic cancer
0,80	Terminal cancer, major neurologic handicap
0,90	Complicated CVA

Step 2: develop a method for distributing care delivery costs

The purpose of this method is to distribute care delivery costs/income proportionally over all clinical conditions linked to an episode of care based on corresponding weight scores. In order to do so, we have first developed the concept of *Comorbidity Index of a diagnosis d* (I_d). The index I_d expresses the importance of a diagnosis within the context of an episode of care and is calculated as follows:

$$I_d = \Sigma W / W_d \quad (2)$$

Where:

- I_d = Comorbidity index of clinical condition *d* for an episode of care.
- ΣW = Sum of all weight scores of all clinical conditions associated to the episode of care
- W_d = Weight score for clinical condition *d*

As a consequence, the value of I_d is at least equal to 1 (e.g. when diagnosis *d* is the sole diagnosis linked to the episode of care), greater values indicating a lower weight of the diagnosis within the global clinical picture of the admission.

Care delivery costs can then be assigned to particular diagnoses using the following formula:

$$C_d = \Sigma C / I_d \quad (3)$$

Where:

- C_d = Care delivery costs/income associated to a clinical condition *d* for an episode of care
- ΣC = Sum of all care delivery costs/income for the episode of care
- I_d = Comorbidity index of clinical condition *d* for the episode of care.

Step 3: develop a method for distributing overhead costs

The purpose of this method is to distribute overhead costs proportionally over all clinical conditions linked to an episode of care based on corresponding weight scores:

$$O_d = \frac{\Sigma O}{\Sigma \delta} \times \frac{\delta}{I_d} \quad (4)$$

Where:

- O_d = overhead costs associated to a clinical condition *d* for an episode of care
- ΣO = the total overhead costs of the health facility for the studied period of time
- $\Sigma \delta$ = the total number of admission days at the health facility in the studied period of time
- δ = duration in days of the episode of care
- I_d = Comorbidity index of clinical condition *d* for the episode of care.

Step 4: calculating the (financial) burden of disease treated at the health facilty in a defined period of time

The total financial burden of a diagnosis *d* at a health facility can then be described by the sum of direct disease-related costs (care deliveries) and indirect disease costs (overhead):

$$F_d = \Sigma C_d + \Sigma O_d \quad (5)$$

Where:

- F_d = the total financial burden of disease for diagnosis *d* over the studied period
- ΣC_d = direct disease-related costs, represented by the sum of all care delivery costs/income associated to a clinical condition *d* for all episodes of care in the studied period
- ΣO_d = indirect disease costs, represented by the sum of all overhead costs associated to a clinical condition *d* for all episodes of care in the studied period

The average financial burden per episode of care for a diagnosis *d* at a health facility would then be:

$$F_{da} = F_d / n_d \quad (6)$$

Where:

- F_{da} = the average financial burden of disease for diagnosis *d* per episode of care over the studied period
- F_d = the total financial burden of disease for diagnosis *d* over the studied period
- n_d = the total number of episodes of care with diagnosis *d* in the study period

Then we also calculate the average comorbidity index for a diagnosis *d* (I_{da}):

$$I_{da} = \Sigma I_d / n_d \quad (7)$$

Where:

I_{da} = the average comorbidity index for diagnosis *d* per episode of care over the studied period

ΣI_d = the sum of all comorbidity indexes for all diagnosis *d*-related episodes of care over the study period

n_d = the total number of episodes of care related to diagnosis *d* in the study period

Step 5: evaluation of the methods developed in steps 1 to 4

The main objective of this evaluation step was to compare the results obtained with the newly developed CALCO method to:

1. A 'golden standard' provided by manual analysis of the same dataset by a hospital physician, calculating F_d and F_{da} based on clinical analysis of every episode of care by manual assignment of care deliveries to individual diagnoses
2. The actual method of equal distribution of care delivery costs over all diagnoses linked to an episode of care (equal weight-score for all diagnoses)

Because no reliable data on care delivery costs was registered in the hospital database, only care delivery income has been taken into account for the evaluation. The comparison was performed for all cases of 4 major clinical conditions treated at the hospital in the period between February 1st and May 1st 2009. The results are shown in Table 2.

Table 2 shows that the total care delivery cost F_d and the average cost per episode of care F_{da} related to 4 important clinical conditions could be estimated by the CALCO method within an acceptable margin of error. The deviations from the results obtained by the 'golden standard' method vary from -8,7% to +8,4%. This certainly presents an important improvement compared to the method of equal distribution of costs over all episode of care-related clinical conditions where deviations vary between -22,1% and +78,4%. However, the improvement seems to be minimal for 'KPGS code 160: Perinatal complications'. This is primarily due to the fact that in the large majority of the related episodes of care, 'Perinatal complications' represented the sole diagnosed clinical condition. This fact is also documented by the low I_{da} score for the 'Equal distribution method', where I_{da} equals to the average number of diagnoses per episode of care related to 'Perinatal complications'.

In a second stage, we have calculated F_d and F_{da} for all clinical conditions treated at the CHUK in the period from February 1st and September 1st 2009 (8.309 episodes of care). Table 3 shows the top 10 of clinical conditions responsible for the highest accumulated costs in the study period (F_d). Table 4 ranks the top 10 clinical conditions according to the average cost of an episode of care (F_{da}).

Table 2 – F_d, F_{da} and I_{da} calculation method comparison

Method	F_d	F_{da}	I_{da}	deviation
KPGS code 01B: Tuberculosis (n=31)				
GS	$4.349,87	$140,32	-	-
CALCO	$4.214,60	$135,95	1,340	-3,1%
ED	$3.461,89	$111,67	1,730	-20,4%
KPGS code 01V: Malaria (n=42)				
GS	$3.338,90	$79,50	-	-
CALCO	$3.046,79	$72,54	1,250	-8,7%
ED	$2.601,26	$61,93	1,610	-22,1%
KPGS code 04D: Nutritional deficiencies (n=29)				
GS	$1.088,97	$37,55	-	-
CALCO	$1.180,11	$40,69	7,860	+8,4%
ED	$1.942,79	$66,99	2,220	+78,4%
KPGS code 160: Perinatal complications (n=93)				
GS	$9.922,18	$106,69	-	-
CALCO	$10.268,56	$110,41	1,360	+3,5%
ED	$10.377,26	$111,58	1,250	+4,6%

GS = Golden standard

ED = Equal distribution of care delivery costs over all diagnoses linked to an episode of care

Table 3 – Top 10 clinical conditions sorted by F_d

Clinical condition	F_d	F_{da}
15B: Pregnancy complications	**$86.819,06**	$122,97
19A: Fractures	**$66.431,48**	$254,53
140: Genito-urinary diseases	**$39.581,10**	$122,54

Discussion

The study provides evidence that the CALCO method enables calculation within acceptable margins of error of the financial burden of diseases in a hospital environment in Sub-Saharan Africa. CALCO has been completely integrated in the OpenClinic® hospital information system used at the CHUK health facility. All necessary calculations can be performed based on information registered in daily routine procedures and require no extra data-entry from hospital staff.

The method documents the distribution of hospital-bound income and costs over 167 clinical entities covering all ICD10 codes. This information can be used for multiple purposes:

- Detecting the clinical conditions that weigh most on the health facility budget. The actual study taught us that the top 3 clinical conditions in Table 3 account for more than 10% of the total hospital income.
- Estimating income/cost evolution related to disease incidence changes
- Comparing episode of care based costs for specific clinical conditions between health facilities
- Monitoring episode of care based costs for specific clinical conditions over time within a health facility

In the near future, the CALCO algorithms will be reused in a number of PBF implementations in Rwanda, notably for the health district of the City of Kigali. However, the actual CALCO method makes no use of international coding standards for procedures and care deliveries, limiting to some extent comparability of health facilities. Future developments will have to focus on this aspect.

Acknowledgments

Abstract

Preventing medication errors by using a barcode administration system has become prevalent in patient safety. Analyses of data captured by bar code systems provide opportunities to understand the actual situation at the point of care. Our study aims at understanding issues of medication safety as well as investigating measures taken to prevent medication accidents, by analyzing data captured by a bar code system and a personal digital assistant (PDA),. The barcode administration system named Point-of-Act-System implemented in Japanese Red Cross Kochi Hospital was designed to capture every activity at the bedside. Complete activity data captured by the system, which included injections, treatment and other nursing activity, as well as injection warning data, were used for our analyses. We describe the data and analyze them statistically to find potentially times of risk and to ascertain the relation between busyness and error. The injection warning rate as a whole was 6.1% on average. The results showed there was a negative correlation between the number of injections given and the injection warning rate (-0.48, $p<0.05$). The warning rate was low during the hours when a large number of injections were administered. The data also showed that a variation in activities being performed has a negative effect on medication safety. A bar code administration system is quite an effective way not only to prevent medication error at point of care, but also to improve patient safety through analyses of data captured by such a system.

Point of Care System, Medication Errors, Administration and Organization, Handheld Computer, Patient Safety

Introduction

It is widely believed that patient safety is an important issue for health care systems. Many organizations and hospitals have been accumulating information on patient safety and medication errors to improve patient safety based on the data collected. These data is accumulated to provide information on threats to patient safety. Such data are quite useful in understanding the threats and actual situations related to medication errors in hospitals. However, most of this evidence is basically information on medical accidents and incidents, compiled from voluntary reports submitted by medical workers. This information is not detailed enough to enable the discovery of underlying general principles, because accidents and errors are part of the reality in a hospital setting. A complete picture of the situation in hospitals, including details of medical accidents and incidents, is essential to identifying general causes and frequencies of medical errors. However, it is extremely costly to obtain by observational research sufficient data to enable an understanding of all the activities conducted in a hospital, and furthermore, the accuracy of data collected by observation is sometimes defective. Information technologies such as electronic medical records and barcode administration systems at the point of care have the potential to provide new opportunities for us to understand the overall picture of medical activities by digital capturing data on daily medications and patient care in hospital settings. By using information systems for all patients in all wards, data captured by the systems become useful resources to understanding various phenomena in medical situations and investigating research questions. In terms of medication accidents, the point of care is a potentially risky area in medical activities [1-3]. Therefore, data captured at the point of care is quite effective in understanding medication accidents. One potential candidate system for this is a barcode administration system for safe injections and medication. Barcode medication administration systems prevent medication errors by authenticating the "5 Rights" of medication: right patient, right drug, right dose, right time, right route. Performed at the bedside, the system offers an excellent opportunity to gather data on medications [4-7]. In addition to their contribution to the authentication of the 5 Rights, data captured by barcode administration systems have the potential to provide sources of research to improve patient safety in terms of actual injections and medication data.

Our study aims to use and analyze complete data on medical activities captured at the point of care by the system to understand all the activities and issues related to medical safety, and to investigate preventive measures for medical accidents to manage healthcare situations. We focused on injections, which

a major cause of medical accidents, and investigated the relation between mistakes and the context of medical activities including how busy staffs were, and shift work.

Materials and Methods

Settings and items to be addressed

Japanese Red Cross Kochi Hospital has 482 registered beds and approximately 290,000 out-patients and 9,355 in-patients per year. The hospital implemented a hospital information system called "Point of Act System," or POAS, in 2004. POAS is a real time bar-code capturing health information system designed to prevent medication errors by capturing the barcodes of patients, workers and drugs, and then authenticating the 5 Rights of each medical action [10-12]. Figure 1 shows a Personal Digital Assistant (PDA) for barcode capturing, nursing work management, and risk management for injections and intravenous drips (IV). When nurses scan the barcodes of drugs or IV bags for patients, the system checks the correctness of the injections and IVs against real-time accurate information in a computerized order entry system and electronic health record within 2 seconds.

At the same time, POAS captures complete data on each medical action including 6W1H information (When, Where What, Why, for What, to Whom and How) conducted in the hospital. The units of data recorded by the system are: Who—the implementer (the person who initiated the order, or the person who carried it out), to Whom—the patient, How—medical activities and changes in them, What—materials used (pharmaceuticals, medical materials and others), How much—amount of materials used and number of applications, for What—name of patient receiving medical services, When—date the order was placed, implemented and discontinued and the activities that were implemented, and Where—place of implementation (department, hospital, ward, etc.). The principal characteristics of data captured by this system are (1) complete data at a specific place including every action recorded in real time and accurately and (2) process data-based process management that enables POAS to ensure the correct process of medication and assures it captures complete data. The collection of complete data including 6W1H information is an innovative source in understanding actual situations directly without estimation or bias, and enables the investigation of solutions to prevent errors.

Data

Data captured at the sites of the injection process were used for our analyses of medication administration. In this study, data on injections means both injections and IVs. 6W1H information was captured at each point of the injection process: Order to give injection, Drug selection, Drug audit, Drug mixing, and Injection. Although the first objective of a bar code administration system is to ensure patient safety by verifying the 5 Rights of medication, another objective is to record the activities of nurses to support nurses' request of drugs and devices consumed, and enforce medication for patients.

At the point of care, nurses uses PDAs to scan the barcodes of ampoules or vials containing the medication to be injected or scan the barcodes of activities to enter information on their actions such as treatment, care, observations, counseling and emergency. This information is primary used for the documentation of nursing activities. However, this information can also be used not only for hospital management—by understanding the workloads of nurses and the actual costs of administering medications—but also for patient safety by understanding the prevailing situations when mistakes are made. In addition to these data entered by nurses, we also used warning data demonstrating mistakes that can be made in scanning the barcodes on drug vials. Warning data do not directly mean data on medication errors, because the system prevents error by alerting staff before a mistake is made. However, warning data are useful sources of information in analyzing the causes of medication errors, because a warning means a potential medication error without a barcode administration system. Therefore, high warning rates at specific times, places, situations and workers mean risky times, places, situations and workers in terms of patient safety. Basic types of warning are basically: a wrong or expired vial scanned by a nurse for a patient; wrong patient; and mixing error meaning incorrect mixing of drugs. Data collected from January 2005 to June 2008 were used for the analyses. The total numbers of activities represented by the data are 14,824,046 individual acts, and the number of injections and IVs administered were 604,847. The data covered almost 100% of the injections and 99% of the activities by nurses in the hospital according to internal research.

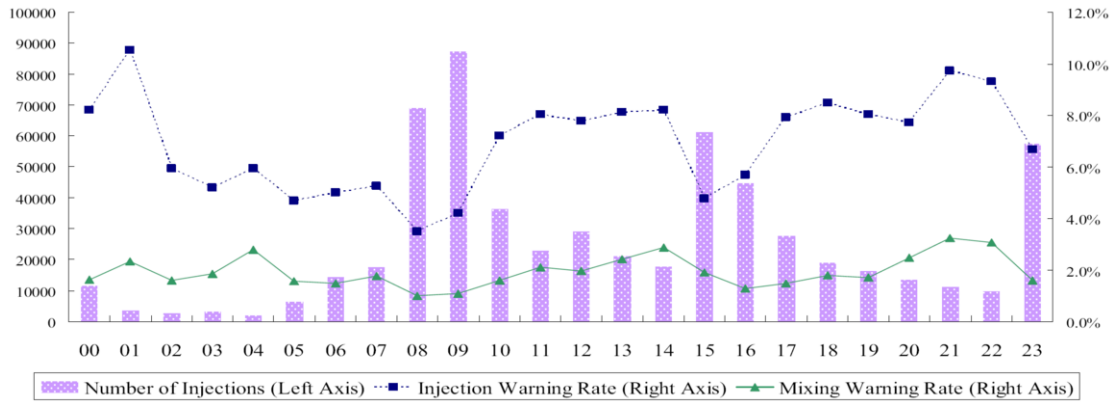

Figure 1 - Number of injections per hour and warning rate

Data Analysis

We accumulated data for each hour (for 24 hours a day) to identify times of high risk so as to understand the big picture of medical activities and medical errors in hospital wards. Warning rates were computed for each hour. These rates were treated as indicators to show risky times and situations.

We described these data, and analyzed them statistically to investigate correlations between situations and warning rates. Total number of injections per hour, total number of activities, total number of injections per PDA by hour, and total number of activities per PDA by hour were used as indicators for a nurse's workload at the time. The fraction out of total activities spent giving injections was used as an indicator for variation in hours. We calculated the proportion of the number of injections among total activities at that time. We employed Pearson Correlation Analysis to investigate relations and the significant level was 5%.

Results

Total number of activities was 14,824,046 including 69,276 injections (0.4%), 535,571 IV starts (3.6%), 483,770 IV finishes (3.3%), 1,979,804 care giving (13.3%), 10,437,250 observations (70.4%), 14,713 counseling (0.1%), 824,743 treatments (5.6%) and 478,919 emergencies (3.2%). The number for observations is extremely high. The total number of injections including IVs was 604,847, and the total warnings for injections were 37,046 (6.1%). The injection warning rate during early periods of implementation was around 9%, but has decreased to around 6 %.

Figure 1 shows the trend in warning rate and activities by the hour. The bar graph shows the number of injections by hour. There is a variability in the number of injections by hour, with three peeks for injections administrated: 9:00, 15:00 and 23:00**.** Most injections were administrated around these three peaks. The two line graphs show injection warning rates and mixing warning rates by the hour. Minimum and maximum of injection warning rates were 4.2% and 10.5%, while the minimum and maximum mixing warning rates were 1.0% and 3.2%. These figures vary quite a bit over the hours.

This graph shows the warning rate was lower when nurses where administrating a large number of injections. For example, the warning rates between 8:00 and 10:00 are lowest, although the numbers of injections are highest. The warning rates between 15:00 and 17:00 are also lower compared with the warning rates around the time.

In this hospital, the nurses work three shifts: Day shift (8:00-16:40), Evening shift (16:00-0:40), and Night shift (0:00-8:40). The warning rates per shift were 5.5% Day shift, 7.3% Evening shift, and 6.0% Night shift. Some researchers have reported that warning rates during nighttime are higher than during daytime [5]. However, there is no clear evidence to support the statement in our analyses. The trends in injection warnings and mixing warnings have basically the same tendency, although the tendency can be recognized more clearly in the injection warning rates. Especially during Day shifts, this tendency was demonstrated quite clearly.

We ran some statistical analyses to investigate the relation between warning rate and other variables. According to the results of a correlation analysis between variables, there was a negative correlation between the number of injections and injection warning rates. Figure 2 is a scatter plot of the number of injections per nurse and injection warning rate. The correlation coefficients between the number of injections and injection warning rates was -0.48 ($p<0.05$), and that between the number of injections per PDA and injection warning rates was -0.34 ($p<0.05$). Both results were statistically significant at the 95% level. This results show there is a tendency that more injections means safer injections at specific times as described above.

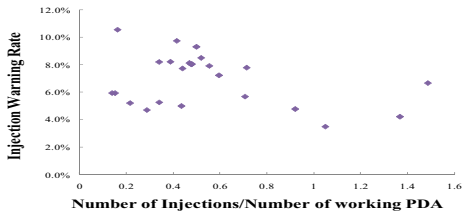

Figure 2 - Number of injections per nurse and warning rate

Variation in activities had a negative effect on the injection warning rate according to other correlation analyses. Figure 3 is scatter plot showing the relation between the injection fraction of total activities computed by the number of injections divided by the total number of activities and injection warning rates. The correlation coefficient between the treatment fraction of total activities and injection warning rates was 0.35 ($p<0.05$) and statistically significant. This indicator implied a high fraction of treatment, meaning nurses should administrate injections along with other treatments for patients and discourage nurses from concentrating on injections.

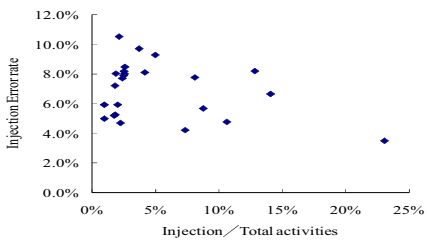

Figure 3 - Number of injections and warning rate

Discussion

There are some differences between our study and previously published literature. In past literature on patient safety, many studies had said workloads and busyness are the principal cause of medication errors, based on observatory studies of nursing practice [13-14]. These studies implied that it was acceptable that healthcare workers were so busy that they had to rush tasks, which caused a lack of due care and attention to be given to the administration of medications, and sometimes resulted in the certification processes being skipped. However, this study shows an opposite tendency in the medication errors rate. This study implies that people made mistakes not because they were doing too many things, but because they were doing too many different kinds of things. During a high frequency time for injections, nurses can concentrate on administrating injections to patients. Literature on human factor engineering indicate the same kinds of conclusions to ensure quality of activities [15-16]. It basically says that doing too many kinds of things is not a good way to ensure quality and reduce costs of activities, and that specialization is essential to redesigning workflow to improve management.

There is also another difference in our results compared with previously published literature. Injection warning rates in this study were relatively high compared to other studies on administration errors in injections [1-3, 13-14]. Many researchers have assumed injection error rates by observation of daily work, and their results gave a figure of around 4% for injection error rates as opposed to the 6.1% found in our study. Of course, there is a possibility that the difference in the injection warning rate came from environmental or other factors. However, the accuracy of data used in the analyses and detection of mixing errors could be regarded as the cause of the difference in results. Data captured by observational study has a bias in that people administrate more carefully when being observed. Therefore, the data captured by observational studies might be better than in reality. Other reason for the difference stem from the fact that other studies could not detect incorrect mixing of drugs. To identify incorrect mixing, drugs need to be managed not by a drug name ID but by a serialized ID [11]. A serialized ID on each product makes it possible to distinguish mixed and unmixed vials by recording the mixing for each drug and injection.

Clarification by time is an aspect of related factors for medication processes. Multivariate analyses with risk adjustment are needed to investigate more precisely reasons for medication errors. It is possible to accumulate data by place and people to identify a risky situation more precisely and in more depth, instead of clarifying by time. Figure 4 shows an example of another type of analysis, a scatter plot for the number of injections and injection warning rates per ward. The numbers of injections administered are totally different, but the injection warning rates are similar.

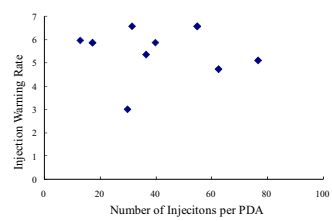

Figure 4 - Number of injections and warning rate per ward

We can identify one outlier whose warning rate is lower than for the other wards. To investigate the reason for this result, we need more in-depth analyses based on multiple variables and qualitative analyses.

One limitation to our research is in treating injections and other activities as the same workload activities, though actually there are quantitative and qualitative differences between these activities. It is necessary to assign weighs to each activity based on a time study or some methodology so as to capture more deeply and accurately the workloads of nurse for subsequent analysis. Another issue to be developed in this kind of analysis is privacy protection. In this analysis, data accumulated by hour and ward was utilized. The results did not contain personal data such as health care workers performance or data on patients. All patients and healthcare workers have unique identification numbers in this hospital. Therefore it is possible to analyze data using the identification numbers—including patient identification and worker

including patient identification and worker identification. To utilize digital data from electronic health records and other hospital information systems, discussions on the utilization of data and privacy protection is essential for the development of methodologies for data utilization and protection, as well as for frameworks supporting and sometimes restricting the use of data.

Conclusion

This study showed general trends in medication mistakes in practice using data captured by the hospital information system "Point-of-Act System" in real time and accurately. The results suggested that a high variation in activities performed might have negative effects on patient safety, and that busyness could not be regarded as the main causes of errors. Our study also implied the possible effects of bar code administration systems. According to the results, the injection warning rate was about 6%, and these warnings prevented nurses from committing errors and accidents. The lack of accidents with respect to injections in the hospital provides the system's ability. In conclusion, the bar code administration system might be quite an effective way not only to prevent medication errors at point of care, but also to improve patient safety through the analyses of data captured by them, if a system were designed correctly. Further research is needed to make progress in digital data usage and the utilization of healthcare IT.

A Business case for HIT Adoption: effects of "meaningful use" EHR financial incentives on clinic revenue

Nima A. Behkami[ab], David A. Dorr[b], Stuart Morrice[b]

[a] *Dept of Engineering & Technology Management, Portland State University, Portland, OR*
[b] *Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR*

Abstract

The goal of this study is to describe a framework that allows decision makers to efficiently evaluate factors that affect Electronic Health Record (EHR) adoption and test suitable interventions; specifically financial incentives. The United States healthcare delivery system is experiencing a transformation to improve population health. There is strong agreement that "meaningful use" of Health Information Technology (HIT) is a major enabler in this effort. However it's also understood that the high cost of implementing an EHR is an obstacle for adoption. To help understand these complexities we developed a simulation model designed to capture the dynamic nature of policy interventions that affect the adoption of EHR. We found that "Effective" use of HIT approaches break-even-point and larger clinic revenue many times faster that "average" or "poor" use of HIT. This study uses a systems perspective to the evaluate EHR adoption process through the "meaningful use" redesign as proposed in the American Reinvestment and Recovery Act 2009 in the United States healthcare industry by utilizing the System Dynamics methodology and Scenario Analysis.

Keywords:

Electronic health record, Health information technology, EHR, HIT, System dynamics, Care management plus, Meaningful use, Adoption, Diffusion, Financial incentives, Revenue, Scenario analysis, Physicians, Care managers, Policy, National healthcare

Introduction

In order to introduce significant and measurable improvements in populations health in the United States, various government and private entities seek to transform the healthcare delivery system by enabling providers with real-time access to medical information and tools to help increase quality and safety of care [1]. Performance improvement priorities have focused on patient engagement, reduction of racial disparities, improved safety, increased efficiency, coordination of care, and improved population health [1]. Using these priorities the Health Information Technology (HIT) Policy Committee, a Federal Advisory Committee (FACA) to the U.S. Department of Health and Human Services (HHS), has initiated the "meaningful use" agenda for adoption of Electronic Health Records (EHR).

Fueled by the $19 billion investment available through the American Recovery and Reinvestment Act of 2009 (Recovery Act), efforts are in full swing to accelerate the national adoption and implementation of health information technology (HIT) [2]. The Recovery act authorizes the Centers for Medicare & Medicaid Services (CMS) to provide payments to eligible physicians and hospitals who succeed in becoming "meaningful users" of an electronic health record (EHR). Incentive payments begin in 2011 and phase out; by 2015, non-adopting providers will be subject to financial penalties under Medicare [1].

Medicare is a social insurance program administered by the United States government providing health insurance to people aged 65 and over, or individuals with disabilities. Similarly Medicaid provides insurance for low income families [3].

CMS will work closely with the Office of the National Coordinator and other parts of HHS to continue defining incentive programs for meaningful use. The Healthcare Information and Management Systems Society (HIMSS) recommend that a mature definition for "meaningful use of certified EHR technology" includes at least four attributes [4]:

1. A functional EHR certified by the Certification Commission for Healthcare Information Technology (CCHIT);

2. Electronic exchange of standardized patient data with clinical and administrative stakeholders using the Healthcare Information Technology Standards Panel's (HITSP) interoperability specifications and Integrating the Healthcare Enterprise's (IHE) frameworks;

3. Clinical decision support providing clinicians with clinical knowledge and intelligently-filtered patient information to enhance patient care; and

4. Capabilities to support process and care measurement that drive improvements in patient safety, quality outcomes and cost reductions.

While existence of such mentioned programs is a motivation to consider using an EHR, historically adoption has been slow and troublesome [5]. One often cited obstacle is the high cost of implementing Electronic Health Records. Since usually incentives for adoption often go to the insurer recouping the

cost are difficult for providers [6-8]. Other challenges existing in the United States healthcare system include variations in practices and proportion of income realized from adoption [9,10].

Hence in this paper we propose that having a complimentary and value-adding care model next to the EHR will facilitate more meaningful use of HIT. One such product is the Care Management Plus (CMP) program developed at Oregon Health & Science University (OHSU)[11]. CMP is a validated and disseminated model of care coordination, information technology, and quality improvement in primary care for older adults and patients with complex, chronic diseases [12].

CMP couples an ambulatory care team with health information technology (HIT). For seniors with complex needs, CMP demonstrated a 20% reduction in mortality, a 24% reduction in hospitalizations and a 15-25% reduction in complications from diabetes [13, 14]. CMP facilitates use of HIT to establish and track care plans and specific patient goals, to teach and encourage self-management, to measure and improve quality, and to manage the complex and interleaving tasks as patients and teams prioritize needs.

Background

The Care Management Plus (CMP) model for primary care, developed by researchers at Intermountain Healthcare through funding from the John A. Hartford Foundation, uses specially trained care managers and tracking software to help clinics better care for patients with complex chronic illness. The model helps the clinical team prioritize health care needs and prevent complications through structured protocols, and it provides tools to assist patients and caregivers to self-manage chronic diseases. Specialized information technology includes the care manager tracking database patient summary sheet and messaging systems to help clinician's access care plans, receive reminders about best practices, and facilitate communication between the health care team.

CMP focuses on two primary areas: well-trained care managers embedded in the clinic and IT technology to help them manage patients with chronic illnesses. Figure 1, describes the primary aspects of the CMP program. Physicians refer patients with complex needs (about 3-5% of the population in primary care clinics) into the program. The care manager then co-creates a care plan with the patient, acts as a guide to help the patient and family meet their goals, and facilitates access to necessary resources when the patient or family needs navigation [15].

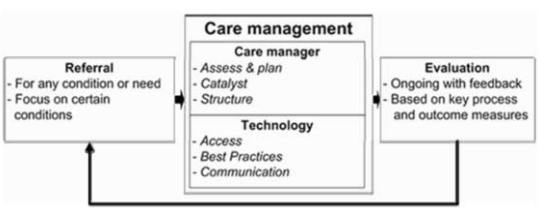

Figure 1- Care Management Plus

Figure2 shows a systems view of the Care Management Plus Program and its interaction with the EHR and various stakeholders. Integrated Care Coordination Information Systems (ICCIS) is the new revision of the Information Technology component of the CMP model. Physicians, Nurse Care Mangers, Patient and Patient family are able to interact and manage the patient's continuous care through the ICCIS web-0based interface. Additionally the ICCIS database is integrated with the EHR database for two way communication and reduced redundancy.

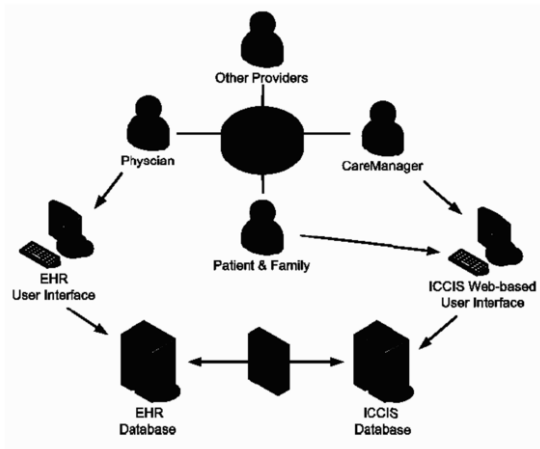

Figure 2- Medinfo 2010 paper submissions

Methodology

The goal of this study is to evaluate a framework that allows decision makers to efficiently evaluate factors that affect EHR adoption and test suitable interventions.

To this end we have develop a comprehensive simulation model designed to capture the dynamic nature of policy interventions that affect the adoption of EHR. We have aimed to capture interactions in the adoption of EHR for hospitals, physicians and Nurse Care Managers.

We have developed scenarios for clinic types based on the representative demographic that have already adopted the Care Management Plus Program which are listed in the results section. Then we have built a model of the adoption process and life cycle using the System Dynamics methodology. System Dynamics was introduced by Jay W. Forrester in the early 1960s to study complex systems such as the urban dynamics problem is used to build our simulation model [16].

To perform the simulation we have ran the System Dynamics model for each of the scenarios and the results are discussed in the next sections.

The model captures the dynamic characteristics of policy interventions and can be used to test different policies that might influence the adoption of EHR while providing insights.

For our model, we chose the following policy interventions, which can affect adoption First, *physician productivity*, which

includes for example activities that would stream line the physician workflow. Second, *financial incentives*, such as government reimbursement for use of HIT. And third, *cost*, for example the resources necessary to implement an EHR. Figure 3 shows a high-level view of the system dynamics based simulation model.

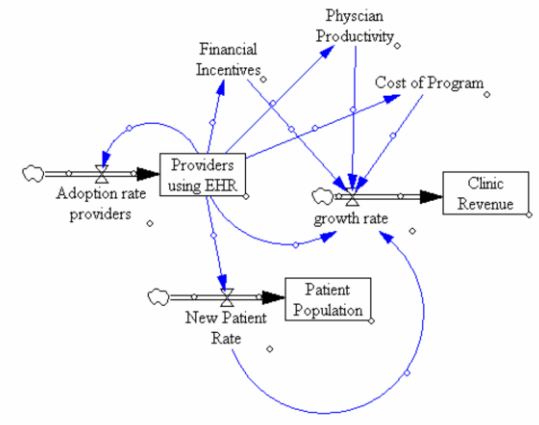

Figure 3- System Boundary

As stated previously it's this experiments goal to evaluate how policy interventions effect the adoption of EHR with meaningful use criteria while using the Care Management Plus program. To assess adoption of EHR, we propose the following set of dynamic conditions:

- *The more a Physician or a Nurse Care Manager is aware of EHR benefits, the higher the likelihood of adoption.*
- *The level and quality of "meaningful use" implemented by the clinic; low, medium or high will affect likelihood of successful adoption.*
- *Presence of Financial incentives will positively influence the adoption rate of EHR in hospitals and physicians offices.*

These hypotheses were examined using the system dynamics model created.

Results

In order to run the simulation three scenarios that were representative of existing CMP adopter clinic types were created and are shown in Table-1[15]. Small and medium sized private practices and a Safety Net Clinic are most common fit profiles of typical CMP users. Statistics of interest in the model included Number of physicians, number of Nurse Care managers in the practice as well as their patient panel size. The last column in Table1 lists the source of financial incentives for each clinic type, these numbers are average numbers based on available data [15]. Government incentive refers to Medicare and Medicaid reimbursements through the various programs available across the United States. Private incentive sources are mainly commercial sources and may include private insurance, employer-based funds or self-funding.

Amongst the listed scenarios a Small Rural Private Practice receives 53% of its total incentives from the government. Of that amount 50% is from Medicaid and 50% from Medicare. A Medium Private Practice in our second scenario receives 20% of it incentive from the government which 100% comes from Medicare. The Safety Net Clinic in our scenario receives 80% of its incentives from the government, with 75% from Medicaid and 25% Medicare. Health care safety net clinics are community-based providers who offer health services to low-income people, including those without insurance [17].

Table 1 - Clinic Type Scenarios

Clinic Type	**# of Physicians** **# of CareManagers** **# of Patients**	**Incentives**
Small Rural Private Practice	2 1 4600	Government: 53% Private: 47%
Medium Private Practice	5 1 11,500	Government: 20% Private: 80%
Safety Net Clinic	5 1 11,500	Government: 80% Private: 20%

In order to exercise the model we define three levels of HIT use with CMP:

- *Effective:* 40 patient referrals/month to CMP– meets meaningful use measures
- *Average:* 20 patient referrals/month to CMP– meets meaningful use measures
- *Poor:* 20 patient referrals/month to CMP– does not meet meaningful use measures

We run the simulation for each clinic for 3 years and the results are shown in Table 2. The new clinic revenue due to implementing CMP with EHR is listed in the second column of this table. New revenue is roughly calculated based on the formula below:

Revenue = (Patient Population Growth + Physician Productivity) - Implementation & Cost

The third column of the table shows the societal cost saving for each scenario. Average societal cost savings is estimated at $10,548 per hospitalization [12]. Societal savings were based on $640-$1,650 per patient per year savings.

Table 2 - Scenario Results after 3 years

Clinic Type	New Clinic Revenue	Societal Savings ($)
Small Rural Private Practice	-$76,776	$163,200 – $420,750
Medium Private Practice	$267,004	$409,600 – $1,056,000
Safety Net Clinic	$178,712	$409,600 – $1,056,000

Discussion

Figure 4 trends the clinic revenue due to implementing CMP with an EHR over roughly three years. The trends show that an initial investment in HIT affects the revenue of clinic adversely, which is expected. The three scenarios trended are with effective HIT use, Average and low as described in earlier sections. Effective use of HIT approaches breakeven point for adoption in 1 year. Average HIT with meaningful use break even at two years and poor usage of HIT almost breaks even in three years.

Therefore suggesting that better use of IT means the clinic recoups the cost earlier. However another interesting point is that effective and average use of HIT will lead to almost 5 times the revenue in three years compared to poor IT use. This is probably due to internal dynamics of the clinic workflow.

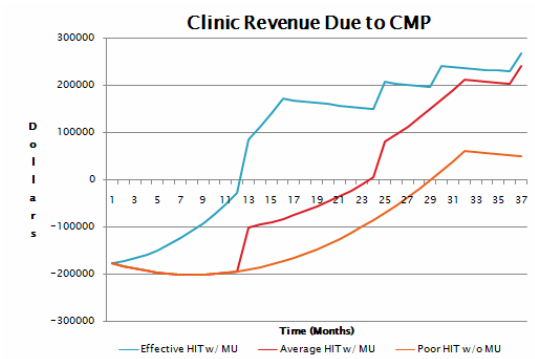

Figure 4 - Clinic Revenue Trend

Figure 5 takes a closer look at the complex system and reveals a positive feedback loop in the system. The more people are referred to Care Management, the more CM patient encounters and therefore larger financial incentives from government and private sources. There will be more revenue for the program which can lead to increased total clinic profit, which requires hiring new care mangers to handle the load. This positive feedback should generate financial incentives that continue to entice the providers to use HIT in a meaningful way.

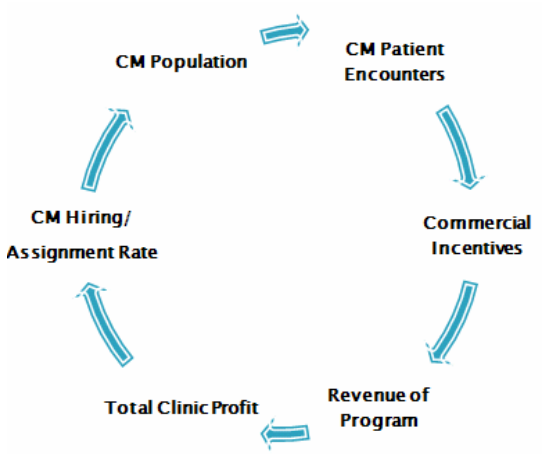

Figure 5- Incentive Positive Feedback Loop

Conclusion

This study uses a systems perspective to the evaluate EHR adoption process through "meaningful use" redesign in the United States healthcare industry by utilizing the System Dynamics methodology with Scenario Analysis. The model provides insights to understanding the factors influencing the adoption process and their interactions.

In this study, we investigated the often troublesome process of EHR adoption among hospitals, physicians, and patients. This study highlights the need for financial incentives with effective HIT meaningful usage for promoting EHR adoption.

Acknowledgments

Why is it so difficult to measure the effects of interruptions in healthcare?

Abstract

Interruptions are a complex phenomenon where multiple variables including the characteristics of primary tasks, the interruptions themselves, and the environment may influence patient safety and workflow outcomes. Observational studies present significant challenges for recording many of the process variables that influence the effects of interruptions. Controlled experiments provide an opportunity to examine the specific effects of variables on errors and efficiency. Computational models can be used to identify the situations in which interruptions to clinical tasks could be disruptive and to investigate the aggregate effects of interruptions.

Keywords:

Interruption, Medical error, Safety, Efficiency, Evaluation studies, Observation, Computer simulation.

Introduction

Interruptions seem to be inherent in the way work is undertaken in many clinical settings [1, 2]. Numerous studies have characterised this phenomenon over the last decade, and examined the extent to which doctors and nurses are interrupted in undertaking routine clinical tasks. Hospital doctors and nurses are interrupted anywhere between once every two hours, up to 23 times every hour in emergency, intensive care and surgery [3]. Interruptions may be a risk to patient safety in certain types of clinical tasks [4].

While there is solid evidence from psychology on the disruptive effects of interruption on human cognition [5], there is little evidence to date about the domain specific consequences of interruptions on clinical work. Interruptions have been reported as a contributing factor in IT-related medication incidents. Examination of 7029 CPOE-related medication incidents in the United States Pharmacopeia Medmarx database found that distractions were a significant contributing factor in eight out of ten errors [6]. In a UK study, interruptions and distractions were reported as a factor in up to 11% of errors in dispensing medications [7]. Interruptions also have a time cost. In one study clinical staff in an emergency department spent 24% of their time in dealing with interruptions [8].

A recent review of clinical interruption studies found that most studies were observational, describing the frequency, duration and types of interruptions [3]. Only one controlled experimental study examined the effect of interruptions on programming an infusion pump [9]. The review concluded that it is currently not possible to be certain about the causal links between interruptions and errors in healthcare. Yet interruptions have been well studied in other domains such as psychology, human-computer interaction [10] and aviation [11]. In most instances interruptions have been found to be disruptive, increasing time spent on a task and leading to errors in completing tasks. Studies also identify some of the characteristics that make interruptions disruptive such as the interruption complexity [12], similarity of an interrupting task to the primary task [13] and the availability of retrieval cues in the primary task [14]. While this literature provides a useful starting point for examining interruptions in healthcare, the disparity in tasks and environmental context make it necessary to investigate the specific consequences of interruptions to clinical work and their impact on patient safety.

In this paper we seek to examine the problem of studying interruptions in healthcare. We argue that the complexity in studying interruptions and measuring their impact on clinical work is one reason why little is still known about the clinical consequences of interruptions and this may require different research methods to those currently used in interruption research.

Methods

This study draws upon general literature about interruptions in non-health domains; experimental studies of the impact of interruption on electronic prescribing [15] and error behaviour [16]; and a series of observational studies in emergency and intensive care [8, 17, 18]. We firstly bring together a range of process and outcome measures to describe the complexity and consequences of interruptions. This is followed by a discussion of how observational studies, controlled experiments and computer simulations can be used to study interruptions and their impact on the safety and efficiency of clinical tasks.

Results

Table 1 lists primary task and interruption variables that may contribute to the outcomes of interruptions.

Task and interruption variables

1) Task type: Primary tasks and interruptions can be described in terms of their phenotype or their genotype. The *phenotype* is used to refer to the surface characteristics of a clinical task. In an observational study we found that doctors attended to a

range of task phenotypes that included prescribing medications, answering their pagers, phone calls, conversations with patients and colleagues on the ward, consulting medical records and reviewing investigation results [19].

The study of interruptions also requires description of underlying task characteristics or *genotype* such as task complexity and working memory load requirements, which have been shown to influence the disruptiveness of an interruption [20, 21]. Few clinical tasks fit neatly under the broad heuristic classes of procedural or problem solving traditionally used in interruption studies to describe task phenotype. A more sophisticated approach may be Wood's definition based on acts and information cues allowing task complexity to be quantified and compared [22, 23]. Models such as GOMS (Goals, Operators, Methods, and Selection rules), a well-recognised cognitive engineering method, also allow differentiation of the relative complexity of computer-based tasks by working memory load requirements. We have applied this method to analyse electronic prescribing tasks [19].

Table 1- Variables associated with effects of interruptions.

Task and interruption variables (process measures)
1. Task type (primary and interrupting task)
2. Point of interruption
3. Duration of interruption
4. Similarity of interruptive task to primary task
5. Modality of interruption
6. Environmental cues
7. Interruption handling strategy
Impact on task performance (outcome measures)
8. Safety: task errors
9. Efficiency: time on task, interruption lag, resumption lag

2) Point of interruption: Interruptions at the beginning of a task appear less disruptive than those in the middle of a task [24]. Interruptions at the end of a task may also be particularly disruptive, especially when the main goal is accomplished and a small sub-task remains. For example, a nurse who administers a medication may fail to complete documentation relating to that medication when interrupted. Such errors are known as post-completion errors [16, 25].

***3) Duration of interruption*:** The longer an interruption, the longer it takes to re-orient and restart the primary task afterwards, indicating that the disruptiveness of an interruption is directly related to its duration [26].

***4) Similarity of interruptive task to primary task*:** In computer-based tasks, interruptions have been found to be less disruptive when they are dissimilar to the primary task [27].

***5) Modality of interruption*:** A range of modalities like heat, smell, sound, vibration, and light can influence interruption effect [28]. For example, a doctor interrupting a nurse who is administering medications, to discuss the care of a patient, is a different experience to a device mediated interruption such as a phone, pager or an alarm, which could be turned off.

***6) Environmental cues*:** The availability of information cues in the primary task, such as an x-ray, should help return to it after interruption. Studies have shown blatant cues are highly effective, but the availability of subtle cues is the same as having no cues at all [29]. While the clinical environment is full of cues, some may be less obvious than others. A doctor who is interrupted when reviewing an x-ray is cued to resume and complete her primary task by the image display. The absence of cues when an interruption dislocates a clinician from her primary task may be particularly relevant in hospital settings where some roles require staff to be highly mobile. For example, when a pharmacist reviewing a chart is called away to a different unit, is not cued by the new environment to return to the primary task.

7) Interruption handling strategy: Clinical workers may use different strategies to handle interruptions, which may influence the extent of disruption to primary tasks. Consider the case of a doctor prescribing a number of medications who is interrupted by a mobile phone call:

a. *Attend to interruption*: The doctor may choose to take the call immediately or, with a momentary delay to rehearse the name of the next medication to be prescribed. The availability of an *interruption lag,* the time taken to attend to an interruption, may allow encoding of the next action. This can be effective in reducing interruption disruptiveness. After attending to the interruption the doctor may either *switch* to the interrupting task (i.e. suspend prescribing) or *multi-task* (i.e. prescribe while on the phone).

b. *Delay interruption*: The doctor may choose to switch off the phone and check for a message after finishing the primary prescribing task.

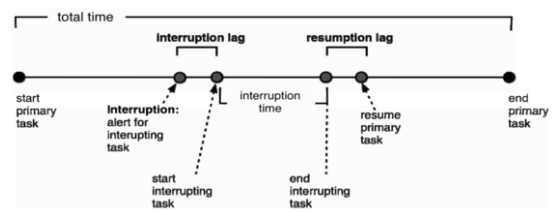

Figure 1- Time-course of an interruption (adapted from [30]).

Effects of interruptions on task completion

Interruption effects are typically quantified by examining errors [11, 16] and time penalties [5, 10].

Errors

An error is a "failure to carry out a planned action as intended, or application of an incorrect plan" [31]. Similar to task type, errors can be described in terms of their phenotype or genotype. We will use the example of electronic prescribing using a computerised physician order entry (CPOE) system to distinguish error phenotypes and genotypes.

Error phenotype: This is the observable property of an error. Or, the clinical manifestation of the error depending on the type of task. For example, a range of prescribing error types can be identified, such as wrong patient; missed allergy status; incorrect medication name dose, route or formulation; admini-

stration time; frequency; missing instructions to administer medications; and failure to prescribe or cease medications [15].

Error genotype: Is used to describe the underlying causes of an error or the ways of making the error.

a. *Errors of commission: are manifest by doing the wrong thing " [31].*

b. *Errors of omission:* are failures to do the right thing [31].

Errors can also be distinguished into slips and mistakes based upon knowledge about the intentions of an actor. A *mistake* is an "action that may conform exactly to the plan, but the plan is inadequate to achieve its intended outcome" [31]. Mistakes are associated with lack of knowledge about a task. A *slip* is an error of action, defined as "an unintended error or execution of a correctly intended action" [31]. Slips are associated with human fallibility in executing routine procedures despite having the correct how-to knowledge.

As with any other risk to patient safety measuring the frequency of errors due to interruption along with identification of potential causes is needed to facilitate investigation of corrective and preventative strategies. For example, in electronic prescribing identifying user interface features (i.e. dropdown menus, text entry) and actions associated with specific errors provides a basis to improve design of the CPOE system.

Measuring task errors: As clinical tasks often provide multiple opportunities to make an error, a normalised error rate, which takes into account the number of opportunities, can be calculated to compare the impact of interruptions across tasks (Equation 1) [16, 25].

$$Error\_rate = \frac{E_j}{E_n} \quad (1)$$

where, E_j=no. of errors and E_n=no. of error opportunities.

Error rate can be aggregated by phenotype. For example, error rates can be calculated for each prescribing error type or an overall error rate can be computed by aggregating all error types. As some errors may pose a greater risk to patient safety than others, another way is to calculate a weighted score. For example, errors can be weighted with a value of 1 (low risk), 2 (moderate risk), 3 (serious risk) to calculate an error score.

Task efficiency

The impact of interruptions on efficiency is examined in terms of the resumption lag and time-on-task (TOT).

Resumption lag: The time taken to re-orient and then restart the primary task after an interruption is generally regarded as a measure to examine the time cost of interruption (Figure 1) [26, 30].

TOT: The time taken to complete a primary task is used to examine any residual effects of an interruption (Equation 2). Studies have shown that for simple office tasks participants tended compensate by speeding up post-interruption [20, 21]. This measure may be highly relevant in a hospital context where clinicians are time pressed with a finite amount of time to complete tasks.

$$TOT = T_{total} - T_i - t_{inlag} - t_{rlag} \quad (2)$$

where, T_{total} = Time taken to complete the primary task including any interrupting tasks;
T_i = Time taken to complete the interrupting task;
t_{inlag} =interruption lag; and t_{rlag} = resumption lag.

Discussion: Challenges in measuring the effects of interruptions

As we have shown, interruptions are a complex phenomenon where multiple variables including characteristics of primary tasks, different dimensions of the interruptions and the environment may influence outcomes. In this section we discuss some of the challenges in using observational studies, controlled experiments and computer simulations to measure the effects of interruptions in healthcare.

Identifying situations where interruptions are problematic

Observational studies have been successfully used to identify *types* and *frequency of primary and interrupting tasks; sources of interruption;* and *time on tasks*. A range of highly resource intensive methods and tools have been used to examine interruptions including audio (e.g. COM [8]), video recordings (e.g. computer screen-capture [32], eye-trackers) and direct observations of work patterns (e.g. PDAs) in clinical settings.

The time cost of interruptions is not easily measured in observational studies. Whilst it is possible to examine time on task, observational studies may only provide rough estimates of resumption lag, which is typically measured in the order of a few seconds. For example, it is possible to only broadly compare resumption times for a medication administration task with a documentation task that may require a nurse to spend some time gathering his thoughts prior to resuming.

The effect of interruptions on errors is less clear-cut. Errors often result from the interplay of multiple events over time, and the error contributed to by an interruption may only occur after a researcher has stopped observation. Whilst slips may be observable in tasks with well-defined structure (for example, a nurse does not check the name of a patient before administering medications) mistakes are less identifiable because the intention of the actor is not always clear to the observer. Further, error identification is complicated in tasks with less rigid task structures, i.e. when there are many ways of achieving a goal.

Given that multiple variables affect the outcome of an interruption, interruptions are likely to be problematic only in certain situations e.g. poor cue availability. While observational studies may be useful to identify particular situations in which interruptions are disruptive, they present significant challenges for recording many of the process variables that influence the effects of interruptions. These variables include the *point at which primary tasks are interrupted, the modality, length* and *similarity of the interruption to the primary task, environmental cues* and *interruption handling strategies* (Table 1).

Quantifying effects in the laboratory

Controlled experiments provide an opportunity to examine the effects of specific *task* and *interruption variables* on task completion (*errors* and *efficiency*) and have been effectively used to examine the effects of interruptions in other disciplines. In healthcare, controlled studies provide an opportunity to exam-

ine the impact of interruptions in a range of task environments from low fidelity laboratory tasks (e.g. use of a CPOE [15], programming of an infusion pump [9]) to high fidelity simulation environments (e.g. surgery [33], medication administration on a ward). However, within a laboratory setting there is a trade-off between obtaining causal relationships among controlled variables and ensuring ecological validity.

One of the challenges is to design tasks and interruptions that are representative of typical tasks undertaken by the intended participants. For example, to examine the impact of interruptions to electronic prescribing using a CPOE by junior doctors, tasks could be based on hypothetical clinical scenarios representing typical prescribing tasks undertaken by doctors working on a medical ward. Interruptions in such a setting will often be initiated by a phone or pager (*modality of interruption*) and require the doctor to walk away from her primary task.

Another challenge is to effectively control for all independent variables. For example, if several different clinical scenarios are used to examine interruptions in electronic prescribing all scenarios must be of similar task complexity. Interruption variables such as the *length of the interruption*, *similarity of the interruption to the primary task* and *cues available in the task environment* require meticulous consideration when designing the experiment. The experimental procedure for such interruptions requires careful coordination by investigators, especially to control for variables such as the *point at which primary tasks are interrupted*, and *interruption handling strategies*.

A third challenge relates to the measurement of outcomes. In particular, error rates as a measurement may not be sensitive enough to detect the disruptive effect of interruptions compared to measures such as resumption lag, which can be reliably measured in laboratory studies. Baseline error rates in clinical tasks are fairly low – for example, baseline error rates in electronic prescribing using a CPOE ranged from 0.5% to 15.6% [15]. Thus, designing an experiment that is adequately powered to detect a small effect size is a challenge (Table 2). While the sample size may be adequate to detect a difference in resumption lag, the study may not be adequately powered to examine the smaller differences in prescribing errors.

Table 2 - Sample size required to detect error rate with interruptions using a paired samples t-test [34]

Effect size (d)	**Small** 0.2	0.3	**Medium** 0.5
Sample size* (n)	156	71	27

α=0.05, 1-β=0.8

In comparison, time on task and resumption lag are highly sensitive measures, which can be accurately captured. For example, screen capture software (e.g. TechSmith Morae®) can be used to record and analyse computer-based tasks and eye-tracking systems can be used for mobile task environments.

Examining impact on patient safety and task efficiency

The impact of interruptions on specific clinical tasks ought to ultimately be examined within the wider clinical workflow within which tasks are typically undertaken. Inbuilt error checking and redundancy within workflow plays a significant role in minimising the effects of errors. By investigating the aggregate effects of interruptions over a large group of clinicians, we may better establish links between errors caused by interruptions and the adverse events that occur relatively infrequently. In addition, we can describe situations in which an individual's interruption time-cost does not necessarily correspond to an overall negative cost in efficiency for the group.

We know that very few errors lead to an adverse event (in one study, 1.4% of the total led to adverse events compared to a 60% error rate [35]). However, when we aggregate the effect of all errors across a hospital, the result is that 10% of admissions are associated with an adverse event [36]. This implies that the aggregate effect of errors on patient safety, whilst low in probability, is considerable and measurable. Since we also know that a considerable proportion of errors are associated interruptions, it follows that large numbers of interruptions contribute to errors that are associated with small but significant numbers of adverse events.

When extending beyond the individual to larger groups of cooperating clinicians, there may be a nonlinear trade-off between efficiency and interruptions. Intuitively, some interruptions are necessary and can improve the net task efficiency of the group (e.g. less need for idle waiting and asynchronous communication). However, given the relationship between interruptions and the potential for medical error, it follows that an increase in some types of interruptions may increase the overall potential for adverse events. This suggests an optimal level of interruptions that minimises error and maximises efficiency. Another limit occurs when the net time-cost of interruptions is negative – the aggregate time-cost to individuals caused by interruption outweighs the aggregate time-savings associated with reductions in idle time and asynchronous communication. There may be a non-intuitive optimal level of interruptions unique to each group and environment.

Computational modelling of interruptions

There is a strong precedent for using computational models in healthcare [37], and computational models have a role in the study of interruptions. They permit the explicit modelling of interactions between individuals and groups beyond what is typically done in a laboratory, assist in the development of hypotheses for controlled studies, and present one way to conduct first-phase validation of interventions prior to controlled studies [38]. Computational models provide an efficient way of examining the effects of different combinations of variables and can be used to identify the situations in which interruptions have the potential to be disruptive. Models of this type may help describe patterns of variability in interruption effects on groups and therefore locate problematic interruptions (problematic to overall efficiency and safety rather than just to the individual's efficiency and error rate).

Conclusion

Interruptions are a complex phenomenon with multiple variables that affect task performance. Disruption to clinical tasks can be understood by firstly using observational studies and computational models to identify the situations in which interruptions are particularly problematic. Secondly, using controlled experiments to measure the extent to which interruptions generate errors and impose a time cost. Computational

models can be used to examine overall impact on patient safety and task efficiency.

Abstract

We discuss a new approach to patients' adherence to enhance to their medication-taking regimen by developing a context-aware alerting system that would optimize the expected utility of alerts. Each patient's instantaneous context is assessed using a real-time sensor network deploying a variety of sensors. The alerts are generated to optimize the expected value to the patient. This paper is focused on the initial assessment of the utility of alerts, including the tradeoff between effectiveness and annoyance.

Keywords:

Medication adherence, Artificial intelligence, Machine learning, Home monitoring, Reminders

Introduction

Medication adherence, defined as adherence to a plan mutually agreed upon between a patient and his or her primary clinician, is key in therapy as well as in clinical trials of new drugs. Insufficient adherence to the planned medication regimen can obviously have a significant impact on the efficacy of care. Population-based studies of medication taking in aging patients and in those with chronic diseases have shown that medication non-adherence leads to increased hospitalization and mortality [1-4]. One population-based study found that drug-related visits accounted for 12.6% of all emergency room visits, with 19% of these visits being directly related to medication non-adherence [5]. Non-adherence is of particular concern in clinical drug trials, where good adherence is essential to accurately assessing the safety and efficacy of the drug [6, 7].

Since more than 3 billion prescriptions worth $203 billion are dispensed annually in the USA [8], strategies to improve medication adherence have the potential to both reduce health care costs, and to significantly improve health outcomes. In a meta-analysis of intervention studies to improve medication adherence, McDonald and colleagues found that most studies had only a modest effect, and the most successful studies involved a variety of interventions including information, self-monitoring, counseling, and reminders. These interventions included behavioral, cognitive, and social aspects, and no single characteristic of the interventions led to improved adherence or outcomes [9]. Kripalani and colleagues also found that although 54% of interventions led to some improvement in adherence, only very small improvements, if any, were seen in clinical outcomes[10]. Thus, while it is clear that strategies to improve adherence are needed, it is still not obvious which strategies are most effective.

Prior research studying patients' adherence to medication taking regimens has been plagued by technical limitations. Even the measurement of adherence has been a difficult problem because of the researchers' frequent reliance on subjective reports of the patients' behaviors [11, 12] or on pill counts [11, 13, 14]. These reports are often unreliable because of patients' memory lapses and sometimes because of their unwillingness to admit missing medications. These problems are exacerbated in older populations because of the combination of typically complex medication-taking regimens and a frequent decline in cognitive abilities, such as memory and executive functions [15, 16].

Two problems must be solved in order to improve patients' adherence to their medication plans. The first one concerns our ability to assess objectively any individual's adherence to their plan. The second problem involves the development of effective and acceptable alerting and reminding systems.

We and other researchers have demonstrated the feasibility of automatically assessing medication taking behaviors [13, 17]. This assessment is generally based on various technological solutions whereby sensors detect the opening and closing of medication containers. The differentiating feature of the technology investigated in our prior study is that the medication dispenser is wirelessly connected to a local area network and permits medication-taking behaviors to be monitored in real time. As described below, this feature is important in order to make the alerting system aware of the patients' medication-taking behaviors. We note that this type of assessment techniques is limited to sense only patients' interactions with the medication dispenser. Although opening the dispenser does

not guarantee medication taking, this technique is more reliable than the approaches based on self-reports or pill counts.

With very few exceptions [18], most of the existing reminding and alerting systems generate alerts at fixed time points prescribed by the medication taking regimen. Although these have been shown to be useful, they frequently fail to achieve adherence for a variety of reasons, mostly associated with the patients' context and concurrent activities. For example, if the patient is involved in various concurrent activities such as sleeping, telephoning or is not near the medication dispenser when the alert is generated, he may not respond to the alert. In addition, if the alerting system is not aware whether or not the patient took the medication, it cannot generate follow up alerts.

To mitigate these problems, we have recently prototyped and investigated a context aware system and compared it to a time based approach [19-21]. The investigated system used a variety of sensors situated in the patients' homes and interconnected by a real-time sensor network designed to assess their state, and used a rule-based approach to infer the patients' state and to generate context aware alerts. The results of this rather limited study suggested the potential of context-based reminding, but the study was limited by the choice of the type and intensity of alerts.

The key challenge for this work is to develop techniques and supporting technology that would remind the patient at times when the patient could act on the reminder, and that the reminder would be most effective and minimally annoying. It would not be hard to generate alerts that would be effective in forcing the medication-taking behavior. For example, one could theoretically install extreme alerts such as a siren used in emergency vehicles that would be very difficult to ignore. The problem is that most patients would not tolerate such annoying devices and would turn them off. The selection of the most effective alerts is, therefore, a compromise between the benefits of the intensity of alerts and their annoyance.

Since the medication-taking behavior is a stochastic process, this optimization can be conveniently cast in a decision-theoretic framework. This paper describes a decision-theoretic framework to implement such a system based on a state representation of the activities of the patient, the prompting actions and the patient's responses. The state of the patient is inferred from a variety of sensors that represent indirect measurements of his or her activities. Therefore, a framework appropriate for optimization should be based on a partially observable, possibly Markov, decision process (POMDP) [22]. However, for the sake of simplicity we illustrate the approach using a simpler, one step maximizing utility approach. The main focus of this paper is to describe the general approach, the theoretical framework and its feasibility, with a particular focus on utility assessment. The ability to assess the utility of the alerts is a key problem in making this approach feasible.

Utility-Based Medication Adherence Framework

Metrics of Adherence

There are numerous ways to describe the degree of adherence. For example, the most frequent metric for adherence is the probability of taking medications within and interval ± 90 minutes of the prescribed time. Another, more sensitive metric is the average deviation from the nominal time. The metrics should also include deviations in the type of medication or the dose, i.e., taking the wrong amount or wrong drug. For the purpose of this paper, we focus on the temporal deviations.

Context and State Assessment

One of the key components of a principled, expected utility-based approach involves a representation of the patient's activity that would in turn enable one to estimate the probability that he will take the medication. For the sake of computational simplicity, i.e., computability, we assume that a patient's activities can be categorized into a small number of discrete states, q. The state of a patient is inferred from a set of contextual measurements implemented as sensors located in the patient's home. The set of sensors may include a variety of devices ranging from passive motion sensors, contact switches, to range measuring systems. The contextual measurements are then used in combination with an appropriate model to infer the state of the patient and ultimately the likelihood of taking a medication.

Explicit Costs and Benefits

As described in the introduction, one of the most important knowledge acquisition and representation tasks in designing a medication reminding system has to do with the explicit incorporation of the costs and benefits associated with all actions that the reminding system might perform. For example, simply detecting that a patient in the home has probably forgotten to take an evening dose of a particular drug does not necessarily imply that a loud alarm should ring. Factors to consider in designing a protocol for reminding include:

- Reminder Intensity - Reminders can be delivered via various media at various stimulus intensities and modalities (text / light display on medication caddy → text / soft beep → louder beep on watch → text message on cell phone → phone message → phone call). Each of these approaches to reminding is associated with a different level of annoyance to the user and different probability of being noticed and attended to.
- Length of time since target time – Reminding too early or too late has a higher cost that reminding on time. However, reminding prior to when the user was going to take the medication anyways has a fairly high annoyance cost.
- Importance of the specific medication – It is more important to remind a user of a critical drug (e.g., anticoagulant) as compared with a noncritical pill (e.g., vitamin). Higher annoyance factors will be tolerated for more critical medications. In addition, for some medications, the

timing is more critical (e.g., 4 times / day) versus others that could be taken any time of day.

- Context for the user – Reminders that account for a user's location and availability to take the medication will be far more successful than a strictly time-based reminder. For example, there is a high utility for reminding when the user is near the medication caddy and when they are occupied with conflicting activities (e.g., sleeping, visiting with others, in the middle of a meal).

Our approach to medication reminding is cast in an expected utility framework for determining when and with what type or "media" and intensity or "strength" to remind a user to take a medication. More formally, the general expression for the expected utility has the form

$$\bar{U}[A,C] = \sum_{q=1}^{M} p(q \mid A,C) u_q(A,C), \qquad (1)$$

where $\bar{U}$ is the expected utility of an alerting action $A(t)$ when the patient is in state q and context $C(t)$. $A(t)$ is one of possible actions generated by the alerting system and may include visual and auditory modalities as well as different alert intensities. We note that one of the possible actions is $A = \varnothing$ or "do nothing." The context $C(t)$ is a vector that represents all available measurements including motion sensors, for all times $t' \le t$. In general, the state of a patient is related to the instantaneous activity, such as sleeping, but in may also be an abstract representation of sensor data.

The probability that the patient is in state q given an action and contextual measurements is denoted by p. This embodies the two levels of uncertainty: (1) uncertainty due to the indirect measurements of the patient's state and (2) the uncertainty of taking the medication, given the state. Within the expected utility framework in Equation (1), the latter uncertainty is incorporated in the utility $u_q(A,C)$.

To illustrate the approach, we assume that the patient is in one of two states: $q = 0$ and $q = 1$ representing the failure and success in taking the medication, respectively. When the patient is in state 1, the time T when he takes the medication is a random variable with a probability distribution $F_1(T)$. Assuming that the only available sensor is the medication dispenser, that indicates that a medication was not taken by time t, it is possible to compute the probability that the patient is in the "forgetting" state by

$$\Pr\{q = 0 \mid T > t\} = \frac{p_0}{1 + (1 - p_0)[1 - F_1(t)]}, \qquad (2)$$

demonstrating that as time increases and medication is not taken, the probability that the patient will forget increases and consequently, the expected utility of an alert increases. With information from additional sensors, it is possible to increase the number of possible states and improve the accuracy of this assessment.

Estimation of Time Probability Distribution

As shown in Equation (2), an essential component of the maximum utility calculation is the probability distribution of times that the medication is taken without prompting. In order to implement this approach, it was necessary to estimate this distribution by monitoring individuals taking medications without any alerts. Such estimates were obtained in a baseline condition of a prior study [19, 20]. Because of the cyclic nature of time, i.e., daily periodicity, we developed a novel approach to the density estimation process. For the purpose of the present discussion, however, we performed a maximum likelihood fit using beta distributions.

Empirical Estimation of Alert Utilities

The goal of this laboratory study is to estimate the utility of alerts and prompts. The utility assessments includes the benefits (positive utility) representing the effectiveness of reminding the patient to take his or her medication, as well the cost (negative utility) associated with the alert annoyance and failure to achieve the desired result. Our current study was designed to investigate several modalities, device form-factors and signal intensities of the prompting systems. The main dependent measures were subjective judgments in response to the various system reminders. In addition to the demonstrated prompts, subjects were asked to rate a number of other prompting devices

Methodology

In order to approximate real-life distractions, we introduced new methodology based on dual task. The dual task consisted of a background continuous activity (watching a comedy show) which was occasionally interrupted by the primary task. The computer generated the video as well as the signals that triggered the alerts.

When an alert was generated, the participants' task was to notice the alert and to respond to the alert by walking over to a medication dispenser and opening a specific compartment. The medication dispenser was designed to record both the time of the interaction and the specific compartment that was opened. The collected information comprised quantitative as well as qualitative data. In addition to the objective data (time duration and the identity of the medication tracker compartment that was opened), the participants were asked to judge the annoyance of the alerts generated by the devices included in the experimental part of the study. In addition, following the active experiment, they were asked to rate several devices that were not part of the experiment. The different devices were presented as much as possible in random order for different subjects.

Prompting Devices

The prompting devices used in this experiment were selected to cover a wide range of form factors and modalities. We used a combination of commercially available devices and our enhanced alerting devices. The following is a list of these devices and the corresponding modality:

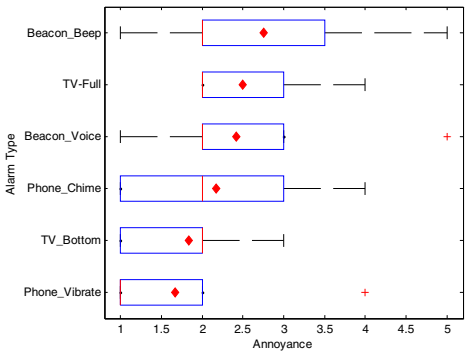

Figure 1- A box plot of the annoyance ratings of different device for 10 subjects.

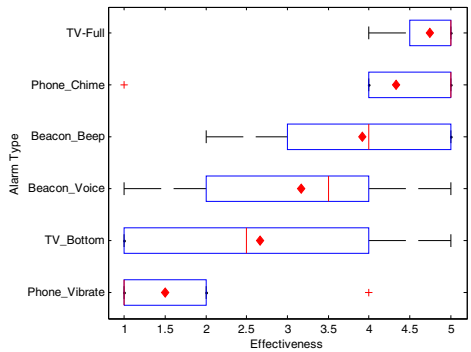

Figure 2- A box plot of the effectiveness ratings of different devices.

1. Vibrating modality, e.g., watch
    a. Adult version of a watch
    b. Pediatric version of a watch
    c. Vibrating Pendant
    d. Vibrating mobile telephone
2. Auditory alert watch with informational display indicating the action to be performed as a part of the secondary task.
3. Medication dispenser with audio-visual alert mechanism
    a. Visual alerts only
    b. Sounds only
4. PDA with auditory and visual (text) alerts and messages
5. Cell phone with voice and/or text messages
6. Office phone alerts
7. Television set (captioned message or full screen)

Procedure

The participants were recruited from a pool of elderly subjects participating in other, ongoing experiments. They were introduced to the study using a brief video in which an experimenter described the purpose, the task, and the procedure. During the video introduction, the participants were asked to adjust the level of the audio to a comfortable level – this was also used to assess their hearing. During the introduction, the participants also learned to use the remote control that enabled them to start and stop the television show. Following this introduction, the participants were consented.

The experiment was initiated by the participants using the remote control that started the television show. The participants were presented the alerts, namely the alert modality and type of signal in a pseudo-random order to reduce the potential of sequential effects. Following the experimental procedure described in the Methodology section above, the participants were asked to rate the devices in several ways including rank-ordering, as well as using a Lickert scale. In particular, they were asked to rate the effectiveness of each alert and its annoyance. In order to ascertain that the participants paid attention to the television show, they were also asked to answer a number of questions about selected details of the show.

Results

In this section we first analyze the data from the empirical utility assessment study and then combine them with the data from our prior study [19, 20]. The results of the annoyance ratings, combined across subjects are shown in Figure 1. Similarly, Figure 2 represents the summary of the effectiveness ratings that appeared to be consistent with subjects' behaviors during the study. Although there appears to be some agreement, there is clearly significant inter-subject variability. A large component of this variability was due to the differences in individual preferences as ascertained by their comments and responses to questionnaires. Using the estimates of the utility and probability distributions from our pilot studies, we simulated a variety of alerting situations in order to determine important details of a potential implementation. An example of such an issue is the notion of a *refractory period*. In particular, after the system issues an alert, the instantaneous annoyance due to potential repetition of the same alert is significantly higher. The actual value of this increase and its temporal course of the refractory period needs to be investigated in a spate study.

Conclusion

We have developed a new decision-theoretic framework and approach to optimize reminding and alerting using contextual information. Our data from several pilot experimental studies, in combination with this theoretical framework, suggest that an optimal, utility-based approach is possible and may improve medication-taking adherence. Additional improvement could be gained by including aspects such as the refractory period and the utility of interruption [23]. However, this study offers evidence to show the feasibility of integrating home monitoring data to infer patient context for reminding systems and also demonstrates the importance of incorporating patient preferences for alerts and reminders. Future directions for work in this area include linking medication adherence data

with personal health records and electronic medical records for broader health management use.

Factors Affecting Physicians Compliance with Enrollment Suggestions into a Clinical Reminders Intervention

Geva Vashitz[a], Joachim Meyer[a], Yisrael Parmet[a], Niki Liebermann[b], and Harel Gilutz[c]

Abstract

Clinical reminders can promote adherence with evidence-based clinical guidelines, but they may also have unintended consequences such as alert fatigue, false alarms and increased workload, which cause clinicians to ignore them. The described clinical reminder system identifies patients eligible for primary prevention of cardiovascular diseases and lets the physician to choose which patients will be included in the reminders intervention. We analyzed data of 87,165 visits of 35,699 patients and evaluated factors which may affect clinicians' decision to enroll patients to the intervention. The physicians included most of the patients suggested for inclusion (85.7%). Yet, they skipped the enrollment suggestion in 62.6% of the visits. Patients with a cardiovascular disease, dyslipidemia, diabetes, or hypertension were more likely to be included in the intervention, while older patients were less likely to be included. Insights regarding the usability of clinical reminders are discussed.

Guideline adherence, Clinical decision support systems, Reminder systems, User-computer interface.

Introduction

Although risk factors contributing to the development of Coronary Artery Disease (CAD) are well known and effective interventions exist, the majority of patients are sub-optimally treated [1]. Clinical reminders (CR) have become a major component in many clinical interventions to promote adherence with evidence-based clinical guidelines [2]. These systems generate patient-tailored reminders for physicians at the point-of-care. The effects of such systems were extensively described in some reviews [3-6]. Many studies showed positive effects on clinical performance [4, 7-9], while others found limited and variable usage [9-13]. Computerized decision-support systems may have unintended consequences, such as alert fatigue, increased workload, workflow issues, communication flaws, and dependence on the technology [14, 15], as well as negative emotions among physicians [16]. Although clinical reminders may provide clinicians with important information, many clinicians may perceive them as a burden and ignore them even when they are critical. We sought to evaluate the extent to which physicians follow a reminder system's suggestions to enroll eligible patients to the prevention program, and the factors effecting this decision.

Method

Setting

The "Computerized Community Cardiovascular Control" (4C) is a nationwide intervention, aimed to promote prevention of clinical atherosclerosis. It is operative since 2007 by "Clalit Health Services", a nationwide HMO serving more than 3.7 million patients in Israel.

Workflow

The system identifies patients at high risk for cardiovascular events (such as cardiovascular disease, dyslipidemia, diabetes, hypertension, smoking, high SCORE [17] or Framingham [18] risk). Once such a patient visits the primary care physician, the system evaluates available clinical information and decides if the patient should be included in the intervention according to the guidelines. If so, it presents an enrollment screen to the physician (Figure 1). The physician can now choose: (1) to include the patient in the intervention, (2) to include the patient, but to postpone the follow-up for one year, or (3) to exclude the patient from the intervention. The physician can also "escape" from the screen by clicking the [X] (in the upper right corner of the screen), which will close the enrollment screen and will end the process without including or excluding the patient. If the patient was excluded from the intervention, the system will ask for the exclusion reason, and will re-suggest inclusion after 6 months. Once a patient was included in the intervention, the system will periodically suggest the physician about therapeutic actions, such as further screenings, pharmacotherapy and expert consultations. After a patient was included in the intervention, the physician can postpone the follow-up or exclude the patient from the intervention at any time.

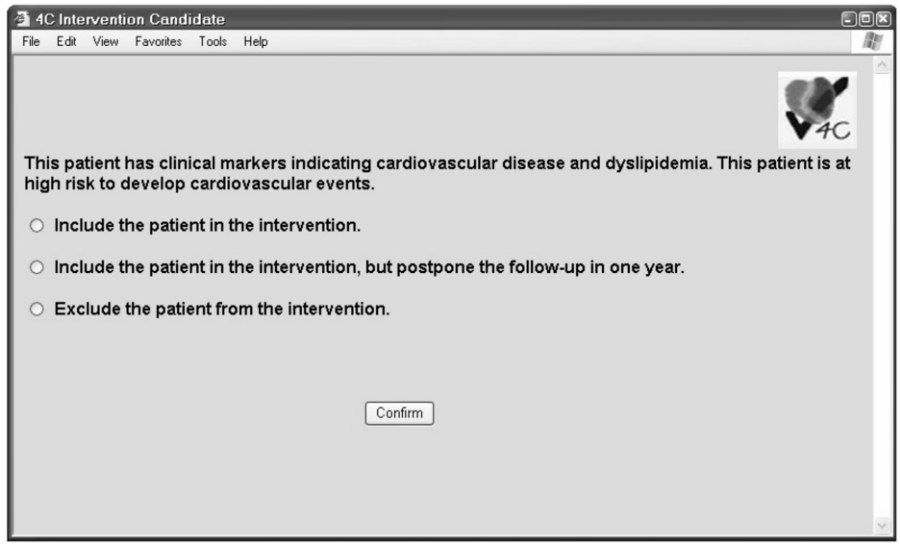

Figure 1 - Enrollment screen

Sample

The data include 87,165 visits in 50 primary care clinics of 35,699 patients (average 2.4 visits per patient), treated by 379 physicians, between 16/10/2007 and 14/12/2008.

Analysis

We analyzed log files collected by the 4C system. We calculated the probabilities to eventually include or exclude patients in the intervention. We analyzed only cases in which the system suggested to enroll the patient to the intervention. We used a logistic regression model with backward elimination for model selection with the binary outcome variable (patient included or not) and patient characteristics of age, gender, and markers of hypertension, diabetes, dyslipidemia, diagnosis of cardiovascular disease, and smoking status as predictors.

Results

Descriptive statistics

Most patients identified for inclusion by the system were male, with an average age of 60 years, diagnosed with hypertension, diabetes, and dyslipidemia. Only about one third of the patients were already diagnosed with cardiovascular disease (due to the primary prevention nature of the project) and about a fifth of them were smokers (Table 1).

Enrollment rates

The system evaluated that patients should not be included in the intervention in 75.4% of the total 355,371 visits analyzed, and hence the enrollment screen was not presented to the physician. The physicians did not make any choices regarding these cases. In the remaining 87,165 visits in which the enrollment screen was presented, the physicians chose to include patients in 30,999 visits (35.6%, with 0.5% postponed inclusions), exited the enrollment screen without explicitly excluding the patient in the intervention in 54,554 visits (62.6%) and excluded patients from the intervention in 1612 visits (1.8%) (see Figure 2). Yet, 85.7% of the 35,669 patients suggested by the system for inclusion were eventually included, 0.2% were literally excluded, and for the rest 14.1% (4,989 patients), the physicians kept ignoring the enrollment suggestion. Apparently, the physicians enrolled the most of the patients (85.7%) in the 35.6% of the visits, and mostly escaped the enrollment screen in the rest of the visits.

Table 1 - Predictors' descriptive statistics

Predictor	Descriptive
Age (Mean±Sd)	60.7±9.6
Gender (% female)	44.2%
Hypertension (% patients)	58.9%
Diabetes (% patients)	56.8%
Dyslipidemia (% patients)	69.6%
Cardiovascular disease (% patients)	32.1%
Smoker (% patients)	24.6%

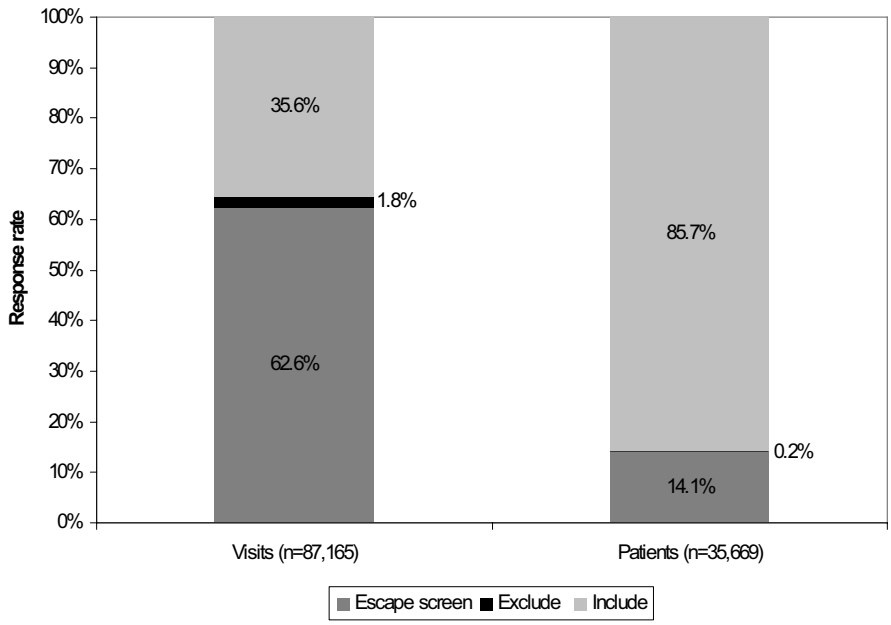

Figure 2 - Inclusion, exclusion and escape rates

Enrollment prediction

The logistic regression model (after backward elimination iterations) yielded that patients with a cardiovascular disease, dyslipidemia, diabetes or hypertension had a better chance to be included in the intervention (OR=1.880, 1.868, 1.729 and 1.278 respectively). Older patients had lower chance to be included (OR=0.991). Patient's gender and being a smoker did not play a significant role to predict the chance of being included in the intervention. Having a cardiovascular disease, dyslipidemia or diabetes were apparently more prominent factors for inclusion than hypertension (Table 2).

Table 2 – Odds-ratios to include patients in the reminders intervention from the logistic regression model (n= 35,669 patients).

Predictor	OR (95.0% CI)
Age	0.991 (0.988, 0.995)
Hypertension	1.278 (1.198, 1.363)
Diabetes	1.729 (1.616, 1.849)
Dyslipidemia	1.868 (1.753, 1.990)
Cardiovascular disease	1.880 (1.744, 2.027)

Note: This table shows the odds ratio of the estimated regression coefficients of the probability to enroll patients to the intervention with their 95% confidence intervals.

Discussion

CR systems are implemented under the assumption that they will be beneficial for the patient and the physician. The effectiveness of these systems relies almost entirely on physicians' compliance with them, and the patient's compliance with the physician. Physicians may respond to information from such systems in various behavioral responses [19].

The described system provides physicians with information about patients who can benefit from being included in a prevention intervention. Ideally, patients identified by the system as eligible for intervention (according to the evidence-based guidelines) should be included in the intervention. Nevertheless, one cannot expect the physicians to include all suggested patients and to include patients necessarily during their first visit (although this may have advantages). The data show that most patients suggested to be included in the intervention were eventually included (85.7%). However, these patients were included in only about one third of the visits (35.6%), and in the remaining 62.6% of the visits the physicians simply ignored the enrollment suggestion (i.e., escaped the enrollment screen). In other words, the physicians could actually prevent 54,554 interruptive pop-ups (62.6% of the total 87,165 visits) by either including or excluding the patient once the enrollment screen appeared. These 54,554 visits were "wasted", both because the patient was not enrolled in the intervention for the benefit of improved prevention, and because the system kept "nudging" the physicians in subsequent visits. This is a seemingly irrational

behavior of the physicians, and the reasons of such behavior require deeper exploration.

One way to explore this behavior is by looking at patients' characteristics, which may affect the physician's decision to include the patients in the intervention. The data show that patients with a cardiovascular disease, dyslipidemia, diabetes and hypertension had a better chance to be included in the intervention. Older patients had lower chance of being included in the intervention. Older patients' usually have more complex clinical conditions and co-morbidities, and the prevention of cardiovascular disease may be only one of conditions to handle. Patients' gender and being a smoker did not play a significant role for predicting the chance of being included in the intervention.

These data show that physicians apparently weighted these clinical markers when deciding whether a patient should be included to the intervention. The physicians are aware that once a patient will be enrolled, the system will send them treatment reminders and suggestions, which may interrupt future clinical encounters. Hence, they carefully pick the patients that will be included. Although they included the majority of the suggested patients, they did not automatically include all suggested patients, but apparently weighted their clinical markers.

The high "escape" rate can be explained by the nature of the reminders, as being interruptive to the current visit. Inclusion will result in further "interruptions", and when the physician chose to exclude a patient, the system will ask the physician to specify the exclusion reason. These two tasks may be unrelated to the reason for which the patient came to the visit, and may distract the physician from the patient's current complaints. "Escaping" the screen may seem to be an easy and less time-consuming option, since the physician can focus on the patient's complaints. Other reasons can be suggested for the high "escape" rate, such as alert fatigue, increased workload, deviance from traditional workflow, low motivation to use, emotional reasons, low perceived alert validity, usability issues, and system-specific reasons (e.g., physicians may ignore alerts when they sense that the specific guideline is not suitable for the specific patient, overall disagreement with a guideline, patient non-compliance, etc). Moreover, because the system was in an operative pilot at this period, it is possible that the physicians didn't know how to use the system, or were unaware of the benefits of using it, and hence chose to "escape" from the screen. The findings may suggest these as possible reasons, yet further research should explore the various reasons for such behaviors and physicians' motives for choosing them.

This system is unique in the physician's ability to choose which patients will be included in the intervention. CR systems typically generate reminders according to automatic patient identification without giving physicians control over the inclusion of patients. Hence physicians' usage of our system may be different from systems with forced reminders in which the physicians cannot choose upon which patients reminders will be given.

These results raise questions regarding the design of such system. System designers should be aware of such unintended consequences and strive to avoid them, either by using alternative ways to disseminate the information to physicians, improved user interfaces, organizational measures such as incentive systems, etc. Physician involvement in the design process, which is a theme which the MEDINFO conference is trying to highlight, is crucial to ensure competent and valuable systems.

Conclusions

We evaluated factors which may affect clinicians' responses to suggestions to enroll patients to a CR intervention. The majority of the patients suggested for inclusion were eventually included. However, these patients were included in only about one third of the visits, and in the remaining visits the physicians ignored the enrollment suggestion. Patients with a cardiovascular disease, dyslipidemia, diabetes, hypertension or younger age had a better chance to be included in the intervention. System designers should be aware of such usage of reminder systems and regard to human-computer interface design and physicians' expectations and motives for use them. Further research should explore the various reasons for such behaviors, aiming at providing physicians with efficient and useful systems.

Abstract

Engaging busy healthcare providers in online continuing education interventions is challenging. In an Internet-delivered intervention for dental providers, we tested a series of email-delivered reminders - cues to action. The intervention included case-based education and downloadable practice tools designed to encourage providers to increase delivery of smoking cessation advice to patients. We compared the impact of email reminders focused on 1) general project announcements, 2) intervention related content (smoking cessation), and 3) unrelated content (oral cancer prevention focused content). We found that email reminders dramatically increased participation. The content of the message had little impact on the participation, but day of the week was important – messages sent at the end of the week had less impact, likely due to absence from clinic on the weekend. Email contact, such as day of week an email is sent and notice of new content posting, is critical to longitudinal engagement. Further research is needed to understand which messages and how frequently, will maximize participation.

Introduction

Use of the Internet for continuing education interventions has risen but little is known about what predicts level of participation and engagement by healthcare providers. Health care providers often access the Internet to search for information. In addition, the Internet is also used for continuing education and quality improvement educational interventions. However, there are various barriers to use of the Internet. Little research has been conducted on overcoming these barriers to sustained participation in Internet interventions. In this analysis we monitored continued participation over time, and utilized various email methods to sustain participation in an Internet intervention.

Providers, generally, have a preference for web-based continuing education as compared to local or national meetings [1]. Many fields have begun to offer online continuing education to meet this preference [2]; however, the format used for continuing education can also be an important factor in predicting online continuing education use. Prior literature has shown that providing content in small amounts, such as cases, spaced over time is more effective than one, large posting of content [3,4] or traditional online continuing education lectures.

Once a website has been accessed, not much is known about maintaining website engagement by providers. One method often used to encourage repeat usage is email. Email has shown promise in encouraging participation in an educational intervention with minimal effort on the part of the provider [1]. When an email message is received, the provider can choose when, where, and how to engage in the website. This ease of use greatly enhances a website's adoption by the provider community. Several studies have found high response rates from email, some as high as 50% [1, 5- 7] and have shown that multiple reminders, even though thought to be intrusive by many, can actually increase participation rates [1]. Reaching an audience with multiple time pressures and scheduling difficulties in such an efficient manner bodes well for future Internet interventions.

Engaging health care providers in educational interventions is especially problematic considering the time constraints of the office setting. Internet delivered programs offer greater flexibility to such schedules. Unfortunately, past studies have found that even if a website is accessed, content is only viewed for short amounts of time [8, 9], indicating the need for in-

creased focus on user retention or "stickiness." This study examines use of targeted email reminders (designed as cues to action) to influence participation by dental providers in an Internet delivered intervention for tobacco control.

Materials and Methods

Study Design

The Dental Tobacco Control.net project (DTC) assessed the use of an Internet-delivered intervention designed to encourage dentists, hygienists, and dental assistants to discuss tobacco use with their patients. Prior to randomization, all practices were required to have Internet access in their practice and complete a run-in phase including baseline data collection from patients. General and periodontal dental practices in both urban and rural settings in Alabama, Georgia, Florida, and North Carolina participating in the Dental Practice-based Research Network (www.dpbrn.org) were enrolled. One hundred and ninety were randomized to the two-year trial from 2005-2007. Of the 190 dental practices, 95 were randomized to the DTC.net intervention website and 95 were randomized to a wait-list control. Our prior published results demonstrate that the DTC.net intervention was successful in increasing smoking cessation advice at six-months of follow-up. For this analysis, we followed the cohort of intervention practices. These 95 intervention practices included 118 dentists and 334 hygienists/dental assistants. The study was approved by the University of Alabama at Birmingham Institutional Review Board.

The intervention website consisted of four educational cases, patient education and practice tools, a forum for chatting, an area to ask questions, and updates in the dental tobacco literature. Users decided how much time they wished to spend on the website. All materials were periodically updated and released over time. The educational cases contained questions to allow interactive learning based on user response and were supported by references and literature. Patient Education Materials and Practice Tools, such as brochures and posters, were available for download or could be requested from the investigative team. The discussion forum allowed providers to directly post questions and receive responses from peers. The "Ask a Question" feature allowed providers to directly communicate with the investigative team.

To encourage more-frequent website participation, push technologies such as email reminders were used by the study to drive participants to the website. Emails were sent to providers to announce cases. The interactive cases (tailored according to provider's responses) were spaced over six months. Dentists received online continuing education credits for completing a case. In addition to case advertisements, to encourage participation, three types of email reminders were sent: 1) general project announcements, 2) intervention related content (smoking cessation), and 3) unrelated content (oral cancer prevention focused content). The new content was summarized in the email reminder and then linked to the updated website content or a full-text version of a new research article. Reminders were delivered on a variable basis, with one or more sent per month for 30-months.

Data Collection

Upon log-in, user authentication was required for all providers and each visit was linked to user tracing logs on the intervention server. The user tracing was used to calculate the various measures of participation including tracking the date, time, pages visited (type and volume), and total time of website visit. We narrowed our user tracing to a group of key web-pages (home, main page of each educational case modules, headlines, etc.). We defined accessing these pages as an "audited event." For this analysis we used longitudinal user tracing follow-up data from the cohort of 95 intervention practices.

Analyses

The main dependent variable was provider participation (number of audited events) collected by user tracing on the intervention server. We first assessed the overall impact of email reminders (independent variable) on website participation. We compared days immediately after the email reminders to days when no reminders were sent. Because the messages were sent on different days, we assessed the impact of day of the week on participation. We then modeled the impact of reminders adjusted for day of the week. Subsequently, we compared the impact of the three categories of email reminders (1. general project announcements, 2. intervention related content (smoking cessation), and 3. unrelated content (oral cancer prevention focused content)) on participation. The dependent variable is a count of tracked pages, and could be modeled with Poisson. Because of over-dispersion in the participation data, we used a negative binomial regression to model the association of email reminders with participation.

Results

Practice Characteristics

Ninety-five intervention dental practices were invited to participate in the Internet intervention (Table 1).

Participation in the Intervention Website

Of the 95 intervention practices, at least one provider from 72 practices (76%) accessed the website at least once. Overall, there were 4,797 audited events (accesses to unique traced pages). These audited events occurred during 531 unique visits to the intervention website by 138 dental providers (73 dentists and 65 hygienists/dental assistants). There were 87 dentists and 249 hygienists/dental assistants in these 72 practices. Thus, 84% of the dentists and 26% of the hygienists/dental assistants in these 72 practices logged on to the intervention website.

The mean number of audited events per day was 5 (SD = 12). Of note, activity occurred only on 28% of days in the 30-month tracing period. On days when activity occurred, the mean audited events was 19 (SD = 18). Our user tracing demonstrated that dentists had higher participation (median audited

events (AE) = 32 (95% CI 22-45)) as compared with hygienists/dental assistants (median AE = 17 (95% CI 14-24), median test p = 0.01. The number of visits to the website was also different (dentist median visits = 3, hygienist/dental assistants median visits = 2, p = 0.001). Participation did not vary by the practice characteristics listed in Table 1.

Impact of Email Reminders on Provider Participation

Thirty announcements about cases were emailed to the practices. In addition, 28 reminders were emailed to the providers over time. Figure 1 shows the resulting website usage after each email reminder. The email reminders resulted in the largest number of visits on the day the email was sent (E-mail release day). The day after the email also showed an increase in website visits, then returning to baseline.

Unadjusted model: Compared with non-reminder days, in our initial *unadjusted* negative binomial model, the day of email reminder release and Release Day + 1 were more likely to have had higher audited events (Incidence Rate Ratios 6.6 (95% CI 1.9-24.0) and 5.0 (95% CI 1.4-17.9) respectively), but release day + 2 and beyond were similar to non-reminder days. Incidence Rate Ratios (IRR) are a measure of observed over expected counts from negative binomial regression.

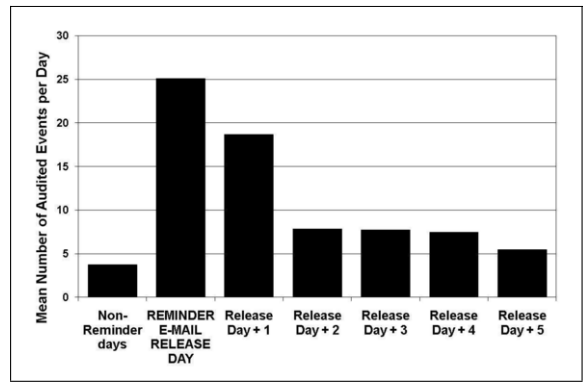

Figure 1- Dentist and staff participation by day of email reminder release

Providers engaged in the website more on weekdays than weekends. As noted in Figure 2, participation peaked on Wednesdays, and began to decline on Thursday, and was quite low on weekends.

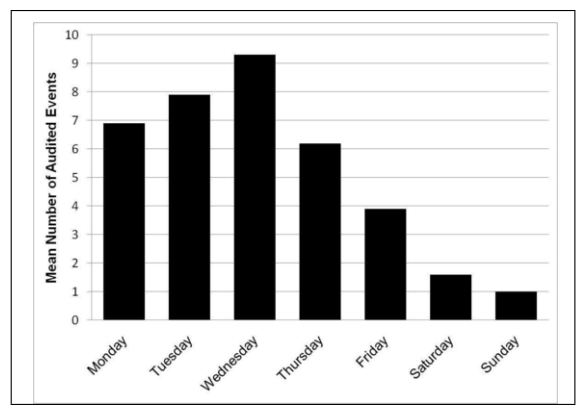

Figure 2- Participation by day of email reminder release

After adjustment for day of the week, when compared to the reference day, the expected count for the number of logons is multiplied by a factor of 5.13 the day the email was sent, and 6.27 on the day after (Table 2). In this multivariable model, adjusting for day of the week, the second day after the email was sent was also significantly greater than the reference.

Of note, six of our messages were sent out on a Thursday or Friday. The negative binomial model provided a better fit than the Poisson model due to over-dispersion of the outcome.

As discussed above, three types of email reminders were sent: five emails were general project announcements (e.g., describing the practices involved, goals, etc.); 13 email reminders were directly related to smoking cessation; and 10 email reminders were about oral cancer prevention, a topic that dental providers in our formative work noted to be of importance to them, a desired area for up-to-date information.

Table 2- Association between email reminders and rate of participation, after adjustment for day of the week and day of education case release

	Adj. IRR*	95% CI	P-value
Reminders Emails			
Non-reminder days	Ref.		
e-Mail release day	5.13	1.53-17.18	0.008
Release day + 1	6.27	1.85-21.31	0.003
Release day + 2	4.79	1.35-16.97	0.015
Release day + 3	2.31	0.67-7.95	0.184

Sunday	0.15	0.06-0.34	0.000
Case Release Email			
No case release	Ref.		
Case Release Day	3.38	1.09-10.50	0.035

*Adjusted Incidence Rate Ratio (IRR) from a negative binomial model, including 4,797 audited events. IRR adjusted for day of the week, and accounts for release of case emails over time.

The reminders related to smoking cessation resulted in the most audited events (mean 16 per day), followed by oral cancer prevention (10) (Figure 3). Of note, general project announcements that did not include links to new content had less impact. In a subsequent negative binomial model, general project email release days were not significantly greater than non-reminder days.

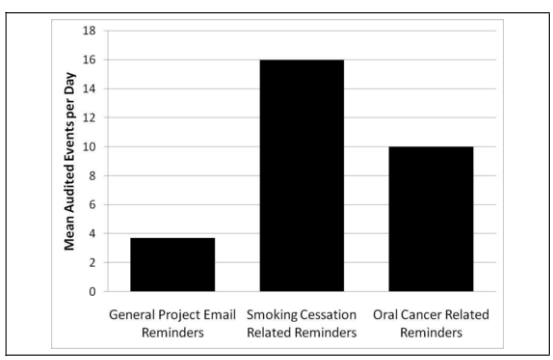

Figure 3- Participation per day for first three days after email release, comparing three types of email reminders

Discussion

In this randomized trial of an Internet-delivered continuing education intervention in dental practices, we were successful in engaging 138 dental providers. We found that email reminders were critical to longitudinal participation in the intervention. On days when no recent reminders had been sent, very little participation occurred. The day after an email was sent, participation had multiplied six-fold, compared with non-reminder days.

As previously published, our randomized trial was successful in increasing rates of smoking cessation advice in these dental practices, compared with control [10]. Intervention dental practices increased rates of smoking cessation advice by 11% from a baseline rate of 44% (OR = 1.55 [95% CI 1.28-1.87]). Control practices did not significantly improve.

The impact of the randomized trial was directly associated with level of participation. Thus, our success in changing provider behavior was dependent on our email reminder system. Without the reminders, level of participation would likely have been too low to have resulted in a change in rates of smoking cessation advice.

Nearly all providers report having access to the Internet [6, 11] but with the growth in new health care knowledge, staying up-to-date can be challenging. Internet use among healthcare providers is at an all-time high and online clinical information seeking and engagement in online education continues to grow. In a study of U.S. physicians of all specialties in active practice, 71.5% of medical providers use the Internet for literature searching and ranked journals as the most important source for clinical information [12]. Updating the content of the website to summarize current news and journal articles and provide training and education in these areas could prove beneficial to the providers and drive website usage.

We have demonstrated the potential improvement in provider website participation and engagement following the introduction of email reminders. Of note, each of our email reminders included an "opt-out" option to no longer receive messages. In all, we sent 28 reminders to 138 dental providers, and received zero opt-out requests despite the nearly 4,000 opt-out opportunities. Future interventions could consider sending email reminders even more frequently.

The email reminders provide a direct cue to engage providers and encourage user retention; however, care should be given to the timing of emails [13] and message content. Provider website visits were higher when the email content was a subject of interest. Our general project announcements had little effect. Only reminders linked to *new content* were effective.

We learned an important lesson – take care to place messages at the beginning of the week, not the end. Because it may take providers two to three days to respond, one must avoid having the time of potential activity overlap with the weekend days. In our multivariable analysis, accounting for day of the week, the association of email reminders and participation was stronger for more days, suggesting reverse confounding by day of the week for Release day + 2.

The results of this analysis are limited to only one intervention. We found that provider characteristics listed in Table 1 were not associated with participation, but other variables may be important predictors. Our analysis did not account for provider variations in interest, time constraints, and computer experience, all of which could influence provider participation in an Internet intervention.

Further research into reasons for participation can enhance website engagement and help researchers learn more about designing effective interventions. Researchers should experiment with varying frequency of email reminders [13], and varying content. In general, additional innovative approaches are needed to engage providers in longitudinal interventions.

Acknowledgments

This project was supported by grants R01-DA-17971, U01-DE-16747, and U01-DE-16746 from the National Institute on Drug Abuse (NIDA) and the National Institute of Dental and Craniofacial Research (NIDCR) at the National Institutes of Health.

Abstract

To investigate best practices for implementing and managing clinical decision support (CDS) in community hospitals and ambulatory settings, we carried out a series of ethnographic studies to gather information from nine diverse organizations. Using the Rapid Assessment Process methodology, we conducted surveys, interviews, and observations over a period of two years in eight different geographic regions of the U.S.A. We first utilized a template organizing method for an expedited analysis of the data, followed by a deeper and more time consuming interpretive approach. We identified five major categories of best practices that require careful consideration while carrying out the planning, implementation, and knowledge management processes related to CDS. As more health care organizations implement clinical systems such as computerized provider order entry with CDS, descriptions of lessons learned by CDS pioneers can provide valuable guidance so that CDS can have optimal impact on health care quality.

Keywords:

Decision support systems, Clinical, Medical order entry systems, Information management

Introduction

Clinical decision support (CDS) provided through computerized provider order entry is essential to enhancing health care quality [1,2]. We define CDS broadly to include "passive and active referential information as well as computer-based order sets, reminders, alerts, and condition or patient-specific data displays that are accessible at the point of care" [3]. Federally funded incentives are sparking intense interest among most health care organizations to implement clinical information systems that include some CDS over the next few years [4]. At present, only 10 to 20 percent of U.S. hospitals have CPOE available [5,6]. Community hospitals account for 86% of the 5708 hospitals in the U.S. [7] However, only 6.9% of community hospitals report having even a basic level system [6]. Little research about CDS has been conducted in community hospitals, and in fact fully 25% of studies included in Chaudhry's systematic review about the impact of health information technology on quality were from just four academic institutions [8]. In ambulatory settings, although 17% of physicians report that they use clinical information systems, only 4% use systems that include CPOE and CDS [9]. A major criticism of current health information technology (HIT) articulated in a recent report is that HIT fails to provide cognitive support to clinicians when they need to make decisions [10]. In fact, it can produce many unintended adverse consequences [11], especially related to clinical workflow [12]. Because many problems with CDS relate to behavioral, organizational, and cognitive issues [13,14], the Provider Order Entry Team (POET) based at Oregon Health & Science University in Portland, OR, U.S.A. is conducting two multi-site ethnographic studies about these issues, one in community hospitals and the other in ambulatory clinics and vendor environments. The purpose is to identify best practices for CDS implementation and knowledge management. We define best practices broadly to include widely recognized and agreed on procedures and practices that have been shown to improve internal processes.

The following sections summarize foci, methods, and results.

Methods

We adapted a form of ethnography which has been used successfully in international health for the rapid assessment of complex site-based situations, the Rapid Assessment Process (RAP) [15]. By using structured assessment instruments, expert interviews, field surveys, and intensive site visits by a multidisciplinary research team, we minimized the need for lengthy periods of time in the field (a characteristic of traditional ethnographic fieldwork). We also held a conference of CDS experts to help us verify what we found in the field.

Sample Selection

Because we aimed to gather information about best practices, we selected clinical sites with reputations for excellence in the use of clinical systems and CDS. Table 1 outlines attributes of our study sites. The hospitals were community hospitals with different commercial systems [16]. The ambulatory sites

Table 1 – Sites and data collected

Number of clinics observed	NA	NA	9	6	5	9	6	NA	NA
Number of interviews	15	12	13	9	9	9	12	6	6

were all members of the Clinical Decision Support Consortium [17]. Four different commercial systems and three locally-developed systems are used at our selected clinical sites. During visits to clinical sites with commercial systems, the team realized that we could not gain a complete picture of knowledge management processes unless we could learn more about the companies that provide CDS content made available through commercial electronic medical record (EMR) systems. We selected two companies to visit first because they provide much of the CDS available through popular EMR*systems; other vendor visits are planned.*

We selected as study sites two community hospitals, five ambulatory settings, and two companies that provide CDS content. Providence Portland Medical Center in Portland, OR is an urban community hospital, part of a larger hospital system, using a commercial system. El Camino Hospital in Mountain View, CA is a stand-alone suburban hospital with the oldest CPOE implementation in the world, also using a commercial system. Ambulatory sites included Partners HealthCare in the Boston, MA area, which primarily uses a locally developed system but also includes some sites with commercial EMRs; Wishard Memorial Hospital, a county hospital in Indianapolis, IN, which uses the locally developed Regenstrief Medical Record System; the Roudebush Veterans Affairs Hospital in Indianapolis, IN which uses the VA's nationally developed CPRS system; the Mid-Valley Independent Practice Association (MVIPA) in the Salem, OR area, which uses a commercial system; and the Robert Wood Johnson (RWJ) Medical Group, in New Brunswick, NJ, which also uses a commercial system. The vendor sites were Zynx Health in Los Angeles, CA, which provides evidence-based order sets and interdisciplinary plans of care and First DataBank in South San Francisco, CA, which provides medication information. We received human subjects approval from each investigator's home organization and from each appropriate site.

Within each organization, we selected subjects with the assistance of a local sponsor. For interviews, we purposively selected a broad spectrum of users who ranged from champions to skeptics, individuals who either develop or customize CDS, support staff, administrators, quality officers, and IT staff members. We observed users entering orders in many areas of the hospitals and in a broad spectrum of primary care and specialty clinics. At vendor sites, we interviewed CEOs, individuals who develop content, technical staff who work with EMR vendors to make content available electronically, training and support staff, and marketing managers. Experts for the expert conference were selected based on their experience with community hospital and ambulatory CDS.

Data Collection

Figure 1 shows the progression of data gathering and reporting that occurred between 2007 and 2009, including the focus of our work, activities, study sites, and publications. After several months of preliminary preparation, including development of an inventory of CDS types and knowledge management practices [18] and a demonstration of each system for each site, four to seven researchers spent three to five days at each clinical site. We visited Zynx and First DataBank for less time. The nature of these last two site visits was quite different since the focus was the vendor perspective and the visits did not involve clinical observations.

For the community hospitals and the ambulatory settings, we asked questions and observed individuals and committees at work to learn more about: Policy, governance, control, culture; User issues including usability, training, and impact on workflow; CDS content/knowledge management practices; and Technology and infrastructure issues. While visiting the content vendors, we asked about: The marketplace, their niche and relations with EMR vendors; CDS content/knowledge

management processes; Customers—types, frustrations, feedback, challenges; and Use of the product.

Data Analysis

The nature of the Rapid Assessment Process is such that we needed to analyze the data quickly so that we could provide feedback to the site in the form of a report, receive comments back from subjects as a form of "member checking" [19], and then prepare for the next site based on what we had learned. We did this expedited analysis by dividing into pairs to scan transcripts and field notes to identify user, administrative, and IT perspectives at each site to write sections of each report. As we did this, we noted general themes, which we began to identify during debriefings held twice a day during site visits. We developed a codebook and used a template method [20] to roughly code the data. For each report, we identified best practices (e.g. what they did especially well) and challenges in addition to themes. We requested feedback about the reports from sites as a form of member checking. Once the reports were written, we began using a more classical qualitative research approach that was inductive and interpretive. This involved content analysis using the words and actions of the subjects to identify patterns and themes to modify and augment the already-identified codes. We discussed the best practices identified across sites with our panel of experts and the CDSC research team.

Iterative Methods

Although we had carefully developed a field guide containing a site inventory profile about CDS at the site, interview question guides, observation guides, and even guides to debriefing, we found that we needed to modify each instrument for each site visit [21]. We made major changes when we started visiting outpatient sites and again when we started vendor visits. The three types of settings vary greatly in their approaches to CDS. Below we describe a number of best practices for optimizing the value of CDS that emerged from our analysis.

Results

Best Practices

Five large categories of best practices emerged from our analysis:

Best Practice 1: View CDS broadly. Experts and users have widely differing definitions and understandings of CDS, causing a barrier to optimization of CDS use and value. The users appreciate CDS that helps them get through their day, a kind of CDS we call "inline" because it is integrated with their workflows. Experts usually describe CDS in terms of sophisticated alerts and reminders. The vendors providing content view CDS as a way to foster the practice of evidence based health care. There is a danger in defining CDS too narrowly in terms of sophisticated alerts and reminders that are available only at elite institutions. While it is useful to learn from their experiences because they are on the cutting edge and can provide models of CDS use for the future, they are not typical of the majority of sites that provide health care nationally. By defining CDS broadly so that it includes passive elements such as default values and workflow enhancement features such as templates to assist with data gathering, documentation, and clinical reports, all stakeholders will be continuously reminded that the clinicians who are the recipients of CDS are the ultimate customers who need to accept and use these features.

Best Practice 2: Move forward with simple CDS no matter what your size. If an organization has the wherewithal to implement CPOE, it can also use CDS. There is some "low hanging fruit" among CPOE-delivered types of CDS. All of our study sites worked hard to review and select appropriate order sets so that they were available electronically when CPOE was introduced. Order sets assist workflow because they streamline ordering and at the same time they help decision-making. Well-designed checklists and templates can provide guidance at the moment the clinician needs it.

Best Practice 3: Focus on "inline" CDS. We use this term to refer to CDS that does not interfere with a clinician's workflow. One type to consider is "background CDS" which works behind the scenes to consider data related to an individual patient along with rules for good care and makes recommendations such as what antibiotic to order. Another kind of inline CDS is that which notifies an intermediary such as a nurse or pharmacist rather than a physician. These strategies can be especially effective in community settings where interrupting the physician in private practice can be particularly burdensome.

Best Practice 4: Use what is available from your vendor but plan to customize the CDS. Each hospital and clinic has its own culture and need for CDS. Sites with locally-developed CDS tend to identify a clinical need and then design a CDS intervention to address it. Organizations with commercial systems may not have the staff to do this, but they can sometimes purchase appropriate CDS content through their EMR vendors. EMR vendors usually do not develop their own CDS. Instead, they rely on content development companies to write content and partner with the EMR vendor to provide it electronically. Usually both the content and EMR vendors provide a wide range of potential CDS interventions, leaving it to the customer (the hospitals and purchasing organizations) to filter out those that are not wanted. This is a necessary, but time and resource-consuming step and often more difficult than expected. Customers must have clinical leaders and skilled "analysts" on staff who understand both clinical work and information technology.

Best Practice 5: Plan knowledge management processes early. The sites we studied that had locally-developed systems are struggling to catch up with their knowledge management needs. Each one found itself at a point where so much CDS had been developed and implemented that it was hard to keep track of it for the purpose of updating and maintenance. Organizations that have implemented commercial EMRs with CPOE more recently can take advantage of knowledge management capabilities available through vendors [22]. First, the EMR vendors track changes made at the vendor level so there is an audit trail available. A wise or-

ganization tracks its customized changes as well so that as time passes, a history of modifications is always available. Second, tools are available from content development vendors specifically designed to help with knowledge management. They can assist with the decision-making and consensus development process, notify customers when updates are needed, and keep an audit trailof decisions. Good knowledge management practices depend on three foundations: the availability of skilled information systems staff, the existence of a well-developed consensus development and decision making structure, and robust computer tools.

Discussion

We have seen that organizations can do this right [23] and can serve as models of best practices. Because we talked with representatives of many stakeholder groups interested in CDS, because we observed clinicians using CDS, because our study sites included a wide variety of sizes and types of health care delivery organizations, and because we verified a number of best practices outlined by others [2,24], we believe the five best practices categories described above represent a high level view that can be useful to all types of organizations planning to implement CPOE with CDS. All of these best practices depend on planning ahead, ideally prior to CPOE implementation. Best Practice 2, moving forward regardless of size, might entail numerous clinics organizing into a larger organization for the purpose of purchasing and maintaining an information system. This is a large undertaking, requiring significant planning, but it can possibly deliver other financial advantages beyond information systems implementation. All of the best practices also involve the availability of skilled informatics specialists. Two of our sites outsourced the customization and maintenance functions to their EMR vendors by contracting with their service organizations. Availability of a clinician leader is absolutely necessary, even if some activities are outsourced. Study limitations include restricted fieldwork and as yet incomplete vendor visits.

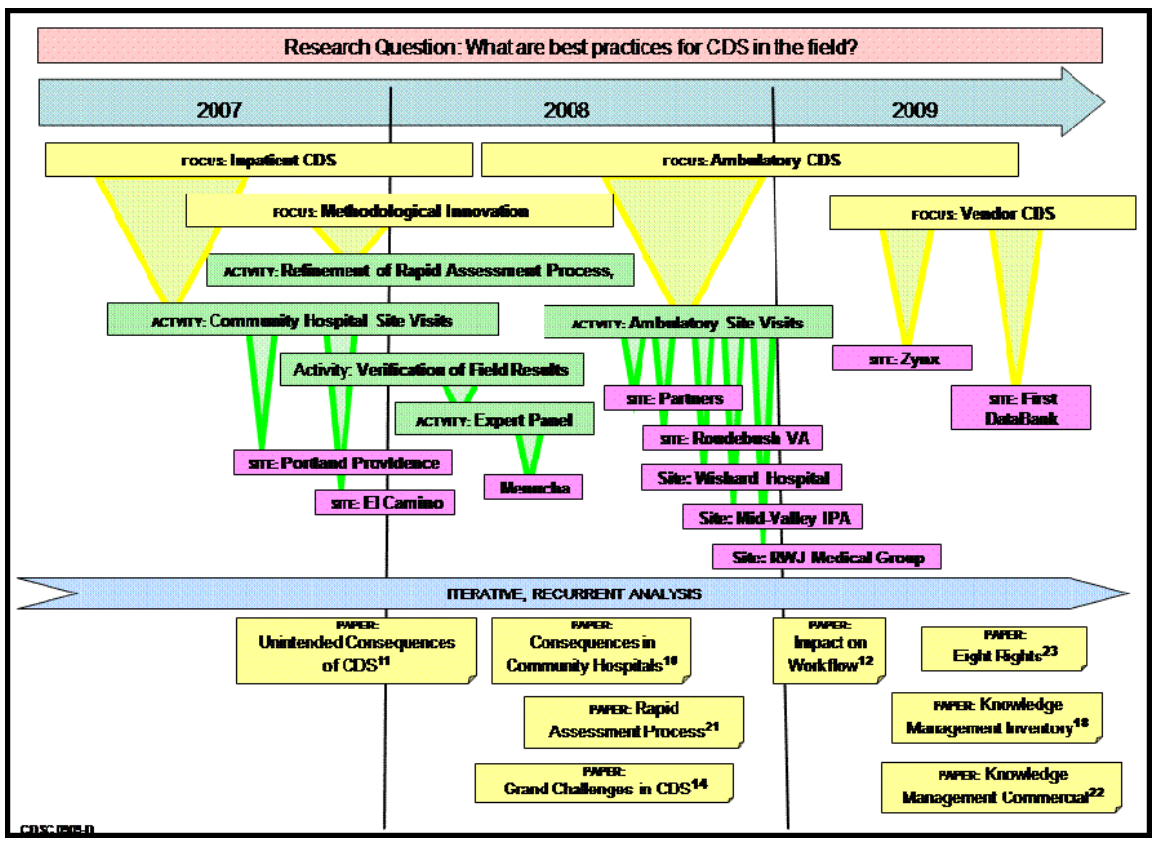

Figure 1- POET research overview 2007-2009
**Foci, activities, and sites as they were approached over time.*

Conclusion

The use of ethnographic techniques to study best practices for CDS and knowledge management in the field allowed us to understand and synthesize a broad range of perspectives. Our study sites included many types of organizations; all of them can be considered pioneers because wide use of CPOE with CDS is still years in the future. Lessons these pioneers teach us now can provide valuable guidance so that CDS can eventually have optimal impact on health care quality worldwide.

Integration of Workflow and Rule Engines for Clinical Decision Support Services

JaeHoon Lee[a], JeongAh Kim[b], InSook Cho[c], Yoon Kim[d]

Abstract

Although recent studies have suggested the feasibility of integrating workflow and rule technology in a Clinical Decision Support System (CDSS), their implementation has not been verified yet. This paper proposes a knowledge engine which integrates workflow and rule engine as a tool for interpretation and execution of computer interpretable clinical guidelines. The objective of this paper is to validate its feasibility in two perspectives: clinical knowledge coverage and execution performance. The two open source engines which were selected and integrated were chosen due to their reliability and consistency. Implementation of workflow and rule engine integration has shown that the integrated knowledge engine (uBrain) is an effective CDSS for the execution of clinical guidelines.

Keywords:

CDSS, Workflow, Rule engine

Introduction

Over the decades, many researchers have tried to develop and implement effective CDSSs. The basic concept of a CDSS is to provide an intelligent tool which can provide clinicians or patients with clinical knowledge and patient-related information to enhance patient care experience. In addition to the revolutionary advances in the field of information technology, recent CDSSs are based on artificial intelligence or knowledge engineering technologies. Furthermore, the architecture of CDSSs has changed from standalone systems to standard-based and service-oriented systems. These advances demonstrate that future research and trends of CDSSs development will aim to maximize the interoperability through separation of their components such as data, rules, processes and services.

Recently, CDSS development basically employs two main components: 1) a clinical knowledge base for what to dispose and 2) an inference engine for how to dispose. The studies on various knowledge bases mainly have focused on computerized and standardized representation of clinical knowledge. One of the most widely used formats is the Computer Interpretable Guidelines (CIGs) which is used as a generic template to facilitate the translation of guidelines from their published formats into computer interpretable algorithms.

The inference engine of a CDSS performs such functions as interpreting and executing the guidelines encoded in the specific representation formats. There are generally two approaches in developing a clinical inference engine. One approach is to develop an engine for a specified clinical guideline format. Well-known guideline formats generally contain their own execution engines [1]. The other approach is to adopt common knowledge tools into clinical decision support. Since the core logic of clinical guidelines consist of complicated rule sets, commercially available rule engines have been adopted on a wide-scale basis. Several researches have reported that commercial rule engines can be an execution engine for clinical knowledge [2].

Although rule engines have been verified as having an alternate core function as an inference engine, they cannot possible provide complete coverage for clinical guidelines. The external part of clinical guidelines consists of triggers, actions and decision-makings. Recent research has focused on reinforcing functions that control the main flow of guidelines, invoking rule execution and interfacing with local applications. The rule invokers were originally embedded in the CDS applications, but as the coverage of clinical guidelines became wider, the necessity to make them independent and to standardize them has increased.

Recent studies have suggested the adoption of the workflow concept into clinical guidelines, particularly in terms of pattern coverage, execution and knowledge representation [3-5]. It is very promising because as the coverage of knowledge bases in CDSS becomes wider spread, so does the original use of workflow as a business process management which can be adequately utilized in clinical processes. The clinical guideline can be effectively separated into the combination of workflow and rule models. Therefore in this paper, we integrate workflow and rule engines as a knowledge engine, and validate its availability.

In this study, a workflow engine is used as an interpreter of the guideline process model, and a rule engine is used as an infer-

ence engine. The workflow definition model represents the logical flow of the guideline model, and the rule model implies unit logics such as clinical concepts, constraint, and criterion. When a service is triggered, the workflow engine invokes the rule engine for execution generating actions according to the results. In this study to increase the integrity in the execution of guidelines, we integrated two open source engines which were verified in a decision supporting system for management information system domain.

The verification of the proposed work is done at two critical points of the CDSS: 1) accuracy of knowledge processing and 2) execution performance. The accuracy of the proposed system can be verified using test cases. The representative clinical guideline models and their test cases can measure the accuracy and reliability of the knowledge engine. Performance was measured as the availability of practical implementation at local institutions. The performance criteria included were service response time, data fetching time, and durability against stress. Acceptable performance and time parameter for a CDSS is two transactions per second [2].

The results of the study show that the elements of the clinical guideline were correctly executed and made within the parameter mentioned above. Additionally, the integrated knowledge engine provided wide coverage and the expression power of the integrated knowledge engine can be extended to other formats for clinical guideline formats. The contribution of this paper is that it verified the availability of an integrated engine using workflow and rule models.

Materials and Methods

Workflow management system and rule engine

A workflow definition model and its management system are widely used in modeling and automation of business processes. A workflow management system employs various tools to support the entire life cycle of workflow from its de-sign to its execution and analysis [6]. The core function of a workflow management system is the enactment service which interprets the workflow definition model step by step, delivers each task to the actual workers and controls and monitors the status of the process. This software component, which acts as the workflow enactment service, is called the workflow engine

Since a workflow model can represent diverse patterns of logical flows such as data, resources, and controls, approaches to workflow for clinical guidelines have been adopted and tried. One of the more significant approaches was the comparison of two concepts in terms of their expression power [4]. These studies systematically analyzed and clustered the process patterns and control structures towards their ability to be automated. The conclusion of these studies showed that CIG modeling languages are remarkably close to traditional workflow languages from the control flow perspective, but cover many fewer workflow patterns. Consequently, workflow management systems may be suitable and applicable for clinical guideline applications [3].

A rule engine is commonly provided as a component of a business rule management system to execute rules. In any IT application, business rules are changed more frequently than the rest of the application code. Rule engines are the pluggable software components that execute business rules that have been externalized from application code. This allows business users to modify the rules frequently without the need of IT intervention and hence allows the applications to be more adaptable with dynamic rules.

Verification of knowledge coverage and performance

In order to apply workflow and rule model into a clinical guideline, the feasibility should be evaluated by measuring the similarity between the two concepts. The verification has two perspectives: 1) knowledge coverage and 2) physical performance. The former is related to the relevance of the proposed method, and the latter is about verifying the applicability for the real clinical field.

Generally speaking, clinical knowledge bases are very complicated and specified to domain experts so it makes it difficult to evaluate and compare with knowledge bases in different domains. One of the significant methods is to compare with generalized models. Recent research concentrates on the similarity of workflow models and CIGs in terms of patterns. The result of the comparison shows that CIG languages such as Abru, EON, GLIF3.5, and PROforma are very similar to process languages of workflow management systems although they do not make use of many of the workflow patterns in such systems [3].

Another dominant point for verification is the physical performance of a knowledge engine, and this may be the biggest benefit for adopting commercial engines. The factors which determine the performance of a knowledge engine are as follows: 1) delivery time of patient data to the engine, 2) response time to make actions when a large number of rule sets are loaded, 3) loading time of rule models. In case of an engine which is a pre-loading type, loading time is negligible [2].

Generally, the operation time of the CDS service is very short; less than a second. Therefore, in case of occurring redundant service requests, the system should endure the stress of multiple accesses to prevent waiting too long a time for the response. Another major bottleneck in service performance is delivery of the data to the engine. In order to minimize the number of round trips between a rule service and an external repository, the rule service should be primed with a large swath of patient data. Consequently, the CDS service system should satisfy not only providing quick response time but also avoid overloading adjacent systems.

Selection of engines

In order to select most suitable workflow and rule engines, the following elements are considered.

- Integrity: In order to achieve fast response and correctness of execution, the two engines should be easily integrated. The ingredients of integrity are the same pro-

gramming language, fully object-oriented design, and simple and extensible interfaces.

- Reliability: The engines are required to contain industrial references in order to assure stable performance against physical stress particularly in practical uses in local institution.
- Extensibility: The framework of engines should be based on a well-known architecture (J2EE etc.) so that its components can be easily added or reconfigured.
- Open source: Because this study was involved from a national perspective, the proposed works should be non-profitable and open to the public.

Consequently, two open source engines; uEngine and BRAIN were selected. uEngine is a workflow engine which has advanced in convenient development of workflow activity types so that it can integrate the other modules with ease. BRAIN is a business rule engine based on an object rule model and <if then> rule expression. Object rule model defines the domain model and interface model. Domain model defines the domain scope and standard value or basis for criterion. Interface model defines the variables to be compared with standards. Various criteria were expressed in if-then statements.

The two engines were fully developed in the Java language platform and based on object-oriented design patterns. These engines were already verified in decision supporting module of management information applications.

Development

The integrated knowledge engine (uBrain) was designed to take a layered approach to partitioning the functions which are provided by the components. Basically, a clinical guideline contains diverse elements which have their own features and functions. The most closed part to users is related to clinical actions such as retrieving patient data, triggering interference, making recommendations or notifications. These kinds of actions can be separated and represented effectively in workflow model. The workflow engine employs basic activity types which have same functions to clinical actions, so a knowledge author can design clinical workflow with them.

The part of clinical guideline for inferences was separated as rule models, and conducted by a rule engine. Logical elements of clinical guidelines such as variables and their values, presence of a status, and composite logics can be interpreted as rule functions in the rule engine. The rule engine reads input data sets at once, executes, and returns the result sets. The role of the workflow engine is activation of rules, delivery of input data sets and the execution results.

The external feature of uBrain was developed as a client-server system which is based on the assumption that there exist many physically distributed clients. Also, standardized clinical guidelines for each disease were defined and registered in the service registry so that a client can find and invoke for the CDS service for a specific type of guideline. Consequently, uBrain defines the business logic of a guideline model, the local EMR provides data, and the associated clinical applications will support the interactions between the users and a guideline implementation system. This architecture is based on service oriented architecture.

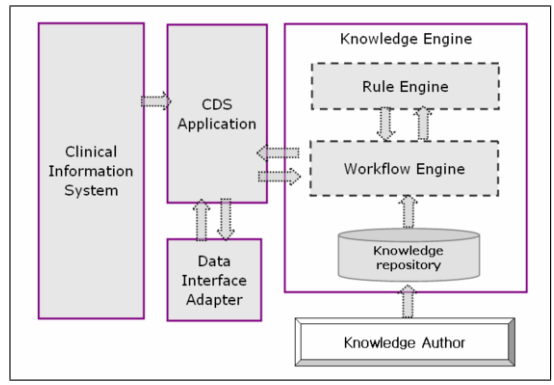

Figure 1- Proposed CDSS architecture

The overall architecture of uBrain is shown in Figure 1. The system architecture was designed to provide flexibility for integration with clinical information system to be taken by a local institution. Clinical guidelines may be stores in a knowledge repository after being encoded by a knowledge author. The engine retrieves the knowledge from the repository according to a request (event) from the CDS application. To load the patient data from the clinical information system to the knowledge engine, the CDS application should fetch the patient data in run time through data interface adapter (DIA).

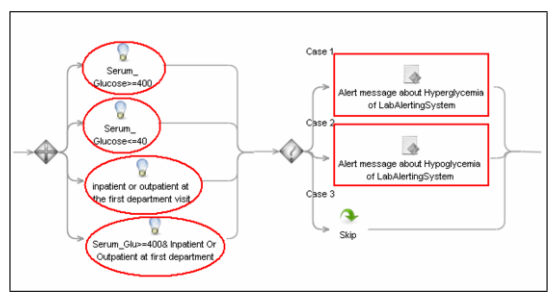

Figure 2- Integration of workflow and rule model

Figure 2 shows the integrated feature of workflow and rule as a guideline model. The rule activity icons (in circles) indicate the invocation points for rule execution, and the result values may be stored at the variables in the process model. At the decision-making points (branching points), the workflow model selects a path to execute based on the rule execution results and activates actions (activity icons in squares), and finishes the process.

Results

Stress test of the integrated engine

To validate the proposed framework, example clinical guidelines were selected. The guidelines are to validate performance, knowledge coverage and extensibility. Lab alerting; a simple type of clinical guideline is first implemented to see the response time of the engine. Lab alerting consists of seven types of sub guidelines which contain one or more rule sets. The stress test is under the assumption that there is a server for guideline service and multiple clients, service requesters. The evaluation points are 1) how the response time decreases according to multiple accesses and 2) how the engine is affordable against overload. The results are shown in Table 1.

Table 1 – Execution results for load test

No. of connections	No. of test cases	Processing time (msec)	
		Average	Std. dev.
1	30	48.3	4.9
2	60	111.3	67.5
3	90	1,368.1	500.9
5	150	4,303.5	562.4
10	300	6,414.3	2,746.6
20	600	14,154.5	7,538.7
30	900	20,823.7	23,638.5

The stress tests were conducted under various conditions. The number of simultaneous requests increased from 1 to 30. In table 1, the average processing time increases proportional to the amount of requests. Standard deviation values increases more sharply than average processing time. This implies that the stressed environment influences the quality of service in both indicators of means and variances. In particular, the largest stress condition makes the variance of processing time much higher so that sometimes users give up waiting for the response.

Performance test in real usage

One of the critical issues in a real environment for CDS uses is the fetching time for the patient data. A DIA was also developed to efficiently retrieve local patient data and make an input data set for the knowledge engine. A test bed which includes a DIA was established based on a clone of the local EMR database which contains real patient data. In all, 323,445 test cases were generated from the database, and the accuracy of uBrain execution results compared to the original lab results was 100%. The performance results for the processing time are shown in Table 2. The results represent that the performance of the system highly depends on the amount of data and rules which should be disposed.

Table 2 – Execution results with test cases

Test name	No. test cases	No. Alerts	Average processing time (msec)		
			DIA	Engine	Total
CBC	39,893	41	137	55	192
Glucose	44,494	229	276	102	378
HCT	62,764	764	457	36	493
Rh typing	10,439	38	787	55	842
WBC	62,612	73	400	32	432
Sodium	51,405	156	446	48	494
Potassium	51,838	349	165	53	218
Total	323,445	1,650	346	52	398

Coverage test

A hypertension guideline was modeled as a case for the complicated knowledge base. It consists of 247 rules and encoded in Sage format. The guideline consists of three recommendation sets; a main guideline which has branches according to existence of diabetes mellitus, and two sub guidelines which make actions for recommendation according to the rule execution results. 201 representative test cases were selected from clinical experts, and the results shows that the integrated engine can cover complicated types of guidelines.

Discussion

The dominant trend in CDSS development is separation of clinical knowledge and reasoning, and their independent disposing. The workflow engine and rule engine were physically integrated in architecture, but independently operated by its own roles. One of the main obstacles which make it hard for CDSSs to spread widely is the hardness to identify or separate the knowledge from other application functionalities and, separation of these components may contribute to increased reliability and maintainability of CDS services.

In the stress test, the engine showed excellent performance and can endure a few simultaneous requests. This will be a factor which needs to be determined to assure the capacity of a CDS server in restricted resources. In run time test, the processing time was found to be divided into three elements: workflow engine processing, rule engine processing, and DIA data fetching. The workflow processing time was almost fixed around 20 micro seconds. The rule processing time was proportional to the number of rule sets. And the data fetching time depends on how many elements should be prepared to execute knowledge engine.

The results of the performance analysis indicate the direction of future works. The number of rule operations is a variable factor to determine the entire processing time so it should be minimized. Some parts of this can be accomplished by caching

for the similar or same conditions. Data fetching operation was still the biggest bottleneck, but this study verifies that the strategy of 'fetching data before execution at a time' is feasible and promising.

Conclusion

The integration of workflow and rule engines is successful in the perspectives of architectural efficiency and availability in clinical domains. The knowledge coverage of the integrated engine was verified by translating and executing Sage based guidelines. Also the engine shows acceptable performance in practical use of CDS services through generation and execution of test cases. Future work is expected utilizing the extensibility and applicability of the proposed methodologies.

Abstract

Numerous studies have shown that the quality of health care is inadequate, and healthcare organizations are increasingly turning to clinical decision support systems (CDSS) to address this problem. In implementing CDSS, a highly promising architectural approach is the use of decision support services. However, there are few reported examples of successful implementations of operational CDSS using this approach. Here, we describe how Hospital Italiano de Buenos Aires evaluated the feasibility of using the SEBASTIAN clinical decision support Web service to implement a CDSS integrated with its electronic medical record system. The feasibility study consisted of three stages: first, end-user acceptability testing of the proposed CDSS through focus groups; second, the design and implementation of the system through integration of SEBASTIAN and the authoring of new rules; and finally, validation of system performance and accuracy. Through this study, we found that it is feasible to implement CDSS using a service-based approach. The CDSS is now under evaluation in a randomized controlled trial. The processes and lessons learned from this initiative are discussed.

Keywords:

Health information system, Clinical Decision Support System (CDSS), Reminder systems, Computerized medical records systems

Introduction

A significant gap exists between actual clinical practice and optimal patient care. Numerous studies have shown that the quality of health care is variable and often inadequate [1, 2]. To address these deficiencies in care, healthcare organizations are increasingly turning to clinical decision support systems (CDSS) that provide clinicians with patient-specific assessments for recommendations to aid clinical decision making [3, 4]

Wright and Sittig describe four distinct architectural phases for decision support: [5]

1. Standalone decision support systems.
2. Integrated systems.
3. Standards-based systems.
4. Service models.

SEBASTIAN is an example of a clinical decision support technology that supports the latest, service-based architectural approach to CDSS implementation[6]. Developed at Duke University, SEBASTIAN is a clinical decision support Web service whose interface is now the basis of the HL7 Decision Support Service draft standard.[7] SEBASTIAN places a standardized interface in front of clinical decision support knowledge modules and makes only limited demands on how relevant patient data are collected or on how decision support inferences are communicated to end-users. Despite this promising, potentially highly scalable approach to decision support, very little has been published related to experiences using this approach to implementing CDSS.[6, 8]

The Hospital Italiano de Buenos Aires (HIBA) is a non-profit academic medical center founded in 1853, with over 1,500 physicians and 3,500 employees. HIBA has a network of two hospitals with 750 beds (200 for intensive care), 500 home care patients under care, and 23 clinics. It has an insurance plan that covers approximately 150,000 people and also coordinates insurance for another 1,500,000 people who are covered by affiliated insurers. Each year over 38,000 inpatients (pediatric and adult) are admitted to its hospitals that are located in Buenos Aires and its suburbs. HIBA has more than 2,200,000 outpatient visits annually from patients from across Argentina and Latin America.

In 1998, HIBA began to implement a Healthcare Information System (HIS) by integrating clinical information with the administrative applications that were already in use. HIS was completely developed in-house and currently collects and leverages the clinical and administration information related to health care for HIBA. Within HIS, the Electronic Health Record (EHR) is a fully-implemented Web-based, problem-oriented, patient-centred record with customized functionalities depending on the level of care (outpatient, inpatient, emergency care and home care) [9]

This EHR system includes a computerized provider order entry (CPOE) system, available throughout the HIBA network. In the ambulatory setting, CDSS was previously used only for prescriptions, but not for preventive care.

The HIBA information infrastructure includes a terminology server that allows the mapping of local vocabularies to SNOMED CT. This terminology server allows for the structured capture of approximately 80% of diagnoses [10, 11].

Within this existing health information infrastructure, the aim of this study was to evaluate the feasibility of implementing a CDSS for preventive care using a service model. Given our institution's collaborative ties with relevant investigators at Duke University, we chose the SEBASTIAN decision support Web service to conduct this evaluation.

Materials and Methods

Design: A feasibility study was performed to assess the necessary changes in processes and systems for the implementation of a services-based approach to CDSS.

For this test, the study was divided into three phases:

1. System usability evaluation through focus groups

In order to determine the preferences of physicians on how to interact with the CDSS, we conducted focus groups to evaluate the acceptance of different reminders by primary care physicians (PCPs).

Two focus groups were conducted. In each focus group, there were two internists, two family medicine practitioners, and two pediatricians. The group was led by a moderator and a qualitative evaluation expert. Each meeting was recorded and analyzed by the statistical and epidemiology group of HIBA.

2. Integration of SEBASTIAN with Hospital Italiano Health Information System

SEBASTIAN is an acronym for System for Evidence-Based Advice through Simultaneous Transaction with an Intelligent Agent across a Network[6]. It interacts synchronously with client software applications to deliver decision support over the Internet. The framework is implemented as a Java servlet and is hosted by the Apache Tomcat servlet container.

SEBASTIAN uses a patient information model based on the Health Level 7 (HL7) Reference Information Model (RIM), the same reference model used in the HIBA system. Concepts are identified using standard vocabularies like SNOMED-CT, the same reference vocabulary used in HIBA. Patients are modeled as entities described by demographic and "act" data, where an act refers to any act or service constituting health care services, such as an encounter, diagnosis, or procedure.

Medical knowledge in SEBASTIAN is captured in XML documents known as Executable Knowledge Modules (EKMs). Each module specifies the data requirements for assessing a patient, the patient specific conclusions that will be returned by the module, and the logic that will be utilized to generate the conclusions using the specified patient data. EKM results are the primary objects returned to client systems following the evaluation of a patient.

Because SEBASTIAN operates as a Web service, all services can be accessed by sending XML requests over HTTP. The core service offered is a patient evaluation service, in which patient data elements are received as the input and machine-interpretable decision support results are returned as the output.

In this phase of the study, the HIBA team and the Duke team held teleconferences to identify how SEBASTIAN could be used within the HIBA system, and the HIBA team implemented the required system modification work. The initial focus of this study was on the appropriate management of breast cancer screening and prevention.

3. Validation study to evaluate system sensitivity and specificity

After completing the integration of SEBASTIAN with the HIBA system, a study was conducted to validate the operation of the system [12].

The objective of this study was to measure the sensitivity and specificity of SEBASTIAN rules in the detection of mammogram completion, mammogram results (in terms of BIRADS values), patient risk factors, and exclusion criteria. This evaluation also assessed the accuracy of the generated recommendations. The gold standard was the manual review of the medical records. The population reviewed was female members of HIBA's health maintenance organization who were enrolled for at least two years in the health system and were between 49 and 60 years of age. Manual review was done on 210 cases randomly selected from this population.

Results

Figure 1 outlines the timeline in which the three phases of the study were completed.

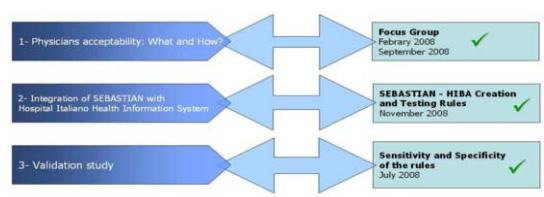

Figure 1- Study phases and completion dates

Usability

The results of the physician focus groups helped to inform the design of the CDSS user interface. Physicians preferred to view the reminders in the following way:

- Reminders displayed in a dedicated frame
- Accessed through main screen or from screen on problems
- No visually intrusive message (i.e., no pop-ups)
- Agile accessibility and handling

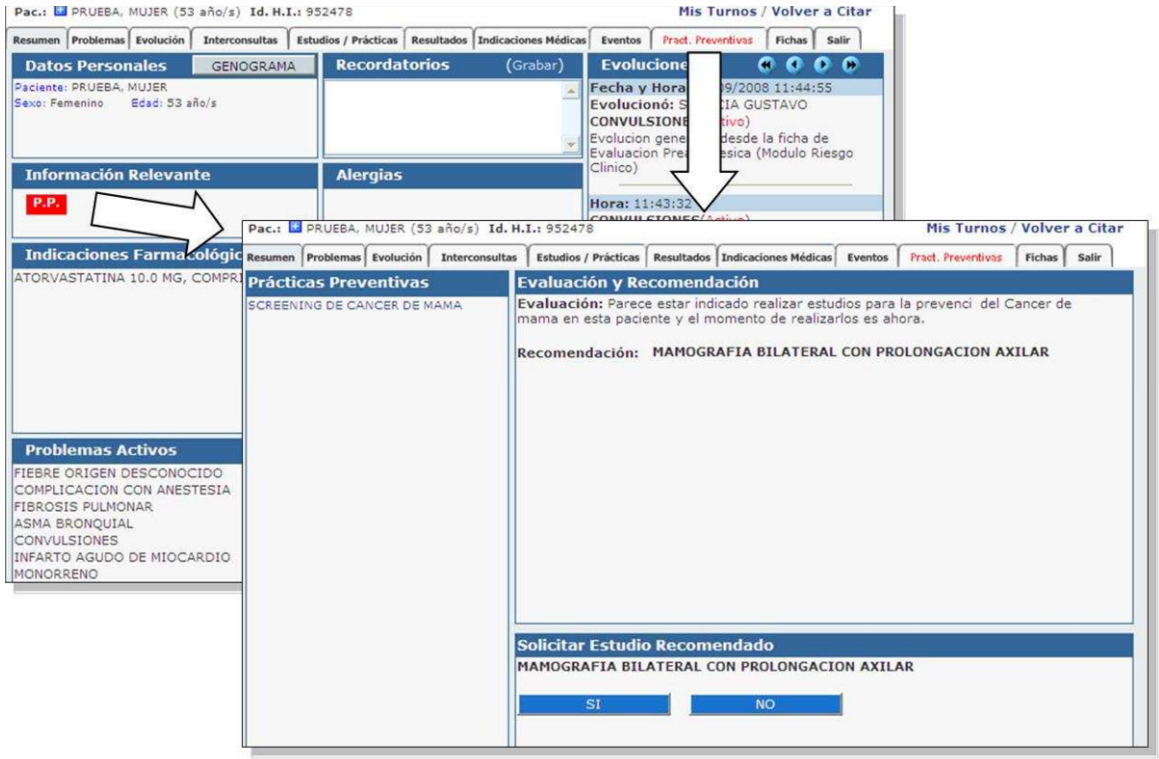

Figure 2 – Sample CDSS Screenshot. Availability of an active reminder for preventive services (breast cancer screening) is indicated by the red "PP" flag in the Important Information section. If the Physician clicks on any red marked section, a recommendation (i.e. order a mammogram) will be shown. If the physician agrees with the recommendation he would order it. In case of non-acceptance the reason should be explained.

- Possibility of personalizing the list of reminders displayed
- Possibility of printing reports as handouts for patients
- Ability to generate a list of patients with pending preventive care needs
- Possibility to graph data trends (for the patient)
- Prioritize patients with unmet care needs for clinic appointments

A screenshot illustrating the availability of one reminder is shown in Figure 2.

Integration of SEBASTIAN with Hospital Italiano Health Information System

To use SEBASTIAN, the developer at HIBA first identified the set of knowledge modules that would best meet application needs. These knowledge modules are captured in XML documents, and they consist of maintenance, library, knowledge, and logic sections [6]. Most module sections are edited using a functionally rich Microsoft InfoPath™ form. This authoring environment was used at HIBA to create and modify rules to enable results-based breast cancer screening.

In addition to developing the SEBASTIAN rules, the HIBA EHR system was configured to send SEBASTIAN the required patient information when an appropriate patient was potentially in need of a breast cancer screening reminder. To enable this data submission, it was necessary to develop a router that understood the demands of the SEBASTIAN rules and collected the required patient data. Also, the EHR system was adapted to parse the patient-specific care recommendations returned by SEBASTIAN for appropriate display in the EHR system. The information flow among the different system components is summarized in Figure 3.

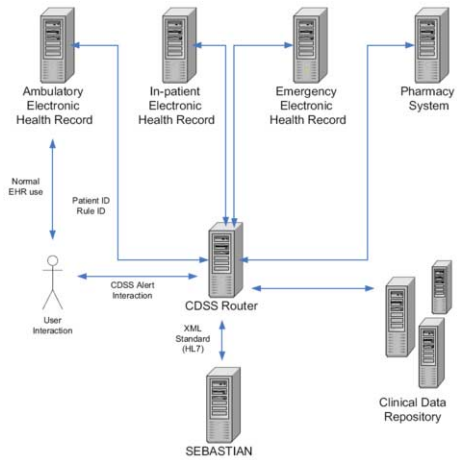

Figure 3 – CDSS System Architecture

Validation study

After implementing the CDSS based on physician feedback, a validation study was conducted to assess the performance characteristics of SEBASTIAN rules. With respect to the detection of an existing mammography report, sensitivity was 94% with a specificity of 91%. For the recommendations generated by the rule for breast caner screening, sensitivity was 97% while the specificity was 72%. For detection of a correct mammography BIRADS score, the sensitivity was 69% and specificity was 70%. Finally, for appropriate detection of exclusion criteria, sensitivity was 100% and specificity was 98%.

The HIBA clinical oversight team considered these values of sensitivity and specificity more than acceptable for production level use of the CDSS. Moreover, in order to further improve CDSS performance, we addressed underlying problems that we identified the testing by incorporating new terminology, implementing new systems for diagnosis and procedure coding, and training pathologists and radiologists to ensure more accurate recoding of the data in the pathology and radiology reports, respectively, that were used by the CDSS.

Discussion

In this paper, we have described the implementation of a Web services approach to clinical decision support that provides effective mechanisms for the transformation of medical knowledge into a machine-interpretable form, and for making that knowledge easily accessible and usable for an external EHR system.

Before the implementation of new technology, it is mandatory to assess with focus groups or other qualitative methods the user's opinion to allow the acceptability and adherence to the use of the this new technology.

One of the strengths of this study is that it demonstrates that it is possible to use the same services-based clinical decision support engine across multiple applications and institutions. Specifically, the SEBASTIAN Web service approach has now been successfully implemented within an academic medical center in the United States[8] and a private teaching hospital in Argentina. Additionally, this study represents only the second published report of an operational implementation of decision support using a system that is the basis for the HL7 Decision Support Service draft standard. Through the implementation described in this paper, we have demonstrated that this system can not only be ported across institutions, but also across international boundaries as well. To accomplish this portability, however, it is essential to have common information models and data standards to exchange and understand the information contained in clinical data repositories.

This report is also significant in that it has shown the ability to use decision support to augment breast cancer screening that traditionally relies only on age and gender, to now also incorporate relevant previous pathologic and radiological findings into breast cancer screening recommendations. The incorporation of these additional data may improve the effectiveness of screening to detect breast cancer. We are currently conducting a randomized clinical trial (RCT) to evaluate the effectiveness of this data-augmented CDSS breast cancer screening resource.

Conclusion

In this study, we have demonstrated that it is feasible to take a services-based approach to clinical decision support and to implement it across institutional and national boundaries. Coupled with usability and system performance testing, we conclude that a clinical decision support service can enable the implementation of CDSS that is accurate and appropriately integrated with existing EHR systems and clinical workflows.

Acknowledgments

We would like to thank the HIBA statistics and epidemiology department for assisting with the study design and analysis.

Evaluation of the use of an "ask-the-expert" e-consultation service for support on health-related requests

Abstract

E-consultation in health care can be used to respond to an increasing demand for care by offering support on health-related requests. In this study we evaluated the use of an "ask-the-expert" e-consultation service in order to assess whether the service is efficient and useful. A content analysis of e-mail exchange between clients and online health professionals was performed to gain insight in the purposes of use of the service. Our findings show that the e-consultation service was used for health requests on not urgent, minor ailments. Clients asked for health information to increase knowledge on the cause of their injury or disease, its consequences, possible self-care solutions and treatment options. Decision support on assessing the necessity to visit a doctor for a certain health problem was another important reason to use the service. We believe that web-based triage systems could be used to more easily assess whether certain symptoms need to be investigated.

Keywords:

Internet, E-mail, e-consultation, Patient-provider communication, Primary care

Introduction

Due to demographic and socio-economic trends, a substantial increase in the use of health care facilities is expected in the years to come. This poses a huge burden on human resources. The use of e-consultation in health care -online asynchronous patient-provider communication- may be part of the solution of this future problem because these services have the potential to save unnecessary visits to the general practice by offering self-care solutions [1-4]. These services are particularly useful for certain patient groups such as the elderly and patients with a chronic disease because of their greater need for care and their willingness to use e-consultation [5].

These days, a growing number of websites offer "ask-the-expert" e-consultation services where patients can consult health professionals via secured e-mail. These e-consultation services can be used to direct patients to the most appropriate source of care and away from using unnecessary and ultimately more expensive services. Despite these potentials, the use of e-consultation is not yet widespread in primary care. In order to foster the use of e-consultation, we believe that more research is needed on which type of patients actually use e-consultation services, how do they use it and why [5-14].

In this study we evaluated an "ask-the-expert" e-consultation service with so-called type-A interactions; these are encounters in which a pre-existing patient-provider relationship is absent [6,7]. Aim of the study was to assess whether the service is beneficial and efficient for giving support on health-related requests. This paper presents the preliminary results of a content analysis of e-mail exchange between clients and online health professionals. We described the users of the service, the purposes of use, the message content and the efficiency (response time) and usefulness of the service (fulfilment of requests).

Methods

Description of the e-consultation service

Since 2001 Medicinfo (http://www.medicinfo.nl) provides an "ask-the-expert" service for medical advice by telephone. The service is offered free of charge to members and clients of homecare organizations and health care insurers. From 2003 the service also provides the possibility to consult nurses and other health professionals online. Depending on fluctuation in workload during the day and week, the service is staffed by a minimum of two and a maximum of five nurses, handling telephone, e-mail and chat-services according to roster. All personnel are registered nurses who have successfully completed a higher vocational training in nursing. All have prior work experience in various health care jobs and most work part time in their present job. They follow an in company communication training and are subject to regular assessments. At all times a physician is on call for consultation.

Before entering their e-mail request via free-text, users have to create a secured personal account for which they have to provide initials, family name, birth date, gender and e-mail address. After

agreeing with a disclaimer, clients are asked to fill out the purpose of their request on a form:

1. I am looking for: general information about a disease or complaint / a treatment or medical examination / the address of a caregiver or institution;
2. A diagnosis has been established and now I want to know more about the cause / the consequences / the treatment / heredity / possible self care;
3. I want to know if I need to see a doctor for my complaint;
4. My question is about something else.

This classification is based on a content analysis of the "ask-the-expert" service for medical advice by telephone. The incoming e-mail requests are handled by the trained nurses and authorized by a physician. All requests are handled within 2 working days. Some questions are referred to the physician (GP) or to other health professionals. The nurses use standard answer protocols, see Figure 1.

Answer 1 is given for a well-defined health-subject such as "What is a trigger finger". For these "subject" requests general health information is given with links to specific web pages for further information about the subject. If the request is about the specific personal health situation of the client e.g., *"I have these symptoms/complaints; what is wrong with me?"* no advice can be given because a reliable diagnosis can usually not be established online [6]. For these "personal requests" clients are advised to contact their regular physician, see answer 3. In some cases the request embraces two aspects: a personal request of a well-defined subject, for example *"I have psoriasis, what can I do about it? I heard that psoriasis can be treated with injections, could you tell me more about it?"* In these cases answer 2 is given. In case of non-health related requests e.g., questions about the reimbursement of a treatment, answer 4 is given.

Some requests are difficult for nurses to answer, for these requests a GP is consulted. Moreover, specific requests are forward to one out of 25 other health professionals among which are a physiotherapist, psychologist, diabetes nurse, dietician, obstetrician, school doctor, pharmacist, dentist, speech therapist, pedagogue, vaccination expert, and more.

Research instruments

Log files were used to store nurse-client e-mail exchange during the period of September 2008 until September 2009. A content analysis was performed using the taxonomy of Sittig [15] and Eysenbach and Diepgen [16]. We analyzed 222 e-mail requests handled by nurses in the period of September 2008 and December 2008. To assess the type of health-related requests, Units of analysis were a request and reply exchange which formed a pair of emails.

Answer 1: information or advice

We received your message of (date). In this message you ask information / advice about … Please find the information you requested below …

AND/OR

We have found information about this subject on the following website… If you have remaining questions after reading this information we are pleased to answer them. If this is the case, please contact us again via the website or by telephone.

Answer 2: information or advice AND see regular physician

We received your message of (date). In this message you ask information / advice about … We can only answer health-related questions if this can be done safely and reliably. After all it concerns your health! To be able to answer your question properly we need extra information that can only be obtained through personal contact with a physician or other caregiver. Therefore, we recommend contacting your own physician to get an answer for this question. However we did find general information about this subject. Please find it below…

AND/OR

However we did find general information about this subject on the following website…If you have remaining questions after reading this information we are pleased to answer them. If this is the case you can contact us again via the website or by telephone.

Answer 3: no information or advice, see regular physician

We received your message of (date). In this message you ask information / advice about …We can only answer health-related questions if this can be done safely and reliably. After all it concerns your health! To be able to answer your question properly we need extra information that can only be obtained through personal contact with a physician or other caregiver. Therefore, we recommend contacting your own physician to get an answer for this question. If you have remaining questions after reading this information we are pleased to answer them. If this is the case you can contact us again via the website or by telephone.

Answer 4: no information or advice, request not health-related

We received your message of (date). Unfortunately we are not able to answer your question. We only answer questions that are related to diseases, health, wellness and lifestyle. For answers on policy and health insurance related questions we advice you to contact the customer service of your health insurance company.

Figure 1 - Standard answers

Results

Users of the service

Users of the e-consultation service were predominantly women (68%, 151/222). Mean age was 44 years (*SD*=14.1, min. age: 14, max. age: 77, *n*=166). 8% (18/222) of the e-mail requests were submitted for other persons such as children or the partner.

Reasons to use the service

Before submitting their request clients had to fill out the reason for their request. The reasons are presented in Table 1. Acquiring more information after a given diagnosis and decision support on whether it is necessary to visit a physician were the main reasons to use the service. Most requests however were categorized by clients as 'something else' (33.2%). These requests could nevertheless be classified by the researcher in one of the standard categories, see Table 1. These requests were probably categorized

by clients as something else because the request was aimed at getting a personal health advice instead of obtaining general health information.

Table 1 – Reasons of clients to use the service (total mentioned reasons n=247)

	n	%
(1) I am searching for general information about…	**39**	**15.7**
a. a disease or complaint	23	9.3
b. a treatment or medical examination	9	3.6
c. the address of a caregiver or institution	7	2.8
(2) A diagnosis is given and now I want to know more about…	**73**	**29.6**
a. the cause of the ailment	15	6.1
b. the consequences of the ailment	12	4.9
c. the treatment of the ailment	28	11.3
d. heredity of the ailment	3	1.2
e. possible self care	15	6.1
(3) I want to know if I need to see a doctor	**53**	**21.5**
(4) My question is about something else	**82**	**33.2**
1a. a disease or complaint	33	13.4
1b. a treatment or medical examination	7	2.8
1c. the address of a caregiver or institution	2	0.8
2b. the consequences of the ailment	1	0.4
2c. the treatment of the ailment	2	0.8
2e. possible self care	1	0.4
4. not health-related (insurance questions)	36	14.6

Type of e-mail requests

Most e-mail requests submitted to the service (*n*=153) were about physical complaints, diseases or symptoms (see Table 2). Some examples: *"I would like to know how and where I can be treated for definitive depilation of unwanted facial hair"*, *"I'm a woman of X years. My mother has recently been diagnosed with breast cancer for the second time. Her sister has also breast cancer and my grandfather deceased from intestinal cancer. I would like to know whether I should be tested on heredity of (breast) cancer"*.

A substantial amount of questions were about insurance and reimbursement issues. These questions could not be answered, because the service is only meant for health-related questions.

Table 2 - Categorization of e-mail requests (n=222)

Type of requests	*n*	%
Physical complaints, symptoms or diseases	153	68.9
Policy and insurance requests	27	12.2
Medication and treatment	22	9.9
Addresses of physicians or practices	9	4.1
Information on harmfulness of products	5	2.2
Travelers' advice	2	0.9
Lab results	2	0.9
Other	2	0.9

Type of answers and response time

The response time of the nurses was quick; 94% (209/222) of the e-mail requests were handled by the nurses within 24 hours. Table 3 presents the type of answers given by nurses. In most cases (67%, 149/222) general health information or advice was given (Figure 1, answer 1 and 2).

Table 3 - Categorization of answers (n=222)

Type of answers	*n*	%
Answer 1: information or advice	78	35.1
Answer 2: information or advice and see physician	71	31.9
Answer 3: no information or advice, see physician	42	18.9
Answer 4: no information or advice, request not health-related	31	14.1

Health information and advice was provided on:

- *the ailment itself*. For example, Patellofemoral Pain Syndrome, Trigger finger, Tietze Syndrome, "Zurich virus";
- *the cause of the ailment*. For example, the cause of a toe contusion, the cause of Thrombocytosis;
- *the consequences of the ailment* e.g., of Paratyphoid fever, Pfeiffer's disease;
- *the heredity of the ailment*. For example, the heredity of breast cancer;
- *self-care options*. For example, for fatigue, high cholesterol;
- *treatment options*. For example, for snoring, excessive smoking, alcohol problems, excessive growth of hair, sleeping problems, weight problems, premature ejaculation, fungal infection of nails, anus pain, scabies, piles, cysts, retractile testis, ADHD, rheumatic disease, Dupuytren's contracture.

In about 20% of the cases (42/222) no information or advice could be given because lack of adequate information to safely do so. In these cases clients were advised to contact their regular physician (answer 3). Most "answer-3" requests were about physical complaints and symptoms without a prior diagnosis given, for example: *"Lately, I've got itch during the night over my whole body and I am also thirsty. What could this be? Do I need to see my GP?"* In one of these cases the advice to contact the doctor was urgent: *"You are advised to see your regular physician today"*.

Four e-mail requests contained health symptoms that were difficult to evaluate on their seriousness. These requests were judged by a GP on the necessity to see a GP. The results are presented in Figure 2. None of the cases were suitable for e-consultation. These results indicate that clients are really in need for decision support on whether a visit to a regular physician is necessary.

Request 1:

"Recently, I've been using this medication X and I feel really tired and absent-minded because of the medication. The other day, I had a blood test which showed that I've got anemia. It also showed that my liver enzymes are not right. Here is my question: could it be that the medication X is causing this? I stopped using the medication, because I was frightened of the results of the blood test".

The urgency of this health request is unsure. It depends on the degree of anemia and the abnormality of the liver values. Probably, the client already had phone contact with his or her regular physician (to hear the test results). This question has therefore more the character of a second opinion. Advice to call the regular physician today is appropriate in this case.

Request 2:

"I woke up and calmly got out of bed. I fell down in the living room and for the rest I don't know anything about it. I've got a constant pain in my chest and heart. What could this be?"

Could be innocent, but urgency nevertheless high because of insufficient information to prove the opposite. Also the client's age is unknown.

Request 3:

"For weeks I have been dizzy and I have got a headache. Sometimes the dizziness so terrible that I have to go home from work. Everything around me seems to stir. What could this be?"

The request is not urgent, because the health problem is there for several weeks. Nevertheless, the request is not appropriate for e-mail. Client should see doctor for physical exam.

Request 4:

"I found my son of three and a half years old this morning weak and absent-minded in his bed. He reacted very slowly; hardly talked and very softly. He had trouble focusing his eyes. His temperature was 33.6 degrees Celsius (ear thermometer). After giving him dextrose, porridge and lemonade he returned to his normal self after 45 minutes. About one year ago he had the same. Apart from that, he is a healthy boy. I was thinking that this might be caused by a low blood sugar level. Do we have to visit the GP?"

Given the quick recovery the health problem is now not very urgent anymore. Nevertheless, a regular visit to the GP is advised for this problem.

Figure 2 - Assessment of urgency of complaints

Discussion and Conclusion

In this study we evaluated the use of an "ask-the-expert" e-consultation service for advice on health-related requests. We assessed whether the service was efficient and useful for providing health support. This study presented the preliminary results of a content analysis of 222 e-mail messages sent between clients and nurses.

Our results showed that the e-consultation service functioned efficiently; most (94%, 209/222) requests were handled within 24 hours. The service was also a useful means for providing advice on a broad range of health-related requests. The majority (69%, 153/247) of the e-mail messages sent by clients concerned requests about physical symptoms, complaints or diseases and could simply be fulfilled by providing general health advice (68%, 149/222) with the use of standard answer protocols. Another part of the e-mail messages (19%, 42/222) concerned specific personal health requests e.g., *"I have these complaints, what is wrong with me?"*. However, this kind of personal advice on specific physical symptoms could not be provided adequately because of lack of sufficient or reliable information.

We also found that the service was used for decision support on assessing the necessity to visit a doctor (21.5%, 53/247). We believe that web-based triage systems can be a useful addition to the service to assess whether certain health complaints need to be investigated by a regular physician. Triage is the process of assessing an individual's health problem and identifying the level of need for clinical care [17]. We think that adding systems for triage of health complaints could increase both the use and usefulness of the service because it facilitates the gatekeepers' function [18].

This paper presented the first results of a broader research on the use of an "ask-the-expert" e-consultation service for support on health-related requests. Notwithstanding the small number of email requests analyzed which limits the external validity of the study, we believe that our study results contributed to the findings of prior studies on the use of e-consultation in primary care [6,16,13]. Our findings showed that clients made proper use of the e-consultation service by sending e-mails for non-urgent health-related requests on minor ailments. Nurses handled e-mail requests according to the principles for giving Type A (absence of a pre-existing patient-provider relationship) advice on the Internet [6]; no specific diagnoses were given, no medicines were prescribed and no general information was given in the guise of individualized information.

Currently, further research is being performed; a content analysis of the e-mail requests handled by other online health professionals such as a GP, dentist, psychologist, etc. A survey is carried out to assess more detailed user characteristics (demographic and health-related) to get a more thorough understanding of the reasons for use of the service, to determine the level of client satisfaction with the service and to assess the impact of the service on visits to the general practice.

Analyzing effects of providing performance feedback at ward rounds on guideline adherence – The importance of feedback usage analysis and statistical control charts

Abstract

Objective: Feedback to clinicians on their past performance is often aimed at increasing adherence to guidelines. We investigate how various analytical approaches influence the interpretation of adherence data. The analytical approaches vary in considering the actual or the intended use of the feedback, and whether outcomes are inspected over time. Material and Methods: At base line, a computerized decision support system was employed at the ICU bedside to increase adherence to a mechanical ventilation strategy. We intervened by providing feedback about adherence to the guideline at the daily ward rounds. The outcome measure was the percentage of ventilation time (V_T) in excess of the guideline's recommendation. Actual usage of the feedback was logged and data analysis was carried out using two approaches: classical statistics, and statistical process control (SPC) that inspect progress of an outcome over time. Design: Prospective, before/after study.
Results: The classical analysis stated that the percentage of ventilation time in excess of the guideline's recommendation decreased significantly due to the feedback (5% reduction, $p<0.001$). When SPC analysis of the outcome was applied, the effect was deemed not significant. When the actual delivery of feedback over time was also included it showed that the experiment does not allow for conclusive results. Conclusions: The concluded effect of providing feedback on adherence to a guideline depends on whether the actual usage pattern of the feedback and the inspection of the outcome over time are considered. Future evaluative studies should report on usage patterns and progression of outcomes over time.

Introduction

Mechanical ventilation (MV) is one of the most important life supporting facilities in intensive care units (ICUs) [1]. Several complications, however, have been associated with the use of MV and various guidelines are used to limit the tidal volumes (V_T) applied to patients [2-4]. Such guidelines rely mainly on the predicted body weight (PBW) of the patient, which relies on the patient's height and gender.

Receiving too large V_T, however, is still the norm rather than the exception [5]. Explanations for this include the use of actual bodyweight instead of PBW, reluctance to accept potential hypercarbia and/or perceived increased sedation needs, and lack of knowledge [6-9]. In addition, it can be hypothesized that implementation of lower V_T is hampered by the fact that at times large V_Ts are simply left unrecognized.

Like in other settings, a clinical computerized decision support system (CDSS) can potentially contribute to increasing adherence to this guideline. We have hence implemented a CDSS at the bedside to alert physicians when the patient had a higher V_T than the guideline prescribes. In this paper we consider, aside from the bedside decision support, the effects of adding feedback on adherence at ward rounds, as they form a notable hospital context in which staff members work as a group [10]. In the sequel we refer to this ward round feedback as the "intervention", which itself can also be considered a form of decision support but provided in a new context. The objective of this paper is to contrast the results of three ways to analyze the data on he intervention: (A1) Using the traditional statistical approach, which is very common in the literature, (A2) applying the time-oriented approach of statistical process control (SPC), and (A3) Adding to A2 the patterns on actual usage of the feedback during the intervention period.

Materials and Methods

Study design

We performed a prospective before-after evaluation study on applied V_Ts to examine the impact of providing feedback at ward rounds on adherence (the intervention) to our local MV–protocol. The experiment was conducted during 2 consecutive phases in a 30–bed mixed medical–surgical ICU of a university hospital in the Netherlands.

Patient Data Management System

Since 2002, our ICU uses a commercial Patient Data Management System (PDMS, Metavision, iMDsoft, Sassenheim, The Netherlands). The PDMS is a point–of–care clinical information system, which runs on a Microsoft Windows platform and includes computerized order entry, automatic data collection, clinical documentation, electronic medication administration record, and a data storage repository. Mechanical ventilators are connected to the PDMS and all respiratory parameters are recorded every minute in the PDMS–database. Clinicians can see all fields related to artificial respiration, including applied V_Ts, by clicking on "respiratory tabs" in the PDMS.

Mechanical ventilation

The vast majority of patients are orotracheally intubated or do have a tracheotomy for MV; non–invasive MV is seldom applied. A written MV–protocol is available for all ICU–members, both on the intranet, and in printed form. In short, this protocol advises pressure–controlled (PC)–MV or pressure support (PS)–MV in all patients. There is a clear recommendation on V_T settings, stating that V_Ts have to be as low as 6 ml/kg PBW in all patients, irrespective of the presence of acute lung injury. With pressure–controlled (PC)–MV or pressure-support (PS)–MV, V_Ts are influenced by the applied airway pressures as well as the compliance of the patient's respiratory system. As compliance may change over time, healthcare workers need to continuously adjust the inspiratory pressure [11].

Recommended tidal volume

To calculate the recommended V_T (ml), the PBW (kg) is multiplied by 6. PBW was calculated by the following formula: in men, PBW = 50 + 0.91 * (height in centimeters – 152.4); in women, PBW = 45.5 + 0.91 * (height in centimeters – 152.4).

Ward round

The ward-round team consists of all ICU physicians and residents with possible additional specialists from other hospital wards like microbiologists or surgeons. The ward-round team has a meeting everyday to review patient progress. The PDMS is used to represent the patient conditions, complications and treatment plans. Patients are selected one by one and the related data are displayed by a beamer. The ward-round team discusses and reviews the patient charts, and decides upon the patients' treatment plan.

Intervention

At baseline, before the intervention, when an ICU–physician or ICU–nurse selected the "respiratory page" in the PDMS, the recorded V_T, maximum pressure (Pmax) and PEEP during the previous 60 minutes were queried. The system calculated the percentage of time that V_T was above the guideline recommended V_T. If the pressure support level was at its minimal value, the V_T was rendered "in range V_T". If V_T was above the guideline recommended V_T for more than 25% (15 minutes) of the previous 60 minutes, a pop–up window was shown displaying the guideline, patient's height, gender, PBW, as well as the percentage of time in which V_T was above 6 ml/kg PBW. In order not to disturb the users and to give them time to correct V_T, V_Ts were again queried and checked after at least two hours. The duration of this phase was almost 16 weeks.

In the intervention phase, in addition to showing the CDSS messages at the bedside, the daily ward round was used to display a list of the patients showing per patient the percentage of time in which V_T was above 6 ml/kg PBW. Patients with percentages below 25% were marked in green, percentages between 25-75% in yellow and above 75% in red. The duration of the intervention was also almost 16 weeks.

Usage of feedback

Although the feedback intervention was intended to be provided daily at the ward round, we logged its actual use: whenever the system displayed feedback at the ward round a record was created in the system to indicate this fact.

Outcome measures

The first outcome measure was the percentage of ventilation time in which the V_T was > 6 ml/kg PBW [4]. Mean V_T in excess of 6 ml/kg PBW over time was also measured. We considered all V_T measurements < 6 ml/kg PBW as if they were 6 ml/kg PBW. The third outcome was frequency of V_T measurements ≤ 6 ml/kg PBW. The unit of analysis is the V_T observation (not the patient).

Patients

This study included all ICU–patients who were mechanically ventilated for more than 24 hours in the ICU [5], were not on Adaptive Support Ventilation (which does not allow changes of V_T–settings by healthcare workers) and did not participate in other respiratory trials in which V_T was manipulated. V_Ts < 150 ml or >1500 ml were excluded as these were most likely measurement errors. When pressure support was at the lowest level, the measurement was considered correct (i.e., not in excess of 6 ml/kg PBW) regardless of its value.

Subgroups

We split up the whole ventilation time into spontaneous mode (pressure support ventilation [PSV]) and non–spontaneous mode (pressure control ventilation [PCV]).

Traditional statistical approach

Categorical variables in the before and after intervention groups were compared by X^2 testing, and continuous variables were compared by Student's *t* test or Mann-Whitney testing as appropriate. A *p*–value<0.05 was considered significant.

Statistical Process Control (SPC)

SPC and its primary tool – the control chart - is a branch of statistics that combines rigorous time series analysis methods with graphical data presentation, often yielding insights into the data more quickly and in a more understandable way than other statistical techniques [12-14]. Control charts can distinguish between common and special cause of variation. With common cause variation (noise), the variation is inherent in the process itself and the process is stable and predictable within certain limits. Special cause variation signifies that the

process is no longer stable or predictable and has changed (for better or worse). A control chart includes a plot of the data over time with three additional lines – the center line (usually the mean) and an upper and lower control limits, typically set at ±3 standard deviations (SD) from the mean. When the data points are, without any special pattern, within the control limits then the process is "in control" and stable. There are several rules that indicate when a special cause variation or special pattern has occurred on a control chart. We used the following four common rules [14]: one or more points above or below the control limit; a run of seven or more points on one side of the center line; two out of three consecutive points appearing beyond 2 SD on the same side of the center line; a run of seven or more points all trending up or down.

For analysis we used the X–MR chart (and not the attribute chart) due to the large size of observations per time point and the increased chance of false positive results [14-16]. Our chosen quality indicators (for guideline adherence) were calculated per two weeks, in order to allow for an adequate number of points, and plotted as points on the X–MR chart.

Results

Patients

During the study period 3,434,268 V_T–records (2,243,862 in the pre-intervention period vs. 1,190,406 in the intervention period) of 352 ventilated patients (202 vs. 150) were analyzed. Patient characteristics (age, height, severity of illness etc) before and after the intervention were similar.

Usage

In the first 5 weeks after the intervention the patients' list with the percentage of time in which V_T was above 6 ml/kg PBW was shown (35 times). After the fifth week, the CDSS was triggered only 1-2 times per week in the ward round (10 times in weeks 5-10, and 8 times in weeks 10-16 weeks).

Tidal volumes

Table 1 shows the outcome measures before and after the intervention. Using the traditional statistical approach the percentage of ventilation time with V_T in excess of 6 ml/kg PBW was shown to decrease significantly after intervening (5% reduction, $p < 0.001$). The average volume in excess of 6 ml/kg PBW remained the same after intervention.

Figure 1 shows the distribution of V_T (ml/kg PBW) by 0.25 ml/kg PBW in the two phases. The decrease in the percentage of time with $V_T \leq 6$ ml/kg PBW seems to come at the expense of the percentage of time with V_T between 6-8 ml/kg PBW, which decreased after the intervention.

Table 1 - Outcome measures reported for patients with >24 hours MV.

Mode	Intervention	Before	After	*p*
All	Mean of excessive V_T^{Φ}	1.3±1.7	1.3±1.7	ns**
	% of time > 6ml/kg PBW#	54	51	<.001*
Spontaneous (PSV)	Mean of excessive V_T	1.5±1.8	1.5±1.8	ns
	% of time > 6ml/kg PBW	58	54	<.001
Non-spontaneous (PCV)	Mean of excessive V_T	0.8±1.1	0.8±1.2	ns
	% of time > 6ml/kg PBW	43.5	44	ns

*chi square, **Student's *t* test, $^{\Phi}$Excessive V_T is tidal volume in excess of 6 ml/kg PBW over the whole phase. #To calculate this percentage we tolerated a discrepancy of 10% above the protocol's suggestion (i.e. 6.6 ml/kg PBW) before considering a measurement as being in excess of 6 ml/kg PB

Tidal volumes in (non)spontaneous ventilation mode

Table 1 also shows the outcome measures separately for spontaneous and non-spontaneous ventilation time. Surprisingly the overall effect of the intervention on spontaneous ventilation mode was larger than in the non-spontaneous mode. Results indicate that showing the patients' V_T information in the ward round did not change the percentage of ventilation time in excess of 6 ml/kg PBW during the non-spontaneous ventilation time. On the other hand, during the spontaneous ventilation time, the percentage of ventilation time with V_T in excess of 6 ml/kg PBW decreased after intervention (7% reduction, $p < 0.001$).

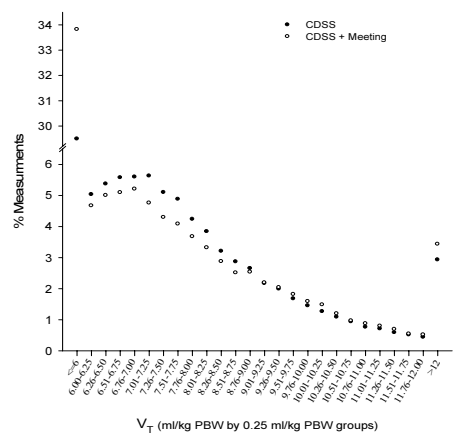

Figure 1 - V_T distribution (PSV mode).

Results based on statistical process control

Figure 2 shows control charts of the main outcome measures, also separately for spontaneous and non-spontaneous ventilation. In contrast to the traditional statistical methods, the control chart showed that the process did not change significantly after the intervention. Also in contrast to classical tests, the reduction pattern after intervention was only shown in the non-spontaneous mode.

Incorporating data on feedback usage

The control charts showed that the percentage of ventilation time with V_T in excess of 6 PBW did decrease steadily during the first 5 weeks but again increased and eventually became stable (The letter "A" in Figure 2 indicates the subgroup of measurements collected in week 5 and week 6). Our data on actual usage of feedback revealed that in these first 5 weeks the feedback delivery was provided daily, as intended. The increase afterwards in the outcome (indicating decrease in adherence to the guideline) is paralleled by the diminished use of feedback during the intervention.

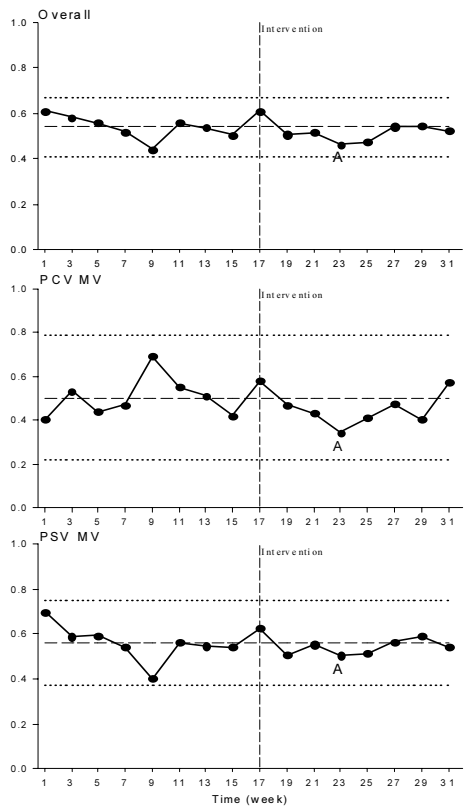

Figure - 2 Control charts of percentage of time > 6ml/kg PBW (overall, during spontaneous (PSV) and non-spontaneous (PCV) mechanical ventilation)

Discussion and Conclusion

Interpreting data pertaining to the effects of providing feedback concerning the performance of clinicians on adherence to a guideline provided three different pictures. In the traditional approach one would have concluded that the effect of our intervention was significant. If one takes into account the progression in the outcome measure over time but disregards the patterns of actual feedback delivery (and hence use) then the conclusion is that the intervention was not effective. If one in addition considers the usage pattern of the feedback then a nuanced picture emerges: as long as the feedback was provided daily, as planned, a decreasing pattern in the main outcome was observable. Once the frequency of feedback delivery has dropped the outcome started increasing again.

To understand the results it is important to point out the ambiguity of the term "intervention". There is the intended intervention (providing feedback daily) and the actual intervention (as was actually provided). Based on our experiments, it would seem too hasty to conclude that there is sufficient evidence (in terms of statistical significance) that our 16 weeks *actual intervention* was effective. An inspection of the SPC charts reveals why it arrived at a different conclusion than classical statistical tests: an apparent initial increase is counterbalanced by an increase in the sequel. Being sensitive to temporal progression, SPC is reluctant to declare statistical significance of this actual intervention (with reduced intensity of the feedback over the weeks). We believe that the SPC's prudent interpretation should prevail. By the same token concluding that the *intended intervention* is not effective is also unfounded. This is because this intended intervention was not implemented. The correct interpretation of the results is that the *intended intervention* does not enjoy enough quantitative support yet (as the usage pattern shows it was not implemented). However, inspecting the patterns of decrease in the first 5 weeks and "bouncing back" afterwards does provide qualitative evidence to the possible effectiveness of this intervention, which should be more properly implemented.

The same logic applies to subgroup analysis. While the control charts showed that the percentage of time > 6ml/kg PBW in the spontaneous mode was stable after the intervention, the traditional approach declared statistical significance.

There are two lessons (serendipitously) learned from our case-study for medical informaticians evaluating effects of IT interventions, such as decision support, on some (quality) indicator. First, measuring the progression over time of an indicator may suggest a different (and better) interpretation of the results than when time is not taken into account. The advantages of this interrupted time-series design is described in [17]. Second, measuring actual usage of an intervention may influence the interpretation of the results. These lessons are important because most of the medical informatics literature reports on results using the traditional approach. The few studies that did apply SPC analysis usually do not consider the possible difference between intended and actual use of the intervention.

Our results stress the importance of reporting or at least reflecting on the possible influence of a time-oriented approach and the CDSS usage on the results. After all, our study could have been reported in three incompatible ways.

Processing Gradual Information with Fuzzy Arden Syntax

Thomas Vetterlein[a], Harald Mandl[b], Klaus Peter Adlassnig[a,b]

Abstract

The programming language Arden Syntax is especially adapted to the needs of computer-based clinical decision support. Recently, an extension of Arden Syntax, named Fuzzy Arden Syntax, was proposed by the authors. Fuzzy Arden Syntax is a conservative extension of Arden Syntax and offers special functionality to process gradual information. The background is the observation that in medicine we frequently deal with statements which are neither clearly false nor clearly true but hold to some intermediate degree. In this paper, we demonstrate under which circumstances a Medical Logic Module (a program unit written in Arden Syntax) may show unintended behavior and how the situation can easily be improved by means of the possibilities offered by Fuzzy Arden Syntax. To this end, an example from the domain of nosocomial infection control is discussed in detail.

Keywords:

Clinical Decision Support Systems, Arden syntax, Fuzzy logic, Nosocomial infections.

Introduction

An important aim in medical information sciences is to define standards to represent clinical data in a computer-interpretable form. This task concerns various levels of abstraction and is generally difficult. We may mention, for example, current efforts to establish standards for the structure of an electronic health record, to establish medical terminologies on a symbolic level, or to define computer-interpretable medical procedures.

In healthcare, an issue which becomes the more relevant the more data is available electronically is the automated and intelligent interpretation of facts concerning a patient's course of disease, like symptoms, signs, diagnoses, and treatment. On the lowest technical level, this purpose is supported by a programming language in which general clinical knowledge can be formulated as directly as possible, minimizing the need for the user to get familiar with technical peculiarities.

Arden Syntax

In this latter field, the developers of Arden Syntax have contributed in a specific but valuable way [1]. The programming language Arden Syntax is endowed with an (institution-dependent) interface to a patient database, can be applied to encode methods to interpret the data, and can be used to trigger appropriate reactions in real time. Its syntax has been chosen to make the program flow easily traceable. Arden Syntax was originally developed by the American Society for Testing and Materials in 1992 and is at present maintained by Health Level Seven, Inc. (HL7). The document containing the official specification [1] can be acquired from HL7; (see www.hl7.org.)

Arden Syntax has been developed as a standard of representing general clinical knowledge. This knowledge needs to be present in modular form; an Arden Syntax system is composed of an unstructured set of so-called Medical Logic Modules, or MLMs for short. Each MLM can be designed to react in real time to some specified event, like for instance a certain change in the patient database, in which case a message to the host system is sent or other reactions are induced.

Fuzzy Arden Syntax

The content of an Arden Syntax MLM can be the result of a formalization of information provided in natural language. When mapping information contained in a text to a computer program, even if this text is meant as a precise specification of facts or procedures, we typically encounter the problem that the level of precision is not sufficient to allow the formulation of the program in a unique way. Often then, the original specification needs to be extended in an ad-hoc way. To give a simple example of what we mean, for a clinician it might not be a problem to interpret statements like "the level of aspartate transaminase (AST) is significantly increased" if the normal range of AST is known; in a computer program however sharp limits must be provided.

Conversely, if precise specifications are provided it might sometimes not be desirable to follow them in a purely mechanical way. For example, consider the condition "body temperature $\geq$ 38.0 °C". If the actual body temperature of a patient is, say, 37.9 °C, a clinician might hesitate to simply consider the condition as not fulfilled or might at least argue differently than in the situation when the temperature is 36.9 °C.

If sharp limit points are not specified or even unknown, some extra effort will be needed to deal with this situation in automated decision support. Furthermore, if sharp limit points are

chosen, borderline cases will in general not be apparent in the output: a condition "temperature ≥ 38.0 °C" will be evaluated negative if the communicated temperature is lower than 38 °C, and positive if it is 38 °C or higher, and information about changes of the result under small changes of the input would again require extra effort. It is the idea of Fuzzy Arden Syntax to include into Arden Syntax additional functionality to make the definition of "soft" limit points possible and furthermore to avoid discontinuities in the results.

Fuzzy Arden Syntax was originally proposed by S. Tiffe [2]. It has recently been further elaborated by the authors; we refer to [3] for a complete specification. The new features have been summarized in [4]. The present note shows the effects of these features on the basis of a specific example.

A case study: nosocomial infection control

We will exhibit some features concerning behavior and performance of Arden Syntax with or without the extension provided by Fuzzy Arden Syntax. To this end, we shall consider a typical example of computer-based clinical decision support.

Computer-supported detection of nosocomial infections

For the surveillance of nosocomial infections in ICUs, standards have been defined [5–7]. If the relevant data is available electronically, the possibility exists to have suspicious cases detected automatically. For instance, at the Vienna General Hospital, a system with exactly this purpose has been developed [8]. It is named Moni/Surveillance-ICU and based on HELICS [5] as well as KISS [6, 7] criteria for nosocomial infections.

The following conditions must be fulfilled:

- It is not the case that the patient has fever (≥ 38.0 °C), or urinary urgency, or frequency, or dysuria, or suprapubic tenderness.
- The patient has had
  1. either a positive urine culture ($\geq 10^5$ microorganisms/cm^3 of ≤ 2 species) and an indwelling urinary catheter within 7 days before the culture
  2. or two positive urine cultures (the ≤ 2 species being the same) and no indwelling urinary catheter within 7 days before the culture

Figure 1 - Definition of asymptomatic bacteriuria (UTI-C)

We shall consider the following example which is a specification of a nosocomial infection according to [5] (coded UTI-C there). This criterion is part of the Moni system as well. We note that we have slightly changed the formulation of [5].

As we will see, the implementation of this rule in Arden Syntax is straightforward. Arden Syntax programs are to a certain extent self-explanatory; for this reason also the reader not familiar with Arden Syntax should be able to follow our argumentation. To be sure, we will however include some basic explanations.

An MLM has a predefined structure. The first two parts are the *maintenance category* and the *library category*, which are not important here. Only the third part, the *knowledge category*, contains the executable program. The latter consists in turn of several so-called *slots*. In particular, the *data slot* contains the commands to read the relevant data from the host and possibly additional commands to preprocess this data; in the *logic slot* the decision is made if the *action slot* is executed. A jump to the action slot is caused by the command `conclude true`, whereas `conclude false` terminates execution.

The relevant slots of the knowledge category of an MLM modeling the criterion for asymptomatic bacteriuria could look as follows.

```
data:
   (Patient, Date) := argument;
     /* Input data: patient ID and date of stay */
   Temperature :=
     read {body_temperature,
           Patient, Date};
     /* Body temperature */
   Fever := Temperature >= 38;
   Urgency :=
     read {urinary_urgency, Patient, Date};
     /* Urge to urinate? */
   Micturition :=
     read {micturition, Patient, Date};
     /* Increased frequency of urination? */
   Dysuria :=
     read {dysuria, Patient, Date};
     /* Painful urination? */
   Suprapubic_tenderness :=
     read {suprap_tenderness, Patient, Date};
     /* Suprapubic tenderness? */
   Organisms_in_1_urine_culture :=
     read {organ_1_urcult, Patient, Date};
     /* Number of microorganisms of ≤ 2 species per
     mm^3 */
   One_urine_culture :=
     Organ_in_1_urine_culture >= 1e5;
   if One_urine_culture
     then Urine_culture_time :=
       time of One_urine_culture;
     endif;
   Organisms_in_2_urine_cultures :=
     read {organ_2_urcult, Patient, Date};
     /* Number of microorganisms of ≤ 2 species per
     mm^3 in the last two cultures */
   Two_urine_cultures :=
     Organisms_in_2_urine_cultures >= 1e5;
   if Two_urine_cultures
     then Urine_culture_time :=
       time of One_urine_culture;
     endif;
   Catheter :=
     read {catheter, Patient, Date};
     /* Latest indwelling urinary catheter */
   ;;

logic:
```

```
   if (Fever OR Urgency OR Micturition OR Dy-
       suria OR Suprapubic_tenderness)
     then conclude false;
     endif;
   if (Catheter is present
       AND time of Catheter is at least 7 days
       before Urine_culture_time)
     then if One_urine_culture
       then conclude true; endif;
     else if Two_urine_cultures
       then conclude true; endif;
     endif;
   ;;
action:
   write "The conditions of an
       asymptomatic bacteriuria are met.";
   ;;
```

Behavior in borderline cases

We may say that this MLM reflects the specification UTI-C of asymptomatic bacteriuria one-to-one. However, we may wonder if this is what we want. As a matter of fact, it is easy to construct a case where a clinician familiar with the facts expressed by UTI-C is likely to conclude differently from the MLM. We have in mind the borderline cases; consider the following situations:

- A patient had three positive urine cultures with the same single species and an indwelling urinary catheter until one day before the first positive culture; he has no urgency, frequency, dysuria, or suprapubic tenderness and a temperature of 38.0 °C.
- A patient had a positive urine culture and a urinary catheter until seven and a half days before the culture; he has no fever, urgency, frequency, dysuria, or suprapubic tenderness.
- In the urine culture of a patient $9 \cdot 10^4$ microorganisms/cm^3 were found, the patient had two days earlier an indwelling urinary catheter, and otherwise no fever, urgency, frequency, dysuria, or suprapubic tenderness.

It would be easy to continue this list of cases, which have all in common that an automated detection of an infection fails. However, a clinician will most likely judge in all three cases that the criterion does apply, at least to a certain extent, even if criterion UTI-C is the only source of information.

Fuzzification of formalized clinical criteria

In computer-assisted decision support, one might certainly opt to have information provided only in the clear cases. After all, nobody would expect that no information about a possible disease means that the disease is not present. On the other hand, there are easy means to make the inference of a program like the above MLM more flexible so as to get results also in those cases which are not entirely conclusive on the basis of some given formal rules. Of course then it is essential to exhibit in the output explicitly that the result has restricted value.

These considerations have led to the development of Fuzzy Arden Syntax. Note first that under Fuzzy Arden Syntax, the above MLM would run without change of effect. That is, the same input would lead to the same output. This is why we call the extension "conservative".

However, Fuzzy Arden Syntax offers convenient possibilities to process not fully determinate truth values and to extend the inference coded in a given MLM to borderline cases. In medicine, the situation frequently occurs that facts about a patient do not fit perfectly to the available notions. Indeed, expressions like "having pain" or "being elevated" involve vagueness in the sense that they possess borderline cases in which it is hard or impossible, in any case unreasonable, to tell if they apply or do not.

As the starting point, we borrow from fuzzy logic [9] the simple idea to extend the two-element set of classical truth values to a continuous set of truth values. In classical propositional logic, we use 0 to denote falsity, 1 to denote truth; in fuzzy logic we use in addition any real value between 0 and 1 to express tendencies.

Examples of vague notions are immediate from the criterion UTI-C. Urinary urgency, frequency, dysuria, suprapubic tenderness may in most cases clearly hold or not hold, but there can be unclear situations as well.

The values allowed for yes-no variables in Fuzzy Arden Syntax certainly include the clear "true" or "false" just like in Arden Syntax. In addition, however, also values like 0.8 meaning, say, "rather true" are possible. We note that if continuous values are used for yes-no statements in the input, no changes in the MLM are necessary.

If intermediate truth values are used, it must however be determined in which way the connectives "and", "or", and "not" are to be interpreted. By default, if the variable `Var_1` contains the value $v_1 \in [0, 1]$ and the variable `Var_2` contains the value $v_2 \in [0, 1]$, then

```
Var_1 AND Var_2, Var_1 OR Var_2,
NOT Var_1
```

will be evaluated as $\min\{ v_1 , v_2 \}$, $\max\{ v_1 , v_2 \}$, and $1 - v_1$, respectively. Other interpretations, in particular other t-norms [10] interpreting `AND` are possible.

Let us next describe the method to avoid sharp limit points. Namely, we may replace sharp values by "soft" ones in a straightforward way. Our above-given example can be modified as follows:

```
data:
   [...]
   Fever :=
     Temperature >= 38 fuzzified by 0.5;
   [...]
   One_urine_culture :=
     Organisms_in_1_urine_culture >=
       1e5 fuzzified by 5e4;
   [...]
   Two_urine_cultures :=
     Organisms_in_2_urine_cultures >=
       1e5 fuzzified by 5e4;
```

```
   [...]
   ;;

logic:
   if (Fever OR Urgency OR Micturition OR Dy-
       suria OR Suprapubic_tenderness)
     then conclude false;
     endif;
   if (Catheter is present AND time of Cathe-
       ter is at least 7 days fuzzified by 2
       days before Urine_culture_time)
     then if One_urine_culture
       then conclude true; endif;
     else if Two_urine_cultures
       then conclude true; endif;
     endif;
   ;;
```

As to be expected, the expression `fuzzified by` is used to create some tolerance around a sharp real value. Formally, the expression

```
38 fuzzified by 0.5
```

is a triangular fuzzy set, namely the following one:

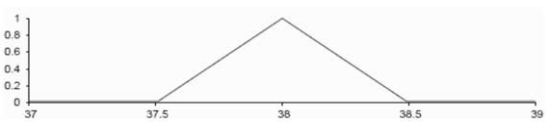

Figure 2- Example of a triangular fuzzy set

We recall that a fuzzy set is a mapping u from some universe of discourse M to the real unit interval [0, 1]. u typically models a natural-language concept, and for any $T \in [36, 42]$, the value $u(T)$ is then the degree to which T is in accordance with the concept modeled by u. The universe is typically R, the reals, and in Fuzzy Arden Syntax, we may use any fuzzy set over R provided it is piecewise linear, at each point left- or right-continuous, and constant outside a finite interval.

A fuzzy set like the displayed one can be used for a comparison: typically, a number like `Temperature`, which in our context is also called a *crisp number*, is compared with a fuzzy set, also called a *fuzzy number*. The expression

```
Fever:= Temperature >= 38 fuzzified by 0.5
```

no longer returns necessarily one of the sharp truth values `true` or `false`. The displayed case rather works as follows; let T be the value in `Temperature`. If $T \geq 38$, then the result is 1, or `true`, in accordance with the original MLM. If T is just slightly smaller than 38, the resulting value will still be close to 1 and in particular not reflect falsity; in the sequel the same consequences will be drawn, but with reduced weight. Falsity is the calculated outcome only if $T \leq 37.5$. This follows from our choice to fuzzify by 0.5. We conclude that `Fever` is no longer a two-valued, but a many-valued concept, with the effect that jumps from one extreme to the other are avoided.

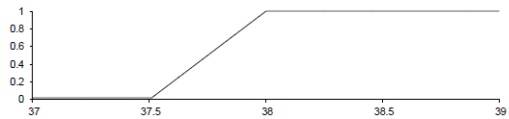

Figure 3 – Fuzzy logic and temperature

We see in particular that the specification of the conditions under which `Fever` applies requires more than determining one delimiting value. It is rather required to determine when this concept clearly applies and when this concept clearly does not apply. Accordingly the width of the transitional region must be set.

The same can be said mutatis mutandis for the variables `One_urine_culture` and `Two_urine_cultures` in our example.

The next question is what happens when an if-then-else construct depends on a many-valued condition. In Fuzzy Arden Syntax, the program splits. If the condition is evaluated to t such that $0 < t < 1$, the "if" block and the "elseif" block are executed in parallel. To any point in the program, there is associated a *program weight*; prior to the execution of the two branches this weight is multiplied by t or $1-t$, respectively.

Test case

We shall next illustrate the effect of this concept. To this end, we shall check the behavior of the above Fuzzy Arden MLM with some specific values, and we will see if the result is in accordance with the conclusions which we would draw intuitively.

Consider the following scenario. The patient does not suffer from urgency, micturition, dysuria, or suprapubic tenderness, and has a temperature of 37.6 °C; a catheter is reported to have been removed eight days before the first urine culture; he has two clearly positive urine cultures where however the number of microorganisms of coinciding species is only $6 \cdot 10^4$.

Let us guess how a clinician would judge this situation in view of the criterion UTI-C. The condition of UTI-C about the absence of symptoms is practically fully fulfilled; the height of the body temperature is not significant. Furthermore, the catheter was removed eight days, so roughly one week, before the first positive culture. Finally, there is some evidence of a second positive culture. All in all, the picture is presumably not entirely clear but rather well compatible with the conditions of UTI-C. In any case, the decision seems natural that the situation should be further examined.

Let us now compare these informal considerations with the result provided by the Fuzzy Arden MLM. We shall trace, step by step, the execution of the logic slot.

The expression

```
Fever OR Urgency OR Micturition OR
Dysuria OR Suprapubic_tenderness
```

returns, if `OR` is interpreted according to default, the largest of the values of the conjuncts. We have that `Fever` is 0.2 and `Urgency`, `Micturition`, `Dysuria`, and `Suprapubic_tenderness` are all 0; thus the result is 0.2.

The program splits; however, the line `conclude false`, to be executed with weight 0.2, terminates the MLM. So the remaining part of the program is continued with weight 1− 0.2= 0.8.

Next, we have that the expression

```
Catheter is present AND time of Catheter is at
least 7 days fuzzified by 2 days
```

is evaluated 0.5. Consequently, the program splits again; the `if` block and the `else` block are executed in parallel, both with weight $0.8 \cdot 0.5 = 0.4$. In the first branch, the program executes `conclude true` under the condition `One_urine_culture`. As this variable contains the value true, i.e., 1, the action slot is executed with weight $0.4 \cdot 1 = 0.4$. In the second branch, the program executes `conclude true` under the condition `Two_urine_cultures`. This variable contains the value 0.2 and the action slot is executed as well, but in this case with weight $0.4 \cdot 0.2 = 0.08$.

The action slot sends to the host the message that asymptomatic bacteriuria is present. This message will be endowed with a value expressing the fact that the program weight is decreased. In our case, the host will get independently twice the same message, once with weight 0.4 and once with weight 0.08; it could add up the two values 0.4 + 0.08 = 0.48. So as the final result, we are provided a message together with a truth value of only 0.48.

The value 0.48 implies that the message is to be understood with great caution. We conclude that the message is weaker than the informally drawn conclusion. But in accordance with our informal considerations it is clearly suggested that the situation needs to be examined.

We may finally observe that the corresponding Arden Syntax MLM would not report anything. We furthermore note that the modified MLM encoding UTI-C is not essentially longer or more complicated than the original one.

Conclusion

Clinical decision support systems depend on clear specifications: criteria must be provided which do not leave room for interpretation. This is the nature of a computer program as opposed to the way a human reasons who always allows some tolerance in considerations. An extended version of Arden Syntax, named Fuzzy Arden Syntax, aims at reducing the undesirable effects of sharp delimitation of situations.

Fuzzy Arden Syntax is based on the principles of fuzzy logic and uses a continuous set of truth values, namely the real unit interval. We have demonstrated on the basis of an example, a criterion of a nosocomial infection which is in practical use, the benefits of this approach. Answers to yes-no questions, like the presence of a specific symptom, need not be decided if they are actually not well decidable. Furthermore, values separating the normal from the abnormal range of a parameter can be specified in a rough manner. Finally, the changes of an Arden Syntax program to benefit from these possibilities are minimal.

If the concepts of fuzzy logic are fully applied, there are no more any discontinuities in the output. However, since the inference becomes more sophisticated, also the output is possibly more differentiated. Namely, the user might be presented a list of alternatives together with weights. But this is not to be considered as a price to pay; it is just natural in the present context. When an input parameter is in a borderline area, more than one alternative in the output should be expected.

The work on the Fuzzy Arden compiler is in progress; the compiler will be available in the first quarter of 2010. The application of Fuzzy Arden Syntax in the above-mentioned system Moni/Surveillance-ICU is scheduled and extended practical experiences can be expected in the course of 2010.

Abstract

Implementation of clinical practice guidelines into daily care is hindered by a variety of barriers related to professional knowledge, collaboration in teams and organizations, and practicability of the guidelines. Clinical computerized decision support (CCDS) has been shown to be one of the most effective instruments to improve compliance to practice guidelines by tackling barriers related to professional knowledge. To address other barriers, however, additional interventions are needed. In this study, a continuous multifaceted guideline-implementation strategy was developed which is based on CCDS but extends beyond the professional knowledge barrier. Two additional interventions were designed and embedded with CCDS in a continuous quality improvement framework. First, to address barriers within teams and organizations guideline compliance data are periodically aggregated into feedback reports for care providers. Second, barriers related to practicability of the underlying guidelines are addressed in a guideline-maintenance cycle. A case study in the field of cardiac rehabilitation is presented to demonstrate the feasibility of the developed strategy.

Keywords

Practice guidelines as topic, Cardiac rehabilitation, Health care quality, access, and evaluation

Introduction

Application of clinical practice guidelines can improve patient outcomes, reduce practice variation, and reduce costs of healthcare [1;2]. However, care professionals' often do not follow the recommendations of practice guidelines, for a variety of reasons [3]. A main challenge in contemporary healthcare is therefore to increase the implementation of practice guidelines in routine care [4]. Dissemination of practice guidelines on paper alone has generally proved to be insufficient. Instead, a carefully designed strategy for change usually needs to be used for effective implementation of guidelines [5].

Before designing such a strategy it is important to identify the various barriers that professionals face when trying to incorporate practice guidelines into daily care [6]. A frequently used classification of those barriers to guideline implementation is the division into internal and external barriers by Cabana et al [6]. Here, 'internal barriers' relate to the professional's knowledge of and attitude towards the guidelines. For instance, a professional may not know the details of a particular guideline by heart, or may in certain cases disagree with its recommendations. To overcome internal barriers, different implementation strategies exist such as professional educational, outreach visits, clinical computerized decision support (CCDS), and reminders [5]. Of those strategies CCDS is known to be highly effective because it provides relevant knowledge at the time and place clinical decisions are made [7,8].

However, modern medicine is no longer a matter of individual health care professionals but largely practiced as part of a team and embedded within complex organizations. Appropriate knowledge and attitudes of the individual are necessary but not sufficient for compliance to clinical standards. Professionals may also encounter so-called 'external' barriers which hamper their ability to execute guideline recommendations. These barriers stem from environmental factors related to the team, organisation or health system they work in [9]. Finally, glitches and impracticability's in the guidelines in question (e.g., ambiguities, omissions, and contradictions) may impede execution of the guidelines' recommendations [6].

Several studies have shown that for improving the implementation of clinical guidelines it is important to apply a multifaceted intervention with supplementary components [3]. In addition, to ensure that implemented changes persist over time, interventions preferably have a continuous character [10].

This paper presents a continuous, multifaceted guideline-implementation strategy that is based on computerized decision support but extends beyond the level of the individual professional. The strategy is illustrated with a case study in the field of cardiac rehabilitation.

Materials and Methods

Several systematic reviews have been conducted concerning the effectiveness of different guideline-implementation interventions [3,11,12]. We based our strategy on the recurring conclusion in these reviews that multifaceted interventions targeting different barriers to change are more effective than single interventions. However, there is limited evidence concerning which combination of guideline implementation strategies is effective under which circumstances.

To guarantee a continuous character of the strategy, the continuous quality improvement (CQI) framework was taken as a starting point [13]. Within this framework an improvement is put into practice by planning it, trying it, observing the results, and acting on what is learned [14]. We note that to support these steps, it is necessary that data of the process being improved is collected, stored, and analyzed.

We chose to direct our strategy at two specific types of external guideline barrier, namely organisational barriers and guideline-related barriers. The key element is to use the CCDS as an input module for a clinical registry that collects data from similar care processes in different clinics into a central database. The CCDS registry will be the basis of two continuous improvement processes, a feedback process and a guideline-revision process. This is depicted in Figure 1 and will be described in more detail below.

The first component of our strategy consists of a CCDS system that is based on a formal (i.e., computer-interpretable) representation of the guideline to be implemented, and that is used in daily patient care to assist clinical decision making [15]. In a review of Shiffman et al it was shown that guideline adherence improved in 14 of 18 guideline-based CCDS systems in which it was measured [16]. In a later review of Kawamoto et al it was shown that CCDS systems in general significantly improve clinical performance [8]. In our strategy an existing CCDS system, aiming to overcome the professional knowledge barrier, is also used to collect clinical data in a central data registry. These data cover demographic and clinical characteristics of the patients, recommendations that were given by the system, the actual decisions that were made by its users, and outcomes of care. Using these data, compliance to the guidelines can be assessed at patient level by comparing system recommendations and actual decisions.

The second component is a benchmark-feedback loop. All clinics using the CCDS system and delivering data to the clinical registry receive feedback reports with benchmark information on a regular (e.g., monthly or quarterly) basis. The feedback reports contain graphical and descriptive (numerical) summaries of all clinic-specific data over the time period in question, with comparison to benchmark values (e.g. national target values or average performance within a peer group). Viewing personal performance within the context of peer performance is an effective motivator for change [17].

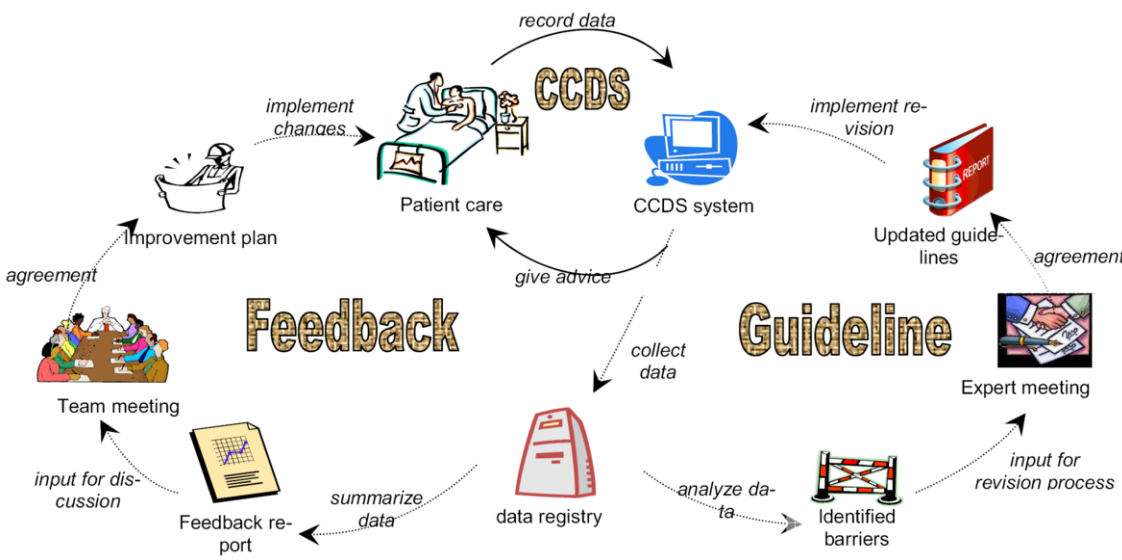

Figure 1 – Schematic depiction of proposed guideline-implementation strategy

CCDS loop: *CCDS system provides guideline-based decision support to clinical professionals in daily care, based on data that are recorded at the bedside.* ***Feedback loop:*** *Data from CCDS systems at different clinics are collected and stored in a central data registry and used to generate feedback reports for each of the clinics. Reports steer discussions in team meetings where a quality improvement plan is formulated, which is subsequently implemented in daily patient care.* ***Guideline loop:*** *The data registry will also serve as input for a guideline revision process by analysing compliance levels. This is supplemented with qualitative information from the users and used by domain experts to formulate the revision, which is subsequently carried through in the knowledge base of the CCDS.*

An essential part of the benchmark-feedback loop is that the reports are discussed during team meetings, and explanations are sought for deviations from benchmarks. Subsequently, organisational improvement initiatives should be formulated and implemented at the shop floor. An example where the benchmark-feedback loop is typically effective is absence of a resource needed to enable patients receiving a particular treatment. The individual professional will be confronted with CCDS advice to offer that treatment but will be unable to comply. The problem is that individual professionals are usually neither responsible nor empowered to acquire resources. When a feedback report reveals the non-compliance for this particular treatment, a team representative empowered to do so (typically a manager) can decide to acquire the resource, resulting in increased compliance to the guideline.

The third component of our strategy consists of a guideline maintenance cycle in which the CCDS data registry is used to identify guideline-related barriers for implementation. The first step of this cycle is to analyze the compliance data in the clinical registry in order to identify possible bottlenecks for carrying out the guideline's recommendations. For instance, excessive complexity of a guideline can result in a consistently low compliance on specific parts. When a procedure is difficult to execute in daily practice professionals may choose to systematically replace this procedure by a simpler one. Another example is the existence of vagueness or ambiguities in the guideline. These may result in high inter-practice variation. When the guidelines are unclear how to assess a specific patient item, different clinics will choose their own assessment method, often resulting in variation among the clinics. A third example is the presence of inconsistencies within the guideline itself or with other guidelines. When the recommended treatment for a subgroup of patients differs between two guidelines, this can result in significant treatment variation for this subgroup, among the clinics.

The second step of the guideline-maintenance cycle is to identify the underlying causes of the phenomena that were observed in the first step. For this purpose the compliance data should be complemented with qualitative information gathered from professionals who use the CCDS, for example during interviews or focus groups.

The final step is to revise the guidelines based on the results from the first two steps in one or more meetings with domain experts. In these meetings identified bottlenecks for guideline implementation are discussed. When proposing revisions experts should be involved to guarantee accordance with the latest scientific evidence. Participation of professional associations in the revision process is advisable to guarantee approval and adequate support of the revised guidelines.

Results

We describe the results of applying the developed strategy to a case study in the field of cardiac rehabilitation (CR). CR is a multidisciplinary treatment to help patients recover quickly from a cardiac incident or a cardiac intervention and improve their overall physical, mental and social functioning [18]. It has proven to be cost-effective in different economic evaluations conducted in North America and Europe [19]. However, in many Western countries cardiac rehabilitation services are under-utilized, poorly standardized, and do not follow the available scientific evidence [18]. Consistent with international standards [18, 20], the Dutch Guidelines for CR 2004 state [21] that professionals should conduct a needs assessment procedure where data items concerning the patient's medical, physical, psychological, and social condition and lifestyle are gathered. Based on the needs assessment procedure an individualized rehabilitation programme should be offered which consists of four possible therapies: exercise training, education and counselling, lifestyle change therapy, and relaxation and stress management training.

For our case study we used data from a recent trial with the CArdiac Rehabilitation Decision Support System (CARDSS) system [22, 23]. This system was developed in a combined guideline-development and formalization process of the Dutch Guideline for CR [24]. Via a structured dialogue CARDSS actively guides its users through the needs assessment procedure and formulates a preliminary rehabilitation programme containing the recommended therapies. Furthermore it contains an Electronic Patient Record (EPR) for CR.

In a multicentre cluster-randomized trial CARDSS was provided to care professionals in 31 Dutch outpatient clinics to stimulate the implementation of the guideline. Participating clinics worked during a minimum of six months with either of two versions of CARDSS: an intervention version with full functionally or a control version with the EPR services but without the therapy recommendations from the CDSS. The trial data from 21 clinics, including 2787 patients, were analyzed on compliance with respect to guideline recommendations, assessed separately for each of the four rehabilitation therapies. CARDSS increased compliance with the recommended decisions for exercise training, education and counselling, and for relaxation therapy. For lifestyle change therapy there was no improvement. All data of the trial were collected in a central registry database. For further details of the trial, we refer the reader to Goud et al [23].

The registry database included data on patient demographics (age and sex), reason for referral to cardiac rehabilitation (e.g. myocardial infarction, CABG, angina pectoris), objective exercise capacity, subjective (i.e., self-perceived) exercise capacity, psychological and social status, marital status, employment status and three lifestyle parameters (smoking status, eating habits, physical activity). These data were used to generate a feedback report for each of the 21 participating clinics. The reports summarized the deployment of needs assessment instruments, assessed risk behaviour and lifestyle parameters, and therapeutic decisions, outlined in the form of tables and charts. For each of the variables that was summarized in the report, also the grand mean and standard deviation (i.e. averaged over all 21 clinics) was reported as benchmark value. In order to leave sufficient room for interpretation and discussion in the team meetings, no other targets were included in the

reports. The feedback reports were positively received by the clinics although there were some doubts about the quality and reliability of the data. Several clinics reported that they created facilities to offer lifestyle change programs to their patients after reading the report. However many clinics found it difficult to create time to discuss the report.

For the guideline-revision process, patterns of compliance to the guidelines were analyzed in the registry database. It appeared that for all the parameters relating to rehabilitation needs, there was significant variation among the clinics. The largest variation was found in the percentages of patients judged to have an insufficient exercise capacity, which ranged from 54.5% to 89.8%. Large variation was also found in the percentages of patients judged to have an unrealistic subjective exercise capacity (37.7% – 63.9%) and to have social problems (31.1% – 60.9%). To identify the causes of this variation, semi-structured interviews with 29 users of CARDSS were conducted. Barriers to change that were mentioned in the interviews were lack of facilities (e.g. to measure all patients' exercise capacities with a bicycle test), vagueness/ambiguity in the guidelines (e.g. unclear how to assess anxiety and depression) and lack of agreement with the guidelines (e.g. criteria for a healthy lifestyle).

The combination of the quantitative compliance data with the qualitative data from the interviews showed that the variation and non-compliance were partly caused by guideline-related barriers. The results of both studies were discussed in a professional focus group set up with representatives of several professional associations (cardiologists, rehabilitation and sport physicians, company doctors, nurse practitioners, physiotherapists, psychologists, social workers and dieticians). They were asked to present revisions to solve the assessed barriers which would fit into daily care practice using their knowledge of the literature. Because of the large variation in assessed patient needs between CR clinics, the revised guidelines advise against using clinical judgment only to assess any rehabilitation needs. In addition, it was decided to add specific instruments to assess the anxiety and depression and a healthy life style and cardiovascular risk.

Discussion

In this study a continuous, multifaceted strategy to implement clinical practice guidelines was developed, and applied in a case study in the field of cardiac rehabilitation. The strategy combines CCDS with a benchmark-feedback loop and periodic updates of the underlying guidelines. As such, our strategy addresses not only the decision-making process of individual professionals but also decisions at higher levels of clinical organisations and in knowledge-management cycles.

A first limitation of our intervention is the need for a CDSS with data registry integrated at the point of care. Another potential limitation of the benchmark-feedback loop is the assumption that a conferring structure with regular team meetings is present at the participating clinics. If this is not the case, sending feedback reports will probably not have impact as they are simply not discussed. Probably this was true in most clinics that participated in our case study because structural follow-up actions on the feedback reports were rare. A recent Cochrane review states that the effects of feedback are likely to be stronger when it is combined with educational meetings directed towards actively involving care professionals in the improvement process [25]. It may therefore be sensible to extend the benchmark-feedback loop in our strategy with educational meetings. A final limitation is that the general professional mentality towards quality assurance should be positive, as professionals must be willing to think and work on quality improvements.

A notorious difficulty in benchmarking is choosing the appropriate target values. We choose to report the mean of all clinics but this can result in an undesirable, passive attitude in clinics whose performance is above average but not optimal. A different option is use full compliance to guideline recommendations as target value. However, this will often be unrealistic. In many clinical domains specific patient characteristics (such as comorbidities) require professionals to deviate from the guidelines. It is then unclear what the ideal compliance rate should be. A possible solution may be found in the Achievable Benchmarks for Care tool. In essence, this tool represents the average performance of the top 10% of the clinics being assessed. It encourages providers to strive for superior performance knowing that the target level of excellence has already been achieved by a select group of their colleagues [26].

Another explanation for difficulties during implementing changes in clinical practice is the presence of patient-related barriers [6]. This group of external barriers to guideline implementation is not specifically addressed in our strategy but could have played a role in our case study, for instance when patients were resistant or perceived no need for guideline recommendations.

The clinical registry based on the CCDS data is used for both the feedback to professionals as well as for the analyses of guideline related barriers for guideline implementation. Results are depending on the data entered in the systems and it is important to avoid data entry errors. Professionals should be thoroughly trained to work with the system and it is advisable to perform periodic data audits to identify data entry errors. In addition, users of the system should be aware that data from all patients that are treated should be entered into the system to prevent a selection bias.

The main novelty in our strategy is found in the combination of different components that supplement each other in a single continuous quality improvement strategy. Our implementation strategy can be used to implement guidelines on multiple levels in health care as part of continuous quality improvement which is advocated as an important mechanism for promoting the implementation of best practices in medical care. However, in our case study the different components were only once applied to the field of CR. Continuous data collection and analyzing is necessary to assess the long-term utility. Further the strategy should be applied during other guideline implementa-

tion projects to learn more about its application in other health care settings.
